1

Drug Product Development in the Pharmaceutical Industry

Gurvinder Singh Rekhi

Leon Shargel

I. INTRODUCTION

A. Active pharmaceutical ingredient (API)

1. A **drug substance** is the API or component that produces pharmacological activity.

2. The API may be **produced by** chemical synthesis, recovery from a natural product, enzymatic reaction, recombinant DNA technology, fermentation, or a combination of these processes. Further purification of the API may be needed before it can be used in a drug product.

3. A **new chemical entity (NCE)** is a drug substance with unknown clinical, toxicologic, physical, and chemical properties. In addition, the U.S. Food and Drug Administration (FDA) considers an NCE as an API that has not been approved for marketing in the United States.

4. The **identity, strength, quality,** and **purity** of a drug substance depend on proper control of the manufacturing and synthetic process.

B. Drug product

1. A drug product is the **finished dosage form** (e.g., capsule, tablet, injectable) that contains the API, generally in association with other excipients, or inert ingredients.

2. The excipients in the drug product may affect the functionality and performance of the drug product, including modification of the rate of drug substance release, improving drug stability, and masking the drug taste.

3. Different **approaches** are generally used to produce drug products that contain NCEs, product line extensions, generic drug products, and specialty drug products.

C. New drug product development

Drug products containing NCE are developed sequentially in the following phases.

1. Preclinical. Animal pharmacology and toxicology data are obtained to determine the safety and efficacy of the drug. Because little is known about the human and the therapeutic/toxicologic potential, many drug products will not reach the marketplace. No attempt is made to develop a final formulation during the preclinical stage. **Nonclinical studies** are nonhuman studies that may continue at any stage of research to obtain additional information concerning the pharmacology and toxicology of the drug.

2. Phase I

a. An **Investigational New Drug (IND)** application for human testing is submitted to the FDA. Clinical testing takes place after the IND application is submitted.

b. Healthy volunteers are used in phase I clinical studies to determine drug tolerance and toxicity.
c. For oral drug administration, a simple hard gelatin capsule formulation containing the API is usually used for IND studies.
d. Toxicologic studies—including acute, chronic, subchronic, and mutagenicity—and other such studies in various animal species are planned during this phase.

3. Phase II

a. A limited number of patients with the disease or condition for which the drug was developed are treated under close supervision.
b. Dose-response studies, bioavailability, and pharmacokinetics are performed to determine the optimum dosage regimen for treating the disease.
c. Safety is measured by attempting to determine the **therapeutic index** (ratio of toxic dose to effective dose).
d. A drug formulation having good physico-chemical stability is developed.
e. Chronic toxicity studies are started in two species; such studies normally last more than 2 years' duration.

4. Phase III

a. Large-scale, **multicenter clinical studies** are performed with the final dosage form developed in phase II. These studies are done to determine the safety and efficacy of the drug product in a large patient population who have the disease or condition for which the drug was developed.
b. Side effects are monitored. In a large population, new toxic effects may occur that were not evident in previous clinical trials.

5. Submission of a **New Drug Application (NDA).** An NDA is submitted to the FDA for review and approval after the completion of clinical trials that show to the satisfaction of the medical community that the drug product is effective by all parameters and is reasonably safe as demonstrated by animal and human studies.

6. Phase IV

a. After the NDA is submitted, and before approval to market the product is obtained from the FDA, manufacturing **scale-up** activities occur. Scale-up is the increase in the batch size from the clinical batch, submission batch, or both to the full-scale production batch size, using the finished, marketed product.
b. The drug product may be improved as a result of equipment, regulatory, supply, or market demands.
c. Additional clinical studies may be performed in special populations, such as the elderly, pediatric, and renal-impaired, to obtain information on the efficacy of the drug in these subjects.
d. Additional clinical studies may be performed to determine if the drug can be used for a new or additional labeling indications.

7. Phase V

a. After the FDA grants market approval of the drug, product development may continue.
b. The **drug formulation** may be modified slightly as a result of data obtained during the manufacturing scale-up and validation processes.

c. **Changes** in **drug formulation** should always be within the scale-up and post-approval change **(SUPAC)** guidelines.

D. Product line extensions are dosage forms in which the physical form or strength, but not the use or indication, of the product changes. Product line extension is usually performed during phase III, IV, or V.

1. Developing a transdermal patch when only tablets have been available, for example:

- Progesterone
- Nicotine
- Estradiol
- Nitroglycerin

2. Additional strengths—as long as these strengths are within the total daily dose, for example:

- Ibuprofen

3. Controlled-release or modified-release dosage forms when only an immediate-release dosage form is available. This is an ongoing project for all brand companies; almost every NCE has or will eventually have a modified-release dosage form of the immediate-release product.

E. Biologic products

1. A biologic product is any virus, serum, toxin, antitoxin, vaccine, blood, blood component or derivative, allergenic product, or analogous product applicable to the prevention, treatment, or cure of diseases or injuries.

2. Biologic products are a **subset** of drug products, distinguished by their manufacturing processes (biologic vs. chemical). In general, the term *drugs* includes biologic products.

3. Biologic license application (BLA). Biologic products are approved for marketing under the provisions of the Public Health Service (PHS) Act.

F. Generic drug products

1. After **patent expiration** of the API and /or brand drug product, a generic drug product may be marketed. A generic drug product is therapeutically equivalent to the brand name drug product and contains the same amount of the drug in the same type of dosage form (e.g., tablet, liquid, injectable).

2. A generic drug product must be **bioequivalent** (i.e., have the same rate and extent of drug absorption) to the brand drug product. Therefore, a generic drug product is expected to give the same clinical response (Chapter 7). These studies are normally performed with healthy human volunteers.

3. Some generic products are not absorbed; for some others bioequivalence is not a good marker. Under those conditions, **comparative clinical trials** or studies with

pharmacodynamic end points are considered to measure the equivalence of two products. Inhalation products and nonabsorbed drug products fall into this category.
4. The generic drug product may differ from the brand product in **physical appearance** (i.e., size, color, shape) or in the amount and type of excipients used in the formulation.
5. A generic drug product may not differ in both the qualitative and the quantitative compositions for liquids, injectables, semisolids, transdermal patches, inhalation products, and ophthalmic products, unless adequate safety studies have been performed.
6. Before a generic drug product is marketed, the manufacturer must submit an **Abbreviated New Drug Application (ANDA)** to the FDA for approval. Because preclinical safety and efficacy studies have already been performed for the NDA-approved brand product, human bioequivalence studies, instead of clinical trials, are generally required for the ANDA. The chemistry, manufacturing, and controls requirements for the generic drug product are similar to those for the brand name drug product.
G. Specialty drug products are existing products developed as a new delivery system or for a new therapeutic indication. The safety and efficacy of the drug product were established in the initial NDA-approved dosage form. For example, the nitroglycerin transdermal delivery system (patch) was developed after experience with nitroglycerin sublingual tablets.

II. PRODUCT DEVELOPMENT.

For each drug, various studies are required to develop a safe, effective, and stable dosage form.
A. New chemical entities
1. Preformulation is the characterization of the physical and chemical properties of the active drug substance and dosage form. The therapeutic indication of the drug and the route of administration dictate the type of drug product or drug delivery system (e.g., immediate release, controlled release, suppository, parenteral, transdermal) that needs to be developed.
a. Preformulation activities are usually performed during the preclinical stage. However, these activities may continue into phases I and II.
b. The following information is obtained during preformulation.

(1) Physical, including particle size and shape, crystallinity, polymorphism, density, surface area, hygroscopicity (ability to take up and retain moisture), and powder flow
(2) Solubility, including intrinsic dissolution, pH solubility profile, and general solubility characteristics in various solvents
(3) Chemical, including surface energy, pH stability profile, pKa, temperature stability (dry or under various humidity conditions), and excipient interactions

(4) Analytical methods development, including development of a stability indicating method (measures both the API and the related substances), and cleaning methods

2. Formulation development is a continuing process. Initial drug formulations are developed for early clinical studies. When the submission of an NDA is considered, the manufacturer attempts to develop the final (marketed) dosage form. The dose of the drug and the route of administration are important in determining the modifications needed.

a. Injectable

(1) A final injectable drug product is usually developed in the preclinical phase.

(2) Major concerns include the stability of the drug in solution and the sterility of the product.

(3) Because few excipients are allowed in injectable products, the formulator must choose a final product early in the development process.

(4) If the formulation is changed, bioavailability studies are not required for intravenous solution injections because the product is injected directly into the body.

(5) Formulation changes may require acute toxicity studies.

b. Topical (for local application). Includes antibacterials, antifungals, corticosteroids, and local anesthetics.

(1) The final dosage form for a topical drug product is usually developed during phase I studies because any major formulation changes may require further clinical trials.

(2) The release of the drug from the matrix is measured in vitro with various diffusion cell models.

(3) Significant problems encountered with locally acting topical drug products include local irritation, skin senistization and systemic drug absorption.

c. **Topical (for systemic drug absorption).** Includes drug delivery through the skin (transdermal), mucous membranes (intranasal), and rectal mucosa.

(1) A prototype formulation is developed for phase I.

(2) A final topical drug product is developed during phase III after the available technology and desired systemic levels are considered.

d. Oral

(1) Prototype dosage forms are often developed during the **preclinical phase** to ensure that the drug is optimally available and that the product dissolves in the gastrointestinal tract.

(2) In the early stages of product development, **hard gelatin capsule** dosage forms are often developed for **phase I** clinical trials. If the drug shows efficacy, the same drug formulation may be used in phase II studies.

(3) Final product development begins when the drug proceeds during phase II and before initiating phase III clinical studies.

3. Marketed Product. Considerations in the development of a final dosage form include the following:

a. Color, shape, size, taste, viscosity, sensitivity, skin feel, and physical appearance of the dosage form

b. Size and shape of the package or container

c. Production equipment
d. Production site
e. Country of origin in which the drug is to be manufactured
f. Country in which the drug will be marketed
B. Product line extensions are generally defined as drug products containing an NDA-approved drug in a different dosage strength or in a different dosage form (e.g., modified release, oral liquid).
1. Oral product line extensions
a. The simplest dosage form to develop is a different dosage strength of a drug in a tablet or capsule. Only bioequivalence studies are needed.

b. A **modified-release** dosage form is more difficult to develop when only an immediate-release dosage form exists. Clinical trials are normally required.
c. Considerations in developing these dosage forms are similar to those for the final drug product (see II.A.3).
d. Marketing has a role in the choice of the dosage form.
e. Because the original brand drug product information contributes to the body of knowledge about the drug, no preformulation is needed. All other factors considered for the original product are similar. If the relation between **in vitro** dissolution and **in vivo** bioavailability is known, the innovator can progress to a finished dosage form relatively quickly.
f. Regulatory approval is based on the following:
(1) Analytical and manufacturing controls
(2) Stability information
(3) Bioavailability and bioequivalence studies
(4) Clinical trials (in the case of modified-release dosage forms)
g. A new therapeutic indication for a drug requires new **efficacy studies** and a new **NDA.**
2. Liquid product line extensions
a. If the current marketed product is a liquid preparation, then the same factors as for the solid oral dosage forms are considered (see II.B.1.a, b, c, d, e, f and g).
b. If the marketed product is a solid oral dosage form and the product line extension is a liquid, product development must proceed with caution because the rate and extent of absorption for liquid and solid dosage forms may not be the same.
c. **Regulatory approval** requires
(1) Analytical and manufacturing controls
(2) Stability information
(3) Bioavailability and bioequivalence studies
(4) Safety studies (e.g., depending on the drug substance, local irritation)
(5) Clinical trials, if the rate and extent of drug absorption are drastically altered from the original dosage form
C. Combination products are made up of two or more regulated components (e.g., drug/device, biologic/device, drug/biologic, or drug/device/biologic) that are

physically, chemically, or otherwise combined or mixed and produced as a single entity.

1. These may be two or more separate products packaged together in a single package or as a unit and may be composed of drug and device products, device and biologic products, or biologic and drug products.

2. An **example** is an inhalation steroid (e.g., beclomethasone inhalation aerosol) in which the device component is important for delivery of the steroid.

III. PREAPPROVAL INSPECTIONS (PAIs)

A. The manufacturing facility is inspected by the FDA after an NDA, abbreviated antibiotic drug application (AADA), or ANDA is submitted and before the application is approved.

B. A PAI may also be initiated if a major change is reported in a supplemental application to an NDA, AADA, or ANDA.

C. During the PAI, the FDA investigator:

1. Performs a general current good manufacturing practice (cGMP) inspection relating specifically to the drug product intended for the market

2. Reviews the development report to verify that the drug product has enough supporting documentation to ensure a validated product and a rationale for the manufacturing directions

3. Consults the chemistry, manufacturing, and control (CMC) section of the NDA, AADA, or ANDA and determines the capability of the manufacturer to produce the drug product as described

4. Verifies the traceability of the information submitted in the CMC section to the original laboratory notebooks, electronic information, and batch records

5. Verifies and ensures that all the quality systems are in place to manufacture the product so it retains the identity, strength, quality, and purity of the drug product that were approved by the center.

6. Recommends approval for the manufacture of the drug product based on the status of the inspection

IV. SCALE-UP AND POSTAPPROVAL CHANGES (SUPACs)

A. Purpose. These guidelines are intended to reduce the number of manufacturing changes that require pre-approval by the FDA. The guidelines are published by the FDA on the Internet (http://www.fda.gov/cder/guidance/index.htm).

B. Function. These guidelines provide recommendations to sponsors of NDAs, AADAs, and ANDAs during the postapproval period when

1. Making slight changes in the amount of the **excipient** to aid in the processing of the product during scale-up

2. Changing the **site** of manufacture

3. Scaling up (increasing) or **scaling down** (decreasing) the batch size of the formulation

4. Changing the manufacturing **process** or **equipment**

C. The FDA must be notified about a proposed change to a drug product through different **regulatory documentation,** depending on the type of change proposed.

1. Annual report. Changes that are unlikely to have any detectable effect on formulation quality and performance can be instituted without approval by the FDA and reported annually. Examples of these changes include:

a. Compliance with an official compendium

b. Label description of the drug product or how it is supplied (not involving dosage strength or dosage form)

c. Deletion of an **ingredient** that affects only the color of the product

d. Extension of the **expiration date** based on full shelf-life data obtained from a protocol approved in the application

e. Container and **closure system** for the drug product (except a change in container size for nonsolid dosage forms) based on equivalency to the approved system under a protocol approved in the application or published in an official compendium

f. Addition or deletion of an **alternate analytical method**

2. Changes being effected (CBE) supplement. Changes that probably would not have any detectable effect but require some validation efforts require specific documentation, depending on the change. A supplement is submitted, and the change can be implemented without previous approval **(CBE-0)** by the FDA or, in some cases, the FDA has 30 days to review the change **(CBE-30).** FDA may reject this supplement. Examples of reasons for submitting a supplement include

a. Addition of a **new specification** or test method or changes in methods, facilities, or controls

b. Label change to add or strengthen a contraindication, warning, precaution, or adverse reaction

c. Use of a **different facility** to manufacture the drug substance and drug product (the manufacturing process in the new facility does not differ materially from that in the former facility, and the new facility has received a satisfactory cGMP inspection within the previous 2 years covering that manufacturing process)

3. Pre-approval supplement. Changes that could have a significant effect on formulation quality and performance require specific documentation. This supplement must be approved before the proposed change is initiated. Appropriate examples for pre-approval supplement are:

a. Addition or deletion of an **ingredient**

b. Relaxation of the limits for a **specification**

c. Establishment of a **new regulatory analytical method**

d. Deletion of a **specification** or regulatory analytical method

e. Change in the method of **manufacture** of the drug product, including changing or relaxing an in-process control

f. Extension of the **expiration date** of the drug product based on data obtained under a new or revised stability testing protocol that was been approved in the application

D. When any change to a drug product is proposed, the manufacturer must show that the resultant drug product is **bioequivalent** and **therapeutically equivalent** to the original approved drug product (**see** Chapter 7).

1. A **minor change** is a change that has minimal potential to have an adverse effect on the identity, strength, quality, purity, or potency of the product as they may relate to the safety or effectiveness of the product. If the proposed change is considered minor by the FDA, bioequivalence may be demonstrated by comparative dissolution profiles for the original and new formulations.

2. A **major change** is one that has substantial potential to have an adverse effect on the identity, strength, quality, purity, or potency of a product as they may relate to the safety or effectiveness of the product. If the proposed change is considered major by the FDA, bioequivalence must be demonstrated by an in vivo bioequivalence study comparing the original and new formulations.

V. GOOD MANUFACTURING PRACTICES (GMPs)

are regulations developed by the FDA. GMPs are minimum requirements that the industry must meet when manufacturing, processing, packing, or holding human and veterinary drugs. These regulations, also known as **cGMPs,** establish criteria for personnel, facilities, and manufacturing processes to ensure that the finished drug product has the correct identity, strength, quality, and purity characteristics.

A. Good Manufacturing Practices are described in the Code of Federal Regulations (CFR), title 21, sections 210 and 211.

B. Quality control (QC) is the group within the manufacturer that is responsible for establishing process and product specifications.

1. Specifications are the criteria to which a drug product should conform to be considered having acceptable quality for its intended use.

2. The QC unit **tests** the product and verifies that the specifications are met. QC testing includes the **acceptance** or **rejection** of the incoming raw materials, packaging components, drug products, water system, and environmental conditions (e.g., heating, ventilation, air-conditioning, air quality, microbial load) that exist during the manufacturing process.

C. Quality assurance (QA) is the group within the manufacturer that determines that the systems and facilities are adequate and that the written procedures are followed to ensure that the finished drug product meets the applicable specifications for quality.

STUDY QUESTIONS

Directions: Each statement in this section can be correctly completed by **one or more** of the suggested phrases. Choose the **correct** answer, A-E:

1. Healthy human volunteers are used in drug development for

I. phase I testing after the submission of an investigational new drug (IND) application.

II. generic drug development for an abbreviated new drug application (ANDA) submission.

III. phase III testing just before the submission of a new drug application (NDA).

A if **I** only is correct

B if **III** only is correct

C if **I** and **II** are correct

D if **II** and **III** are correct

E if **I, II,** and **III** are correct

View Answer***1. The answer is C[see].*****2. The required information contained in a new drug application (NDA) that is *not* included in the abbreviated new drug application (ANDA) consists of**

I. preclinical animal toxicity studies.

II. clinical efficacy studies.

III. human safety and tolerance studies.

A if **I** only is correct

B if **III** only is correct

C if **I** and **II** are correct

D if **II** and **III** are correct

E if **I, II,** and **III** are correct

View Answer***2. The answer is E[see].*****3. A product line extension contains the new drug application (NDA) approved drug in a new**

I. dosage form.

II. dosage strength.

III. therapeutic indication.

A if **I** only is correct

B if **III** only is correct

C if **I** and **II** are correct

D if **II** and **III** are correct

E if **I, II,** and **III** are correct

View Answer***3. The answer is C[see].*****Directions:** Each statement in this section can be correctly completed by **one** of the suggested phrases. Choose the **best** answer.

4. The regulations developed by the U.S. Food and Drug Administration (FDA) for the pharmaceutical industry for meeting the minimum requirements in the manufacturing, processing, packing, or holding of human and veterinary drugs are known as

(A) good manufacturing practices (GMPs).

(B) quality assurance (QA).

(C) quality control (QC).

(D) pre-approval inspection (PAI).
(E) scale-up and post-approval changes (SUPACs).

View Answer***4. The answer is A[see].*****5. The unit within the pharmaceutical manufacturer that ensures that the finished dosage form has met all the specifications for its intended use is the**
(A) analytical methods unit.
(B) marketing and sales unit.
(C) pre-approval inspection (PAI) unit.
(D) quality assurance (QA) unit.
(E) quality control (QC) unit.

View Answer***5. The answer is E[see].*****6. Manufacturers may make a change in the formulation after market approval. If the change in the formulation is considered a minor change, the manufacturer needs to report the change to the FDA only in the**
(A) annual report.
(B) pre-approval supplement.
(C) investigational new drug (IND) submission.
(D) changes being effected supplement, 30 days (CBE-30).
(E) no report is required for a minor change.

View Answer***6. The answer is A[see].***P.9

ANSWERS AND EXPLANATIONS

1. The answer is C (I, II) *[see* I.C.2.b; I.F.2*].*
Phase I testing is the first set of human studies performed during new drug development. Phase I studies establish the tolerance and toxicity of the drug in humans. Bioequivalence studies for generic drug development are most often performed in healthy human volunteers. These studies establish the bioequivalence of the generic drug product against the brand drug product. Phase III testing entails large-scale, multicenter clinical studies performed in patients with the disease or condition to be treated. Phase III studies determine the safety and efficacy of the drug in a large patient population.
2. The answer is E (I, II, and III) *[see* I.C.5; I.F.6*].*
The development of a new drug requires extensive toxicity and efficacy testing in animals and humans. The NDA documents all studies performed on the drug. The ANDA is used for generic drug product submissions. The generic drug product is similar to the original brand drug product that has already been marketed. Because the efficacy, safety, and toxicity of this drug product have been studied and documented, further studies of this nature are unnecessary.
3. The answer is C (I, II) *[see* I.D*].*
Product line extensions are developed after further studies with the original NDA-approved drug product. From these studies, the manufacturer may develop a new dosage form (e.g., controlled-release product) or a new dosage strength. A new therapeutic indication requires an NDA.

4. The answer is A *[see* V*].*
Quality control and quality assurance follow GMP regulations to ensure that the finished product meets all applicable specifications for quality. The FDA may inspect a manufacturing site (PAI) before the drug application is approved. In addition, the FDA must be notified about any proposed changes to an approved drug product.
5. The answer is E *[see* V.B*].*
The QC unit performs the appropriate tests on the dosage form. PAI is performed by FDA compliance inspectors, who examine the pharmaceutical manufacturer and review the procedures and records for manufacturing the finished dosage form before the administration grants market approval. The analytical development unit develops the analytical methods used in testing the drug product.
6. The answer is A *[see* IV.C.1*].*
All changes in the formulation must be reported to the FDA. A minor change is a change that has minimal potential to have an adverse effect on the identity, strength, quality, purity, or potency of the product as they may relate to the product's safety or effectiveness. Changes that are unlikely to have any detectable effect on formulation quality and performance can be instituted without approval by the FDA and need only to be reported in the annual report.

Pharmaceutical Calculations and Statistics

Riccardo L. Boni

I. FUNDAMENTALS OF MEASUREMENT AND CALCULATION.

The pharmacist is often required to perform or evaluate a variety of calculations in his or her practice. Many of these calculations involve the use of direct or inverse proportions. **Dimensional** (or **unit**) **analysis** and **approximation** can be useful in solving these problems. In dimensional analysis, dimensions (or units) are included with each number used in the calculation. Units common to the numerator and denominator may be canceled and the remaining units provide the units for the final answer. In approximation, each number used in the calculation is rounded to a single significant digit. Factors common to the numerator and denominator may be canceled and the answer to this approximation should be reasonably close to the final exact answer.

A. Ratio and proportion

1. Ratio. The relative magnitude of two like quantities is a ratio, which is expressed as a fraction. Certain basic principles apply to the ratio, as they do to all fractions.
a. When the two terms of a ratio are multiplied or divided by the same number, the value of the ratio is unchanged.

$$\frac{1}{3} \times \frac{2}{2} = \frac{2}{6} = \frac{1}{3}$$

b. Two ratios with the same value are equivalent. Equivalent ratios have equal cross products and equal reciprocals. For example:

$$\frac{1}{3} = \frac{2}{6}$$

and

$1 \times 6 = 3 \times 2 = 6$

If two ratios are equal, then their reciprocals are equal:

$$\text{if } \frac{1}{3} = \frac{2}{6}, \text{ then } \frac{3}{1} = \frac{6}{2}$$

2. Proportion. The expression of the equality of two ratios is a proportion. The product of the extremes is equal to the product of the means for any proportion. Furthermore, the numerator of the one fraction equals the product of its denominator and the other fraction (i.e., one missing term can always be found given the other three terms). Most pharmaceutical calculations can be performed by use of proportion.

a. Proper ratios. Some pharmacists use proper ratios (in which similar units are used in the numerator and denominator of each ratio) in their proportion calculations. Several examples follow.

(1) If 240 mL of a cough syrup contains 480 mg of dextromethorphan hydrobromide, then what mass of drug is contained in a child's dose, 1 teaspoonful (5 mL) of syrup?

$$\frac{240 \text{ mL}}{5 \text{ mL}} = \frac{480 \text{ mg}}{x \text{ mg}}$$

$$x = \frac{480 \times 5}{240} = 10 \text{ mg}$$

(2) If a child's dose (5 mL) of a cough syrup contains 10 mg of dextromethorphan hydrobromide, what mass of drug is contained in 240 mL?

$$\frac{240 \text{ mL}}{5 \text{ mL}} = \frac{x \text{ mg}}{10 \text{ mg}}$$

$$x = \frac{240 \times 10}{5} = 480 \text{ mg}$$

(3) If the amount of dextromethorphan hydrobromide in 240 mL of cough syrup is 480 mg, what would be the volume required for a child's dose of 10 mg?

$$\frac{x \text{ mL}}{240 \text{ mL}} = \frac{10 \text{ mg}}{480 \text{ mg}}$$

$$x = \frac{10 \times 240}{480} = 5 \text{ mL}$$

(4) How many milligrams of dextromethorphan base (molecular weight = 271.4) are equivalent to 10 mg of dextromethorphan hydrobromide (molecular weight = 352.3)?

$$\frac{x \text{ mg}}{10 \text{ mg}} = \frac{271.4}{352.3}$$

$$x = 10 \times \frac{271.4}{352.3} = 7.7 \text{ mg}$$

b. Mixed ratios. Some pharmacists use mixed ratios (in which dissimilar units are used in the numerator and denominator of each ratio) in their proportion calculations. Such computations generally give correct answers, providing the conditions in which mixed ratios cannot be used are known. A later example shows mixed ratios leading to failure in the case of dilution, when inverse proportions are required. For **inverse proportions,** similar units must be used in the numerator and denominator of each ratio. Following is an example of a mixed ratio calculation using the previous problem.

$$\frac{480 \text{ mg}}{10 \text{ mL}} = \frac{240 \text{ mg}}{x \text{ mL}}$$

$$x = 240 \times \frac{10}{480} = 5 \text{ mL}$$

The **same answer** is obtained in this example whether we use proper ratios, with similar units in numerator and denominator, or mixed ratios. This is not the case when dealing with inverse proportions.

3. Inverse proportion. The most common example of the need for inverse proportion for the pharmacist is the case of **dilution.** Whereas in the previous examples of proportion the relationships involved direct proportion, the case of dilution calls for an inverse proportion (i.e., as volume increases, concentration decreases). The necessity of using inverse proportions for dilution problems is shown in this example.

If 120 mL **of a 10% stock solution is diluted to 240** mL, **what is the final concentration?** Using inverse proportion,

$$\frac{120 \text{ mL}}{240 \text{ mL}} = \frac{x\%}{10\%}$$

$$120 \times \frac{10}{240} = 5\%$$

As expected, the final concentration is one half the original concentration because the volume is doubled. However, if the pharmacist attempts to use direct proportion and neglects to estimate an appropriate answer, the

resulting calculation would provide an answer of 20%, which is twice the actual concentration.

$$\frac{120\ \text{mL}}{240\ \text{mL}} = \frac{10\%}{x\%}$$

$$240 \times \frac{10}{120} = 20\%\ \text{(incorrect answer)}$$

Likewise, the pharmacist using mixed ratios fails in this case.

$$\frac{120\ \text{mL}}{10\%} = \frac{240\ \text{mL}}{x\%}$$

and

$$10 \times \frac{240}{120} = 20\%\ \text{(again, incorrect answer)}$$

B. Aliquot. A pharmacist requires the aliquot method of measurement when the **sensitivity** (the smallest quantity that can be measured with the required accuracy and precision) of the measuring device is not great enough for the required measurement. Aliquot calculations can be used for measurement of solids or liquids, allowing the pharmacist to realize the required precision through a process of measuring a multiple of the desired amount followed by dilution and finally selection and measurement of an aliquot part that contains the desired amount of material. This example problem involves weighing by the aliquot method, using a prescription balance.

A prescription balance has a sensitivity requirement of 6 mg. How would you weigh 10 mg of drug with an accuracy of ± 5%, using a suitable diluent?

1. First, calculate the least weighable quantity for the balance with a sensitivity requirement of 6 mg, assuming ± 5% accuracy is required.

$$\frac{6\ \text{mg}}{x\ \text{mg}} = \frac{5}{100};\ x = 120\ \text{mg (least weighable quantity for our}$$

2. Now it is obvious that an aliquot calculation is required because 10 mg of drug is required, whereas the least weighable quantity is 120 mg to achieve the required percentage of error. Using the least weighable quantity method of aliquot measurement, use the smallest quantity weighable on the balance at each step to preserve materials.

a. Weigh 12 × 10 mg = 120 mg of drug.

b. Dilute the 120 mg of drug (from step **a**) with a suitable diluent by geometrical dilution to achieve a mixture that will provide 10 mg of drug in each 120-mg aliquot. The amount of diluent to be used can be determined through **proportion.**

$$\frac{120 \text{ mg drug}}{10 \text{ mg drug}} = \frac{x \text{ mg total mixture}}{120 \text{ mg aliquot mixture}}$$

$$x = 1440 \text{ mg total mixture}$$

$$1440 \text{ mg total} - 120 \text{ mg drug} = 1320 \text{ mg diluent}$$

c. Weigh 120 mg (1/12) of the total mixture, which will contain the required 10 mg of drug.

II. SYSTEMS OF MEASURE.

The pharmacist must be familiar with **three systems** of measure: the **metric system** and two common systems of measure (the **avoirdupois** and **apothecaries'** systems). The primary system of measure in pharmacy and medicine is the metric system. Most students find it easiest to convert measurements in the common systems to metric units. A table of conversion equivalents is provided and should be memorized by the pharmacist (see Appendix A). The metric system, because of its universal acceptance and broad use, will not be reviewed here.

A. Apothecaries' system of fluid measure. The apothecaries' system of fluid measure is summarized in Appendix A.

B. Apothecaries' system for measuring weight. The apothecaries' system for measuring weight includes units of grains, scruples, drams, ounces, and pounds (see Appendix A).

C. Avoirdupois system of measuring weight. The avoirdupois (AV) system of measuring weight includes the grain, ounce, and pound. The grain is a unit common with the apothecaries' system and allows for easy conversion between the systems. The avoirdupois pound, however,

is 16 AV ounces in contrast to the apothecaries' pound, which is 12 apothecaries' ounces (see Appendix A).

D. Conversion equivalents. See Appendix A.

III. REDUCING AND ENLARGING FORMULAS.

The pharmacist is often required to reduce or enlarge a recipe. Problems of this type are solved through proportion, or by multiplication or division by the appropriate factor to obtain the required amount of each ingredient that will give the desired total mass or volume of the formula. Formulas can be provided in amounts or in parts.

A. Formulas that indicate parts. When dealing with formulas that specify parts, parts by weight will require the determination of weights of ingredients, whereas parts by volume warrant the calculation of volumes of ingredients. Always find the total number of parts indicated in the formula, and equate that total with the total mass or volume of the desired formula in order to set up a proportion. Such a proportion will allow calculation of the

mass or volume of each ingredient in units common to the total mass or volume.

What quantities should be used to prepare 100 g of camphorated parachlorophenol?

R_x	parachlorophenol	7 parts
	camphor	13 parts
	7 parts + 13 parts = 20 parts total	

$$\frac{7 \text{ parts}}{20 \text{ parts}} = \frac{x \text{ g}}{100 \text{ g}}; \; x = 35 \text{ g of parachlorophenol}$$

$$\frac{13 \text{ parts}}{20 \text{ parts}} = \frac{x \text{ g}}{100 \text{ g}}; \; x = 65 \text{ g of camphor}$$

B. Formulas that indicate quantities. The previous prescription for cold cream provides a 100 g quantity.

What mass of each ingredient is required to provide 1 pound (AV) of cream?

R_x	white wax	12.5 g
	mineral oil	60.0 g
	lanolin	2.5 g
	sodium borate	1.0 g
	rose water	24.0 g

1 lb = 454 g

$$1\ \text{lb} = 454\ \text{g}$$

$$\frac{454}{100} = 4.54\ \text{(factor to use in calculating the quantities of eac}$$

12.5 g × 4.54	=	56.8 g of white wax
60.0 g × 4.54	=	272 g of mineral oil
2.5 g × 4.54	=	11.4 g of lanolin
1.0 g × 4.54	=	4.54 of sodium borate
24.0 g × 4.54	=	109 g of rose water

IV. CALCULATING DOSES.

Calculation of doses generally can be performed with dimensional analysis. **Problems** encountered in the pharmacy include calculation of the number of doses, quantities in a dose or total mass/volume, amount of active or inactive ingredients, and size of dose. Calculation of **children's doses** is commonly performed by the pharmacist. Dosage is optimally calculated by using the child's body weight or mass and the appropriate dose in milligrams per kilogram (mg/kg). Without these data, the following formulas based on an adult dose can be used.

A. Fried's rule for infants

$$\frac{\text{age (in months)} \times \text{adult dose}}{150} = \text{dose for infant}$$

B. Clark's rule

$$\frac{\text{weight (lb)} \times \text{adult dose}}{150\ \text{lb (avg wt of adult)}} = \text{dose for child}$$

C. Child's dosage based on body surface area (BSA**)**

$$\frac{\text{BSA of child } (\text{m}^2) \times \text{adult dose}}{1.73\ \text{m}^2\ \text{(avg adult BSA)}} = \text{approximate dose for chil}$$

D. Young's rule for children ≥ 2 years old

$$\frac{\text{age (in years)}}{\text{age (in years)} + 12} \times \text{adult dose} = \text{dose for child}$$

E. Constant rate intravenous infusions. Some drugs are administered intravenously at a constant (zero-order) rate by using a continuous-drip infusion set or a constant-rate infusion pump. The flow rate (volume per unit time) required can be calculated from the volume to be administered and the duration of the infusion. The rate of drug administration can be calculated from the concentration of drug in the infused solution and the flow rate of the infusion set or pump. Conversion factors may be required to obtain the final answer in the correct units (drops per minute or milliliters per hour).

A vancomycin solution containing 1000 mg of vancomycin hydrochloride diluted to 250 mL with D5W is to be infused at a constant rate with a continuous-drip intravenous infusion set that delivers 25 drops/mL. **What flow rate (drops/min) should be used to infuse all 250** mL **of the vancomycin hydrochloride solution in 2 hr?**

$$\frac{250 \text{ mL}}{2 \text{ hr}} \times \frac{1 \text{ hr}}{60 \text{ min}} \times \frac{25 \text{ drops}}{1 \text{ mL}} = 52 \text{ drops/min}$$

V. PERCENTAGE, RATIO STRENGTH, AND OTHER CONCENTRATION EXPRESSIONS

A. Percentage weight in volume (w/v)

1. Definition. Percentage, indicating parts per hundred, is an important means of expressing concentration in pharmacy practice. Percentage w/v indicates the number of grams of a constituent per 100 mL of solution or liquid formulation. The pharmacist may be required to perform **three types** of calculations: determine the **weight** of active ingredient in a certain volume when given the percentage strength, determine the **percentage w/v** when the weight of substance and volume of liquid formulation are known, and determine the **volume** of liquid mixture when the percentage strength and amount of substance are known.

2. Tolu balsam syrup. Tolu balsam tincture contains 20% w/v tolu balsam. **What is the percentage concentration of tolu balsam in the syrup?**

tolu balsam tincture	50 mL
magnesium carbonate	10 g
sucrose	820 g
purified water, qs ad	1000 mL

a. First, determine what the amount of tolu balsam is in the 50 mL quantity of tincture used for the syrup. Then, by proportion, calculate the concentration of tolu balsam in the syrup.

$$\text{tolu balsam tincture} = 50 \text{ mL} \times \frac{20 \text{ g}}{100 \text{ mL}} = 10 \text{ g tolu bals}$$

$$\frac{10 \text{ g}}{1000 \text{ mL}} = \frac{x \text{ g}}{100 \text{ mL}}; \; x = \frac{1 \text{ g}}{100 \text{ mL}} = 1\% \text{ tolu balsam in the}$$

In answering this one question, the first two types of problems listed above have been solved, while exhibiting two methods of solving percentage problems—namely, by **dimensional analysis** and **proportion.**

b. For an example of the **third type** of percentage w/v problem, determine what volume of syrup could be prepared if we had only 8 g of magnesium carbonate. Use proportion to find the total volume of syrup that can be made using only 8 g of magnesium

carbonate. If we have 8 g of magnesium carbonate in 1000 mL of solution, then, according to the recipe, 800 mL of solution can be prepared using all 8 g of the drug.

$$\frac{10 \text{ g}}{1000 \text{ mL}} = \frac{8 \text{ g}}{x \text{ mL}}; \; x = 800 \text{ mL}$$

B. Percentage volume in volume (v/v). Percentage v/v indicates the number of milliliters of a constituent in 100 mL of liquid formulation. The percentage strength of mixtures of liquids in liquids is indicated by percent v/v, which indicates the parts by volume of a substance in 100 parts of the liquid preparation. The **three types** of problems that are encountered involve calculating **percentage strength,** calculating **volume of ingredient,**

and calculating **volume of the liquid preparation.** Using the same tolu balsam syrup formula from earlier, we'll now work a percent v/v problem. **What is the percentage strength v/v of the tolu balsam tincture in the syrup preparation?** By proportion, we can solve the problem in one step.

$$\frac{50 \text{ mL tolu balsam tincture}}{x \text{ mL tolu balsam tincture}} = \frac{1000 \text{ mL syrup}}{100 \text{ mL syrup}}; \; x = 5\%$$

C. Percentage weight in weight (w/w). Percentage w/w indicates the number of grams of a constituent per 100 g of formulation (solid or liquid). Solution of problems involving percentage w/w is straightforward when the total mass of the mixture is available or when the total mass can be determined from the available data. In calculations similar to those for percentage w/v and v/v, the pharmacist might need to solve several types of problems, including determination of the weight of a constituent, the total weight of a mixture, or the percentage w/w.

1. How many grams of drug substance should be used to prepare 240 g **of a 5% w/w solution in water?**

a. The first step in any percentage w/w problem is to attempt identification of the total mass of the mixture. In this problem, the total mass is, obviously, provided (240 g).

b. The problem can be easily solved through **dimensional analysis.**

$$240 \text{ g mixture} \times \frac{5.0 \text{ g drug}}{100 \text{ g drug}} = 12 \text{ g}$$

2. When the total mass of the mixture is unavailable or cannot be determined, an **extra step** is required in the calculations. Because it is usually impossible to know how much volume is displaced by a solid material, the pharmacist is unable to prepare a specified volume of a solution given the percentage w/w.

How much drug should be added to 30 mL **of water to make a 10% w/w solution?** The volume of water that is displaced by the drug is unknown, so the final volume is unknown. Likewise, even though the mass of solvent is known (30 mL × 1 g/mL = 30 g), it is not known how much drug is needed, so the total mass is unknown. The water represents 100% - 10% = 90% of the total mixture. Then, by proportion, the mass of drug to be used can be identified.

$$\frac{30 \text{ g of mixture (water)}}{x \text{ g of mixture (drug)}} = \frac{90\%}{10\%}; \; x = 3.33 \text{ g of drug required to r}$$

The **common error** that many students make in solving problems of this type is to assume that 30 g is the total mass of the mixture. Solving the problem with that assumption gives the following incorrect answer.

$$\frac{x \text{ g drug}}{10 \text{ g drug}} = \frac{30 \text{ g mixture}}{100 \text{ g mixture}}; \; x = 3 \text{ g of drug (incorrect answ}$$

D. Ratio strength. Solid or liquid formulations that contain low concentrations of active ingredients will often have concentration expressed in **ratio strength.** Ratio strength, as the name implies, is the expression of concentration by means of a ratio. The numerator and denominator of the ratio indicate grams (g) or milliliters (mL) of a solid or liquid constituent in the total mass (g) or volume (mL) of a solid or liquid preparation. Because **percentage strength** is

essentially a ratio of parts per hundred, conversion between ratio strength and percentage strength is easily accomplished by proportion.

1. Express 0.1% w/v as a ratio strength.

a. Ratio strengths are by convention expressed in reduced form, so in setting up our proportion to solve for ratio strength, use the numeral 1 in the numerator of the righthand ratio as shown:

$$\frac{0.1 \text{ g}}{100 \text{ mL}} = \frac{1 \text{ part}}{x \text{ parts}}; \; x = 1000 \text{ parts, for a ratio strength of 1:1}$$

b. Likewise, conversion from ratio strength to percentage strength by proportion is easy, as seen in the following example. Keep in mind the definition of percentage strength (parts per hundred) when setting up the proportion.

2. Express 1:2500 as a percentage strength.

$$\frac{1 \text{ part}}{2500 \text{ parts}} = \frac{x \text{ parts}}{100 \text{ parts}}; \; x = 0.04, \text{ indicating } 0.04\%$$

E. Other concentration expressions

1. Molarity (M) is the expression of the number of moles of solute dissolved per liter of solution. It is calculated by dividing the moles of solute by the volume of solution in liters.

$$M_A = \frac{n_A}{\text{solution (L)}}$$

2. Normality. A convenient way of dealing with acids, bases, and electrolytes involves the use of equivalents. One equivalent of an acid is the quantity of that acid that supplies or donates 1 mole of H^+ ions. One equivalent of a base is the quantity that furnishes 1 mole of OH^- ions. One equivalent of acid reacts with 1 equivalent of base. Equivalent weight can be calculated for atoms or molecules.

$$\text{Equivalent weight} = \frac{\text{atomic weight or molecular weight}}{\text{valence}}$$

The **normality** (N) of a solution is the number of gram-equivalent weights (equivalents) of solute per liter of solution. Normality is analogous to molarity; however, it is defined in terms of equivalents rather than moles.

$$\text{Normality} = \frac{\text{\# equivalents of solute}}{\text{\# liters of solution}}$$

3. Molality (m) is the moles of solute dissolved per kilogram of solvent. Molality is calculated by dividing the number of moles of solute by the number of kilograms of solvent. Molality offers an advantage over molarity because it is based on solvent weight and avoids problems associated with volume expansion or contraction owing to the addition of solutes.

$$m_A = \frac{n_A}{\text{mass}_{\text{solvent (kg)}}}$$

4. Mole fraction (X) is the ratio of the number of moles of one component to the total moles of a mixture or solution.

$$X_A = \frac{n_A}{n_A, n_B, n_C \ldots}, \text{ where } X_A + X_B + X_C + \ldots = 1$$

VI. DILUTION AND CONCENTRATION.

If the amount of drug remains constant in a dilution or concentration, then any change in the mass or volume of a mixture is inversely proportional to the concentration.

A. Dilution and concentration problems can be solved by:

1. Inverse proportion (as mentioned earlier)

2. The equation $\text{quantity}_1 \times \text{concentration}_1 = \text{quantity}_2 \times \text{concentration}_2$

3. Determining the amount of active ingredient present in the initial mixture and, with the assumption that the initial quantity does not change, calculating of the final concentration of the new total mass or volume

4. Alligation medial. A method for calculating the average concentration of a mixture of two or more substances

5. Alligation alternate. A method for calculating the number of parts of two or more components of known concentration to be mixed when the final desired concentration is known

B. Dilution of alcohols and acids

1. Dilution of alcohols. When alcohol and water are mixed, a contraction of volume occurs. As a result, the final volume of solution cannot be determined accurately. Nor can the volume of water needed to dilute to a certain percentage v/v be identified. Accordingly, percentage w/w is often used for solutions of alcohol.

2. The **percentage strength** of concentrated acids is expressed as percentage w/w. The concentration of diluted acids is expressed as percentage w/v. Determining the volume of concentrated acid to be used in preparing a diluted acid requires the specific gravity of the concentrated acid.

C. Dilution and concentration of liquids and solids. Dilution and concentration problems are often easily solved by identifying the amount of drug involved followed by use of an appropriate proportion.

1. How many milliliters of a 1:50 stock solution of ephedrine sulfate should be used in compounding the following prescription?

R_x	ephedrine sulfate	0.25%
	rose water, ad	30 mL

$$\frac{0.25\ \text{g}}{100\ \text{mL}} \times 30\ \text{mL} = 0.075\ \text{g drug required}$$

$$\frac{50\ \text{mL}}{1\ \text{g}} = \frac{x\ \text{mL}}{0.075\ \text{g}}$$

$$x = 3.75\ \text{mL of stock solution required for}$$

2. How many milliliters of a 15% w/v concentrate of benzalkonium chloride should be used in preparing 300 mL **of a stock solution such that 15** mL **diluted to 1** L **will yield a 1: 5000 solution?**

a. First, determine the amount of drug in 1 L of a 1:5000 solution.

$$\frac{5000\ \text{mL}}{1000\ \text{mL}} = \frac{1\ \text{g}}{x\ \text{g}}\ x = 0.2\ \text{g of benzalkonium chloride in the}$$

b. Now, because 15 mL of the stock solution is being diluted to 1 L, a stock solution is needed in which 15 mL contain 0.2 g of drug. The amount of drug required to make 300 mL of the stock solution is found by proportion.

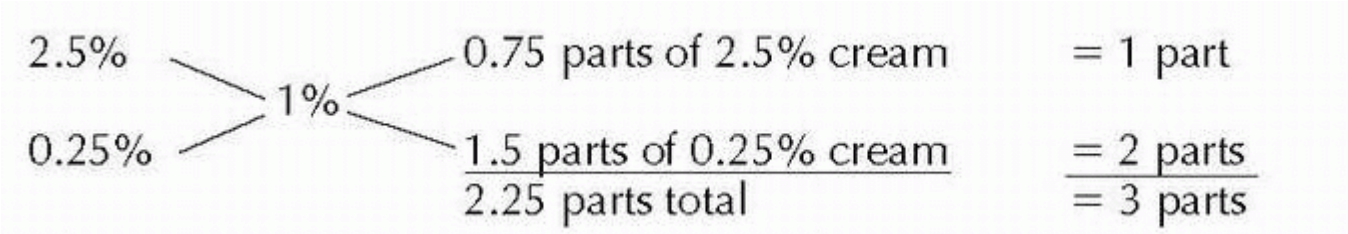
$$\frac{0.2\text{ g}}{x\text{ g}} = \frac{15\text{ mL}}{300\text{ mL}};\ x = 4\text{ g of drug required to make 300 mL}$$

c. Finally, to determine the amount of 15% concentrate required,

$$\frac{15\text{ g}}{4\text{ g}} \times \frac{100\text{ mL}}{x\text{ mL}};\ x = 26.7\text{ mL of 15\% solution required to obtain necessary drug}$$

3. When the relative amount of components must be determined for preparation of a mixture of a desired concentration, the problem is most easily solved using alligation alternate.

How many grams of 2.5% hydrocortisone cream should be mixed with 360 g of 0.25% cream to make a 1% hydrocortisone cream?



The relative amounts of the 2.5% and 1% creams are 1 to 2, respectively. By proportion, the mass of 2.5% cream to use can be determined. **If 2 parts of 0.25% cream is represented by 360 g, then the total mass (3 parts) is represented by what mass?**

$$\frac{2\text{ parts}}{3\text{ parts}} = \frac{360\text{ g}}{x\text{ g}};\ x = 540\text{ g total}$$

With the total mass known, the amount of 2.5% cream can be identified. If 3 parts represent the total mass of 540 g, then 1 part represents the mass of 2.5% cream (x g = 180 g).

$$\frac{1\text{ part}}{3\text{ parts}} = \frac{x\text{ g}}{540\text{ g}};\ x = 180\text{ g of 2.5\% cream}$$

VII. ELECTROLYTE SOLUTIONS.

Electrolyte solutions contain species (electrolytes) that dissociate into ions. The **milliequivalent** (mEq) is the unit used to express the concentration of

electrolytes in solution. Table 2-1 exhibits some physiologically important ions and their properties.

A. Milliequivalents. The milliequivalent is the amount, in milligrams, of a solute equal to 1/1000 of its gram-equivalent weight. Conversion of concentrations in the form of milliequivalent to concentrations in percentage strength, milligrams per milliliters (mg/mL) or any other terms, begins with calculation of the number of milliequivalents of drug. The following examples demonstrate the computation of milliequivalents and manipulation of data from Table 2-1 to perform the required calculations for preparing electrolyte solutions.

What is the concentration, in percent w/v, of a solution containing 2 mEq of potassium chloride per milliliter?

Calculations involving milliequivalents are easily solved if the practitioner follows a predefined procedure to determine the milliequivalent weight. This involves three steps.

1. Find the molecular weight (mol wt).

Atomic wt K	=	39
Atomic wt Cl	=	35.5
39 + 35.5 = 74.5 g	=	mol wt of KCl

2. Calculate the equivalent weight (Eq wt) of KCl.

$$\text{Eq wt} = \frac{\text{mol wt}}{\text{valence}} = \frac{74.5}{1} = 74.5 \text{ g}$$

3. Determine the milliequivalent weight, which is of the equivalent weight.

mEq wt = 74.5 g / 1000 = 0. 745 g or 74.5 mg

Table 2-1. Valences, Atomic Weights, and Milliequivalent Weights of Selected Ions

Ion	Formula	Valence	Atomic/Formula Weight	Milliequivalent Weight (mg)
Aluminum	A^{+++}	3	27	9
Ammonium	NH_4^+	1	18	18
Calcium	Ca^{++}	2	40	20
Ferric	Fe^{+++}	3	56	18.7
Ferrous	Fe^{++}	2	56	28
Lithium	Li^+	1	7	7
Magnesium	Mg^{++}	2	24	12
Bicarbonate	HCO_3^-	1	61	61
Carbonate	CO_3^-	1	60	30
Chloride	Cl^-	1	35.5	35.5
Citrate	$C_6H_5O_7^{---}$	3	189	63
Gluconate	$C_6H_{11}O_7^-$	1	195	195
Lactate	$C_3H_5O_3^-$	1	89	89
Phosphate	$H_2PO_4^-$	1	97	97
Sulfate	SO_4^{--}	2	96	48
Potassium	K^+	1	29	39

Sodium	Na^+	1	23	23
Acetate	$C_2H_3O_2^-$	1	59	59

Now that we know the milliequivalent weight, we can calculate by dimensional analysis and proportion the concentration in percentage in a fourth step.

4. 0.0745 g/mEq × 2 mEq = 0.149 g of drug

$$\frac{0.149 \text{ g drug}}{1 \text{ mL}} = \frac{x \text{ g drug}}{100 \text{ mL}}, \; x = 14.9\text{g}/100 \text{ mL} = 14.9\%$$

How many milliequivalents of Na^+ would be contained in a 15-mL volume of the following buffer?

$Na_2HPO_4 \cdot 7H_2O$		180 g
$NaH_2PO_4 \cdot H_2O$		480 g
Purified water	ad	1000 mL

For each salt, the mass (and milliequivalents) must be found in a 15-mL dose.

mol wt $Na_2HPO_4 \cdot 7H_2O$ (disodium hydrogen phosphate)

Eq wt = 268 / 2 = 134 g

1 mEq = 0.134 g or 134 mg

$$\frac{180 \text{ g}}{x \text{ g}} = \frac{1000 \text{ mL}}{15 \text{ mL}};\ x = 2.7 \text{ g of disodium hydrogen phosphat}$$

$$2.7 \text{ g} \times \frac{1 \text{ mEq}}{0.134 \text{ g}} = 20.1 \text{ mEq of disodium hydrogen p}$$

mol wt $NaH_2PO_4 \cdot H_2O$ (sodium biphosphate) = 1

Eq wt = 138 g

1 mEq = 0.138 g

$$\frac{480 \text{ g}}{x \text{ g}} = \frac{1000 \text{ mL}}{15 \text{ mL}};\ x = 7.2 \text{ g of sodium biphosphate in e}$$

$$7.2 \text{ g} \times \frac{1 \text{ mEq}}{0.138 \text{ g}} = 52.2 \text{ mEq of sodium biphosph}$$

20.1 mEq + 52.2 mEq = 72.3 mEq of sodium in each 15 r

B. Milliosmoles (mOsmol). Osmotic pressure is directly proportional to the total number of particles in solution. The milliosmole is the unit of measure for osmotic concentration. For nonelectrolytes, 1 millimole represents 1 milliosmole. However, for electrolytes, the total number of particles in solution is determined by the number of particles produced in solution and influenced by the degree of dissociation. Assuming complete dissociation, 1 millimole of KCl represents 2 milliosmoles of total particles, 1 millimole of $CaCl_2$ represents 3 milliosmoles of total particles, etc. The ideal osmolar concentration can be calculated with the following equation.

$$\text{mOsmol/L} = \frac{\text{wt of substance in g/L}}{\text{mol wt in g}} \times \text{number of species} \times$$

The pharmacist should recognize the difference between **ideal** osmolar concentration and **actual** osmolarity. As the concentration of solute increases, interaction between dissolved particles increases, resulting in a reduction of the actual osmolar values.

C. Isotonic solutions. An **isotonic** solution is one that has the same osmotic pressure as body fluids. **Isosmotic** fluids are fluids with the same osmotic pressure. Solutions to be administered to patients should be

isosmotic with body fluids. A **hypotonic** solution is one with a lower osmotic pressure than body fluids, whereas a **hypertonic** solution has an osmotic pressure that is greater than body fluids.

1. Preparation of isotonic solutions. Colligative properties, including freezing point depression, are representative of the number of particles in solution and considered in preparation of isotonic solutions.

a. When 1 g mol wt of any nonelectrolyte is dissolved in 1000 g of water, the freezing point of the solution is depressed by 1.86°C. By proportion, the weight of any nonelectrolyte needed to make the solution isotonic with body fluid can be calculated.

b. Boric acid (H_3BO_3) has a mol wt of 61.8 g. Thus 61.8 g of H_3BO_3 in 1000 g of water should produce a freezing point of 1.86°C. Therefore, knowing that the freezing point depression of body fluids is -0.52°C,

$$\frac{-1.86°C}{-0.52°C} = \frac{61.8\ g}{x\ g};\ x = 17.3\ g$$

and 17.3 g of H_3BO_3 in 1000 g of water provides a solution that is **isotonic.**

c. The degree of dissociation of electrolytes must be taken into account in such calculations. For example, NaCl is approximately 80% dissociated in weak solutions, yielding 180 particles in solution for each 100 molecules of NaCl. Therefore,

$$\frac{-1.86°C \times 1.8}{-0.52°C} = \frac{58\ g}{x\ g};\ x = 9.09\ g$$

indicating that 9.09 g of NaCl in 1000 g of water (0.9% w/v) should make a solution isotonic. Lacking any information on the degree of dissociation of an electrolyte, the following **dissociation values** (*i*) may be used.

(1) Substances that dissociate into two ions: 1.8

(2) Substances that dissociate into three ions: 2.6

(3) Substances that dissociate into four ions: 3.4

(4) Substances that dissociate into five ions: 4.2

2. Sodium chloride equivalents. The pharmacist will often be required to prepare an isotonic solution by adding an appropriate amount of another substance (drug or inert electrolyte or nonelectrolyte). Considering that isotonic fluids contain the equivalent of 0.9% NaCl, the question arises, How much of the added ingredient is required to make the solution isotonic? A **common method** for computing the amount of added ingredient to use for reaching isotonicity involves the use of **sodium chloride equivalents.**

a. Definition. The sodium chloride equivalent represents the amount of NaCl that is equivalent to the amount of particular drug in question. For

every substance, there is one quantity that should have a constant tonic effect when dissolved in 1000 g of water. This is 1 g mol wt of the substance divided by its dissociation value (*i*).

b. Examples

(1) Considering H_3BO_3, from the last section, 17.3 g of H_3BO_3 is equivalent to 0.52 g of NaCl in tonicity. Therefore, the relative quantity of NaCl that is equivalent to H_3BO_3 in tonicity effects is determined as follows:

$$\frac{\text{mol wt of NaCl}/i \text{ value}}{\text{mol wt of } H_3BO_3/i \text{ value}} = \frac{58.5/1.8}{61.8/1.0}$$

Applying this method to atropine sulfate, recall that the molecular weight of NaCl and the molecular weight of atropine sulfate are 58.5 and 695 g, respectively, and their *i* values are 1.8 and 2.6, respectively. Calculate the mass of NaCl represented by 1 g of atropine sulfate (Table 2-2).

$$\frac{695 \times 1.8}{58.5 \times 2.6} = \frac{1 \text{ g}}{x \text{ g}}; \; x = 0.12 \text{ g NaCl represented by 1 g of a}$$

Table 2-2. Sodium Chloride (NaCl) Equivalents

Substance	NaCl Equivalent
Atropine sulfate (H_2O)	0.12
Boric acid	0.52
Chlorobutanol	0.24
Dextrose (anhydrous)	0.18
Ephedrine hydrochloride	0.29
Phenacaine hydrochloride	0.20
Potassium chloride	0.78

(2) An example of the practical use of sodium chloride equivalents is seen in the following problem.

How many grams of boric acid should be used in compounding the following prescription?

R_x	phenacaine hydrochloride	1%
	chlorobutanol	0.5%
	boric acid	qs
	purified water, ad	60.0 mL
	make isotonic solution	

The prescription calls for 0.3 g of chlorobutanol and 0.6 g of phenacaine. How much boric acid is required to prepare this prescription? The question is best answered in four steps.

(a) Find the mass of sodium chloride represented by all ingredients.

0.20 × 0.6	=	0.120 g	of sodium chloride represented by phenacaine hydrochloride
0.24 × 0.3	=	0.072 g	of sodium chloride represented by chlorobutanol
		0.192 g	of sodium chloride represented by the two active ingredients

(b) Find the mass of sodium chloride required to prepare an equal volume of isotonic solution.

$$\frac{0.9 \text{ g NaCl}}{100 \text{ mL}} = \frac{X \text{ g NaCL}}{60 \text{ mL}}; \; x = 0.540 \text{ g of sodium chloride}$$

in 60 mL of an isotonic sodium chloride solution

(c) Calculate, by subtraction, the amount of NaCl required to make the solution isotonic.

0.540 g NaCl required for isotonicity
0.192 g NaCl represented by ingredients
0.348 g NaCl required to make isotonic solution

(d) Because the prescription calls for boric acid to be used, one last step is required.

$$\frac{0.348\ \text{g}}{0.52}\ \text{(sodium chloride equivalent for boric acid)} = 0.669\ \text{to be used}$$

VIII. STATISTICS

A. Introduction. Statistics can be used to describe and compare data distributions. Such **frequency distributions** are constructed by classifying individual observations into categories corresponding to fixed numeric intervals and plotting the number of observations in each such category (i.e., **interval frequency**) versus the category descriptor (e.g., the interval mean or range). Because of random errors, repeated observations or measurements (of the same value) are not identical. These observations have a **normal distribution.** Normally distributed data are described by a **bell-shaped (Gaussian) curve** with a maximum, μ (**population mean**), corresponding to the central tendency of the population and a spread characterized by the **population standard deviation** (σ). Statistics derived from a **sample** or subset of a population can be used as estimates of the population parameters.

B. Frequency distribution

1. Estimates of population mean. The population mean, μ, is the best estimate of the true value.

a. The sample mean. For a finite number of observations, the arithmetic average or mean (*[X with bar above]*) is the best estimate of the true value, μ.

$$\bar{X} = \frac{\sum x_i}{n}$$

where Σx_i is the sum of all (n) observations.

(1) Accuracy is the degree to which a measured value (*X* or *[X with bar above]*) agrees with the "true" value (μ).
(2) Error (or bias) is the difference between a measured value (*X* or *[X with bar above]*) and the "true" value (μ).
b. Median. The median is the midmost value of a data distribution. When all the values are arranged in increasing (or decreasing) order, the median is the middle value for an **odd** number of observations. For an **even** number of observations, the median is the arithmetic mean of the two middle values. For a **normal distribution, the median equals the mean.** The median is less affected by "outliers" or by a skewed distribution.
c. **Mode.** The mode is the most frequently occurring value (or values) in a frequency distribution. The mode is useful for non-normal distributions, especially those that are **bimodal.**
2. Estimates of variability. For an **infinite** number of observations, the **population variance** (σ^2) can be used to describe the variability or "spread" of observations in a data distribution. For a **finite** number of observations, the **sample variance** (s^2) can be used to describe the variability or spread of observations in a data distribution.
a. Sample variance (s^2) is estimated by

$$s^2 = \frac{\sum(x_i - \overline{X})^2}{(n-1)}$$

$$s^2 = \frac{\sum x_i^2 - \frac{(\sum x_i)^2}{n}}{(n-1)}$$

where *[X with bar above]* is the mean and (*n* - 1) is the number of degrees of freedom (df).
b. Range. For a very small number of observations, the **range** (*w*) can be used to describe the variability in the data set:
$w = |X_{largest} - X_{smallest}|$
c. The **standard deviation** (*s* or SD), one of the most commonly encountered estimates of variability, is equal to the square root of the variance.

$$s = \sqrt{s^2} = \sqrt{\frac{\sum(x_i - \overline{X})^2}{(n-1)}}$$

or

$$s = \sqrt{s^2} = \sqrt{\frac{\sum x_i^2 - \frac{(\sum x_i)^2}{n}}{(n-1)}}$$

d. Precision (reproducibility) is the degree to which replicate measurements "made in exactly the same way" agree with each other. **Precision** is often expressed as the **relative standard deviation** (RSD or %RSD):

$$\%\text{RSD} = \left(\frac{s}{\bar{x}} \times 100\right)$$

3. The **standard deviation of the mean** (s_m), or standard error of the mean (SEM), is an estimate of the **variability** or **error in the mean** obtained from *n* observations. It is often used to establish confidence intervals for describing the mean of a data set or when comparing the means of two data sets.

$$s_m = \frac{s}{\sqrt{n}}$$

STUDY QUESTIONS

Directions for questions 1-30: Each question, statement, or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. If a vitamin solution contains 0.5 mg **of fluoride ion in each milliliter, then how many milligrams of fluoride ion would be provided by a dropper that delivers 0.6** mL**?**

(A) 0.3 mg

(B) 0.1 mg

(C) 1 mg

(D) 0.83 mg

View Answer***1. The answer is A[see].*****2. How many chloramphenicol capsules, each containing 250** mg**, are needed to provide 25** mg **per kg per day for 7 days for a person weighing 200 lb?**

(A) 90 capsules

(B) 64 capsules

(C) 13 capsules

(D) 25 capsules

View Answer*2. The answer is B[see].*3. If 3.17 kg of a drug is used to make 50,000 tablets, how many milligrams will 30 tablets contain?

(A) 1.9 mg

(B) 1900 mg

(C) 0.0019 mg

(D) 3.2 mg

View Answer*3. The answer is B[see].*4. A capsule contains 1/8 gr of ephedrine sulfate, ¼ gr of theophylline, and gr of phenobarbital. What is the total mass of the active ingredients in milligrams?

(A) 20 mg

(B) 8 mg

(C) 28 mg

(D) 4 mg

View Answer*4. The answer is C[see].*5. If 1 fluid ounce of a cough syrup contains 10 gr of sodium citrate, how many milligrams are contained in 10 mL?

(A) 650 mg

(B) 65 mg

(C) 217 mg

(D) 20 mg

View Answer*5. The answer is C[see].*6. How many capsules, each containing ¼ gr of phenobarbital, can be manufactured if a bottle containing 2 avoirdupois ounces of phenobarbital is available?

(A) 771 capsules

(B) 350 capsules

(C) 3500 capsules

(D) 1250 capsules

View Answer*6. The answer is C[see].*7. Using the formula for calamine lotion, determine the amount of calamine (in grams) necessary to prepare 240 mL of lotion.

Calamine	80 g
Zinc oxide	80 g
Glycerin	20 mL
Bentonite magma	250 mL

Calcium hydroxide topical solution	sufficient quantity to make 1000 mL

(A) 19.2 g

(B) 140 g

(C) 100 g

(D) 24 g

View Answer***7. The answer is A[see].***8. From the following formula, calculate the amount of white wax required to make 1 lb of cold cream. Determine the mass in grams.

Cetyl esters wax	12.5 parts
White wax	12.0 parts
Mineral oil	56.0 parts
Sodium borate	0.5 parts
Purified water	19.0 parts

(A) 56.75 g

(B) 254.24 g

(C) 54.48 g

(D) 86.26 g

View Answer***8. The answer is C[see].***9. How many grams of aspirin should be used to prepare 1.255 kg of the powder?

ASA	6 parts
Phenacetin	3 parts
Caffeine	1 part

(A) 125 g
(B) 750 g
(C) 175 g
(D) 360 g

View Answer***9. The answer is B[see].***P.24

10. A solution contains 1.25 mg **of a drug per milliliter. At what rate should the solution be infused (drops/min) if the drug is to be administered at a rate of 80** mg**/hr? (1** mL **= 30 drops)**

(A) 64 drops/min
(B) 1.06 drops/min
(C) 32 drops/min
(D) 20 drops/min

View Answer***10. The answer is C[see].*****11. The recommended maintenance dose of aminophylline for children is 1.0** mg**/kg/hr by injection. If 10** mL **of a 25-**mg/mL **solution of aminophylline is added to a 100-**mL **bottle for dextrose, what should be the rate of delivery in** mL**/hr for a 40-lb child?**

(A) 2.30 mL/hr
(B) 8.00 mL/hr
(C) 18.9 mL/hr
(D) 18.2 mL/hr

View Answer***11. The answer is B[see].*****12. For children, streptomycin is to be administered at a dose of 30** mg**/kg of body weight daily in divided doses every 6-12** hr. **The dry powder is dissolved by adding water for injection,** USP **in an amount to yield the desired concentration as indicated in the following table (for a 1-g vial).**

Approximate	
Concentration (mg/mL)	Volume (mL)
200	4.2
250	3.2
400	1.8

Reconstituting at the lowest possible concentration, what volume (in mL) would be withdrawn to obtain one day's dose for a 50-lb child?

(A) 3.4 mL

(B) 22.73 mL

(C) 2.50 mL

(D) 2.27 mL

View Answer***12. The answer is A[see].***13. **The atropine sulfate is available only in the form of 1/150 gr tablets. How many atropine sulfate tablets would you use to compound the following prescription?**

Atropine sulfate	1/200 gr
Codeine phosphate	1/4 gr
Aspirin	5 gr
d.t.d.	#24 capsules
Sig:	1 capsule p.r.n.

(A) 3 tablets

(B) 6 tablets

(C) 12 tablets

(D) 18 tablets

View Answer***13. The answer is D[see].***14. **In 25.0 mL of a solution for injection, there are 4.00 mg of the drug. If the dose to be administered to a patient is 200 µg, what quantity (in mL) of this solution should be used?**

(A) 1.25 mL

(B) 125 mL

(C) 12.0 mL

(D) None of the above

View Answer***14. The answer is A[see].***15. **How many milligrams of papaverine will the patient receive each day?**

R_x	papaverine	1.0 g
	hydrochloride aqua	30.0 mL
	syrup tolu, qs ad	90.0 mL
	Sig:	1 teaspoon t.i.d.

(A) 56 mg

(B) 5.6 mg

(C) 166 mg

(D) 2.5 mg

View Answer***15. The answer is C[see].***16. **Considering the following formula, how many grams of sodium bromide should be used in filling this prescription?**

R_x	sodium bromide	1.2 g
	syrup tolu	2.0 mL
	syrup wild cherry, qs ad	5.0 mL
	d.t.d.	#24

(A) 1.2 g

(B) 1200 g

6. The answer is C *[see* II*].*

7. The answer is A *[see* III*].*

8. The answer is C *[see* II; III.A*].*

The formula tells the pharmacist that white wax (W.W.) represents 12 parts out of the total 100 parts in the prescription. What we wish to determine is the mass of white wax required to prepare 454 g (1 lb) of the recipe. This can be easily solved by proportion:

$$\frac{12 \text{ parts W.W.}}{100 \text{ parts total}} = \frac{x}{454 \text{ parts (grams)}}; \; x = 54.48 \text{ g}$$

9. The answer is B *[see* III.A*].*

10. The answer is C *[see* IV.E*].*

11. The answer is B *[see* II; IV*].*

12. The answer is A *[see* IV*].*

13. The answer is D *[see* II; III.B*].*

14. The answer is A *[see* I.A.2; II*].*

Dimensional analysis is often useful for calculating doses. Considering that 4 mg of the drug is present in each 25 mL of solution, we can easily calculate the number of milliliters to be used to give a dose of 0.200 mg (200 µg). Always include units in your calculations.

$$\frac{25 \text{ mL}}{4 \text{ mg}} \times 0.200 \text{ mg} = 1.25 \text{ mL}$$

15. The answer is C *[see* III.B*].*

16. The answer is C *[see* III.B*].*

17. The answer is B *[see* V.A; VI*].*

First, determine the mass of drug in the final diluted solution.

$$\frac{1 \text{ part}}{5000 \text{ parts}} = \frac{x \text{ g}}{500 \text{ g}}; \; x = 0.1 \text{ g}$$

Now, if 0.1 g of drug is present in 500 mL of 1:5000 solution, 2 teaspoonfuls (10 mL) of the prescription contains the same amount of drug (0.1 g) before dilution. From this, the amount of drug in 1000 mL (the total volume) of the prescription can be determined:

$$\frac{0.1 \text{ g}}{10 \text{ mL}} = \frac{x \text{ g}}{1000 \text{ mL}}; \; x = 10 \text{ g}$$

Finally, to obtain the correct amount of drug to formulate the prescription (10 g), we are to use a 7.5% stock solution. Recalling the definition of percentage strength w/v:

$$\frac{100 \text{ mL}}{7.5 \text{ g}} \times 10 \text{ g} = 133.3 \text{ mL or } 133 \text{ mL}$$

18. The answer is B *[see* III.B*].*

19. The answer is B *[see* V.C; VI.C*].*

20. The answer is A *[see* I.A.2; V.A*].*

Using dimensional analysis

$$\frac{20\text{ g} \times 100\text{ mL}}{0.9\text{ g}} = 2222\text{ mL}$$

21. The answer is B *[see* V.D.1*].*

22. The answer is C *[see* I.A; V.A.1*].*

Using the density, the weight of 125 mL of syrup can be calculated:

125 mL × 1.313g/mL = 164.125 g

Using proportion and the sucrose concentration in w/v, the weight of sucrose in 125 mL of syrup can be calculated:

$$\frac{100\text{ mL}}{125\text{ mL}} = \frac{85\text{ g}}{x\text{ g}};\ x = 106.25\text{g}$$

Finally, the weight of water in 125 mL of syrup can be calculated:

164.125 g - 106.25 g = 57.875 g

which has a volume of 57.9 mL.

23. The answer is C *[see* I; II; V*].*

24. The answer is A *[see* I; V*].*

25. The answer is A *[see* I; V*].*

The problem is easily solved by proportion. The question to be answered is, If 1 g of drug is present in 1500 mL of solution, what volume can be made with 4.8 g of drug?

$$\frac{1\text{ g}}{4.8\text{ g}} = \frac{1500\text{ mL}}{x\text{ mL}};\ x = 7200\text{ mL}$$

(the volume of 1 to 1500 solution that can be prepared from 4.8 g of drug)

26. The answer is A *[see* I; V*].*

27. The answer is C *[see* VII.B*].*

Recalling the expression for ideal osmolar concentration:

$$\begin{aligned}\text{mOsmol/L} &= \frac{100\text{ g/L}}{147\text{ g/mol}} \times 3 \times 1000\\ &= \text{mOsmol/L} \times 0.147\text{ L}\\ &= 300\text{ mOsmol}\end{aligned}$$

28. The answer is A *[see* VII.C*].*

29. The answer is D *[see* VII.A*].*

30. The answer is B *[see* IV.E*].*

Using dimensional anaylsis:

$$\frac{1000\text{ mg}}{250\text{ mL}} \times \frac{250\text{ mL}}{2\text{ hr}} \times \frac{1\text{ hr}}{60\text{ min}} = 8.33\text{ mg/min}$$

31. The answer is C *[see* VIII.B.1*].*

The mean is calculated directly from the equation:

$$\bar{X} = \frac{\sum X_i}{n} = \frac{998.1}{5} = 199.6\text{ mg}$$

32. The answer is C *[see* VIII.B.3*].*

The standard deviation can be calculated with the most commonly used equation:

x_i	x_i^2
198.2	39,283.24*
199.7	39,880.09
202.5	41,006.25
201.3	40,521.69
196.4	38,572.96
$\sum x_i = 998.1$	$\sum x_i^2 = 199{,}264.23$

$$\sqrt{s^2} = \sqrt{\frac{199{,}264.23 - \frac{(988.1)^2}{5}}{(5-1)}} = 2.42 \text{ mg}$$

*Note: It is important to carry enough significant figures through the calculation off error.

33. The answer is B *[see VIII.B.4].*

$$\%\text{RSD} = \left(\frac{s}{\bar{x}}\right) \times 100 = \left(\frac{2.42}{199.6}\right) \times 100 = 1.21\%$$

34. The answer is D *[see VIII.C].*

$$s_m = \frac{s}{\sqrt{n}} = \frac{2.42}{\sqrt{5}} = 1.08 \text{ mg}$$

Pharmaceutical Principles and Drug Dosage Forms

Lawrence H. Block

I. INTRODUCTION.

Pharmaceutical principles are the underlying physicochemical principles that allow a drug to be incorporated into a pharmaceutical **dosage form** (e.g., solution, capsule). These principles apply whether the drug is extemporaneously compounded by the pharmacist or manufactured for commercial distribution as a **drug product.**

A. The finished **dosage form** contains the active drug ingredient in association with nondrug (usually inert) ingredients (**excipients**) that make up the **vehicle,** or **formulation matrix.**

B. The **drug delivery system** concept, which has evolved since the 1960s, is a more holistic concept. It embraces not only the drug (or prodrug) and its formulation matrix, but also the dynamic interactions among the drug, its formulation matrix, its container, and the physiologic milieux of the patient. These dynamic interactions are the subject of **biopharmaceutics** (see Chapter 4).

II. INTERMOLECULAR FORCES OF ATTRACTION

A. Introduction. The application of pharmaceutical principles to drug dosage forms is illustrated when drug dosage forms are **categorized** according to their **physical state, degree of heterogeneity,** and **chemical composition.** The usual relevant states of matter are **gases, liquids,** and **solids.** Intermolecular forces of attraction are weakest in gases and strongest in solids. Conversions from one physical state to another can involve simply overcoming intermolecular forces of attraction by adding energy (heat). Chemical composition can have a dramatic effect on physicochemical properties and behavior. For this reason, it is necessary to distinguish between **polymers,** or **macromolecules,** and more conventional (i.e., smaller) molecules, or **micromolecules.**

B. Intermolecular forces of attraction. Because atoms vary in their electronegativity, electron sharing between different atoms is likely to be unequal. This asymmetric electron distribution causes a shift in the overall electron cloud in the molecule. As a result, the molecule tends to behave as a **dipole** (i.e., as if it had a positive and a negative pole). The dipole associated with each covalent bond has a corresponding **dipole moment** (μ) defined as the product of the distance of charge separation (d) and the charge (q):

$$\mu = q \times d$$

The molecular dipole moment may be viewed as the vector sum of the individual bond moments.

1. Nonpolar molecules that have **perfect symmetry** (e.g., carbon tetrachloride) have dipole moments of zero (Figure 3-1).
2. Polar molecules are **asymmetric** and have nonzero dipole moments.
3. When **dipolar** molecules approach one another close enough—"positive to positive" or "negative to negative"—so that their electron clouds interpenetrate, **intermolecular repulsive forces** arise. When these dipolar molecules approach one another so that the positive

pole of one is close to the negative pole of the other, molecular **attraction** occurs (**dipoledipole interaction**). When the identically charged poles of the two molecules are closer, **repulsion** occurs.

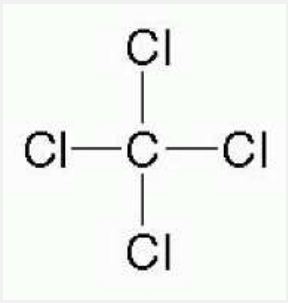

Figure 3-1. The carbon tetrachloride molecule.

C. Types of intermolecular forces of attraction include the following:
1. Nonpolar molecules do not have permanent dipoles. However, the instantaneous electron distribution in a molecule can be asymmetric. The resultant transient dipole moment can induce a dipole in an adjacent molecule. This **induced dipole-induced dipole interaction (London dispersion force),** with a force of 0.5-1 kcal/mol, is sufficient to facilitate order in a molecular array. These relatively weak electrostatic forces are responsible for the liquefaction of nonpolar gases.
2. The transient dipole induced by a permanent dipole, or **dipole-induced dipole interaction (Debye induction force),** is a stronger interaction, with a force of 1-3 kcal/mol.
3. Permanent dipole interactions (Keesom orientation forces), with a force of 1-7 kcal/mol, together with Debye and London forces, constitute **van der Waals forces.** Collectively, they are responsible for the more substantive structure and molecular ordering found in liquids.
4. Hydrogen bonds. Because they are small and have a large electrostatic field, hydrogen atoms can approach highly electronegative atoms (e.g., fluorine, oxygen, nitrogen, chlorine, sulfur) and interact electrostatically to form a hydrogen bond. Depending on the electronegativity of the second

atom and the molecular environment in which hydrogen bonding occurs, hydrogen bond energy varies from approximately 1 to 8 kcal/mol.

5. Ion-ion, ion-dipole, and ion-induced dipole forces. Positive-negative ion interactions in the solid state involve forces of 100-200 kcal/mol. Ionic interactions are reduced considerably in liquid systems in the presence of other electrolytes. **Ion-dipole** interaction, or **dipole induction by an ion,** can also affect molecular aggregation, or ordering, in a system.

III. STATES OF MATTER

A. Gases. Molecules in the gaseous state can be pictured as moving along straight paths, in all directions and at high velocities (e.g., mean velocity for H_2O vapor: 587 m/sec; for O_2: 440 m/sec), until they collide with other molecules. As a result of these random collisions, molecular velocities and paths change, and the molecules continue to collide with other molecules and with the boundaries of the system (e.g., the walls of a container holding the gas). This process, repeated incessantly, is responsible for the **pressure** exhibited within the confines of the system.

1. The interrelation among **volume (*V*), pressure (*P*),** and the **absolute temperature (*T*)** is given by the **ideal gas law,** which is the equation of state for an ideal gas:

$PV = nRT$

$PV = (g/M)RT$

where n is the number of moles of gas—equivalent to the number of grams (g) of gas divided by the molecular weight of the gas (M)—and R is the **molar gas constant** (0.08205 L atm/mole deg).

2. Pharmaceutical gases include the **anesthetic gases** (e.g., nitrous oxide, halothane). **Compressed gases** include oxygen (for therapy), nitrogen, and carbon dioxide. **Liquefiable gases,** including certain **halohydrocarbons** and **hydrocarbons,** are used as propellants in **aerosol products (pressurized packaging),** as are compressed gases, such as nitrous oxide, nitrogen, and carbon dioxide. Ethylene oxide is a gas used to sterilize or disinfect heat-labile objects.

3. In general, as the temperature of a substance increases, its **heat content,** or **enthalpy,** increases as well.

a. Substances can undergo a change of state, or phase change, from the solid to the liquid state (**melting**) or from the liquid to the gaseous state (**vaporization**).

b. Volatile liquids (e.g., ether, halothane, methoxyflurane) are used as inhalation anesthetics. Amyl nitrite is a volatile liquid that is inhaled for its vasodilating effect in acute angina.

c. **Sublimation** occurs when a solid is heated directly to the gaseous, or vapor, state without passing through the liquid state (e.g., camphor, iodine). Ice sublimes at pressures below

3 torr. The process of **freeze-drying,** or **lyophilization,** is a form of vacuum drying in which water is removed by sublimation from the frozen product. It is an especially useful process for drying aqueous solutions or dispersions of heat- or oxygen-sensitive drugs and biologicals (e.g., proteins, peptides).
d. The reverse process (i.e., direct transition from the vapor state to the solid state) is also referred to as sublimation, but the preferred term is **deposition.** Some forms of sulfur and colloidal silicon dioxide are prepared in this way.
4. The intermolecular forces of attraction in gases are virtually nonexistent at room temperature. Gases display little or no ordering.
B. Liquids. The intermolecular forces of attraction in liquids (**van der Waals forces**) are sufficient to impose some ordering, or regular arrangement, among the molecules. **Hydrogen bonding** increases the likelihood of cohesion in liquids and further affects their physicochemical behavior. However, these forces are much weaker than **covalent** or **ionic** forces. Therefore, liquids tend to display short-range rather than long-range order. Hypothetically, although molecules of a liquid would tend to aggregate in localized clusters, no defined structuring would be evident.
1. Surface and interfacial tension
a. Molecules in the bulk phase of a liquid are surrounded by other molecules of the same kind (Figure 3-2A). Molecules at the surface of a liquid are not completely surrounded by like molecules (Figure 3-2B). As a result, molecules at or near the surface of a liquid experience a net inward pull from molecules in the interior of the liquid. Because of this net inward intermolecular attraction, the liquid surface tends to spontaneously contract. Thus liquids tend to assume a spherical shape (i.e., a volume with the minimum surface area). This configuration has the least free energy.
b. Any expansion of the surface increases the free energy of the system. Thus **surface free energy** can be defined by the work required to increase the surface area A of the liquid by 1 area unit. This value is expressed as the number of milli-Newtons (mN) needed to expand a 1-m2 surface by 1 unit:
work = $\gamma \times \Delta A$
where ΔA is the increase in surface area and γ is the **surface tension,** or **surface free energy,** in mN m^{-1}—equivalent to centimeter-gram-second (CGS) units of dynes cm^{-1}. At 20°C. water has a surface tension of 72 mN m^{-1}, whereas *n*-octanol has a surface tension of 27 mN m^{-1}. Thus more work must be expended to expand the surface of water than to expand the surface of *n*-octanol (i.e., to proceed from a given volume of bulk liquid to the corresponding volume of small droplets).
c. At the **boundary,** or **interface,** between two immiscible liquids that are in contact with one another, the corresponding **interfacial tension** (i.e., free energy, or work required to expand the interfacial area) reflects the extent of the intermolecular forces of attraction and repulsion at the interface.

When the interface is between two liquids, substantial molecular interaction occurs across the interface between the two phases. This interaction

reduces the imbalance in forces of attraction within each phase. The interfacial tension between *n*-octanol and water is reduced to 8.5 mN m^{-1} from 72 mN m^{-1} (γ air/water). This reduction indicates, in part, the interfacial interaction between *n*-octanol and water.

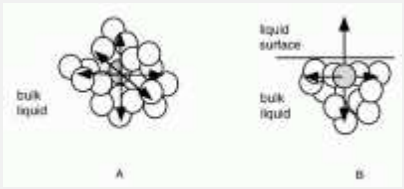

Figure 3-2. A. Molecules in the bulk phase. **B.** Molecules at the surface of a liquid.

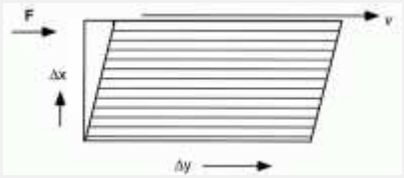

Figure 3-3. Liquid flow.

2. The flow of a liquid across a solid surface can be examined in terms of the **velocity,** or rate of movement, of the liquid relative to the surface across which it flows. More insight can be gained by visualizing the flow of liquid as involving the movement of numerous parallel layers of liquid between an upper, movable plate and a lower, fixed plate (Figure 3-3). The application of a constant force (*F*) to the upper plate causes both this plate and the uppermost layer of liquid in contact with it to move with a velocity $\Delta y/\Delta x$. The interaction between the fixed bottom plate and the liquid layer closest to it prevents the movement of the bottom layer of liquid. The

velocity (*v*) of the remaining layers of liquid between the two plates is proportional to their distance from the immovable plate (i.e., $\Delta y/\Delta x$). The **velocity gradient** leads to deformation of the liquid with time. This deformation is the **rate of shear,** dv/dx, or *D*. **Newton** defined flow in terms of the ratio of the force *F* applied to a plate of area *A*—**shear stress** (τ)—divided by the velocity gradient (*D*) induced by τ:

$$\frac{F}{A} = \eta \frac{dv}{dx}$$

or

$$\frac{\tau}{D} = \eta$$

The proportionality constant η is the coefficient of **viscosity.** It indicates the resistance to flow of adjacent layers of fluid. The reciprocal of η is **fluidity.** Units of viscosity in the CGS system are dynes $cm^{-2}s^{-1}$, or poise. In the SI system, the units are Newtons $m^{-2}s^{-1}$, which corresponds to 10 poise. The viscosity of water at 20°C is approximately 0.01 poise, or 1 centipoise (cps), which corresponds to 1 mN $m^{-2}s^{-1}$.

a. Substances that flow in accordance with the equation in III.B.2 (Newton's law) are known as **Newtonian substances.** Liquids that consist of simple molecules and dilute dispersions tend to be **Newtonian.** For a Newtonian fluid, a plot of shear stress as a function of shear rate (a **flow curve** or **rheogram**) yields a straight line with a slope of η (Figure 3-4, *Curve 1*).

b. Non-Newtonian substances do not obey Newton's equation of flow. These substances tend to exhibit **shear-dependent** or **time-dependent viscosity.** In either case, viscosity is more aptly termed **apparent viscosity** because Newton's law is not strictly obeyed. Heterogeneous liquids and solids are most likely non-Newtonian.

(1) Shear-dependent viscosity involves either an *increase* in apparent viscosity (i.e., **shear thickening,** or **dilatancy**) (Figure 3-4, *Curve 3*) or a *decrease* in apparent viscosity (i.e., **shear thinning,** or **pseudo-plasticity**) (Figure 3-4, *Curve 2*) with an increase in the rate of shear. Shear thickening is displayed by suspensions that have a high solids content of small, deflocculated particles. Shear thinning is displayed by polymer

or macromolecule solutions. **Plastic,** or **Bingham body,** behavior (Figure 3-4, *Curve 4*) is exemplified by flocculated particles in concentrated suspensions that show no apparent response to low-level stress. Flow begins only after a limiting yield stress (**yield value**) is exceeded.

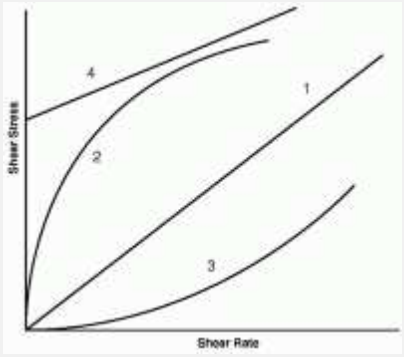

Figure 3-4. Non-Newtonian flow curves.

(2) Time-dependent viscosity

(a) The yield value of **plastic** systems may be time dependent (i.e., may depend on the time scale involved in the application of force). **Thixotropic** systems display shear-thinning behavior but do not immediately recover their higher apparent viscosity when the rate of shear is lowered. In a thixotropic system, structural recovery is relatively slow compared with structural breakdown.

(b) Thixotropy occurs with heterogeneous systems that involve a three-dimensional structure or network. When such a system is at rest, it appears to have a relatively rigid consistency. Under shear, the structure breaks down and fluidity increases (i.e., **gel-sol** transformation).

(c) Rheopexy (negative thixotropy, or antithixotropy) occurs when the apparent viscosity of the system continues to increase with continued application of shear up to some equilibrium value at a given shear rate. These systems display a **sol-gel** transformation. One explanation for antithixotropic behavior is that continued shear increases the frequency of particle or macromolecule interactions and leads to increased structure in the system.

C. Solids. Intermolecular forces of attraction are stronger in solids than in liquids or gases. Molecular arrangements in solids may be characterized as either crystalline or amorphous.

1. Crystalline solids have the following attributes:

a. Fixed **molecular order** (i.e., molecules occupy set positions in a specific array)

b. A distinct melting point

c. **Anisotropicity** (i.e., their properties are not the same in all directions), with the exception of cubic crystals

2. Amorphous solids have the following attributes:

a. Randomly arranged molecules with the short-range order typical of liquids

b. No melting points

c. **Isotropicity** (i.e., properties are the same in all directions)

P.35

d. Less thermodynamic stability than the corresponding crystalline solid and therefore more apt to exhibit chemical and physical instability, increased dissolution rate, etc.

3. Polymorphism is the condition wherein substances can exist in more than one crystalline form. These **polymorphs** have different molecular arrangements or crystal lattice structures. As a result, the different polymorphs of a drug solid can have different properties. For example, the melting point, solubility, dissolution rate, density, and stability can differ considerably among the polymorphic forms of a drug. Many drugs exhibit polymorphic behavior. Fatty (triglyceride) excipients (e.g., theobroma oil, cocoa butter) are recognized for their polymorphic behavior.

4. The incorporation of solvent molecules into the crystal lattice of a solid results in a molecular adduct known as a **solvate** or **hydrate** (the latter term is used when water is the solvent). In general, solvates or hydrates exhibit different solubilities and dissolution rates than their unsolvated/anhydrous counterparts.

5. Melting point and heat of fusion. The melting point of a solid is the temperature at which the solid is transformed to a liquid. When 1 g of a solid is heated and melts, the heat absorbed in the process is referred to as the **latent heat of fusion.**

D. Phase diagrams and phase equilibria. A **phase diagram** represents the states of matter (i.e., solid, liquid, and gas) that exist as temperature and pressure are varied (Figure 3-5). The data

P.36

arrays separating the phases in Figure 3-5 delineate the temperatures and pressures at which the phases can coexist. Thus gas (or vapor) and liquid coexist along “curve” *BC,* solid and liquid coexist along “curve” *AB,* and solid and gas (or vapor) coexist along “curve” *DB.* Depending on the change in temperature and pressure, **evaporation** or **condensation** occur along curve *BC,* **fusion** or **melting** along curve *AB,* and **sublimation** or **deposition** along curve *DB.* The three “curves” intersect at point *B.* Only at this unique temperature and pressure, known as the **triple point,** do all three phases exist in equilibrium. (The triple point for water is 0.01°C and 6.04×10^{-3} atm.) Continuing along curve *BC,* to higher temperatures and pressures, one ultimately reaches point *C,* known as the **critical point,** above which there is no distinction between the liquid and the gas phases. Substances that exist above this critical point are known as **supercritical fluids.** Supercritical fluids such as carbon dioxide (critical point, 30.98°C and 73.8 atm) often exhibit markedly altered physicochemical properties (e.g., density, diffusivity, or solubility characteristics) that render them

useful as solvents and processing aids in the production of pharmaceuticals and drug delivery systems.

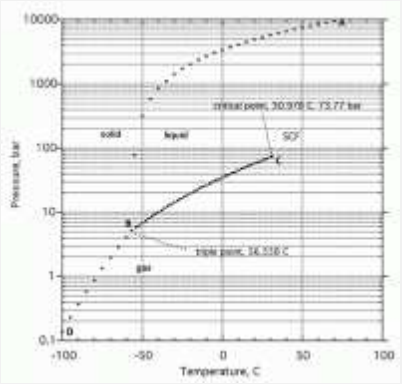

Figure 3-5. Phase diagram for CO_2 showing the variation of the state of matter as pressure and temperature are varied. The solid state exists in the region *ABD;* the liquid state, in the region *ABC;* and the gas state, in the region to the right of curve *CD. B* corresponds to the triple point, the pressure and temperature at which all three phases coexist. *C* corresponds to the critical point, the pressure and temperature above which the liquid and gas phases are indistinguishable.

IV. PHYSICOCHEMICAL BEHAVIOR

A. Homogeneous systems

1. A **solution** is a homogeneous system in which a **solute** is molecularly dispersed, or dissolved, in a **solvent.** The solvent is the predominant species. **Saturated solutions** are solutions that, at a given temperature and pressure, contain the maximum amount of solute that can be accommodated by the solvent. If the saturation, or solubility, limit is exceeded, a fraction of the solute can separate from the solution and exist in equilibrium with it.

a. Solutes can be gases, liquids, or solids, and nonelectrolytes or electrolytes.

(1) Nonelectrolytes are substances that **do not form ions** when dissolved in water. Examples are estradiol, glycerin, urea, and sucrose. Their aqueous solutions do not conduct electric current.

(2) Electrolytes are substances that **do form ions** in solution. Examples are sodium chloride, hydrochloric acid, and atropine. As a result, their aqueous solutions conduct electric current. Electrolytes are characterized as **strong** or **weak.** Strong electrolytes (e.g., sodium chloride, hydrochloric acid) are **completely ionized** in water at all concentrations. Weak electrolytes (e.g., aspirin, atropine) are **partially ionized** in water.

b. The **colligative properties of a solution** depend on the total **number of ionic and nonionic solute molecules in the solution.** These properties depend on ionization but are **independent of other chemical properties of the solute.**

2. Colligative properties include the following:

a. Lowering of vapor pressure. The **partial vapor pressure** of each volatile component in a solution is equal to the product of the mol fraction

of the component in the solution and the vapor pressure of the pure component. This is **Raoult's law:**

$$P_A = P_A^0 \times x_A$$

where p_A is the partial vapor pressure above a solution in which the mol fraction of the solute A is x_A and is the **vapor pressure** of the pure component A. The vapor pressure is the pressure at which an equilibrium is established between the molecules of A in the liquid state and the molecules of A in the gaseous (vapor) state in a closed, evacuated container. The vapor pressure is temperature dependent, but independent of the amount of liquid and vapor. Raoult's law holds for ideal solutions of nonelectrolytes. For a **binary solution** (i.e., a solution of component B in component A)

$$\frac{P_A^0 - P_A}{P_A^0} = (1 - x_A) = x_B$$

The lowering of the vapor pressure of the solution relative to the vapor pressure of the pure solvent is proportional to the number of molecules of solute in the solution. The actual lowering of the vapor pressure by the solute, Δp_A, is given by

$$\Delta p_A = (P_A^0 - p_A) = x_B P_A^0$$

b. Elevation of the boiling point. The **boiling point** is the temperature at which the vapor

pressure of a liquid equals an external pressure of 760 mm Hg. A solution of a nonvolatile solute has a higher boiling point than a pure solvent because the solute lowers the vapor pressure of the solvent. The amount of elevation of the boiling point (ΔT_b) depends on the concentration of the solute:

$$\Delta T_b = \frac{RT_0^2 M_1 m}{1000 \times \Delta H_{vap}} = K_b m$$

where K_b is the molal boiling point elevation constant, R is the molar gas constant, T is absolute temperature (degrees K), M_1 is the molecular weight of the solute, m is the molality of the solution, and ΔH_{vap} is the molal enthalpy of vaporization of the solvent.

c. **Depression of the freezing point.** The **freezing point,** or melting point, of a pure compound is the temperature at which the solid and the liquid phases are in equilibrium under a pressure of 1 atmosphere (atm). The freezing point of a solution is the temperature at which the solid phase of the pure solvent and the liquid phase of the solution are in equilibrium under a pressure of 1 atm. The amount of depression of the freezing point (ΔT_f) depends on the molality of the solution:

$$\Delta T_f = \frac{RT_0^2 M_1 m}{1000 \times \Delta H_{fusion}} = K_f m$$

where K_f is the molal freezing point constant and ΔH_{fusion} is the molal heat of fusion.

d. Osmotic pressure. Osmosis is the process by which solvent molecules pass through a semipermeable membrane (a barrier through which only solvent molecules may pass) from a region of dilute solution to one of more concentrated solution. Solvent molecules transfer because of the inequality in chemical potential on the two sides of the membrane. Solvent molecules in a concentrated solution have a lower chemical potential than solvent molecules in a more dilute solution.

(1) Osmotic pressure is the **pressure** that must be applied to the solution to prevent the flow of pure solvent into the concentrated solution.

(2) Solvent molecules move from a region where their **escaping tendency is high** to one where their **escaping tendency is low.** The presence of dissolved solute lowers the escaping tendency of the solvent in proportion to the solute concentration.

(3) The **van't Hoff equation** defines the osmotic pressure π as a function of the number of moles of solute n_2 in the solution of volume V:

$\pi V = n_2 RT$

3. Electrolyte solutions and ionic equilibria

a. Acid-base equilibria

(1) According to the **Arrhenius dissociation theory,** an **acid** is a substance that liberates H^+ in aqueous solution. A **base** is a substance that liberates hydroxyl ions (OH^-) in aqueous solution. This definition applies only under aqueous conditions.

(2) The **Lowry-Brønsted theory** is a more powerful concept that applies to aqueous and nonaqueous systems. It is most commonly used for pharmaceutical and biologic systems because these systems are primarily aqueous.

(a) According to this definition, an **acid** is a substance (charged or uncharged) that is capable of donating a proton. A **base** is a substance (charged or uncharged) that is capable of accepting a proton from an acid. The dissociation of an acid (HA) always produces a base (A^-) according to the following formula:

$HA \leftrightarrow H^+ + A^-$

(b) HA and A^- are a **conjugate acid-base pair** (an acid and a base that exist in equilibrium and differ in structure by a proton). The proton of an acid does not exist free in solution, but combines with the solvent. In water, this **hydrated proton** is a **hydronium ion** (H_3O^+).

(c) The relative **strengths** of acids and bases are determined by their ability to donate or accept protons. For example, in water, HCl donates a proton more readily than does acetic acid. Thus HCl is a stronger acid. Acid strength is also determined by the affinity of the solvent for protons. For

example, HCl may dissociate completely in liquid ammonia, but only very slightly in glacial acetic acid. Thus HCl is a strong acid in liquid ammonia and a weak acid in glacial acetic acid.

P.38

(3) The **Lewis theory** extends the acid-base concept to reactions that do not involve protons. It defines an **acid** as a molecule or ion that accepts an electron pair from another atom and a **base** as a substance that donates an electron pair to be shared with another atom.

b. H^+ concentration values are very small. Therefore, they are expressed in **exponential notation as pH.** The pH is the logarithm of the reciprocal of the H^+ concentration

$$pH = \log\left(\frac{1}{[H^+]}\right)$$

where $[H^+]$ is the molar concentration of H^+. Because the logarithm of a reciprocal equals the **negative logarithm** of the number, this equation may be rewritten as:

$pH = -\log [H^+]$

or

$[H^+] = 10^{-pH}$

Thus the pH value may be defined as the negative logarithm of the $[H^+]$ value. For example, if the H^+ concentration of a solution is 5×10^{-6}, the pH value may be calculated as follows:

pH	=	$-\log (5 \times 10^{-6})$
$\log 5$	=	0.699
$\log 10^{-6}$	=	-6.0
pH	=	-(-6 + 0.699)
	=	-(-5.301)
	=	5.301

c. As pH decreases, **H^+ concentration increases exponentially.** When the pH decreases from 6 to 5, the H^+ concentration increases from 10^{-6} to 10^{-5},

or 10 times its original value. When the pH falls from 5 to 4.7, the H^+ concentration increases from 1×10^{-5} to 2×10^{-5}, or double its initial value.

d. Dissociation constants. Ionization is the complete separation of the ions in a crystal lattice when the salt is dissolved. **Dissociation** is the separation of ions in solution when the ions are associated by interionic attraction.

(1) For **weak electrolytes,** dissociation is a reversible process. The equilibrium of this process can be expressed by the law of mass action. This law states that the rate of the chemical reaction is proportional to the product of the concentration of the reacting substances, each raised to a power of the number of moles of the substance in solution.

(2) For **weak acids,** dissociation in water is expressed as:

$HA \leftrightarrow H^+ + A^-$

The dynamic equilibrium between the simultaneous forward and reverse reactions is indicated by the arrows. By the law of mass action,

rate of forward reaction = $K_1[HA]$

rate of reverse reaction = $K_2[H^+][A^-]$

At equilibrium, the forward and reverse rates are equal. Therefore,

$K_1[HA] = K_2[H^+][A^-]$

Thus **the equilibrium expression for the dissociation of a weak acid** is written as:

$$K_a = \frac{K_1}{K_2} = \frac{[H^+][A^-]}{[HA]}$$

where $K_a$represents the acid dissociation constant. For a weak acid, the **acid dissociation constant** is conventionally expressed as **pK_a,** which is -log K_a. For example, the K_a of acetic acid at 25°C is 1.75×10^{-5}. The pK_a is calculated as follows:

pKa	=	$-\log (1.75 \times 10^{-5})$
log 1.75	=	0.243
$\log 10^{-5}$	=	-5
pH	=	-(-5 + 0.243)

	=	-(-4.757)
	=	4.76

(3) For **weak bases,** dissociation may also be expressed with the K_a expression for the **conjugate acid of the base.** This acid is formed when a proton reacts with the base. For a base that does not contain a hydroxyl group,

$BH^+ \leftrightarrow H^+ + B$

The **dissociation constant** for this reaction is expressed as:

$$K_a = \frac{[H^+][B]}{[BH^+]}$$

However, a **base dissociation constant** is traditionally defined for a weak base with this expression:

$B + H_2O \leftrightarrow OH^- + BH^+$

$$B + H_2O \leftrightarrow OH^- + BH^+$$

$$K_b = \frac{[OH^-][BH^+]}{[B]}$$

where K_b represents the dissociation constant of a weak base. This **dissociation constant** can be expressed as **pK_b,** as follows:

$pK_b = -\log K_b$

(4) Certain compounds (acids or bases) can accept or donate more than one proton. Consequently, they have **more than one dissociation constant.**

e. Henderson-Hasselbalch equations describe the relation between the ionized and the unionized species of a weak electrolyte.

(1) For **weak acids,** the Henderson-Hasselbalch equation is obtained from the equilibrium relation described in IV.A.3d.(2):

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

(2) Similarly, the Henderson-Hasselbalch equation for **weak bases** is as follows:

$$pH = pK_a + \log \frac{[B]}{[BH^+]}$$

where B is the unionized weak base and BH^+ is the protonated base.

f. The **degree of ionization (α),** the fraction of a weak electrolyte that is ionized in solution, is calculated from the following equation:

$$\alpha = \frac{[I]}{[I] + [U]}$$

where [I] and [U] represent the concentrations of the ionized and unionized species, respectively. The degree of ionization depends solely on the pH of the solution and the pK_a of the weak electrolyte. **When pH = pK_a,** the Henderson-Hasselbalch equations are, for a weak acid and a weak base, respectively:

$$pH - pK_a = 0 = \log \frac{[A^-]}{[HA]}$$

thus

$$\frac{[A^-]}{[HA]} = 1$$

$$pH - pK_a = 0 = \log \frac{[B]}{[BH^+]}$$

thus

$$\frac{[B]}{[BH^+]} = 1$$

In effect, when the pH of the solution is numerically equivalent to the pK_a of the weak electrolyte, whether a weak base or a weak acid, [I] = [U] and the degree of ionization α = 0.5 (i.e., 50% of the solute is ionized).

g. Solubility of a weak electrolyte varies as a function of pH.

(1) For a **weak acid,** the total solubility C_s is given by the expression:

$C_s = [HA] + [A^-]$

where [HA] is the intrinsic solubility of the unionized weak acid and is denoted as C_0, whereas $[A^-]$ is the concentration of its anion. Because $[A^-]$ can be expressed in terms of C_0 and the dissociation constant K_a,

$$C_s = C_0 + \frac{K_a C_0}{[H^+]}$$

Thus the **solubility of a weak acid increases with increasing pH** (i.e., with an increasing degree of ionization, as the anion is more polar and therefore more water soluble than the unionized weak acid).

(2) Similarly, for **weak bases,**

$$C_s = C_0 + \frac{C_0[H^+]}{K_a}$$

Thus the **solubility decreases with increasing pH** because more of the weak base is in the unprotonated form. This form is less polar and therefore less water soluble.

h. **Buffers and buffer capacity**

(1) A **buffer** is a mixture of salt with acid or base that resists changes in pH when small quantities of acid or base are added. A buffer can be a **combination** of a weak acid and its conjugate base (salt) or a combination of a weak base and its conjugate acid (salt). However, buffer solutions are more **commonly prepared** from weak acids and their salts. They are not ordinarily prepared from weak bases and their salts because weak bases are often unstable and volatile.

(a) For a **weak acid and its salt,** the following buffer equation is satisfactory for calculations with a pH of 4-10. It is important in the preparation of buffered pharmaceutical solutions:

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

(b) For a **weak base and its salt,** the buffer equation is similar but also depends on the dissociation constant of water (pK_w). The equation becomes:

$$pH = pK_w - + pK_b \log \frac{[base]}{[salt]}$$

(2) Buffer action is the resistance to a change in pH.

(3) Buffer capacity is the ability of a buffer solution to resist changes in pH. The **smaller the pH change** caused by addition of a given amount of acid or base, the **greater the buffer capacity** of the solution.

(a) Buffer capacity is the number of gram equivalents of an acid or base that changes the pH of 1 L of buffer solution by 1 unit.

(b) Buffer capacity is affected by the concentration of the buffer constituents. A higher concentration provides a greater acid or base reserve. Buffer capacity (β) is related to total concentration (*C*) as follows:

$$\beta = \frac{2.3CK_a[H^+]}{(K_a + [H^+])^2}$$

where *C* represents the molar concentrations of the acid and the salt.

(c) Thus buffer capacity depends on the value of the ratio of the salt to the acid form. It increases as the ratio approaches unity. Maximum buffer capacity occurs when pH = pK_a, and is represented by $\beta = 0.576C$.

B. Heterogeneous (disperse) systems

1. Introduction

a. A **suspension** is a two-phase system that is composed of a solid material dispersed in an oily or aqueous liquid. The particle size of the dispersed solid is usually > 0.5 μm.

b. An **emulsion** is a heterogeneous system that consists of at least one immiscible liquid that is intimately dispersed in another in the form of droplets. The droplet diameter usually exceeds 0.1 μm. Emulsions are **inherently unstable** because the droplets of the dispersed liquid tend to coalesce to form large droplets until all of the dispersed droplets have coalesced. The third component of the system is an **emulsifying agent.** This agent prevents coalescence and maintains the integrity of the individual droplets.

2. Dispersion stability. In an **ideal dispersion,** the dispersed particles do not interact. The particles are uniform in size and undergo no change in position other than the random movement that results from Brownian motion. In contrast, in a **real dispersion,** the particles are not uniformly sized (i.e., they are not **monodisperse**). The particles are subject to particulate aggregation, or clumping, and the dispersion becomes more heterogeneous with time. The **rate of settling (separating, or creaming)** of the dispersed phase in the dispersion medium is a function of the particle size, dispersion phase viscosity, and difference in density between the dispersed phase and the dispersion medium, in accordance with **Stokes's law:**

$$\text{sedimentation rate} = \frac{d^2 g(\rho_1 - \rho_2)}{18\,\eta}$$

where *d* is the particle diameter, *g* is the acceleration owing to gravity, η is the viscosity of the dispersion medium, and (ρ_1 - ρ_2) is the difference between the density of the particles (ρ_1) and the density of the dispersion medium (ρ_2). Although Stokes's law was derived to determine the settling, or sedimentation, of noninteracting spherical particles, it also provides guidance for determining the stabilization of dispersion:

a. Particle size should be as **small** as possible. Smaller particles yield slower sedimentation, or flotation, rates.

b. High particulate (dispersed phase) concentrations increase the rate of particle-particle collisions and interaction. As a result, particle aggregation occurs, and instability increases as the aggregates behave as larger particles. In the case of liquid-liquid dispersions, particle-particle collisions can lead to coalescence (i.e., larger particles) and decrease dispersion stability.

c. **Avoidance of particle-particle interactions**

(1) Aggregation can be prevented if the particles have a similar electrical charge. Particles in an aqueous system always have some electrical charge because of **ionization** of chemical groups on the particle surface or **adsorption** of charged molecules or ions at the interface. If the adsorbed species is an **ionic surfactant** (e.g., sodium lauryl sulfate), the charge associated with the surfactant ion (e.g., lauryl sulfate anion) will accumulate at the interface. However, if a relatively non-surface-active electrolyte is adsorbed, the sign of the charge of the adsorbed ion is less readily predicted.

(2) The **magnitude of the charge** is the difference in electrical potential between the charged surface of the particle and the bulk of the dispersion medium. This magnitude is approximated by the **electrokinetic,** or **zeta, potential (ζ).** The zeta potential is measured from the fixed, avidly bound layers of ions and solvent molecules on the particle surface. When ζ is high (e.g., ≥ 25 mV), interparticulate **repulsive forces** exceed the attractive forces. As a result, the dispersion is **deflocculated** and relatively stable to collision and subsequent aggregation (**flocculation**). When ζ is so low that interparticulate **attractive forces** predominate, loose particle aggregates, or **flocs,** form (i.e., **flocculation** occurs).

d. Density can be manipulated to decrease the rate of dispersion instability. The settling

rate decreases as ($\rho_1 - \rho_2$) approaches zero. However, the density of the dispersion medium usually cannot be altered sufficiently to halt the settling (or flotation) process. In the dispersed phase, the density of solid particles is not readily altered; altering the density of liquid particles would require the addition of a miscible liquid of higher (or lower) density. Altering the composition of suspensions is also problematic because most solid particles are denser than the dispersion medium. Additives of higher (or lower) density might alter the biopharmaceutical characteristics of the formulation (e.g., rate of drug release, residence time at the site of administration, or absorption).

e. The **sedimentation,** or **flotation, rate** is inversely proportional to the **viscosity.** An **increase** in the **viscosity of the dispersion medium** decreases the rate of settling, or flotation. However, although the rate of destabilization can be slowed by an increase in viscosity, it cannot be halted.

3. Emulsion stability. Coalescence occurs in emulsion systems when the liquid particles of the dispersed phase merge to form larger particles. Coalescence is largely prevented by the **interfacial film** of surfactant around the droplets. This film prevents direct contact of the liquid phase of the droplets. Coalescence of droplets in oil in water (o/w) emulsions is also inhibited by the **electrostatic repulsion** of similarly charged particles. **Creaming** is the **reversible** separation of a layer of emulsified particles.

Because mixing or shaking may be sufficient to reconstitute the emulsion system, creaming is not necessarily unacceptable. However, **cracking,** or **irreversible phase separation,** is never acceptable. **Phase inversion,** or emulsion-type reversal, involves the reversion of an emulsion from an o/w to a water in oil (w/o) form, or vice versa. Phase inversion can change the consistency or texture of the emulsion or cause further deterioration in its stability.

V. CHEMICAL KINETICS AND DRUG STABILITY

A. Introduction. The **stability** of the **active component** of a drug is a major criterion in the rational design and evaluation of drug dosage forms. Problems with **stability** can determine whether a given formulation is accepted or rejected.

1. Extensive chemical degradation of the active ingredient can cause **substantial loss** of active ingredient from the dosage form.

2. Chemical degradation can produce a **toxic product** that has undesirable side effects.

3. Instability of the drug product can cause **decreased bioavailability.** As a result, the therapeutic efficacy of the dosage form may be substantially reduced.

B. Rates and orders of reactions

1. The **rate of a reaction,** or degradation rate, is the velocity with which the reaction occurs. This rate is expressed as d*C*/d*t* (the change in concentration, or *C,* within a given time interval, or d*t*).

a. Reaction rates depend on certain conditions (e.g., **reactant concentration, temperature, pH, presence of solvents or additives**). Radiation and catalytic agents (e.g., polyvalent cations) also have an effect.

b. The effective study of reaction rates in the body requires application of **pharmacokinetic principles** (see Chapter 6).

2. The **order of a reaction** is the way in which the concentration of the drug or reactant in a chemical reaction affects the rate. The rate of a reaction, d*C*/d*t,* is proportional to the concentration to the *n*th power, where *n* is the order of the reaction—that is,

$$\frac{dC}{dt} \propto C^n$$

The study of reaction orders is a crucial aspect of pharmacokinetics (see Chapter 6). Usually, **pharmaceutical degradation** can be treated as a **zero-order, first-order,** or **higher-order reaction.** The first two are summarized as follows.

a. In a **zero-order reaction,** the **rate is independent of the concentration of the reactants** (i.e., $dC/dt \propto C^0$) (see Chapter 6). Other factors, such as absorption of light in certain photochemical reactions, determine the rate.

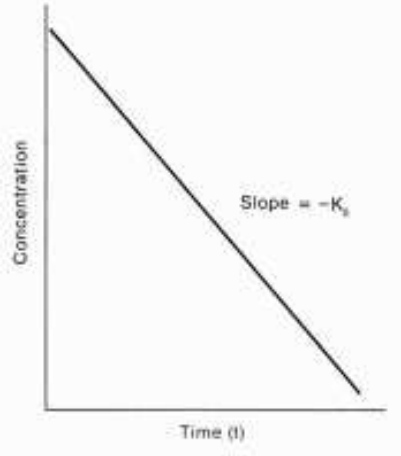

Figure 3-6. Concentration *(C)* versus time *(t)* for a zero-order reaction. The slope of the line equals $-k_0$. The slope of the line is not equal to the rate constant because it includes the minus sign.

(1) A **zero-order reaction** can be expressed as:

$C = -k_0 t + C_0$

where C is the drug concentration, k_0 is the zero-order rate constant in units of concentration/time, t is the time, and C_0 is the initial concentration.

(2) When this equation is plotted with C on the vertical axis (ordinate) against t on the horizontal axis (abscissa), the **slope of the line is equal to $-k_0$** (Figure 3-6). The negative sign indicates that the slope is decreasing.

b. In a **first-order reaction,** the **rate depends on the first power of the concentration of a single reactant** (i.e., $dC/dt \propto C^1$).

(1) In a first-order reaction, **drug concentration decreases exponentially with time,** in accordance with the equation

$C = C_0 e^{-k_1 t}$

where C is the concentration of the reacting material, C_0 is the initial concentration, k_1 is the first-order rate constant in units of reciprocal time, and t is time. A plot of the logarithm of concentration against time produces a straight line with a slope of $-k/2.303$ (Figure 3-7).

(2) The **half-life** ($t_{1/2}$) of a reaction is the time required for the concentration of a drug to decrease by one half. For a first-order reaction, half-life is expressed by:

$$t_{1/2} = \frac{0.693}{k_1}$$

(3) The **time required for a drug to degrade** to 90% of its original concentration ($t_{90\%}$) is also important. This time represents a reasonable limit of degradation for the active ingredients. The $t_{90\%}$ can be calculated as:

$$t_{90\%} = \frac{2.303}{k_1} \log \frac{100}{90} = \frac{0.105}{k_1}$$

(a) Because

$k_1 = 0.693 / t_{½}$

(b) Then

$$t_{90\%} = \frac{0.105}{0.693/t_{1/2}} = 0.152 \times t_{1/2}$$

P.44

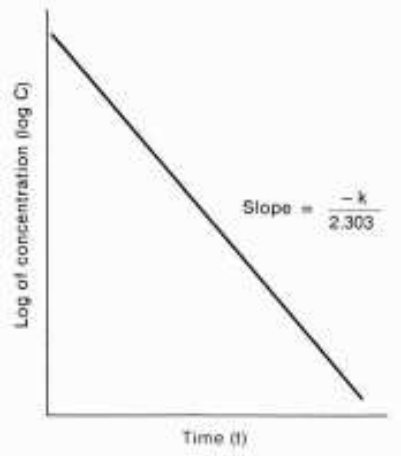

Figure 3-7. Logarithm of concentration (log *C*) versus time (*t*) for a first-order reaction. The slope of the line equals -*k*/2.303.

(4) Both $t_{½}$ and $t_{90\%}$ are **concentration independent.** Thus, for $t_{½}$, it takes the same amount of time to reduce the concentration of the drug from 100 mM to 50 mM as it does from 50 mM to 25 mM.

C. Factors that affect reaction rates. Factors other than concentration can affect the reaction rate and stability of a drug. These factors include temperature, the presence of a solvent, pH, and the presence of additives.

1. Temperature. An **increase in temperature** causes an increase in reaction rate, as expressed in the equation first suggested by Arrhenius:

$k = Ae^{-Ea/RT}$

or

$$\log k = \log A - \left(\frac{Ea}{2.303} \times \frac{1}{RT}\right)$$

where *k* is the specific reaction rate constant, *A* is a constant known as the frequency factor, *Ea* is the energy of activation, *R* is the molar gas constant (1.987 cal/degree × mole), and *T* is the absolute temperature.

a. The **constants *A* and *Ea*** are obtained by determining *k* at several temperatures and then plotting log *k* against 1/*T*. The slope of the resulting line equals -*Ea*/(2.303 × *R*). The intercept on the vertical axis equals log *A*.

b. The activation energy (*Ea*) is the amount of energy required to put the molecules in an **activated state.** Molecules must be activated to react. As

temperature increases, more molecules are activated, and the **reaction rate increases.**

2. Presence of solvent. Many dosage forms require the incorporation of a water-miscible solvent—for example, low molecular weight alcohols, such as the polyethylene glycols (PEGs)—to stabilize the drug.

a. A change in the solvent system **alters** the transition state and the **activity coefficients** of the reactant molecules. It can also cause simultaneous changes in physicochemical parameters, such as pK_a, surface tension, and viscosity. These changes **indirectly affect the reaction rate.**

b. In some cases, **additional reaction pathways** are generated. For example, with an increasing concentration of ethanol in an aqueous solution, aspirin degrades by an extra route and forms the ethyl ester of acetylsalicylic acid. However, a **change in solvent can also stabilize the drug.**

3. Change in pH. The magnitude of the rate of a hydrolytic reaction catalyzed by H^+ and OH^- can vary considerably with pH.

a. H^+ catalysis predominates at **lower pH,** whereas **OH^- catalysis** operates at **higher pH.** At **intermediate pH,** the rate may be **pH independent** or may be catalyzed by **both H^+ and OH^-.** Rate constants in the intermediate pH range are typically less than those at higher or lower pH.

b. To determine the **effect of pH on degradation kinetics,** decomposition is measured at several H^+ concentrations. The **pH of optimum stability** can be determined by plotting the logarithm of the rate constant (*k*) as a function of pH (Figure 3-8). The **point of inflection** of the plot is the pH of optimum stability. This value is useful in the development of a stable drug formulation.

4. Presence of additives

a. Buffer salts must be added to many drug solutions to maintain the formulation at optimum pH. These salts **can affect the rate of degradation,** primarily as a result of salt increasing the ionic strength.

(1) Increasing salt concentrations, particularly from polyelectrolytes (e.g., citrate, phosphate), can **substantially affect the magnitude of pK_a.** In this way, they change the rate constant.

(2) Buffer salts can also **promote drug degradation** through general acid or base catalysis.

b. The **addition of surfactants** may accelerate or decelerate drug degradation.

(1) Acceleration of degradation is common and is caused by micellar catalysis.

(2) Stabilization of a drug through the addition of a surfactant is less common.

c. **Complexing agents** can improve drug stability. Aromatic esters (e.g., benzocaine, procaine, tetracaine) **increase in half-life** in the presence of caffeine. This increased stability appears to result from the formation of a less reactive complex between the aromatic ester and the caffeine.

D. Modes of pharmaceutical degradation. The decomposition of active ingredients in a dosage form occurs through several pathways (e.g., hydrolysis, oxidation, photolysis; see Chapter 12, II.A).

1. Hydrolysis is the most common type of degradation because many medicinal compounds are esters, amides, or lactams.

a. H^+ **and** OH^- are the most common catalysts of hydrolytic degradation in solution.

b. Esters usually undergo hydrolytic reactions that cause drug instability. Because esters are rapidly degraded in aqueous solution, formulators are reluctant to incorporate drugs that have ester functional groups into liquid dosage forms.

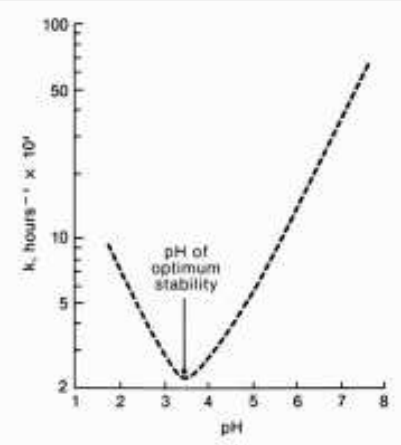

Figure 3-8. Semilogarithmic plot of the rate constant (*k*) versus pH. This plot is used to determine the pH of optimum stability.

2. Oxidation is usually mediated through reaction with atmospheric oxygen under ambient conditions (auto-oxidation).

a. Medicinal compounds that undergo auto-oxidation at room temperature are affected by **oxygen dissolved in the solvent** and in the head space of their packages. These compounds should be packed in an **inert atmosphere** (e.g., nitrogen) to exclude air from their containers.

b. Most oxidation reactions involve a **free radical mechanism** and a **chain reaction.** Free radicals tend to take electrons from other compounds.

(1) Antioxidants in the formulation react with the free radicals by providing electrons and easily available hydrogen atoms. In this way, they prevent the propagation of chain reactions.

(2) Commonly used antioxidants include ascorbic acid, butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), propyl gallate, sodium bisulfite, sodium sulfite, and the tocopherols.

3. Photolysis is the degradation of drug molecules by normal sunlight or room light.

a. Molecules may absorb the proper wavelength of light and **acquire sufficient energy to undergo reaction.** Usually, photolytic degradation occurs on exposure to light of wavelengths < 400 nm.

b. An **amber glass bottle** or an **opaque container** acts as a barrier to this light, thereby preventing or retarding photolysis. For example, sodium nitroprusside in aqueous solution has a shelf life of only 4 hr if exposed to normal room light. When protected from light, the solution is stable for at least 1 year.

E. Determination of shelf life. The shelf life of a drug preparation is the amount of time that the product can be stored before it becomes unfit for use, through either chemical decomposition or physical deterioration.

1. Storage temperature affects shelf life. It is generally understood to be ambient temperature unless special storage conditions are specified.

2. In general, a preparation is considered fit for use if it varies from the nominal concentration or dose by no more than 10%, provided that the decomposition products are not more toxic or harmful than the original material.

3. Shelf-life testing aids in determining the standard shelf life of a formulation. **a.** Samples are stored at 3-5°C and at room temperature (20-25°C). The samples are then analyzed at various intervals to determine the **rate of decomposition.** Shelf life is calculated from this rate.

b. Because storage time at these temperatures can result in an extended testing time, **accelerated testing** is conducted as well, with a range of higher temperatures. The **rate constants** obtained from these samples are used to predict shelf life at ambient or refrigeration temperatures. **Temperature-accelerated stability testing** is not useful if temperature changes are accompanied by changes in the reaction mechanism or by physical changes in the system (e.g., change from the solid to the liquid phase).

c. **Stability at room temperature** can be predicted from accelerated testing data by the Arrhenius equation:

$$\log\left(\frac{k_{T_2}}{k_{T_1}}\right) = \frac{Ea(T_2 - T_1)}{2.303 \times R \times T_2 \times T_1}$$

where k_{T2} and k_{T1} are the rate constants at the absolute temperatures T_2 and T_1, respectively; R is the molar gas constant; and Ea is the energy of activation.

d. Alternatively, an expression of concentration can be plotted as a linear function of time. Rate constants (k) for degradation at several temperatures are obtained. The logarithm of the rate constant (log k) is plotted against

the reciprocal of absolute temperature (1/*T*) to obtain, by extrapolation, the rate constant for degradation at room temperature (Figure 3-9).

e. The **length of time that the drug will maintain its required potency** can also be predicted by calculation of the $t_{90\%}$ (see V.B.2.b.(3)). This method applies to chemical reactions with activation energies of 10-30 kcal/mol, the magnitude of the activation energy for many pharmaceutical degradations that occur in solution.

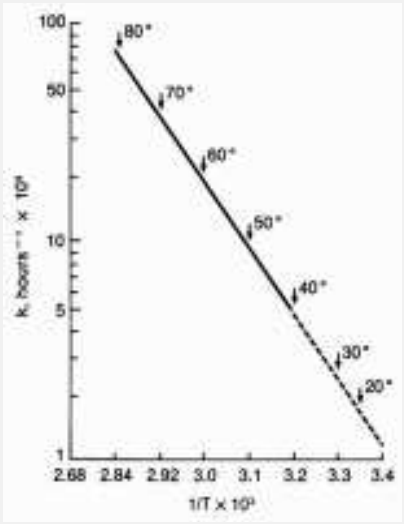

Figure 3-9. Semilogarithmic plot of the rate constant (*k*) versus the reciprocal of absolute temperature (1/*T*), showing the temperature dependency of degradation rates.

VI. DRUG DOSAGE FORMS AND DELIVERY SYSTEMS

A. Oral solutions. The ***United States Pharmacopeia*** **(**USP**) 31/*National Formulary* (*NF*) 26** categorizes **oral solutions** as "liquid preparations, intended for oral administration, that contain one or more substances with or without flavoring, sweetening, or coloring agents dissolved in water or cosolvent-water mixtures." Oral solutions can contain certain polyols (e.g., sorbitol, glycerin) to inhibit crystallization and to modify solubility, taste, mouth feel, and other vehicle properties. They can be "formulated for direct oral administration to the patient or they may be dispensed in a more concentrated form that must be diluted prior to administration." **Drugs in solution** are more homogeneous and easier to swallow than drugs in solid form. For drugs that have a slow dissolution rate, onset of action and bioavailability are also improved. However, drugs in solution are bulkier dosage forms, degrade more rapidly, and are more likely to interact with constituents than those in solid form.

1. Water is the **most commonly used vehicle** for drug solutions. The USP recognizes seven types of water for the preparation of dosage forms:

a. Purified water USP is water obtained by distillation, ion exchange, reverse osmosis, or other suitable treatment. It cannot contain more than 10 parts per million (ppm) of total solid and should have a pH between 5 and 7. Purified water is used in prescriptions and finished manufactured products except parenteral and ophthalmic products.
b. Water for injection USP is water obtained by distillation or by reverse osmosis. It conforms to the standards of purified water but is also free of pyrogen. Water for injection is used as a solvent for the preparation of parenteral solutions.
c. **Sterile water for injection** USP is water for injection that is sterilized and packaged in single-dose containers of type I and II glass. These containers do not exceed a capacity of 1 L. The limitations for total solids depend on the size of the container.
d. Bacteriostatic water for injection USP is sterile water for injection that contains one or more suitable antimicrobial agents. It is also packaged in single- or multiple-dose containers of type I or II glass. These containers do not exceed the capacity of 30 mL.
e. Sterile water for inhalation USP is water that is purified by distillation or by reverse osmosis (i.e., water for injection) and rendered sterile. It contains no antimicrobial agents, except when used in humidifiers or similar devices. This type of water should not be used for parenteral administration or for other sterile dosage forms.
f. Sterile water for irrigation USP is water for injection that is sterilized and suitably packaged. It contains no antimicrobial agents or other added substance.

g. Sterile purified water USP is purified water sterilized and suitably packaged. It contains no antimicrobial agent. It is not intended for use in parenterals.
2. Oral drug solutions include **syrups** and **elixirs** as well as other less widely prescribed classic (**galenical**) formulations, such as **aromatic waters, tinctures, fluidextracts,** and **spirits.**
a. Syrups are traditionally peroral solutions that contain high concentrations of sucrose or other sugars. Through common usage, the term *syrup* has also come to include any other liquid dosage form prepared in a sweet, viscous vehicle, including peroral suspensions.
(1) Syrup *NF* (simple syrup) is a concentrated or nearly saturated aqueous solution of sugar (85%; 65% w/w).
(2) Syrups have a **low solvent capacity for water-soluble drugs** because the hydrogen bonding between sucrose and water is very strong. For this reason, it can be difficult or impossible to dissolve a drug in a syrup. Often, the drug is best dissolved in a small quantity of water, and the flavoring syrup is added.

(3) The **sucrose concentration** of syrup plays a crucial role in the control of microbial growth. Dilute sucrose solutions are excellent media for microorganisms. As the concentration of sucrose approaches saturation, the syrup becomes self-preserving (i.e., requires no additional preservative). However, a saturated solution is undesirable because temperature fluctuations may cause crystallization. **Syrup *NF*** is a selfpreserved solution with a minimal tendency to undergo crystallization.

b. Elixirs are traditionally peroral solutions that contain alcohol as a cosolvent. Many peroral solutions are not described as elixirs but contain alcohol.

(1) To be considered an elixir, the solution **must contain alcohol.** Traditionally, the alcohol content of elixirs has varied from 5% to 40%. Most elixirs become turbid when moderately diluted by aqueous liquids. Elixirs are not the preferred vehicle for salts because alcohol accentuates saline taste. Salts also have limited solubility in alcohol. Therefore, the alcoholic content of salt-containing elixirs must be low.

(2) Aromatic elixir *NF,* prepared in part from syrup, contains approximately 22% alcohol. The limited usefulness of this elixir as a solvent for drugs was offset by the development of **iso-alcoholic elixir.** It is a combination of **low-alcoholic elixir,** an elixir with low alcoholic content (8%-10% alcohol), and **high-alcoholic elixir,** an elixir with high alcoholic content (73%-78% alcohol). Mixing appropriate volumes of the two elixirs provides an alcoholic content sufficient to dissolve the drugs.

B. Miscellaneous solutions

1. Aromatic waters are clear, **saturated aqueous solutions of volatile oils** or other aromatic or volatile substances. Aromatic waters may be used as pleasantly flavored vehicles for a water-soluble drug or as an aqueous phase in an emulsion or suspension. If a large amount of water-soluble drug is added to an aromatic water, then an insoluble layer may form at the top. This **"salting out"** is a competitive process. The molecules of water-soluble drugs have more attraction for the solvent molecules of water than the "oil" molecules. The associated water molecules are pulled away from the oil molecules, which are no longer held in solution. Aromatic waters should be stored in tight, light-resistant bottles to reduce volatilization and degradation from sunlight. Aromatic waters are usually prepared by one of the following methods:

a. Distillation is a universal method but is not practical or economical for most products. It is the only method, however, for preparing strong rose water and orange flower water.

b. With the **solution method,** the volatile, or aromatic, substance is admixed with water, with or without the use of a dispersant (e.g., talc).

2. Spirits, or **essences,** are alcoholic or hydroalcoholic solutions of volatile substances, that contain 50%-90% alcohol. This **high alcoholic content** maintains the water-insoluble volatile oils in solution. If water is added to a spirit, the oils separate. Some spirits are **medicinal** (e.g., aromatic

ammonia spirit). Many spirits (e.g., compound orange spirit, compound cardamom spirit) are used as flavoring agents. Spirits should be stored in tight containers to reduce loss by evaporation.

3. Tinctures are alcoholic or hydroalcoholic solutions of chemicals or soluble constituents of vegetable drugs. Although tinctures vary in drug concentration (≤ 50%), those prepared from potent drugs are usually 10% in strength (i.e., 100 mL of the tincture has the activity of 10 g of the drug). Tinctures are usually considered stable. The alcohol content of the official tinctures varies from 17% to 21% for opium tincture USP and from 74% to 80% for compound benzoin tincture USP. Most tinctures are prepared by an **extraction process** of

maceration or percolation. The selection of a **solvent,** or menstruum, is based on the solubility of the active and inert constituents of the crude drugs. Aging can cause precipitation of the inactive constituents of tinctures. Glycerin may be added to the hydroalcoholic solvent to increase the solubility of the active constituent and reduce precipitation on storage. Tinctures must be tightly stoppered and kept from excessive temperatures. Because many of their constituents undergo a photochemical change when exposed to light, tinctures must be stored in light-resistant containers.

4. Fluidextracts are liquid extracts of vegetable drugs that contain alcohol as a solvent, preservative, or both. Fluidextracts are prepared by percolation so that each milliliter contains the therapeutic constituents of 1 g of the standard drug. Because of their high drug content, fluidextracts are sometimes referred to as “100% tinctures.” Fluidextracts of potent drugs are usually 10 times as concentrated, or potent, as the corresponding tincture. For example, the usual dose of tincture belladonna is 0.6 mL; the equivalent dose of the more potent fluidextract is 0.06 mL. Many fluidextracts are considered too potent for self-administration by patients, so they are almost never prescribed. In addition, many fluidextracts are simply too bitter. Today, most fluidextracts are modified by either flavoring or sweetening agents.

5. Nasal, ophthalmic, otic, and **parenteral solutions** are classified separately because of their specific use and method of preparation.

6. Mouthwashes are solutions that are used to cleanse the mouth or treat diseases of the oral mucous membrane. They often contain alcohol or glycerin to aid in dissolving the volatile ingredients. Mouthwashes are more often used cosmetically than therapeutically.

7. Astringents are locally applied solutions that precipitate protein. They reduce cell permeability without causing injury. Astringents cause **constriction,** with wrinkling and blanching of the skin. Because astringents **reduce secretions,** they can be used as antiperspirants.

a. Aluminum acetate and **aluminum subacetate solutions** are used as wet dressings in contact dermatitis. The precipitation is minimized by the addition of boric acid.

b. Calcium hydroxide solution is a mild stringent that is used in lotions as a reactant and an alkalizer.

8. Antibacterial topical solutions (e.g., benzalkonium chloride, strong iodine, povidoneiodine) kill bacteria when applied to the skin or mucous membrane in the proper strength and under appropriate conditions.

C. Suspensions

1. Lotions, magmas (i.e., suspensions of finely divided material in a small amount of water), and **mixtures** are all suspensions that have had official formulas for some time (e.g., calamine lotion USP, kaolin mixture with pectin *NF*). Official formulas are given in the USP/*NF.*

a. A **complete formula** and a **detailed method of preparation** are available for some official suspensions. For others, only the **concentration** of the active ingredients is given, and the manufacturer has considerable latitude in the formulation.

b. Some drugs are packaged in a **dry form** to circumvent the instability of aqueous dispersions. Water is added at the time of dispensing to reconstitute the suspension.

2. Purposes of suspension

a. Sustaining effect. For a sustained-release preparation, a suspension necessitates drug dissolution before absorption.

b. Stability. Drug degradation in suspension or solid dosage forms occurs much more slowly than degradation in solution form.

c. **Taste.** A drug with an unpleasant taste can be converted into an insoluble form and then prepared as a suspension.

d. Basic solubility. When suitable solvents are not available, the suspension provides an alternative. For example, only water can be used as a solvent for ophthalmic preparations because of the possibility of corneal damage. Ophthalmic suspensions provide an alternative to ophthalmic solutions.

3. Suspending agents include hydrophilic colloids, clays, and a few other agents. Some are also used as **emulsifying agents** (see VI.D.3).

a. Hydrophilic colloids (i.e., **hydrocolloids**) increase the viscosity of water by binding water molecules, thus limiting their mobility, or fluidity. Viscosity is proportional to the concentration of the hydrocolloid. These agents **support the growth of microorganisms** and require a preservative. They are mostly **anionic,** with the exception of methyl cellulose

(neutral) and chitosan (cationic). Thus the anionic hydrocolloids are incompatible with quaternary antibacterial agents and other positively charged drugs. Chitosan is incompatible with negatively charged drugs and excipients. Most hydrocolloids are **insoluble in alcoholic solutions.**

(1) Acacia is usually used as a 35% dispersion in water (mucilage). Its viscosity is greatest between pH 5 and pH 9. Acacia is susceptible to microbial decomposition.

(2) Tragacanth is usually used as a 6% dispersion in water (mucilage). One advantage of tragacanth over acacia is that less is needed. Also, tragacanth does not contain the oxidase that is present in acacia. This oxidase catalyzes the decomposition of organic chemicals. The viscosity of tragacanth is greatest at pH 5.

(3) Methyl cellulose is a polymer that is nonionic and stable to heat and light. It is available in several viscosity grades. Because it is soluble in cold water, but not in hot water, dispersions are prepared by adding methyl cellulose to boiling water and then cooling the preparation until the material dissolves.

(4) Carboxymethylcellulose is an anionic material that is soluble in water. Prolonged exposure to heat causes loss of viscosity.

b. Clays (e.g., bentonite, Veegum) are silicates that are anionic in aqueous dispersions. They are strongly hydrated and exhibit **thixotropy** (the property of forming a gel-like structure on standing and becoming fluid on agitation).

(1) The official form of **bentonite** is the 5% magma.

(2) Veegum is hydrated to a greater degree than bentonite. Thus it is more viscous at the same concentration.

c. **Other agents** include agar, chondrus (carrageenan), gelatin, pectin, and gelatinized starch. Their use is limited by their susceptibility to bacterial attack, their incompatibilities, and their cost. Xanthan gum is used in many modern suspension formulations because of its cosolvent compatibility, its stability, and its solution's high viscosity relative to concentration.

4. Preparation

a. Solids are wetted initially to separate individual particles and coat them with a layer of dispersion medium. Wetting is accomplished by **levigation** (i.e., addition of a suitable nonsolvent, or **levigating agent,** to the solid material, followed by blending to form a paste), using a glass mortar and pestle or an ointment slab. A **surfactant** can also be used.

b. Suspending agents are then added as dry powder along with the active ingredient. For best results, the suspending agent is added in the form of its **aqueous dispersion.**

(1) The aqueous dispersion is added to the solid (or the levigated solid) by **geometric dilution.**

(2) The preparation is brought to the desired volume by stirring in the appropriate vehicle.

D. Emulsions

1. Purposes of emulsions

a. Increased drug solubility. Many drugs have limited aqueous solubility but have maximum solubility in the oil phase of an emulsion. Drug

partitioning from the oil phase to the water phase can maintain or enhance activity.

b. Increased drug stability. Many drugs are more stable when incorporated into an emulsion rather than an aqueous solution.

c. **Prolonged drug action.** Incorporation of a drug into an emulsion can prolong bioavailability, as with certain intramuscular injection preparations.

d. Improved taste. Drugs with an unpleasant taste are more palatable and thus more conveniently administered in emulsion form.

e. Improved appearance. Oily materials intended for topical application are more appealing in an emulsified form.

2. Phases of emulsions. Most emulsions are considered **two-phase systems.**

a. The **liquid droplet** is known as the **dispersed, internal,** or **discontinuous phase.** The other liquid is known as the **dispersion medium, external phase,** or **continuous phase.**

b. In pharmaceutical applications, one phase is usually an **aqueous solution.** The other phase is usually **lipid** or **oily.** The lipids range from vegetable or hydrocarbon oils to semisolid hydrocarbons and waxes. Emulsions are usually described in terms of water and oil. Oil is the lipid, or nonaqueous, phase, regardless of its composition.

(1) If water is the **internal phase,** the emulsion is classified as **w/o.**

(2) If water is the **external phase,** the emulsion is classified as **o/w.**

c. The **type of emulsion** formed is primarily determined by the **relative phase volumes** and the **emulsifying agent** used.

(1) For an ideal emulsion, the maximum concentration of internal phase is 74% (i.e., theoretically, an o/w emulsion can be prepared containing ≤ 74% oil).

(2) The choice of an emulsifying agent is more important than the relative phase volumes in determining the final emulsion type. Most agents preferentially form one type of emulsion or the other if the phase volume permits.

3. Emulsifying agents. Any compound that lowers the interfacial tension and forms a film at the interface can potentially function as an emulsifying agent. The effectiveness of the emulsifying agent depends on its chemical structure, concentration, solubility, pH, physical properties, and electrostatic effect. **True emulsifying agents** (primary agents) can form and stabilize emulsions by themselves. **Stabilizers** (auxiliary agents) do not form acceptable emulsions when used alone, but assist primary agents in stabilizing the product (e.g., increase viscosity). Emulsifying agents are either **natural** or **synthetic.**

a. Natural emulsifying agents:

(1) Acacia forms a good, stable emulsion of low viscosity. It tends to cream easily, is acidic, and is stable at a pH range of 2-10. Like other gums, it is negatively charged, dehydrates easily, and usually requires a preservative. It is incompatible with Peruvian balsam, bismuth salts, and carbonates.
(2) Tragacanth forms a stable emulsion that is coarser than acacia emulsion. It is anionic, is difficult to hydrate, and is used mainly for its effects on viscosity. Less than of the amount used for acacia is needed.
(3) Agar is an anionic gum that is primarily used to increase viscosity. Its stability is affected by heating, dehydration, and destruction of charge. It is also susceptible to microbial degradation.
(4) Pectin is a quasi-emulsifier that is used in the same proportion as tragacanth.
(5) Gelatin provides good emulsion stabilization in a concentration of 0.5%-1.0%. It may be anionic or cationic, depending on its isoelectric point. Type A gelatin (+), prepared from an acid-treated precursor, is used in acidic media. Type B gelatin (-), prepared from an alkali-treated precursor, is used in basic media.
(6) Methyl cellulose is nonionic and induces viscosity. It is used as a primary emulsifier with mineral oil and cod liver oil, and yields an o/w emulsion. It is usually used in 2% concentration.
(7) Carboxymethylcellulose is anionic and is usually used to increase viscosity. It tolerates alcohol up to 40%, forms a basic solution, and precipitates in the presence of free acids.
b. Synthetic emulsifying agents are anionic, cationic, or nonionic. Although these surfactants are amphiphilic molecules, their lipophilic and hydrophilic regions are seldom inverse equals of each other: Some surfactant molecules tend to be predominantly lipophilic, whereas others are predominantly hydrophilic. This imbalance is reflected in the hydrophilic-lipophilic balance (HLB) scale: The larger the HLB value, the more hydrophilic the molecule. Table 3-1 lists HLB values for surfactants and their corresponding uses.

Table 3-1. Hydrophilic-Lipophilic Balance (HLB)

HLB Value Range	Surfactant Application
0-3	Antifoaming agents
4-6	Water-in-oil emulsifying agents
7-9	Wetting agents
8-18	Oil-in-water emulsifying agents
13-15	Detergents
10-18	Solubilizing agents

(1) Anionic synthetic agents include **sulfuric acid esters** (e.g., sodium lauryl sulfate), **sulfonic acid derivatives** (e.g., dioctyl sodium sulfosuccinate), and **soaps.** Soaps are for external use. They have a high pH and are, therefore, sensitive to the addition of acids and electrolytes.
(a) Alkali soaps are hydrophilic and form an o/w emulsion.
(b) Metallic soaps are water insoluble and form a w/o emulsion.
(c) Monovalent soaps form an o/w emulsion.
(d) Polyvalent soaps form a w/o emulsion.
(2) Cationic synthetic agents (e.g., benzalkonium chloride) are used as surface-active agents in 1% concentration. They are incompatible with soaps.
(3) Nonionic synthetic agents are resistant to the addition of acids and electrolytes.
(a) The **sorbitan esters** known as **Spans** are hydrophobic in nature and form w/o emulsions. They have low hydrophilic-lipophilic balance values (1-9) (Table 3-2).
(b) The **polysorbates** known as **Tweens** are hydrophilic and tend to form o/w emulsions. They may form complexes with phenolic compounds. They have high hydrophilic-lipophilic balance values (11-20).
4. Preparation. Various methods are used to prepare emulsions, depending on the type of emulsifying agent.
a. Classical, acacia-stabilized emulsions are prepared by one of the following four methods:

(1) Wet gum (English) method. A primary emulsion of fixed oil, water, and acacia (in a 4:2:1 ratio) is prepared as follows:
(a) Two parts of water are added all at once to one part of acacia. The mixture is triturated until a smooth mucilage is formed.
(b) Oil is added in small increments (1-5 mL), with continuous trituration, until the primary emulsion is formed.
(c) The mixture (an o/w emulsion) is triturated for another 5 min.
(d) The o/w mixture can then be brought to volume with water and mixed to achieve homogeneity.
(2) Dry gum (continental) method. A primary emulsion of the fixed oil, water, and acacia (in a 4:2:1 ratio) is prepared as follows:

Table 3-2. Commonly Used Surfactants and Their Hydrophilic-Lipophilic Balance (HLB) Values

Agent	HLB Value
Sorbitan trioleate (Span 85, Arlacel 85)	1.8
Sorbitan tristearate (Span 65)	2.1
Propylene glycol monostearate (pure)	3.4
Sorbitan sesquioleate (Arlacel C)	3.7
Sorbitan monooleate (Span 80y)	4.3
Sorbitan monostearate (Arlacel 60)	4.7
Sorbitan monopalmitate (Span 40, Arlacel 40)	6.7
Sorbitan monolaurate (Span 20, Arlacel 20)	8.6
Glyceryl monostearate (Aldo 28, Tegin)	5.5
Gelatin	9.8
Triethanolamine oleate (Trolamine)	12.0

Polyoxyethylene alkyl phenol (Igepal CA-630)	12.8
Tragacanth	13.2
Polyoxyethylene sorbitan monolaurate (Tween 21)	13.3
Polyoxyethylene castor oil (Atlas G-1794)	13.3
Polyoxyethylene sorbitan monooleate (Tween 80)	15.0
Polyoxyethylene sorbitan monopalmitate (Tween 40)	15.6
Polyoxyethylene sorbitan monolaurate (Tween 20)	16.7
Polyoxyethylene lauryl ether (Brij 35)	16.9
Sodium oleate	18
Sodium lauryl sulfate	40

(a) Oil is added to the acacia, and the mixture is triturated until the powder is distributed uniformly throughout the oil. Water is added all at once, followed by rapid trituration to form the primary emulsion.
(b) Any remaining water and other ingredients are added to finish the product.
(i) Electrolytes in high concentration tend to crack an emulsion. They should be added last and in as dilute a form as possible.
(ii) Alcoholic solutions tend to dehydrate and precipitate hydrocolloids. They should be added in as dilute a concentration as possible.
(3) Bottle method (a variation of the dry gum method used for volatile oils). Oil is added to the acacia in a bottle. The ratio of oil, water, and acacia should be 3:2:1 or 2:1: 1. The low viscosity of the volatile oil requires a higher proportion of acacia.
(4) Nascent soap method. A soap is formed by mixing relatively equal volumes of an oil and an aqueous solution that contains a sufficient amount of alkali. The soap acts as an emulsifying agent.

(a) This method is used to form an o/w or a w/o emulsion, depending on the soap formed. For example, olive oil, which contains oleic acid, is mixed with lime water during the preparation of calamine lotion to calcium oleate, an emulsifying agent.
(b) A 50:50 ratio of oil to water ensures sufficient emulsion, provided that the oil contains an adequate amount of free fatty acid. Olive oil usually does. Cottonseed oil, peanut oil, and some other vegetable oils do not.
(c) The addition of an acid destroys the emulsifying soap and causes the emulsion to separate.
b. Emulsions stabilized by synthetic emulsifying agents are readily prepared by a two-phase procedure:
(1) Oil-miscible ingredients and water-miscible ingredients are separately admixed, using heat if necessary to ensure liquefaction and ease of mixing of each phase.
(a) High melting point oil-miscible ingredients (e.g., waxes) are melted before lower melting point ingredients (e.g., oils) are added.
(2) The two phases are heated to 70°-80° and then combined with stirring until the resultant emulsion has cooled.
(a) In general, heat-labile or volatile ingredients should not be incorporated in the separate phases but in the resultant emulsion after it has cooled to about 40°C. or less.
(3) Further mechanical processing of the emulsion by a hand homogenizer, immersion blender, or other equipment may be warranted to improve the homogeneity and stability of the product.
5. Incorporation of medicinal agents. Medicinal agents can be incorporated into an emulsion either during or after its formation.
a. Addition of a drug during emulsion formation. It is best to incorporate a drug into a vehicle during emulsion formation, when it can be incorporated in molecular form. Soluble drugs should be dissolved in the appropriate phase (e.g., drugs that are soluble in the external phase of the emulsion should be added as a solution to the primary emulsion).
b. Addition of a drug to a preformed emulsion can present some difficulty, depending on the type of emulsion and the nature of the emulsifier (Table 3-3).
(1) Addition of oleaginous materials to a w/o emulsion presents no problem because of the miscibility of the additive with the external phase. However, **addition of oleaginous materials to an o/w emulsion** can be difficult after emulsion formation.
(a) Occasionally, a small amount of oily material is added if excess emulsifier was used in the original formation.
(b) A small amount of an oil-soluble drug can be added if it is dissolved in a very small quantity of oil with geometric dilution techniques.
(2) Addition of water or an aqueous material to a w/o emulsion is extremely difficult, unless enough emulsifier has been incorporated into the emulsion. However, **addition of aqueous materials to an o/w emulsion**

usually presents no problems if the added material does not interact with the emulsifying agent. Potential interactions should be expected with cationic compounds and salts of weak bases.

(3) Addition of small quantities of alcoholic solutions to an o/w emulsion is possible if the solute is compatible or dispersible in the aqueous phase of the emulsion. If

acacia or another gum is used as the emulsifying agent, the alcoholic solution should be diluted with water before it is added. Table 3-3 lists some commercial emulsion bases and their general composition.

Table 3-3. Selected Commercial Emulsion Bases: Emulsion Type and Emulsifier Used

Commercial Base	Emulsion Type	Emulsifier Type
Allercreme skin lotion	o/w	Triethanolamine stearate
Almay emulsion base	o/w	Fatty acid glycol esters
Cetaphil	o/w	Sodium lauryl sulfate
Dermovan	o/w	Fatty acid amides
Eucerin	w/o	Wool wax alcohol
HEB base	o/w	Sodium lauryl sulfate
Keri lotion	o/w	Nonionic emulsifiers
Lubriderm	o/w	Triethanolamine stearate
Neobase	o/w	Polyhydric alcohol esters
Neutrogena lotion	o/w	Triethanolamine lactate
Nivea cream	w/o	Wool wax alcohols

pHorsix	o/w	Polyoxyethylene emulsifiers
Polysorb hydrate	w/o	Sodium sesquioleate
Velvachol	o/w	Sodium lauryl sulfate

o/w, oil in water; *w/o,* water in oil.

(4) Addition of crystalline drugs to a w/o emulsion occurs more easily if the drugs are dissolved or dispersed in a small quantity of oil before they are added.

E. Ointments

1. Introduction. Ointments are **semisolid preparations intended for external use.** They are easily spread. Modifying the formulation controls their plastic viscosity. Ointments are typically used as:

a. Emollients to make the skin more pliable

b. Protective barriers to prevent harmful substances from coming in contact with the skin

c. **Vehicles** in which to incorporate medication

2. Ointment bases

a. Oleaginous bases are anhydrous and insoluble in water. They cannot absorb or contain water and are not washable in water.

(1) Petrolatum is a good base for oil-insoluble ingredients. It forms an occlusive film on the skin, absorbs < 5% water under normal conditions, and does not become rancid. Wax can be incorporated to stiffen the base.

(2) Synthetic esters are used as constituents of oleaginous bases. These esters include glyceryl monostearate, isopropyl myristate, isopropyl palmitate, butyl stearate, and butyl palmitate. Long-chain alcohols (e.g., cetyl alcohol, stearyl alcohol, PEG) can also be used.

(3) Lanolin derivatives are often used in topical and cosmetic preparations. Examples are lanolin oil and hydrogenated lanolin.

b. Absorption bases are anhydrous and water insoluble. Therefore, they are not washable in water, although they can absorb water. These bases permit water-soluble medicaments to be included through prior solution and uptake as the internal phase.

(1) Wool fat (anhydrous lanolin) contains a high percentage of cholesterol as well as esters and alcohol that contain fatty acids. It absorbs twice its weight in water and melts between 36°C and 42°C.

(2) Hydrophilic petrolatum is a white petrolatum combined with 8% beeswax, 3% stearyl alcohol, and 3% cholesterol. These components are added to a w/o emulsifier. Prepared forms include Aquaphor, which uses wool alcohol to render white petrolatum emulsifiable. Aquaphor is superior in its ability to absorb water.

c. **Emulsion bases** may be w/o emulsions, which are water insoluble and are not washable in water. These emulsions can absorb water because of their aqueous internal phase. Emulsion bases may also be o/w emulsions, which are water insoluble but washable in water. They can absorb water in their aqueous external phase.

(1) Hydrous wool fat (lanolin) is a w/o emulsion that contains approximately 25% water. It acts as an emollient and occlusive film on the skin, effectively preventing epidermal water loss.

(2) Cold cream is a w/o emulsion that is prepared by melting white wax, spermaceti, and expressed almond oil together; adding a hot aqueous solution of sodium borate; and stirring until the mixture is cool.

(a) The use of mineral oil rather than almond oil makes a more stable cold cream. However, cold cream prepared with almond oil makes a better emollient base.

(b) This ointment should be freshly prepared.

(3) Hydrophilic ointment is an o/w emulsion that uses sodium lauryl sulfate as an emulsifying agent. It absorbs 30%-50% w/w without losing its consistency. It is readily miscible with water and is removed from the skin easily.

(4) Vanishing cream is an o/w emulsion that contains a large percentage of water as well as humectant (e.g., glycerin, propylene glycol) that retards moisture loss. An excess of stearic acid in the formula helps form a thin film when the water evaporates.

(5) Other emulsion bases include Dermovan, a hypoallergenic, greaseless emulsion base, and Unibase, a nongreasy emulsion base that absorbs approximately 30% of its weight in water and has a pH close to that of the skin.

d. Water-soluble bases may be anhydrous or may contain some water. They are washable in water and absorb water to the point of solubility.

(1) PEG ointment is a blend of water-soluble polyethylene glycols that form a semisolid base. This base can solubilize water-soluble drugs and some water-insoluble drugs. It is compatible with a wide range of drugs.

(a) This base contains 40% PEG 3350 and 60% PEG 400. It is prepared by the fusion method (see VI.E.3.b).

(b) Only a small amount of liquid (< 5%) can be incorporated without loss of viscosity. This base can be made stiffer by increasing the amount of PEG 3350 to 60%.

(c) If 6% to 25% of an aqueous solution is to be incorporated, 5 g of the 40 g of PEG 3350 can be replaced with an equal amount of stearyl alcohol.

(2) Propylene glycol and **propylene glycol-ethanol** form a clear gel when mixed with 2% hydroxypropyl cellulose. This base is a popular dermatologic vehicle.

3. Incorporation of medicinal agents. Medicinal substances may be incorporated into an ointment base by **levigation** or by the **fusion method.** Insoluble substances should be reduced to the finest possible form and levigated before incorporation with a small amount of compatible levigating agent or with the base itself.

a. Levigation. The substance is incorporated into the ointment by levigation on an ointment slab.

(1) A stainless-steel spatula with a long, broad, flexible blade should be used. If the substance may interact with a metal spatula (e.g., when incorporating iodine and mercuric salts), then a hard rubber spatula can be used.

(2) Insoluble substances should be powdered finely in a mortar and mixed with an equal quantity of base until a smooth, grit-free mixture is obtained. The rest of the base is added in increments.

(3) Levigation of powders into a small portion of base is facilitated by the use of a melted base or a small quantity of compatible levigation aid (e.g., mineral oil, glycerin).

(4) Water-soluble salts are incorporated by dissolving them in the smallest possible amount of water and incorporating the aqueous solution directly into a compatible base.

(a) Usually, organic solvents (e.g., ether, chloroform, alcohol) are not used to dissolve the drug because the drug may crystallize as the solvent evaporates.

(b) Solvents are used as levigating aids only if the solid will become a fine powder after the solvent evaporates.

b. Fusion method. This method is used when the base contains solids that have higher melting points (e.g., waxes, cetyl alcohol, glyceryl monostearate). This method is also useful for solid medicaments, which are readily soluble in the melted base.

(1) The oil phase should be melted separately, starting with materials that have the highest melting point. All other oil-soluble ingredients are added in decreasing order of melting point.

(2) The ingredients in the water phase are combined and heated separately to a temperature that is equal to or several degrees above that of the melted oil phase.

(3) The two phases are combined. If a w/o system is desired, then the hot aqueous phase is incorporated into the hot oil phase with agitation. If an

o/w system is preferred, then the hot oil phase is incorporated into the hot aqueous phase.

(4) Volatile materials (e.g., menthol, camphor, iodine, alcohol, perfumes) are added after the melted mixture cools to 40°C or less.

F. Suppositories

1. Introduction. A suppository is a **solid or semisolid mass intended to be inserted into a body orifice** (i.e., rectum, vagina, urethra). After it is inserted, a suppository either melts at body temperature or dissolves (or disperses) into the aqueous secretions of the body cavity.

a. Suppositories are often used for local effects (e.g., relief of hemorrhoids or infection).

b. When used rectally, suppositories can provide systemic medication. The absorption of a drug from a suppository through the rectal mucosa into the circulation involves two steps:

(1) The drug is released from a vehicle and partitions/diffuses through the mucosa.

(2) The drug is transported through the veins or lymph vessels into systemic fluids or tissues. The first-pass effect is avoided because the rectal veins "bypass" the liver.

c. Rectal suppositories are useful when oral administration is inappropriate, as with infants, debilitated or comatose patients, and patients who have nausea, vomiting, or gastrointestinal disturbances. Some drugs can cause disturbances of the gastrointestinal tract.

2. Types of suppositories

a. Rectal suppositories are usually cylindrical and tapered to a point, forming a bullet-like shape. As the rectum contracts, a suppository of this shape moves inward rather than outward. Suppositories for adults weigh approximately 2 g. Suppositories for infants and children are smaller.

b. Vaginal suppositories are oval and typically weigh approximately 5 g. Drugs administered by this route are intended to have a local effect, but systemic absorption can occur. Antiseptics, contraceptive agents, and drugs used to treat trichomonal, monilial, or bacterial infections are often formulated as vaginal suppositories.

c. **Urethral suppositories** are typically long and tapered. They are approximately 60 mm long and 4-5 mm in diameter. They are administered for a local effect and are most often used for anti-infective agents. Alprostadil, or prostaglandin E_1 (PGE_1), when used to treat erectile dysfunction, is available for urethral insertion in the form of a micropellet, or microsuppository, that is only 3-6 mm long and 1.4 mm in diameter.

3. Suppository bases

a. Criteria for satisfactory suppository bases. Suppository bases should

(1) Remain firm at room temperature to allow insertion. The suppository should not soften < 30°C to avoid melting during storage.

(2) Have a narrow, or sharp, melting range

(3) Yield a clear melt just below body temperature or dissolve rapidly in the cavity fluid
(4) Be inert and compatible with a variety of drugs
(5) Be nonirritating and nonsensitizing
(6) Have wetting and emulsifying properties
(7) Have an acid value of < 0.2, a saponification value of 200-245, and an iodine value of < 7 if the base is fatty
b. Selecting a suppository base. Lipid-water solubility must be considered because of its relation to the drug-release rate.
(1) If an oil-soluble drug is incorporated into an oily base, then the rate of absorption is somewhat less than that achieved with a water-soluble base. The lipid-soluble drug tends to remain dissolved in the oily pool from the suppository. It is less likely to escape into the mucous secretions from which it is ultimately absorbed.
(2) Conversely, a water-soluble drug tends to pass more rapidly from the oil phase to the aqueous phase. Therefore, if rapid onset of action is desired, the water-soluble drug should be incorporated into the oily base.
c. **Bases that melt** include **cocoa butter,** other **combinations of fats and waxes, Witepsol bases,** and **Wecobee bases** (Table 3-4).
(1) Cocoa butter (theobroma oil) is the most widely used suppository base. It is firm and solid up to a temperature of 32°C, at which point it begins to soften. At 34-35°C, it melts to produce a thin, bland, oily liquid.

Table 3-4. Composition, Melting Range, and Congealing Range of Selected Bases That Melt

Base	Composition	Melting Range (°C)	Congealing Range (°C)
Cocoa butter	Mixed triglycerides of oleic, palmitic, and stearic acids	34-35	28 or less
Cotmar	Partially hydrogenated cottonseed oil	34-75	—
Dehydag	Hydrogenated fatty alcohols and esters		
Base I		33-36	32-33
Base		37-39	36-37

	II			
	Base III		9 ranges	9 ranges
Wecobee R		Glycerides of saturated fatty acids C_{12}-C_{18}	33-35	31-32
Wecobee SS		Triglycerides derived from coconut oil	40-43	33-35
Witepsol		Triglycerides of saturated fatty acids C_{12}-C_{18}, with varied portions of the corresponding partial glycerides		
	H-12		32-33	29-32
	H-15		33-35	32-34
	H-85		42-44	36-38

(a) Cocoa butter is a good base for a **rectal suppository,** but it is less than ideal for a vaginal or urethral suppository.

(b) A mixture of triglycerides, cocoa butter exhibits polymorphism. Depending on the fusion temperature, it can crystallize into any one of four crystal forms.

(c) Major limitations of cocoa butter. Because of the following limitations, many combinations of fats and waxes are used as substitutes (Table 3-4):

(i) An inability to absorb aqueous solutions. The addition of nonionic surfactants to the base ameliorates this problem to some extent. However, the resultant suppositories have poor stability and may turn rancid rapidly.

(ii) The lowering of the melting point produced by certain drugs (e.g., chloral hydrate).

(2) Witepsol bases contain natural saturated fatty acid chains between C12 and C18. Lauric acid is the major component. All 12 bases of this series are colorless and almost odorless. The drug-release characteristics of Witepsol H15 are similar to those of cocoa butter.

(a) Unlike cocoa butter, Witepsol bases do not exhibit polymorphism when heated and cooled.

(b) The interval between softening and melting temperatures is very small. Because Witepsol bases solidify rapidly in the mold, lubrication of the mold is not necessary.

(3) Wecobee bases are derived from coconut oil. Their action is similar to that of Witepsol bases. Incorporation of glyceryl monostearate and propylene glycol monostearate makes these bases emulsifiable.

d. Bases that dissolve include **PEG** polymers with a molecular weight of 400-6000.

(1) At room temperature, PEG 400 is a liquid, PEG 1000 is a semisolid, PEG 1500 and 1600 are fairly firm semisolids, and PEG 3350 and 6000 are firm wax-like solids.

(2) These bases are water soluble, but the dissolution process is very slow. In the rectum and vagina, where the amount of fluid is very small, they dissolve very slowly, but they soften and spread.

(3) PEGs complex with several drugs and affect drug release and absorption.

(4) Mixtures of PEG polymers in varying proportions provide a base of different properties (Table 3-5).

4. Preparation. Suppositories are prepared by the following three methods:

a. Hand-rolling involves molding the suppository with the fingers after a plastic mass is formed.

(1) A finely powdered drug is mixed with the grated base in a mortar and pestle, using levigation and geometric dilution techniques. A small quantity of fixed oil may be added to facilitate preparation.

Table 3-5. Mixtures of Polyethylene Glycol (PEG) Bases Providing Satisfactory Room Temperature Stability and Dissolution Characteristics

Base	Comments	Components	Proportion (%)
1	Provides a good general-purpose, water-soluble suppository	PEG 6000	50
		PEG 1540	30
		PEG 400	20
2	Provides a good general-purpose base that is slightly softer than base 1 and dissolves	PEG 4000	60

	more rapidly	PEG 1500	30
		PEG 400	10
3	Has a higher melting point than the other bases, which is usually sufficient to compensate for the melting-point lowering effect of such drugs as chloral hydrate and camphor	PEG 6000	30
		PEG 1540	70

(2) The uniformly mixed semiplastic mass is kneaded further, rolled into a cylinder, and divided into the requisite number of suppositories. Each small cylinder is rolled by hand until a suppository shape is fashioned.

b. Compression is generally used when cocoa butter is used as a base.

(1) A uniform mixture of drug and base is prepared as for the hand-rolling method.

(2) The mixture is placed into a suppository compression device. Pressure is applied, and the mixture is forced into lubricated compression mold cavities. The mold is then cooled and the suppositories ejected.

(3) This procedure generally produces a 2-g suppository. However, a large volume of the active ingredients can affect the amount of cocoa butter required for an individual formula.

(a) The amount of cocoa butter needed is determined by calculating the total amount of active ingredient to be used, dividing this number by the cocoa butter density factor (Table 3-6), and subtracting the resulting number from the total amount of cocoa butter required for the desired number of suppositories.

(b) For example, suppose 12 suppositories, each containing 300 mg aspirin, are required. Each mold cavity has a 2-g capacity. For 13 suppositories (calculated to provide one extra), 3.9 g aspirin (13 × 0.3 g = 3.9 g) is required. This number is divided by the density factor of aspirin (1.1) (Table 3-6). Thus 3.9 g of aspirin replaces 3.55 g of cocoa butter. The total amount of cocoa butter needed for 13 suppositories of 2 g each equals 26 g. The amount of cocoa butter required is 26 g - 3.55 g, or 22.45 g.

c. The **fusion method** is the principal way that suppositories are made commercially. This method is used primarily for suppositories that contain cocoa butter, PEG, and glyceringelatin

bases. Molds made of aluminum, brass, or nickel-copper alloys are used and can make 6-50 suppositories at one time.

Table 3-6. Cocoa Butter Density Factors of Drugs Commonly Used in Suppositories

Drug	Cocoa Butter Density Factor	Drug	Cocoa Butter Density Factor
Aloin	1.3	Dimenhydrinate	1.3
Aminophylline	1.1	Diphenhydramine hydrochloride	1.3
Aminopyrine	1.3	Gallic acid	2.0
Aspirin	1.1	Morphine hydrochloride	1.6
Barbital sodium	1.2	Pentobarbital	1.2
Belladonna extract	1.3	Phenobarbital sodium	1.2
Bismuth subgallate	2.7	Salicylic acid	1.3
Chloral hydrate	1.3	Secobarbital sodium	1.2
Codeine phosphate	1.1	Tannic acid	1.6
Digitalis leaf	1.6		

(1) The **capacity of the molds** is determined by melting a sufficient quantity of base over a steam bath, pouring it into the molds, and allowing it to congeal. The “blank” suppositories are trimmed, removed, and weighed. Once the weight is known, the drug-containing suppositories are prepared.

(a) To prepare suppositories, the drug is reduced to a fine powder. A small amount of grated cocoa butter is liquefied in a suitable container placed in a water bath at 33°C or less.
(b) The finely powdered drug is mixed with melted cocoa butter with continuous stirring.
(c) The remainder of the grated cocoa butter is added with stirring. The temperature is maintained at or below 33°C. The liquid should appear creamy rather than clear.
(d) The mold is very lightly lubricated with mineral oil, and the creamy melt is poured into the mold at room temperature. The melt is poured continuously to avoid layering.
(e) After the suppositories congeal, they are placed in a refrigerator to harden. After 30 min, they are removed from the refrigerator, trimmed, and unmolded.
(2) The fusion process should be used carefully with **thermolabile drugs** and **insoluble powders.**
(a) Insoluble powders in the melt may settle or float during pouring, depending on their density. They may also collect at one end of the suppository before the melt congeals, and cause a nonuniform drug distribution.
(b) Hard crystalline materials (e.g., iodine, merbromin) can be incorporated by dissolving the crystals in a minimum volume of suitable solvent before they are incorporated into the base.
(c) Vegetable extracts can be incorporated by moistening with a few drops of alcohol and levigating with a small amount of melted cocoa butter.

G. Powders

1. Introduction. A pharmaceutical powder is a mixture of finely divided drugs or chemicals in dry form. The powder may be used internally or externally.

a. Advantages of powders
(1) Flexibility of compounding
(2) Good chemical stability
(3) Rapid dispersion of ingredients because of the small particle size

b. Disadvantages of powders
(1) Time-consuming preparation
(2) Inaccuracy of dose
(3) Unsuitability for many unpleasant-tasting, hygroscopic, and deliquescent drugs

c. **Milling** is the mechanical process of reducing the particle size of solids (**comminution**) before mixing with other components, further processing, or incorporation into a final product (Tables 3-7 and 3-8). The particle size of a powder is related to the proportion of the powder that can pass through the opening of standard sieves of various dimensions in a specified amount of time. **Micromeritics** is the study of particles.

Table 3-7. *United States Pharmacopeia* Standards for Powders of Animal and Vegetable Drugs

Type of Powder	Sieve Size All Particles Pass Through	Sieve Size Percentage of Particles Pass Through
Very coarse (#8)	#20 sieve	20% through a #60 sieve
Coarse (#20)	#20 sieve	40% through a #60 sieve
Moderately coarse (#40)	#40 sieve	40% through a #80 sieve
Fine (#60)	#60 sieve	40% through a #100 sieve
Very fine (#80)	#80 sieve	No limit

Table 3-8. *United States Pharmacopeia* Standards for Powders of Chemicals

Type of Powder	Sieve Size All Particles Pass Through	Sieve Size Percentage of Particles Pass Through
Coarse (#20)	#20 sieve	60% through a #40 sieve
Moderately coarse (#40)	#40 sieve	60% through a #60 sieve
Fine (#80)	#80 sieve	No limit
Very fine (#120)	#120 sieve	No limit

(1) Advantages of milling

(a) Increases the surface area, which may increase the dissolution rate as well as bioavailability (e.g., griseofulvin)

(b) Increases extraction, or leaching, from animal glands (e.g., liver, pancreas) and from crude vegetable extracts

(c) Facilitates drying of wet masses by increasing the surface area and reducing the distance that moisture must travel to reach the outer surface.

Micronization and subsequent drying, in turn, increase stability as occluded solvent is removed.

(d) Improves mixing, or blending, of several solid ingredients if they are reduced to approximately the same size; also minimizes segregation and provides greater dose uniformity

(e) Permits uniform distribution of coloring agents in artificially colored solid pharmaceuticals

(f) Improves the function of lubricants used to coat the surface of the granulation or powder in compressed tablets and capsules

(g) Improves the texture, appearance, and physical stability of ointments, creams, and pastes

(2) Disadvantages of milling

(a) Can change the polymorphic form of the active ingredient, rendering it less active

(b) Can degrade the drug as a result of heat buildup, oxidation, or adsorption of unwanted moisture because of increased surface area

(c) Decreases the bulk density of the active compound and excipients, causing flow problems and segregation.

(d) Decreases the particle size of the raw materials and may create problems with static charge, which may cause particle aggregation and decrease the dissolution rate

(e) Increases surface area, which may promote air adsorption and inhibit wettability

(3) Comminution techniques. On a large scale, various mills and pulverizers (e.g., rotary cutter, hammer, roller, fluid energy mill) are used during manufacturing. On a small scale, the pharmacist usually uses one of the following comminution techniques:

(a) Trituration. The substance is reduced to small particles by rubbing it in a mortar with a pestle. Trituration also describes the process by which fine powders are intimately mixed in a mortar.

(b) Pulverization by intervention. Substances are reduced and subdivided with an additional material (i.e., solvent) that is easily removed after pulverization. This technique is often used with gummy substances that reagglomerate or resist grinding. For example, camphor is readily reduced after a small amount of alcohol or other volatile solvent is added. The solvent is then permitted to evaporate.

(c) Levigation. The particle size of the substance is reduced by adding a suitable nonsolvent (levigating agent) to form a paste. The paste is then rubbed in a mortar and pestle or using an ointment slab and spatula. This method is often used to prevent a gritty feel when solids are incorporated into dermatologic or ophthalmic ointments and suspensions. Mineral oil is a common levigating agent.

2. Mixing powders. Powders are mixed, or blended, by the following five methods:

a. Spatulation. A spatula is used to blend small amounts of powders on a sheet of paper or a pill tile.

(1) This method is not suitable for large quantities of powders or for powders that contain potent substances because homogeneous blending may not occur.

(2) This method is particularly useful for solid substances that liquefy or form **eutectic mixtures** (i.e., mixtures that melt at a lower temperature than any of their ingredients) when in close, prolonged contact with one another because little compression or compaction results.

(a) These substances include phenol, camphor, menthol, thymol, aspirin, phenylsalicylate, and phenacetin.

(b) To diminish contact, powders prepared from these substances are commonly mixed with an inert diluent (e.g., light magnesium oxide or magnesium carbonate, kaolin, starch, bentonite).

(c) Silicic acid (approximately 20%) prevents eutexia with aspirin, phenylsalicylate, and other troublesome compounds.

b. Trituration is used both to comminute and to mix powders.

(1) If comminution is desired, a porcelain or ceramic mortar with a rough inner surface is preferred to a glass mortar with a smooth working surface.

(2) A glass mortar is preferable for chemicals that stain a porcelain or ceramic surface as well as for simple admixture of substances without special need for comminution. A glass mortar cleans more readily after use.

c. **Geometric dilution** is used when potent substances must be mixed with a large amount of diluent.

(1) The potent drug and an approximately equal volume of diluent are placed in a mortar and thoroughly mixed by trituration.

(2) A second portion of diluent, equal in volume to the powder mixture in the mortar, is added, and trituration is repeated. The process is continued; equal volumes of diluent are added to the powder mixture in the mortar until all of the diluent is incorporated.

d. Sifting. Powders are mixed by passing them through sifters similar to those used to sift flour. This process results in a light, fluffy product. Usually, it is not acceptable for incorporating potent drugs into a diluent base.

e. Tumbling is the process of mixing powders in a large container rotated by a motorized process. These blenders are widely used in industry, as are large-volume powder mixers that use motorized blades to blend the powder in a large mixing vessel.

3. Use and packaging of powders. Depending on their intended use, powders are packaged and dispensed by pharmacists as bulk powders or divided powders.

a. Bulk powders are dispensed by the pharmacist in bulk containers. A **perforated,** or **sifter, can** is used for external dusting, and an **aerosol container** is used for spraying onto skin. A **wide-mouthed glass jar** permits easy removal of a spoonful of powder.

(1) Powders commonly dispensed in bulk form

(a) Antacid and laxative powders are used by mixing the directed amount of powder (usually approximately 1 teaspoon) in a portion of liquid, which the patient then drinks.

(b) Douche powders are dissolved in warm water and applied vaginally.

(c) Medicated and nonmedicated powders for external use are usually dispensed in a sifter for convenient application to the skin.

(d) Dentifrices, or **dental cleansing powders,** are used for oral hygiene.

(e) Powders for the **ear, nose, throat, tooth sockets,** or **vagina** are administered with an insufflator, or powder blower.

(2) Nonpotent substances are usually dispensed in bulk powder form. Those intended for external use should be clearly labeled.

(3) Hygroscopic, deliquescent, or **volatile** powders should be packed in glass jars rather than pasteboard containers. Amber or green glass should be used if needed to prevent decomposition of light-sensitive components. All powders should be stored in tightly closed containers.

b. Divided powders are dispensed in individual doses, usually in folded **papers** (i.e., chartulae). They may also be dispensed in metal foil, small heat-sealed or resealable **plastic bags,** or other containers.

(1) After the ingredients are weighed, comminuted, and mixed, the powders must be accurately **divided** into the prescribed number of doses.

(2) Depending on the potency of the drug substance, the pharmacist decides whether to **weigh** each portion separately before packaging or to approximate portions by the **block-and-divide method.**

(3) Powder papers can be of any convenient size that fits the required dose. Four basic types are used:

(a) Vegetable parchment is a thin, semiopaque, moisture-resistant paper.

(b) White bond is an opaque paper that has no moisture-resistant properties.

(c) Glassine is a glazed, transparent, moisture-resistant paper.

(d) Waxed paper is a transparent waterproof paper.

(4) Hygroscopic and volatile drugs are best protected with waxed paper that is double wrapped and covered with a bond paper to improve the appearance. Parchment and glassine papers are of limited use for these drugs.

4. Special problems. Volatile substances, eutectic mixtures, liquids, and hygroscopic or deliquescent substances present problems when they are mixed into powders that require special treatment.

a. Volatile substances (e.g., camphor, menthol, essential oils) can be lost by volatilization after they are incorporated into powders. This process is prevented or retarded by the use of heat-sealed plastic bags or by double wrapping with waxed or glassine paper inside white bond paper.

b. Liquids are incorporated into divided powders in small amounts.

(1) Magnesium carbonate, starch, or lactose can be added to increase the absorbability of the powders by increasing the surface area.

(2) When the liquid is a solvent for a nonvolatile heat-stable compound, it is evaporated gently in a water bath. Some fluidextracts and tinctures are treated in this way.

c. **Hygroscopic and deliquescent substances** that become moist because of an affinity for moisture in the air can be prepared as divided powders by adding inert diluents. Double wrapping is desirable for further protection.

d. Eutectic mixtures

H. Capsules

1. Introduction. Capsules are solid dosage forms in which one or more medicinal or inert substances (as powder, compact, beads, or granulation) are enclosed within a small gelatin shell. Gelatin capsules may be hard or soft. Most capsules are intended to be swallowed whole, but occasionally, the contents are removed from the gelatin shell and used as a premeasured dose.

2. Hard gelatin capsules

a. Preparation of filled hard capsules includes preparing the formulation, selecting the appropriate capsule, filling the capsule shells, and cleaning and polishing the filled capsules.

(1) Empty hard capsule shells are manufactured from a mixture of gelatin, colorants, and sometimes an opacifying agent (e.g., titanium dioxide). The USP also permits the addition of 0.15% sulfur dioxide to prevent decomposition of gelatin during manufacture.

(2) Gelatin USP is obtained by partial hydrolysis of collagen obtained from the skin, white connective tissue, and bones of animals. Types A and B are obtained by acid and alkali processing, respectively.

(3) Capsule shells are cast by dipping cold metallic molds or pins into gelatin solutions that are maintained at a uniform temperature and an exact degree of fluidity.

(a) Variation in the viscosity of the gelatin solution increases or decreases the thickness of the capsule wall.

(b) After the pins are withdrawn from the gelatin solution, they are rotated while being dried in kilns. A strong blast of filtered air with controlled humidity is forced through the kilns. Each capsule is then mechanically stripped, trimmed, and joined.

b. Storage. Hard capsules should be stored in tightly closed glass containers and protected from dust and extremes of humidity and temperature.

(1) These capsules contain 12%-16% water, varying with storage conditions. When humidity is low, the capsules become brittle. When humidity is high, the capsules become flaccid and shapeless.
(2) Storage at high temperatures also affects the quality of hard gelatin capsules.
c. **Sizes.** Hard capsules are available in a variety of sizes.

(1) Empty capsules are **numbered** from 000, which is the largest size that can be swallowed, to 5, the smallest size. The approximate capacity of capsules ranges from 600 to 30 mg for capsules from 000 to 5, respectively. The capacity varies because of varying densities of powdered drug materials and the degree of pressure used to fill the capsules.
(2) Large capsules are available for **veterinary medicine.**
(3) Selecting capsules. Capsule size should be chosen carefully. A properly filled capsule should have its body filled with the drug mixture and its cap fully extended down the body. The cap is meant to enclose the powder, not to retain additional powder. Typically, hard gelatin capsules are used to encapsulate between 65 mg and 1 g of powdered material, including the drug and any diluents needed.
(a) If the drug dose is inadequate to fill the capsule, a diluent (e.g., lactose) is added.
(b) If the amount of drug needed for a usual dose is too large to place in a single capsule, two or more capsules may be required.
(c) Lubricants such as magnesium stearate (frequently, 1%) are added to facilitate the flow of the powder when an automatic capsule-filling machine is used.
(d) Wetting agents (e.g., sodium lauryl sulfate) may be added to capsule formulations to enhance drug dissolution.
d. Filling capsules. Whether on a large- or a small-production scale, the cap is first separated from the body of the capsule before filling the capsule body with the formulation and then reattaching the cap. Automated and semiautomated capsule-filling equipment fill the capsule bodies with the formulation by gravity fill, tamping, or a screw-feed (i.e., auger) mechanism. Extemporaneously compounded capsules are usually filled by the punch method.
(1) The powder is placed on paper and flattened with a spatula so that the layer of powder is no more than approximately one third the length of the capsule. The paper is held in the left hand. The body of the capsule is held in the right hand and repeatedly pressed into the powder until the capsule is filled. The cap is replaced and the capsule weighed.
(2) Granular material that does not lend itself well to the punch method can be poured into each capsule from the powder paper on which it was weighed.

(3) Crystalline materials, especially those that consist of a mass of filament-like crystals (e.g., quinine salts) will not fit into a capsule easily unless they are powdered.
(4) After they are filled, capsules must be cleaned and polished.
(a) On a **small scale,** capsules are cleaned individually or in small numbers by rubbing them on a clean gauze or cloth.
(b) On a **large scale,** many capsule-filling machines have a cleaning vacuum that removes any extraneous material as the capsules leave the machine.

3. Soft gelatin capsules

a. Preparation

(1) Soft gelatin capsules are prepared from gelatin shells. Glycerin or a polyhydric alcohol (e.g., sorbitol) is added to these shells to make them elastic or plastic-like.
(2) These shells contain preservatives (e.g., methyl and propyl parabens, sorbic acid) to prevent the growth of fungi.
b. Uses. Soft gelatin shells are oblong, elliptical, or spherical. They are used to contain liquids, suspensions, pastes, dry powders, or pellets.
(1) Drugs that are commercially prepared in soft capsules include demeclocycline hydrochloride (Declomycin, Lederle), chloral hydrate, digoxin (Lanoxicaps, GlaxoSmithKline), vitamin A, and vitamin E.
(2) Soft gelatin capsules are usually prepared by the plate process or by the rotary or reciprocating die process.

4. Uniformity and disintegration

a. The **uniformity** of dosage forms can be demonstrated by either weight variation or content uniformity methods. The official compendia should be consulted for details of these procedures.
b. Disintegration tests are not usually required for capsules unless they have been treated to resist solution in gastric fluid (enteric coated). In this case, they must meet the requirements for disintegration of enteric-coated tablets.

I. TABLETS

1. Introduction

a. The **oral route** is the most important method for administering drugs for systemic effect. Oral drugs can be given as solids or liquids.

(1) Advantages of solid dosage forms

(a) Accurate dosage
(b) Easy shipping and handling
(c) Less shelf space needed per dose than for liquid
(d) No preservation requirements
(e) No taste-masking problem
(f) Generally more stable than liquids, with longer expiration dates

(2) Advantages of liquid dosage forms

(a) For some drugs (e.g., adsorbents, antacids), greater effectiveness than solid form

(b) Useful for patients who have trouble swallowing solid dosage forms

b. Tablets are the **most commonly used solid dosage form.**

(1) Advantages

(a) Precision and low content variability of the unit dose

(b) Low manufacturing cost

(c) Easy to package and ship

(d) Simple to identify

(e) Easy to swallow

(f) Appropriate for special-release forms

(g) Best suited to large-scale production

(h) Most stable of all oral dosage forms

(i) Essentially tamperproof

(2) Disadvantages

(a) Some drugs resist compression into tablets.

(b) Some drugs (i.e., those with poor wetting, slow dissolution properties, intermediate to large doses, optimum absorption high in the gastrointestinal tract, or any combination of these features) may be difficult to formulate to provide adequate bioavailability.

(c) Some drugs (e.g., those with an objectionable taste or odor, those sensitive to oxygen or atmospheric moisture) require encapsulation or entrapment before compression. These drugs are more appropriate in capsule form.

2. Tablet design and formulation

a. Characteristics of ideal tablets

(1) Free of defects (e.g., chips, cracks, discoloration, contamination)

(2) Strong enough to withstand the mechanical stresses of production

(3) Chemically and physically stable over time

(4) Capable of releasing medicinal agents in a predictable and reproducible manner

b. Tablet excipients. Tablets are manufactured by **wet granulation, dry granulation,** or **direct compression.** Regardless of the method of manufacture, tablets for oral ingestion usually contain excipients, which are components added to the active ingredients that have special functions (Table 3-9).

(1) Diluents are fillers designed to make up the required bulk of the tablet when the drug dosage amount is inadequate. Diluents may also improve cohesion, permit direct compression, or promote flow.

(a) Common diluents include kaolin, lactose, mannitol, starch, microcrystalline cellulose, powdered sugar, and calcium phosphate.

(b) Selection of the diluent is based on the experience of the manufacturer as well as on the cost of the diluent and its compatibility with the other tablet ingredients. For example, calcium salts cannot be used as

fillers for tetracycline products because calcium interferes with the absorption of tetracycline from the gastrointestinal tract.

(2) Binders and adhesives are added in either dry or liquid form to promote granulation or to promote cohesive compacts during direct compression.

(a) Common binding agents include a 10%-20% aqueous preparation of cornstarch, a 25%-50% solution of glucose, molasses, various natural gums (e.g., acacia), cellulose derivatives (e.g., methylcellulose, carboxymethylcellulose, microcrystalline

cellulose), gelatins, and povidone. The natural gums are variable in composition and are usually contaminated with bacteria.

Natural sweetener

D&C, drugs and cosmetics; *FD&C,* food, drugs, and cosmetics; *NF, National Formulary; PEG,* polyethylene glycol; *PVP,* polyvinylpyrrolidone (more commonly, povidone); *USP, United States Pharmacopeia.*

(b) If the drug substance is adversely affected by an aqueous binder, a **nonaqueous binder** can be used or the binder can be added dry. The binding action is usually more effective when the binder is mixed in liquid form.

(c) The **amount** of binder or adhesive used depends on the experience of the manufacturer as well as on the other tablet ingredients. Overwetting usually produces granules that are too hard to allow proper tableting. Underwetting usually produces tablets that are too soft and tend to crumble.

(3) Disintegrants are added to tablet formulations to facilitate disintegration when the tablet contacts water in the gastrointestinal tract. Disintegrants function by drawing water into the tablet, swelling, and causing the tablet to burst.

(a) Tablet disintegration may be critical to the subsequent dissolution of the drug and to satisfactory drug bioavailability.

(b) Common disintegrants include cornstarch and potato starch; starch derivatives (e.g., sodium starch glycolate); cellulose derivatives (e.g., sodium carboxymethylcellulose, croscarmellose sodium); clays (e.g., VEEGUM, bentonite); and cation exchange resins.

(c) The total **amount of disintegrant** is not always added to the drug-diluent mixture. A portion can be added, with the lubricant, to the prepared granulation of the drug. This approach causes double disintegration of the tablet. The portion of disintegrant that is added last causes the tablet to break into small pieces, or chunks. The portion that is added first breaks the pieces of tablet into fine particles.

(4) Lubricants, antiadherents, and **glidants** have overlapping function.
(a) Lubricants reduce the friction that occurs between the walls of the tablet and the walls of the die cavity when the tablet is ejected. Talc, magnesium stearate, and calcium stearate are commonly used.

(b) Antiadherents reduce sticking, or adhesion, of the tablet granulation or powder to the faces of the punches or the die walls.
(c) Glidants promote the flow of the tablet granulation or powder by reducing friction among particles.
(5) Colors and dyes disguise off-color drugs, provide product identification, and produce a more aesthetically appealing product. **Food, drug,** and **cosmetic dyes** are applied as solutions. **Lakes** are dyes that have been absorbed on a hydrous oxide. Lakes are typically used as dry powders.
(6) Flavoring agents are usually limited to chewable tablets or tablets that are intended to dissolve in the mouth.
(a) Water-soluble flavors usually have poor stability. For this reason, flavor oils or dry powders are typically used.
(b) Flavor oils may be added to tablet granulations in solvents, dispersed on clays and other adsorbents, or emulsified in aqueous granulating agents. Usually, the maximum amount of oil that can be added to a granulation without affecting its tablet characteristics is 0.5%-0.75%.
(7) Artificial sweeteners, like flavors, are typically used only with chewable tablets or tablets that are intended to dissolve in the mouth.
(a) Some **sweetness** may come from the diluent (e.g., mannitol, lactose). Other agents (e.g., saccharin, aspartame) may also be added.
(b) Saccharin has an unpleasant aftertaste.
(c) Aspartame is not stable in the presence of moisture and heat.
(8) Adsorbents (e.g., magnesium oxide, magnesium carbonate, bentonite, silicon dioxide) hold quantities of fluid in an apparently dry state.
3. Tablet types and classes. Tablets are classified according to their route of administration, drug delivery system, and form and method of manufacture (Table 3-10).
a. Tablets for oral ingestion are designed to be swallowed intact, with the exception of chewable tablets. Tablets may be coated for a number of reasons: to mask the taste, color, or odor of the drug; to control drug release; to protect the drug from the acid environment of the stomach; to incorporate another drug and provide sequential release or avoid incompatibility; or to improve appearance.
(1) Compressed tablets are formed by compression and have no special coating. They are made from powdered, crystalline, or granular materials, alone or in combination with excipients such as binders, disintegrants, diluents, and colorants.

(2) Multiple compressed tablets are layered or compression-coated.
(a) Layered tablets are prepared by compressing a tablet granulation around a previously compressed granulation. The operation is repeated to produce multiple layers.
(b) Compression-coated, or dry-coated, tablets are prepared by feeding previously compressed tablets into a special tableting machine. This machine compresses an outer shell around the tablets. This process applies a thinner, more uniform coating than sugar coating, and it can be used safely with drugs that are sensitive to moisture. This process can be used to separate incompatible materials, to

produce repeat-action or prolonged-action products or to produce tablets with a multilayered appearance.

Table 3-10. Tablet Types and Classes

Sublingual
Troches, lozenges, and dental cones
Tablets used to prepare solutions
Effervescent
Dispensing
Hypodermic
Triturates

(3) Repeat-action tablets are layered or compression-coated tablets in which the outer layer or shell rapidly disintegrates in the stomach (e.g., Repetabs, Schering; Extentabs, Wyeth). The components of the inner layer or inner tablet are insoluble in gastric media but soluble in intestinal media.

(4) Delayed-action and **enteric-coated tablets** delay the release of a drug from a dosage form. This delay is intended to prevent destruction of the drug by gastric juices, to prevent irritation of the stomach lining by the drug, or to promote absorption, which is better in the intestine than in the stomach.

(a) Enteric-coated tablets are coated and remain intact in the stomach, but yield their ingredients in the intestines (e.g., Ecotrin, GlaxoSmithKline). Enteric-coated tablets are a form of delayed-action tablet. However, not all delayed-action tablets are enteric or are intended to produce an enteric effect.

(b) Agents used to coat these tablets include fats, fatty acids, waxes, shellac, and cellulose acetate phthalate.

(5) Sugar-coated and **chocolate-coated tablets** are compressed tablets that are coated for various reasons. The coating may be added to protect the drug from air and humidity, to provide a barrier to a drug's objectionable taste or smell, or to improve the appearance of the tablet.

(a) Tablets may be coated with a colored or an uncolored sugar. The process includes **seal coating** (waterproofing), **subcoating, syrup coating** (for smoothing and coloring), and **polishing.** These steps take place in a series of mechanically operated coating pans.
(b) Disadvantages of sugar-coated tablets include the time and expertise required for the process and the increase in tablet size and weight. Sugar-coated tablets may be 50% larger and heavier than the original tablets.
(c) Chocolate-coated tablets are rare today.
(6) Film-coated tablets are compressed tablets that are coated with a thin layer of a water-insoluble or water-soluble polymer (e.g., hydroxypropyl methylcellulose, ethylcellulose, povidone, PEG).
(a) The film is usually colored. It is more durable, less bulky, and less time-consuming to apply than sugar coating. Although the film typically increases tablet weight by only 2%-3%, it increases formulation efficiency, resistance to chipping, and output.
(b) Film-coating solutions usually contain a film former, an alloying substance, a plasticizer, a surfactant, opacifiers, sweeteners, flavors, colors, glossants, and a volatile solvent.
(c) The volatile solvents used in these solutions are expensive and potentially toxic when released into the atmosphere. Specifically formulated **aqueous dispersions** of polymers (e.g., ethylcellulose) are now available as alternatives to organic solvent-based coating solutions.
(7) Air suspension-coated tablets are fed into a vertical cylinder and supported by a column of air that enters from the bottom of the cylinder. As the coating solution enters the system, it is rapidly applied to the suspended, rotating solids (**Wurster process**). Rounding coats can be applied in < 1 hr when blasts of warm air are released in the chamber.
(8) Chewable tablets disintegrate smoothly and rapidly when chewed or allowed to dissolve in the mouth. These tablets contain specially colored and flavored mannitol and yield a creamy base.
(a) Chewable tablets are especially useful in formulations for children.
(b) They are commonly used for multivitamin tablets and are used for some antacids and antibiotics.
b. Tablets used in the oral cavity are allowed to dissolve in the mouth.
(1) Buccal and sublingual tablets allow absorption through the oral mucosa after they dissolve in the buccal pouch (buccal tablets) or below the tongue (sublingual tablets). These forms are useful for drugs that are destroyed by gastric juice or poorly absorbed from the intestinal tract. Examples include sublingual nitroglycerin tablets, which dissolve promptly to give rapid drug effects, and buccal progesterone tablets, which dissolve slowly.

(2) Troches, lozenges, and dental cones dissolve slowly in the mouth and provide primarily local effects.

c. Tablets used to prepare solutions are dissolved in water before administration.

(1) Effervescent tablets are prepared by compressing granular effervescent salts or other materials (e.g., citric acid, tartaric acid, sodium bicarbonate) that release carbon dioxide gas when they come into contact with water. Commercial alkalinizing analgesic tablets are often made to effervesce to encourage rapid dissolution and absorption (e.g., Alka-Seltzer, Bayer).

(2) Other tablets used to prepare solutions include dispensing tablets, hypodermic tablets, and tablet triturates.

4. Processing problems

a. Capping is the partial or complete separation of the top or bottom crown from the main body of the tablet. Lamination is separation of a tablet into two or more distinct layers. These problems are usually caused by entrapment of air during processing.

b. Picking is removal of the surface material of a tablet by a punch. Sticking is adhesion of tablet material to a die wall. These problems are caused by excessive moisture or the inclusion of substances with low melting temperatures in the formulation.

c. Mottling is unequal color distribution, with light or dark areas standing out on an otherwise uniform surface. This problem occurs when a drug has a different color than the tablet excipients or when a drug has colored degradation products. Colorants solve the problem but can create other problems.

5. Tablet evaluation and control

a. The general appearance of tablets is an important factor in consumer acceptance. It also allows monitoring of lot-to-lot uniformity, tablet-to-tablet uniformity, and elements of the manufacturing process. The appearance of the tablet includes visual identity and overall appearance. The appearance of the tablet is controlled by measurement of attributes such as size, shape, color, odor, taste, surface, texture, physical flaws, consistency, and legibility of markings.

b. Hardness and resistance to friability are necessary for tablets to withstand the mechanical shocks of manufacture, packaging, and shipping, and to ensure consumer acceptance. Hardness involves both tablet disintegration and drug dissolution. Certain tablets that are intended to dissolve slowly are made hard. Other tablets that are intended to dissolve rapidly are made soft. Friability is the tendency of the tablet to crumble.

(1) Tablet hardness testers measure the degree of force required to break a tablet.

(2) Friabilators determine friability by allowing the tablet to roll and fall within a rotating tumbling apparatus. The tablets are weighed before and after a specified number of rotations, and the weight loss is determined.

(a) Resistance to weight loss indicates the ability of the tablet to withstand abrasion during handling, packaging, and shipping. Compressed tablets that lose < 0.5%-1% of their weight are usually considered acceptable.

(b) Some chewable tablets and most effervescent tablets are highly friable and require special unit packaging.
c. Tablets are routinely weighed to ensure that they contain the proper amount of drug.
(1) The USP defines a weight variation standard to which tablets must conform.
(2) These standards apply to tablets that contain 50 mg or more of drug substance when the drug substance is 50% or more (by weight) of the dosage form unit.
d. Content uniformity is evaluated to ensure that each tablet contains the desired amount of drug substance, with little variation among contents within a batch. The USP defines content uniformity tests for tablets that contain 50 mg or less of drug substance.
e. Disintegration is evaluated to ensure that the drug substance is fully available for dissolution and absorption from the gastrointestinal tract.
(1) All USP tablets must pass an official disintegration test that is conducted in vitro with special equipment.
(a) Disintegration times for uncoated USP tablets are as low as 2 min (nitroglycerin) to 5 min (aspirin). Most have a maximum disintegration time of less than 30 min.
(b) Buccal tablets must disintegrate within 4 hr.
(c) Enteric-coated tablets must show no evidence of disintegration after 1 hr in simulated gastric fluid. In simulated intestinal fluid, they should disintegrate in 2 hr plus the time specified.

(2) Dissolution requirements in the USP have replaced earlier disintegration requirements for many drugs.
f. Dissolution characteristics are tested to determine drug absorption and physiologic availability.
(1) The USP gives standards for tablet dissolution.
(2) An increased emphasis on testing tablet dissolution and determining drug bioavailability has increased the use of sophisticated testing systems.
J. Aerosol products
1. Introduction. Aerosol products, or aerosols, are pressurized dosage forms. They are designed to deliver drug systemically or topically with the aid of a liquefied or propelled gas (propellant). Aerosol products consist of a pressurizable container (tin-plated steel, aluminum, glass, or plastic); a valve that allows the pressurized product to be expelled from the container (either continuously or intermittently) when the actuator is pressed; and a dip tube that conveys the formulation from the bottom of the container to the valve assembly. Aerosols are prepared by special methods (cold filling, pressure filling) because of the gaseous components.

2. Systemic or pulmonary drug delivery is provided by aerosol drug delivery systems, or metered dose inhalers (MDIs). These devices allow a drug to be inhaled as a fine mist of drug or drug-containing particles. MDIs use special metering valves to regulate the amount of formulation and drug that is dispensed with each dose (i.e., each actuation of the container). Aerosol products are used for topical drug delivery. The formulations range from solutions to dispersions. Metering valves may also be used with topical aerosol products to regulate the amount of drug applied per application.

3. Propellants used in aerosol products

a. Compressed gases include carbon dioxide, nitrogen, and nitrous oxide. Aerosol products that contain compressed gas tend to lose pressure over time as the product is dispensed. The drop in pressure reflects the expansion of the head space in the container (i.e., increase in the volume that the gas can occupy) as formulation is withdrawn for use. For this reason, higher initial pressures are typically used with compressed gas-based systems than with liquefiable gas-based formulations.

b. Liquefiable gases include saturated hydrocarbons (n-butane, isobutane, propane); chlorofluorocarbons (CFCs), including tetrafluorodichloroethane (propellant 114), dichlorodifluoromethane (propellant 12), and trichlorofluoromethane (propellant 11); dimethyl ether; and hydrofluorocarbons, such as 1,1,1,2-fluoroethane (propellant 134a) and 1,1-difluoroethane (propellant 152a). The negative effect of older CFCs on atmospheric ozone and the potential for global warming led to the worldwide reduction in CFC production under the Montreal Protocol. This plan called for a general ban on CFC production in industrialized countries by January 1996. As a result, the use of CFCs in pharmaceutical products is being phased out. Temporary exemptions for CFCs in MDIs will eventually lapse (in 2008) as stable, safe, and effective alternative formulations are developed with more acceptable propellants (e.g., hydrofluorocarbons).

4. Advantages of aerosol products include the convenience of push-button dispensing of medication and the stability afforded by a closed, pressurized container that minimizes the likelihood of tampering and protects the contents from light, moisture, air (oxygen), and microbial contamination. Aerosol formulations and packaging components (valves, actuators) permit a wide range of products to be dispensed as sprays, foams, or semisolids.

5. The principal disadvantage of aerosol products is environmental (e.g., disposal of pressurized packages, venting of propellants to the atmosphere).

K. Controlled-release dosage forms

1. Introduction. Controlled-release dosage forms are also known as delayed-release, sustained-action, prolonged-action, sustained-release, prolonged-release, timed-release, slow-release, extended-action, and extended-release forms. They are designed to release drug substance slowly to provide prolonged action in the body.

2. Advantages of controlled-release forms
a. Fewer problems with patient compliance
b. Use of less total drug
c. Fewer local or systemic side effects
d. Minimal drug accumulation with long-term dosage
e. Fewer problems with potentiation or loss of drug activity with long-term use
f. Improved treatment efficiency
g. More rapid control of the patient's condition
h. Less fluctuation in drug level
i. Improved bioavailability for some drugs
j. Improved ability to provide special effects (e.g., morning relief of arthritis by bedtime dosing)
k. Reduced cost
3. Sustained-release forms can be grouped according to their pharmaceutical mechanism.
a. Coated beads or granules (e.g., Spansules, GlaxoSmithKline; Sequels, Wyeth) produce a blood level profile similar to that obtained with multiple dosing.
(1) A solution of the drug substance in a nonaqueous solvent (e.g., alcohol) is coated onto small, inert beads, or granules, made of a combination of sugar and starch. When the drug dose is large, the starting granules may be composed of the drug itself.
(2) Some of the granules are left uncoated to provide immediate release of the drug.
(3) Coats of a lipid material (e.g., beeswax) or a cellulosic material (e.g., ethylcellulose) are applied to the remaining granules. Some granules receive few coats, and some receive many. The various coating thicknesses produce a sustained-release effect.
b. Microencapsulation is a process by which solids, liquids, or gases are encased in microscopic capsules. Thin coatings of a “wall” material are formed around the substance to be encapsulated.
(1) Coacervation is the most common method of microencapsulation. It occurs when a hydrophilic substance is added to a colloidal drug dispersion and causes layering and the formation of microcapsules.
(2) Film-forming substances that are used as the coating material include a variety of natural and synthetic polymers. These materials include shellacs, waxes, gelatin, starches, cellulose acetate phthalate, and ethylcellulose. After the coating material dissolves, all of the drug inside the microcapsule is immediately available for dissolution and absorption. The thickness of the wall can vary from 1 to 200 mm, depending on the amount of coating material used (3%-30% of total weight).

c. Matrix tablets use insoluble plastics (e.g., polyethylene, polyvinyl acetate, polymethacrylate), hydrophilic polymers (e.g., methylcellulose, hydroxypropyl methylcellulose), or fatty compounds (e.g., various waxes, glyceryl tristearate). Examples include Gradumet (Abbott) and Dospan (Aventis).

(1) The most common method of preparation is mixing of the drug with the matrix material followed by compression of the material into tablets.

(2) The primary dose, or the portion of the drug to be released immediately, is placed on the tablet as a layer, or coat. The rest of the dose is released slowly from the matrix.

d. Osmotic systems include the Oros system (Alza), which is an oral osmotic pump composed of a core tablet and a semipermeable coating that has a small hole (0.4 mm in diameter) for drug exit. The hole is produced by a laser beam. Examples include Glucotrol XL (glipizide extended-release tablets, Pfizer) and Procardia XL (nifedipine extended-release tablets, Pfizer).

(1) This system requires only osmotic pressure to be effective. It is essentially independent of pH changes in the environment.

(2) The drug-release rate can be changed by changing the tablet surface area, the nature of the membrane, or the diameter of the drug-release aperture.

e. Ion-exchange resins can be complexed with drugs by passage of a cationic drug solution through a column that contains the resin. The drug is complexed to the resin by replacement of hydrogen atoms. Examples include Ionamin capsules (Celltech; resin complexes of phentermine) and the Pennkinetic system (Celltech), which incorporates a polymer barrier coating and bead technology in addition to the ion-exchange mechanism.

(1) After the components are complexed, the resin-drug complex is washed and tableted, encapsulated, or suspended in an aqueous vehicle.

(2) Release of drug from the complex depends on the ionic environment within the gastrointestinal tract and on the properties of the resin. Usually, release is greater in the highly acidic stomach than in the less acidic small intestine.

f. Complex formation is used for certain drug substances that combine chemically with other agents. For example, hydroxypropyl-β-cyclodextrin forms a chemical complex that can be only slowly soluble from body fluids, depending on the pH of the environment. Tannic acid (i.e., tannates) complexes with the amino groups of weak bases dissolve at a slow rate in the gastrointestinal tract, thereby providing for a prolonged release of drug. Examples of the latter include brompheniramine tannate (Brovex, Athlon) and chlorpheniramine/phenylephrine tannates (Rynatan, Wallace).

STUDY QUESTIONS

Directions for questions 1-28: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

1. Which substance is classified as a weak electrolyte?

(A) glucose

(B) urea

(C) ephedrine

(D) sodium chloride

(E) sucrose

View Answer***1. The answer is C[see].***2. The pH value is calculated mathematically as the

(A) log of the hydroxyl ion (OH-) concentration.

(B) negative log of the OH^- concentration.

(C) log of the hydrogen ion (H^+) concentration.

(D) negative log of the H^+ concentration.

(E) ratio of H^+/OH^- concentration.

View Answer***2. The answer is D[see].***3. Which property is classified as colligative?

(A) solubility of a solute

(B) osmotic pressure

(C) hydrogen ion (H^+) concentration

(D) dissociation of a solute

(E) miscibility of the liquids

View Answer***3. The answer is B[see].***4. The colligative properties of a solution are related to the

(A) pH of the solution.

(B) number of ions in the solution.

(C) total number of solute particles in the solution.

(D) number of unionized molecules in the solution.

(E) pKa of the solution.

View Answer***4. The answer is C[see].***5. The pH of a buffer system can be calculated with the

(A) Noyes-Whitney equation.

(B) Henderson-Hasselbalch equation.

(C) Michaelis-Menten equation.

(D) Young equation.

(E) Stokes equation.

View Answer***5. The answer is B[see].***6. Which mechanism is most often responsible for chemical degradation?

(A) racemization

(B) photolysis

(C) hydrolysis

(D) decarboxylation

(E) oxidation

View Answer***6. The answer is C[see].*****7. Which equation is used to predict the stability of a drug product at room temperature from experiments at accelerated temperatures?**

(A) Stokes equation

(B) Young equation

(C) Arrhenius equation

(D) Michaelis-Menten equation

(E) Hixson-Crowell equation

View Answer***7. The answer is C[see].kkk*****8. Based on the relation between the degree of ionization and the solubility of a weak acid, the drug aspirin (pK_a 3.49) will be most soluble at**

(A) pH 1.0

(B) pH 2.0

(C) pH 3.0

(D) pH 4.0

(E) pH 6.0

View Answer***8. The answer is E[see].*****9. Which solution is used as an astringent?**

(A) strong iodine solution USP

(B) aluminum acetate topical solution USP

(C) acetic acid *NF*

(D) aromatic ammonia spirit USP

(E) benzalkonium chloride solution *NF*

View Answer***9. The answer is B[see].*****10. The particle size of the dispersed solid in a suspension is usually greater than**

(A) 0.5 µm

(B) 0.4 µm

(C) 0.3 µm

(D) 0.2 µm

(E) 0.1 µm

View Answer***10. The answer is A[see].*****11. In the extemporaneous preparation of a suspension, levigation is used to**

(A) reduce the zeta potential.

(B) avoid bacterial growth.

(C) reduce particle size.

(D) enhance viscosity.

(E) reduce viscosity.

View Answer***11. The answer is C[see].*****12. Which compound is a natural emulsifying agent?**

(A) acacia

(B) lactose

(C) polysorbate 20

(D) polysorbate 80

(E) sorbitan monopalmitate

View Answer***12. The answer is A[see].Acacia,***P.73

13. Vanishing cream is an ointment that may be classified as

(A) a water-soluble base.

(B) an oleaginous base.

(C) an absorption base.

(D) an emulsion base.

(E) an oleic base.

View Answer***13. The answer is D[see].*****14. Rectal suppositories intended for adult use usually weigh approximately**

(A) 1 g.

(B) 2 g.

(C) 3 g.

(D) 4 g.

(E) 5 g.

View Answer***14. The answer is B[see].*****15. In the fusion method of making cocoa butter suppositories, which substance is most likely to be used to lubricate the mold?**

(A) mineral oil

(B) propylene glycol

(C) cetyl alcohol

(D) stearic acid

(E) magnesium silicate

View Answer***15. The answer is A[see].*****16. A very fine powdered chemical is defined as one that**

(A) completely passes through a #80 sieve.

(B) completely passes through a #120 sieve.

(C) completely passes through a #20 sieve.

(D) passes through a #60 sieve and not more than 40% through a #100 sieve.

(E) passes through a #40 sieve and not more than 60% through a #60 sieve.

View Answer***16. The answer is B[see].*****17. Which technique is typically used to mill camphor?**

(A) trituration

(B) levigation

(C) pulverization by intervention

(D) geometric dilution

(E) attrition

View Answer***17. The answer is C[see].***18. **The dispensing pharmacist usually blends potent powders with a large amount of diluent by**

(A) spatulation.

(B) sifting.

(C) trituration.

(D) geometric dilution.

(E) levigation.

View Answer***18. The answer is D[see].***19. **Which type of paper best protects a divided hygroscopic powder?**

(A) waxed paper

(B) glassine

(C) white bond

(D) blue bond

(E) vegetable parchment

View Answer***19. The answer is A[see].***20. **Which capsule size has the smallest capacity?**

(A) 5

(B) 4

(C) 1

(D) 0

(E) 000

View Answer***20. The answer is A[see].***21. **The shells of soft gelatin capsules may be made elastic or plastic-like by the addition of**

(A) sorbitol.

(B) povidone.

(C) polyethylene glycol (PEG).

(D) lactose.

(E) hydroxypropyl methylcellulose.

View Answer***21. The answer is A[seeand].***22. **The *United States Pharmacopeia* (USP) content uniformity test for tablets is used to ensure which quality?**

(A) bioequivalency

(B) dissolution

(C) potency

(D) purity

(E) toxicity

View Answer***22. The answer is C[see].***23. **All of the following statements about chemical degradation are true *except***

(A) as temperature increases, degradation decreases.

(B) most drugs degrade by a first-order process.

(C) chemical degradation may produce a toxic product.

(D) chemical degradation may result in a loss of active ingredients.

(E) chemical degradation may affect the therapeutic activity of a drug.

View Answer***23. The answer is A[seeand].kAe$^{-Ea/RT}$kAEaRT*****24. All of the following statements concerning zero-order degradation are true *except***

(A) its rate is independent of the concentration.

(B) a plot of concentration versus time yields a straight line on rectilinear paper.

(C) its half-life is a changing parameter.

(D) its concentration remains unchanged with respect to time.

(E) the slope of a plot of concentration versus time yields a rate constant.

View Answer***24. The answer is D[see].Ct***P.74

25. All of the following statements about first-order degradation are true *except*

(A) its rate is dependent on the concentration.

(B) its half-life is a changing parameter.

(C) a plot of the logarithm of concentration versus time yields a straight line.

(D) its $t_{90\%}$ is independent of the concentration.

(E) a plot of the logarithm of concentration versus time allows the rate constant to be determined.

View Answer***25. The answer is B[see].tkt*****26. A satisfactory suppository base must meet all of the following criteria *except***

(A) it should have a narrow melting range.

(B) it should be nonirritating and nonsensitizing.

(C) it should dissolve or disintegrate rapidly in the body cavity.

(D) it should melt < 30°C.

(E) it should be inert.

View Answer***26. The answer is D[see].*****27. Cocoa butter (theobroma oil) exhibits all of the following properties *except***

(A) it melts at temperatures between 33°C and 35°C.

(B) it is a mixture of glycerides.

(C) it is a polymorph.

(D) it is useful in formulating rectal suppositories.

(E) it is soluble in water.

View Answer***27. The answer is E[see].Theobroma cacao.*****28. *United States Pharmacopeia* (USP) tests to ensure the quality of drug products in tablet form include all of the following *except***

(A) disintegration.

(B) dissolution.

(C) hardness and friability.

(D) content uniformity.

(E) weight variation.

View Answer***28. The answer is C[see].*****Directions for questions 29-42:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

29. Forms of water that are suitable for use in parenteral preparations include

I. purified water USP.

II. water for injection USP.

III. sterile water for injection USP.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***29. The answer is D[see].*****30. The particles in an ideal suspension should satisfy which of the following criteria?**

I. Their size should be uniform.

II. They should be stationary or move randomly.

III. They should remain discrete.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***30. The answer is E[see].*****31. The sedimentation of particles in a suspension can be minimized by**

I. adding sodium benzoate.

II. increasing the viscosity of the suspension.

III. reducing the particle size of the active ingredient.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***31. The answer is D[see].*****32. Ingredients that may be used as suspending agents include**

I. methylcellulose.

II. acacia.

III. talc.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer*32. The answer is C[see].*33. **Mechanisms that are thought to provide stable emulsifications include the**

I. formation of interfacial film.

II. lowering of interfacial tension.

III. presence of charge on the ions.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer*33. The answer is E[see].*34. **Nonionic surface-active agents used as synthetic emulsifiers include**

I. tragacanth.

II. sodium lauryl sulfate.

III. sorbitan esters (Spans).

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* IV.A.1.a; IV.A.3.d*].*
Glucose, urea, and sucrose are nonelectrolytes. Sodium chloride is a strong electrolyte. Electrolytes are substances that form ions when dissolved in water. Thus they can conduct an electric current through the solution. Ions are particles that bear electrical charges: Cations are positively charged, and anions are negatively charged. Strong electrolytes are completely ionized in water at all concentrations. Weak electrolytes (e.g., ephedrine) are only partially ionized at most concentrations. Because nonelectrolytes do not form ions when in solution, they are nonconductors.

2. The answer is D *[see* IV.A.3.b*].*
The pH is a measure of the acidity, or hydrogen ion concentration, of an aqueous solution. The pH is the logarithm of the reciprocal of the hydrogen ion (H^+) concentration expressed in moles per liter. Because the logarithm of a reciprocal equals the negative logarithm of the number, the pH is the negative logarithm of the H^+ concentration. A pH of 7.0 indicates neutrality. As the pH decreases, the acidity increases. The pH of arterial blood is 7.35-7.45; of urine, 4.8-7.5; of gastric juice, approximately 1.4; and of cerebrospinal fluid, 7.35-7.40. The concept of pH was introduced by Sörensen in the early 1900s. Alkalinity is the negative logarithm of [OH^-] and is inversely related to acidity.

3. The answer is B *[see* IV.A.2.d*].*
Osmotic pressure is an example of a colligative property. The osmotic pressure is the magnitude of pressure needed to stop osmosis across a semipermeable membrane between a solution and a pure solvent. The colligative properties of a solution depend on the total number of dissociated and undissociated solute particles. These properties are independent of the size of the solute. Other colligative properties of solutes are reduction in the vapor pressure of the solution, elevation of its boiling point, and depression of its freezing point.

4. The answer is C *[see* IV.A.1.b*].*
The colligative properties of a solution are related to the total number of solute particles that it contains. Examples of colligative properties are the osmotic

pressure, lowering of the vapor pressure, elevation of the boiling point, and depression of the freezing, or melting, point.

5. The answer is B *[see* IV.A.3.e*].*

The Henderson-Hasselbalch equation for a weak acid and its salt is as follows:

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

where pK_a is the negative log of the dissociation constant of a weak acid and [salt]/[acid] is the ratio of the molar concentration of salt and acid used to prepare a buffer.

6. The answer is C *[see* V.D.1*].*

Although all of the mechanisms listed can be responsible, the chemical degradation of medicinal compounds, particularly esters in liquid formulations, is usually caused by hydrolysis. For this reason, drugs that have ester functional groups are formulated in dry form whenever possible. Oxidation is another common mode of degradation and is minimized by including antioxidants (e.g., ascorbic acid) in drug formulations. Photolysis is reduced by packaging susceptible products in amber or opaque containers. Decarboxylation, which is the removal of COOH groups, affects compounds that include carboxylic acid. Racemization neutralizes the effects of an optically active compound by converting half of its molecules into their mirror-image configuration. As a result, the dextrorotatory and levorotatory forms cancel each other out. This type of degradation affects only drugs that are characterized by optical isomerism.

7. The answer is C *[see* V.E.3.d*].*

Testing of a drug formulation to determine its shelf life can be accelerated by applying the Arrhenius equation to data obtained at higher temperatures. The method involves determining the rate constant (*k*) values for the degradation of a drug at various elevated temperatures. The log of *k* is plotted against the reciprocal of the absolute temperature, and the *k* value for degradation at room temperature is obtained by extrapolation.

8. The answer is E *[see* IV.A.3.g*].*

The solubility of a weak acid varies as a function of pH. Because pH and pK_a (the dissociation constant) are related, solubility is also related to the degree of ionization. Aspirin is a weak acid that is completely ionized at a pH that is 2 units greater than its pK_a. Therefore, it is most soluble at pH 6.0.

9. The answer is B *[see* VI.B.7*].*

Aluminum acetate and aluminum subacetate solutions are astringents that are used as antiperspirants and as wet dressings for contact dermatitis. Strong iodine solution and benzalkonium chloride are topical antibacterial solutions. Acetic acid is added to products as an acidifier. Aromatic ammonia spirit is a respiratory stimulant.

10. The answer is A *[see* IV.B.1.a*].*

A suspension is a two-phase system that consists of a finely powdered solid dispersed in a liquid vehicle. The particle size of the suspended solid should be as small as possible to minimize sedimentation, but it is usually > 0.5 μm.

11. The answer is C *[see* VI.E.3.a*].*

Levigation is the process of blending and grinding a substance to separate the particles, reduce their size, and form a paste. Levigation is performed by adding a small amount of suitable levigating agent (e.g., glycerin) to the solid and blending the mixture with a mortar and pestle.

12. The answer is A *[see* VI.D.3*].*

Acacia, or gum arabic, is the exudate obtained from the stems and branches of various species of *Acacia,* a woody plant native to Africa. Acacia is a natural emulsifying agent that provides a stable emulsion of low viscosity. Emulsions are droplets of one or more immiscible liquids dispersed in another liquid. Emulsions are inherently unstable: the droplets tend to coalesce into larger and larger drops. The purpose of an emulsifying agent is to keep the droplets dispersed and prevent them from coalescing. Polysorbate 20, polysorbate 80, and sorbitan monopalmitate are also emulsifiers, but are synthetic, not natural, substances.

13. The answer is D *[see* VI.E.2*].*

Ointments are typically used as emollients to soften the skin, as protective barriers, or as vehicles for medication. A variety of ointment bases are available. Vanishing cream, an emulsion type of ointment base, is an oil-in-water emulsion that contains a high percentage of water. Stearic acid is used to create a thin film on the skin when the water evaporates.

14. The answer is B *[see* VI.F.2.a*].*

By convention, a rectal suppository for an adult weighs approximately 2 g. Suppositories for infants and children are smaller. Vaginal suppositories typically weigh approximately 5 g. Rectal suppositories are usually shaped like an elongated bullet (cylindrical and tapered at one end). Vaginal suppositories are usually ovoid.

15. The answer is A *[see* VI.F.4.c*].*

In the fusion method of making suppositories, molds made of aluminum, brass, or nickel-copper alloys are used. Finely powdered drug mixed with melted cocoa butter is poured into a mold that is lubricated very lightly with mineral oil.

16. The answer is B *[see* VI.G; Table 3-8*].*

The USP defines a very fine chemical powder as one that completely passes through a standard #120 sieve, which has 125-μm openings. The USP classification for powdered vegetable and animal drugs differs from that for powdered chemicals. To be classified as very fine, powdered vegetable and animal drugs must pass completely through a #80 sieve, which has 180-μm openings.

17. The answer is C *[see* VI.G.1.c.(3.(b)*].*

Pulverization by intervention is the milling technique that is used for drug substances that are gummy and tend to reagglomerate or resist grinding (e.g., camphor, iodine). In this sense, intervention is the addition of a small amount of material that aids milling and can be removed easily after pulverization is complete. For example, camphor can be reduced readily if a small amount of volatile solvent (e.g., alcohol) is added. The solvent is then allowed to evaporate.

18. The answer is D *[see* VI.G.2.c*].*
The pharmacist uses geometric dilution to mix potent substances with a large amount of diluent. The potent drug and an equal amount of diluent are first mixed in a mortar by trituration. A volume of diluent equal to the mixture in the mortar is added, and the mix is again triturated. The procedure is repeated, and each time, diluent equal in volume to the mixture then in the mortar is added, until all of the diluent is incorporated.
19. The answer is A *[see* VI.G.3.b.(4)*].*
Hygroscopic and volatile drugs are best protected by waxed paper, which is waterproof. The packet may be double-wrapped with a bond paper to improve the appearance of the completed powder.
20. The answer is A *[see* VI.H.2.c.(1)*].*
Hard capsules are numbered from 000 (largest) to 5 (smallest). Their approximate capacity ranges from 600 to 30 mg; however, the capacity of the capsule depends on the density of the contents.
21. The answer is A *[see* VI.H.3.a *and* b*].*
The shells of soft gelatin capsules are plasticized by the addition of a polyhydric alcohol (polyol), such as glycerin or sorbitol. An antifungal preservative can also be added. Both hard and soft gelatin capsules can be filled with a powder or another dry substance. Soft gelatin capsules are also useful dosage forms for fluids or semisolids.
22. The answer is C *[see* VI.H.4.a*].*
A content uniformity test is a test of potency. To ensure that each tablet or capsule contains the intended amount of drug substance, the USP provides two tests: weight variation and content uniformity. The content uniformity test can be used for any dosage unit, but is required for coated tablets, for tablets in which the active ingredient makes up < 50% of the tablet, for suspensions in single-unit containers or in soft capsules, and for many solids that contain added substances. The weight variation test can be used for liquid-filled soft capsules, for any dosage form unit that contains at least 50 mg of a single drug if the drug makes up at least 50% of the bulk, for solids that do not contain added substances, and for freeze-dried solutions.
23. The answer is A *[see* V.A *and* V.B*].*
The reaction velocity, or degradation rate, of a pharmaceutical product is affected by several factors, including temperature, solvents, and light. The degradation rate increases two to three times with each 10° increase in temperature. The effect of temperature on reaction rate is given by the Arrhenius equation:
$k = Ae^{-Ea/RT}$
where *k* is the reaction rate constant, *A* is the frequency factor, *Ea* is the energy of activation, *R* is the gas constant, and *T* is the absolute temperature.
24. The answer is D *[see* V.B.2.a*].*

In zero-order degradation, the concentration of a drug decreases over time. However, the change of concentration with respect to time is unchanged. In the equation:

$$-\frac{dC}{dt} = k$$

the fact that d*C*/d*t* is negative signifies that the concentration is decreasing. However, the velocity of the concentration change is constant.

25. The answer is B *[see* V.B.2.b.(2)*].*

The half-life ($t_{1/2}$) is the time required for the concentration of a drug to decrease by one half. For a first-order degradation:

$$t_{1/2} = \frac{0.693}{k}$$

Because both *k* and 0.693 are constants, $t_{1/2}$ is a constant.

26. The answer is D *[see* VI.F.3*].*

A satisfactory suppository base should remain firm at room temperature. Preferably, it should not melt < 30°C to avoid premature softening during storage and insertion. It should also be inert, nonsensitizing, nonirritating, and compatible with a variety of drugs. Moreover, it should melt just below body temperature and should dissolve or disintegrate rapidly in the fluid of the body cavity into which it is inserted.

27. The answer is E *[see* VI.F.3.c.(1)*].*

Cocoa butter is a fat that is obtained from the seed of *Theobroma cacao.* Chemically, it is a mixture of stearin, palmitin, and other glycerides that are insoluble in water and freely soluble in ether and chloroform. Depending on the fusion temperature, cocoa butter can crystallize into any one of four crystal forms. Cocoa butter is a good base for rectal suppositories, although it is less than ideal for vaginal or urethral suppositories.

28. The answer is C *[see* VI.I.5*].*

To satisfy the USP standards, tablets are required to pass one of two tests. A weight variation test is used if the active ingredient makes up the bulk of the tablet. A content uniformity test is used if the tablet is coated or if the active ingredient makes up < 50% of the bulk of the tablet. Many tablets for oral administration are required to meet a disintegration test. Disintegration times are specified in the individual monographs. A dissolution test may be required instead if the active component of the tablet has limited water solubility. Hardness and friability would affect the disintegration and dissolution rates, but hardness and friability tests are in-house quality control tests, not official USP tests.

29. The answer is D (II, III) *[see* VI.A.1*].*

Water for injection USP is water that has been purified by distillation or by reverse osmosis. This water is used to prepare parenteral solutions that are subject to final

sterilization. For parenteral solutions that are prepared aseptically and not subsequently sterilized, sterile water for injection USP is used. Sterile water for injection USP is water for injection USP that has been sterilized and suitably packaged. This water meets the USP requirements for sterility. Bacteriostatic water for injection USP is sterile water for injection USP that contains one or more antimicrobial agents. It can be used in parenteral solutions if the antimicrobial additives are compatible with the other ingredients in the solution, but it cannot be used in newborns. Purified water USP is not used in parenteral preparations.

30. The answer is E (I, II, III) *[see* IV.B.2*].*

An ideal suspension would have particles of uniform size, minimal sedimentation, and no interaction between particles. Although these ideal criteria are rarely met, they can be approximated by keeping the particle size as small as possible, the densities of the solid and the dispersion medium as similar as possible, and the dispersion medium as viscous as possible.

31. The answer is D (II, III) *[see* IV.B.2*].*

As Stokes's law indicates, the sedimentation rate of a suspension is slowed by reducing its density, reducing the size of the suspended particles, or increasing its viscosity by incorporating a thickening agent. Sodium benzoate is an antifungal agent and would not reduce the sedimentation rate of a suspension.

32. The answer is C (I, II) *[see* VI.C.3*].*

Acacia and methylcellulose are common suspending agents. Acacia is a natural product, and methylcellulose is a synthetic polymer. By increasing the viscosity of the liquid, these agents enable particles to remain suspended for a longer period.

33. The answer is E (I, II, III) *[see* VI.D.3*].*

Emulsifying agents provide a mechanical barrier to coalescence. They also reduce the natural tendency of the droplets in the internal phase (oil or water) of the emulsion to coalesce. Three mechanisms appear to be involved. Some emulsifiers promote stability by forming strong, pliable interfacial films around the droplets. Emulsifying agents also reduce interfacial tension. Finally, ions (from the emulsifier) in the interfacial film can lead to charge repulsion that causes droplets to repel one another, thereby preventing coalescence.

34. The answer is B (III) *[see* VI.D.3*].*

All of the substances listed are emulsifying agents, but only sorbitan esters are nonionic synthetic agents. Tragacanth, like acacia, is a natural emulsifying agent. Sodium lauryl sulfate is an anionic surfactant. Sorbitan esters (known colloquially as Spans because of their trade names) are hydrophobic and form water-in-oil emulsions. The polysorbates (known colloquially as Tweens) are also nonionic, synthetic sorbitan derivatives. However, they are hydrophilic and therefore form oil-in-water emulsions. Sodium lauryl sulfate, as an alkali soap, is also hydrophilic and thus forms oil-in-water emulsions.

35. The answer is C (I, II) *[see* VI.F.1 *and* 2*].*

Rectal suppositories are useful for delivering systemic medication under certain circumstances. Absorption of a drug from a rectal suppository involves release of the drug from the suppository vehicle, diffusion through the rectal mucosa, and transport to the circulation through the rectal veins. The rectal veins bypass the liver, so this route avoids rapid hepatic degradation of certain drugs (first-pass effect). The rectal route is also useful when a drug cannot be given orally (e.g., because of vomiting). However, the extent of drug release and absorption is variable. It depends on the properties of the drug, the suppository base, and the environment in the rectum.

36. The answer is E (I, II, III) *[see* VI.G.1.c*].*

Milling is the process of mechanically reducing the particle size of solids before they are formulated into a final product. To work effectively, a lubricant must coat the surface of the granulation or powder. Hence fine particle size is essential. Decreasing the particle size increases the surface area and can enhance the dissolution rate. Thermolabile drugs may undergo degradation because of the buildup of heat during milling.

37. The answer is D (II, III) *[see* VI.G.2.a.(2)*].*

Some solid substances (e.g., aspirin, phenylsalicylate, phenacetin, thymol, camphor) liquefy or form eutectic mixtures when in close, prolonged contact with one another. These substances are best insulated by the addition of light magnesium oxide or magnesium carbonate. Other inert diluents that can be used are kaolin, starch, and bentonite.

38. The answer is B (III) *[see* VI.G.2.b*].*

When powders are mixed, if comminution is especially important, a porcelain or ceramic mortar that has a rough inner surface is preferred over the smooth working surface of a glass mortar. Because a glass mortar cleans more easily after use, it is preferred for chemicals that may stain a porcelain or ceramic mortar as well as for simple mixing of substances that do not require comminution.

39. The answer is A (I) *[see* VI.G.3.a *and* b*].*

Powders for oral use can be dispensed by the pharmacist in bulk form or divided into premeasured doses (divided powders). Divided powders are traditionally dispensed in folded paper packets (chartulae) made of parchment, bond paper, glassine, or waxed paper. However, individual doses can be packaged in metal foil or small plastic bags if the powder needs greater protection from humidity or evaporation.

40. The answer is C (I, II) *[see* VI.I.2.b*].*

Tablets for oral ingestion usually contain excipients that are added to the formulation for their special functions. Binders and adhesives are added to promote granulation or compaction. Diluents are fillers that are added to make up the required tablet bulk. They can also aid in the manufacturing process. Disintegrants aid in tablet disintegration in gastrointestinal fluids. Lubricants, antiadherents, and glidants aid in reducing friction or adhesion between particles or between tablet and die. For example, lubricants are used in the manufacture of tablets to reduce friction when the tablet is ejected from the die cavity. Lubricants are usually hydrophobic substances that can affect the dissolution rate of the active ingredient.

41. The answer is E (I, II, III) *[see VI.2.b.(3)].*
Disintegrants are added to tablet formulations to facilitate disintegration in gastrointestinal fluids. Disintegration of the tablet in the body is critical to its dissolution and subsequent absorption and bioavailability. The binder and the compression force used during tablet manufacturing affect the hardness of the tablet as well as tablet disintegration and drug dissolution.
42. The answer is B (III) *[see* VI.I.3.a.(4)*].*
An enteric-coated tablet has a coating that remains intact in the stomach, but dissolves in the intestines to yield the tablet ingredients there. Enteric coatings include various fats, fatty acids, waxes, and shellacs. Cellulose acetate phthalate remains intact in the stomach because it dissolves only when the pH > 6. Other enteric-coating materials include povidone (polyvinylpyrrolidone), polyvinyl acetate phthalate, and hydroxypropyl methylcellulose phthalate.
43. The answer is A *[see* VI.I.4*].*
44. The answer is D *[see* VI.I.4*].*
45. The answer is B *[see* VI.I.4*].*
P.82

46. The answer is A *[see* VI.I.4*].*
Sticking is adhesion of tablet material to a die wall. It may be caused by excessive moisture or by the use of ingredients that have low melting temperatures. Mottling is uneven color distribution. It is most often caused by poor mixing of the tablet granulation but may also occur when a degraded drug produces a colored metabolite. Capping is separation of the top or bottom crown of a tablet from the main body. Capping implies that compressed powder is not cohesive. Reasons for capping include excessive force of compression, use of insufficient binder, worn tablet tooling equipment, and entrapment of air during processing. Picking is adherence of tablet surface material to a punch. It can be caused by a granulation that is too damp, by a scratched punch, by static charges on the powder, and particularly by the use of a punch tip that is engraved or embossed.
47. The answer is A *[see* VI.G.1.c; VI.G.2*].*
48. The answer is D *[see* VI.G.1.c; VI.G.2*].*
49. The answer is C *[see* VI.G.1.c; VI.G.2*].*
Comminution is the process of reducing the particle size of a powder to increase its fineness. Several comminution techniques are suitable for small-scale use in a pharmacy. Trituration is used both to comminute and to mix dry powders. If comminution is desired, the substance is rubbed in a mortar that has a rough inner surface. Pulverization by intervention is often used for substances that tend to agglomerate or resist grinding. A small amount of easily removed (e.g., volatile) solvent is added. After the substance is pulverized, the solvent is allowed to evaporate or is otherwise removed. Levigation is often used to prepare pastes or ointments. The powder is reduced by adding a suitable nonsolvent (levigating agent) to form a paste and then either rubbing the paste in a mortar with a pestle or rubbing it on an ointment slab with a spatula. Spatulation and tumbling are

techniques that are used to mix or blend powders, not to reduce them. Spatulation is blending small amounts of powders by stirring them with a spatula on a sheet of paper or a pill tile. Tumbling is blending large amounts of powder in a large rotating container.

50. The answer is B *[see* VI.K.3.e*].*

51. The answer is E *[see* VI.K.3.a*].*

52. The answer is C *[see* VI.K.3.f*].*

53. The answer is D *[see* VI.K.3.d*].*

Controlled-release dosage forms are designed to release a drug slowly for prolonged action in the body. A variety of pharmaceutical mechanisms are used to provide the controlled release. Ion-exchange resins may be complexed to drugs by passing a cationic drug solution through a column that contains the resin. The drug is complexed to the resin by replacement of hydrogen atoms. Release of drug from the complex depends on the ionic environment within the gastrointestinal tract and on the properties of the resin. Coated beads (e.g., Thorazine Spansule capsules) or granules produce blood levels similar to those obtained with multiple dosing. The various coating thicknesses produce a sustained-release effect.

Matrix devices may use insoluble plastics, hydrophilic polymers, or fatty compounds. These components are mixed with the drug and compressed into a tablet. The primary dose, or the portion of the drug to be released immediately, is placed on the tablet as a layer or coat. The remainder of the dose is released slowly from the matrix. Relatively insoluble tannate-amine complexes provide for a prolonged gastrointestinal absorption phase and sustained systemic concentrations of the weak bases. Osmotic systems employ osmotic pressure to control the release of the active ingredient from the formulation. Osmotic tablet formulations provide a semipermeable membrane as a coating that surrounds the osmotically active core. The coating allows water to diffuse into the core but does not allow drug to diffuse out. As water flows into the tablet, the drug dissolves. The laser-drilled hole in the coating allows the drug solution within the tablet to flow to the outside at a rate that is equivalent to the rate of water flow into the tablet. The osmotic pressure gradient and a zero-order drug-release rate will be maintained as long as excess osmotically active solute (e.g., electrolyte) remains in the tablet core.

4

Biopharmaceutics and Drug Delivery Systems

Lawrence H. Block

I. INTRODUCTION

A. Biopharmaceutics is the study of the relation of the physical and chemical properties of a drug to its bioavailability, pharmacokinetics, and pharmacodynamic and toxicologic effects.

1. A **drug product** is the finished dosage form (e.g., tablet, capsule, solution) that contains the active drug ingredient in association with nondrug (usually inactive) ingredients (**excipients**) that make up the **vehicle,** or **formulation matrix.**

2. The phrase *drug delivery system* is often used interchangeably with the terms *drug product* or *dosage form.* However, a **drug delivery system** is a more comprehensive concept, which includes the drug formulation and the dynamic interactions among the drug, its formulation matrix, its container, and the patient.

3. Bioavailability is a measurement of the rate and extent (amount) of systemic absorption of the therapeutically active drug.

B. Pharmacokinetics is the study of the time course of drug movement in the body during absorption, distribution, and elimination (excretion and biotransformation).

C. Pharmacodynamics is the study of the relation of the drug concentration or amount at the site of action (receptor) and its pharmacologic response as a function of time.

II. DRUG TRANSPORT AND ABSORPTION

A. Transport of drug molecules *across* cell membranes. Drug absorption requires the drug to be transported across various cell membranes. Drug molecules may enter the bloodstream and be transported to the tissues and organs of the body. Drug molecules may cross additional membranes to enter cells. Drug molecules may also cross an intracellular membrane, such as the nuclear membrane or endoplasmic reticulum, to reach the site of action. Figure 4-1 demonstrates some of the key transport processes involved in drug absorption.

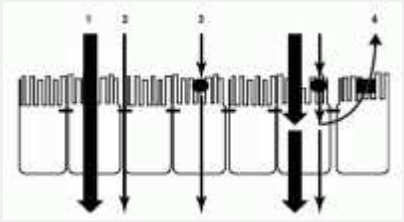

Figure 4-1. The key drug transport processes in intestinal epithelial cells. *1,* Transcellular passive (diffusion and partitioning); *2,* paracellular transport (diffusion and convection); *3,* carrier-mediated transport; *4,* P-glycoproteinmediated efflux. [Modified from Brayden DJ, Pharm News 4(1);1997:11-15.]

1. General principles

a. A **cell membrane** is a semipermeable structure composed primarily of lipids and proteins.

b. Drugs may be transported by **passive diffusion, partitioning, carrier-mediated transport, paracellular transport,** or **vesicular transport.**

c. Usually, **proteins, drugs bound to proteins,** and **macromolecules** do not easily cross cell membranes.

d. Nonpolar lipid-soluble drugs traverse cell membranes more easily than do **ionic** or **polar water-soluble drugs.**

e. Low molecular weight drugs diffuse across a cell membrane more easily than do **high molecular weight drugs.**

2. Passive diffusion and partitioning

a. ***Within*** **the cytoplasm** or in **interstitial fluid,** most drugs undergo transport by simple diffusion.

b. Fick's law of diffusion. Simple passive diffusion involves the transfer of drugs from an area of high concentration (C_1) to an area of lower concentration (C_2) according to Fick's law of diffusion:

$$\frac{dQ}{dt} = \frac{DA}{h}(C_1 - C_2)$$

where dQ/dt is the rate of drug diffusion, D is the diffusion coefficient for the drug, A is the surface area of the plane across which transfer occurs, h is the thickness of the region through which diffusion occurs, and (C_1 - C_2) is the difference between the drug concentration in area 1 and area 2, respectively.

c. Passive drug transport *across* cell membranes involves the successive **partitioning** of a solute between aqueous and lipid phases as well as **diffusion** within the respective phases. Modifying Fick's law of diffusion to accommodate the partitioning of drug gives the following:

$$\frac{dQ}{dt} = \frac{DAK}{h}(C_1 - C_2)$$

The rate of drug diffusion, dQ/dt, now reflects its direct dependence on K, the oil to water partition coefficient of the drug, as well as on A and (C_1 - C_2).

d. Ionization of a weak electrolyte is affected by the pH of the medium in which the drug is dissolved as well as by the pK_a of the drug. The nonionized species is more lipid soluble than the ionized species, and it partitions more readily across cell membranes.

3. Carrier-mediated transport

a. Active transport of the drug across a membrane is a carrier-mediated process that has the following characteristics.

(1) The drug moves against a concentration gradient.

(2) The process requires energy.

(3) The carrier may be selective for certain types of drugs that resemble natural substrates or metabolites that are normally actively transported.
(4) The carrier system may be saturated at a high drug concentration.
(5) The process may be competitive (i.e., drugs with similar structures may compete for the same carrier).
b. Facilitated diffusion is also a carrier-mediated transport system. However, facilitated diffusion occurs with (i.e., in the direction of) a concentration gradient and does not require energy.
4. Paracellular transport. Drug transport across tight (narrow) junctions between cells or transendothelial channels of cells is known as **paracellular transport.** It involves both diffusion and the **convective** (bulk) flow of water and accompanying water-soluble drug molecules through the paracellular channels.
5. Vesicular transport is the process of engulfing particles or dissolved materials by a cell. Vesicular transport is the only transport mechanism that does not require a drug to be in an aqueous solution to be absorbed. **Pinocytosis** and **phagocytosis** are forms of vesicular transport.
a. Pinocytosis is the engulfment of small solute or fluid volumes.

b. Phagocytosis is the engulfment of larger particles, or macromolecules, generally by macrophages.
c. **Endocytosis** and **exocytosis** are the movement of macromolecules into and out of the cell, respectively.
6. Other transport mechanisms: transporter proteins. Various **transporter proteins** (e.g., **P-glycoprotein**) are embedded in the lipid bilayer of cell membranes in tandem in α-helical transmembrane regions or domains. These proteins are adenosine triphosphate- (ATP; energy) dependent “pumps,” which can facilitate the efflux of drug molecules from the cell. Because these transmembrane efflux pumps are often found in conjunction with metabolizing enzymes such as **cytochrome P450 3A4,** their net effect is to substantially reduce intracellular drug concentrations. Thus they determine, to a large extent, the pharmacokinetic disposition and circulating plasma concentrations of drugs (e.g., cyclosporin, nifedipine, digoxin) that are substrates for these proteins.
B. Routes of drug administration
1. Parenteral administration
a. Intravenous bolus injection. The drug is injected directly into the bloodstream, distributes throughout the body, and acts rapidly. Any side effects, including an intense pharmacologic response, anaphylaxis, or overt toxicity, also occur rapidly.
b. Intra-arterial injection. The drug is injected into a specific artery to achieve a high drug concentration in a specific tissue before drug distribution occurs throughout the body. Intra-arterial injection is used for diagnostic agents and occasionally for chemotherapy.
c. **Intravenous infusion.** The drug is given intravenously at a constant input rate. Constantrate intravenous infusion maintains a relatively constant plasma drug

concentration once the infusion rate is approximately equal to the drug's elimination rate from the body (i.e., once steady state is reached).

d. Intramuscular injection. The drug is injected deep into a skeletal muscle. The rate of absorption depends on the vascularity of the muscle site, the lipid solubility of the drug, and the formulation matrix.

e. Subcutaneous injection. The drug is injected beneath the skin. Because the subcutaneous region is less vascular than muscle tissues, drug absorption is less rapid. The factors that affect absorption from intramuscular depots also affect subcutaneous absorption.

f. Miscellaneous parenteral routes

(1) Intra-articular injection. The drug is injected into a joint.

(2) Intradermal (intracutaneous) injection. The drug is injected into the dermis (i.e., the vascular region of the skin below the epidermis).

(3) Intrathecal injection. The drug is injected into the spinal fluid.

2. Enteral administration

a. Buccal and sublingual administration. A tablet or lozenge is placed under the tongue (**sublingual**) or in contact with the mucosal (**buccal**) surface of the cheek. This type of administration allows a nonpolar, lipid-soluble drug to be absorbed across the epithelial lining of the mouth. After buccal or sublingual administration, the drug is absorbed directly into the systemic circulation, bypassing the liver and any first-pass effects.

b. Peroral (oral) drug administration. The drug is administered orally, is swallowed, and undergoes absorption from the gastrointestinal tract through the mesenteric circulation to the hepatic portal vein into the liver and then to the systemic circulation. The peroral route is the most common route of administration.

(1) The peroral route is the most convenient and the safest route.

(2) Disadvantages of this route include the following.

(a) The drug may not be absorbed from the gastrointestinal tract consistently or completely.

(b) The drug may be digested by gastrointestinal enzymes or decomposed by the acid pH of the stomach.

(c) The drug may irritate mucosal epithelial cells or complex with the contents of the gastrointestinal tract.

(d) Some drugs may be incompletely absorbed because of first-pass effects or presystemic elimination (e.g., the drug is metabolized by the liver before systemic absorption occurs).

(e) The absorption rate may be erratic because of delayed gastric emptying or changes in intestinal motility.

(3) Most drugs are **xenobiotics** or **exogenous** molecules and, consequently, are absorbed from the gastrointestinal tract by **passive diffusion** and **partitioning. Carrier-mediated transport, paracellular transport,** and **vesicular transport** play smaller, but critical, roles, particularly for endogenous molecules.

(4) Drug molecules are absorbed throughout the gastrointestinal tract; but the **duodenal region,** which has a large surface area because of the villi and microvilli, is the primary absorption site. The large blood supply provided by the mesenteric vessels allows the drug to be absorbed more efficiently (see II.A.2).
(5) Altered gastric emptying affects arrival of the drug in the duodenum for systemic absorption. **Gastric emptying time** is affected by food content, emotional state, and drugs that alter gastrointestinal tract motility (e.g., anticholinergics, narcotic analgesics, prokinetic agents).
(6) Normal intestinal motility from **peristalsis** brings the drug in contact with the intestinal epithelial cells. A sufficient period of contact (residence time) is needed to permit drug absorption across the cell membranes from the mucosal to the serosal surface.
(7) Some drugs, such as **cimetidine** and **acetaminophen,** when given in an immediate-release peroral dosage form to fasted subjects produce a systemic drug concentration time with two peaks. This **double-peak phenomenon** is attributed to variability in stomach emptying, variable intestinal motility, and enterohepatic cycling.
c. **Rectal administration.** The drug in solution (enema) or suppository form is placed in the rectum. Drug diffusion from the solution or release from the suppository leads to absorption across the mucosal surface of the rectum. Drug absorbed in the lower two thirds of the rectum enters the systemic circulation directly, bypassing the liver and any first-pass effects.
3. Respiratory tract administration
a. Intranasal administration. The drug contained in a solution or suspension is administered to the nasal mucosa, either as a spray or as drops. The medication may be used for local (e.g., nasal decongestants, intranasal steroids) or systemic effects.
b. Pulmonary inhalation. The drug, as liquid or solid particles, is inhaled perorally (with a nebulizer or a metered-dose aerosol) into the pulmonary tree. In general, **particles > 60 µm** are primarily deposited in the **trachea. Particles > 20 µm** do not reach the bronchioles, and **particles < 0.6 µm** are not deposited and are **exhaled.** Particles between **2 and 6 µm** can reach the **alveolar ducts,** although only particles of **1-2 µm are retained in the alveoli.**
4. Transdermal and topical administration
a. Transdermal (percutaneous) drug absorption is the placement of the drug (in a lotion, ointment, cream, paste, or patch) on the skin surface for systemic absorption. An occlusive dressing or film improves systemic drug absorption from the skin. Small lipid-soluble molecules, such as nitroglycerin, nicotine, scopolamine, clonidine, fentanyl, and steroids (e.g., 17-β-estradiol, testosterone), are readily absorbed from the skin.
b. Drugs (e.g., antibacterials, local anesthetic agents) are applied **topically** to the skin for a local effect.
5. Miscellaneous routes of drug administration include **ophthalmic, otic, urethral,** and **vaginal** administration. These routes of administration are generally used for local therapeutic activity. However, some systemic drug absorption may occur.

C. Local drug activity versus **systemic drug absorption.** The route of administration, absorption site, and bioavailability of the drug from the dosage form are major factors in the design of a drug product.

1. Drugs intended for **local activity,** such as topical antibiotics, anti-infectives, antifungal agents, and local anesthetics are formulated in dosage forms that minimize systemic absorption. The concentration of these drugs at the application site affects their activity.

2. When **systemic absorption** is desired, the bioavailability of the drug from the dosage form at the absorption site must be considered (e.g., a drug given intravenously is 100% bioavailable because all of the drug is placed directly into the systemic circulation). The amount, or dose, of drug in the dosage form is based on the extent of drug absorption and the desired systemic drug concentration. The type of dosage form (e.g., immediate release, controlled release) affects the rate of drug absorption.

III. BIOPHARMACEUTIC PRINCIPLES

A. Physicochemical properties

1. Drug dissolution. For most drugs with limited water solubility, the rate at which the solid drug enters into solution (i.e., the rate of dissolution) is often the rate-limiting step in bioavailability. The **Noyes-Whitney** equation describes the diffusion-controlled rate of drug dissolution (d*m*/d*t;* i.e., the change in the amount of drug in solution with respect to time):

$$\frac{dm}{dt} = \frac{DA}{\delta}(C_s - C_b)$$

where *D* is the diffusion coefficient of the solute, *A* is the surface area of the solid undergoing dissolution, δ is the thickness of the diffusion layer, C_s is the concentration of the solvate at saturation, and C_b is the concentration of the drug in the bulk solution phase at time t.

2. Drug solubility in a saturated solution (see Chapter 3, IV) is a static (equilibrium) property. The dissolution rate of a drug is a dynamic property related to the rate of absorption.

3. Particle size and **surface area** are inversely related. As solid drug particle size decreases, particle surface area increases.

a. As described by the Noyes-Whitney equation, the dissolution rate is directly proportional to the surface area. An increase in surface area allows for more contact between the solid drug particles and the solvent, resulting in a faster dissolution rate (see III.A.1).

b. With certain **hydrophobic drugs,** excessive particle size reduction does not always increase the dissolution rate. Small particles tend to reaggregate into larger particles to reduce the high surface free energy produced by particle size reduction.

c. To prevent the formation of aggregates, small drug particles are molecularly dispersed in polyethylene glycol (PEG), polyvinylpyrrolidone (PVP; povidone), dextrose, or other agents. For example, a molecular dispersion of griseofulvin in a water-soluble carrier such as PEG 4000 (e.g., Gris-PEG) enhances its dissolution and bioavailability.

4. Partition coefficient and extent of ionization

a. The **partition coefficient** of a drug is the ratio of the solubility of the drug, at equilibrium, in a nonaqueous solvent (e.g., *n*-octanol) to that in an aqueous solvent (e.g., water; pH 7.4 buffer solution). Hydrophilic drugs with higher water solubility have a faster dissolution rate than do hydrophobic or lipophilic drugs, which have poor water solubility.

b. Extent of ionization. Drugs that are weak electrolytes (acids or bases) exist in both an ionized form and a nonionized form in solution. The extent of ionization depends on the pK_a of the weak electrolyte and the pH of the solution. The ionized form is more polar, and therefore more water soluble, than the nonionized form. The **Henderson-Hasselbalch equation** describes the relation between the ionized and the nonionized forms of a drug as a function of pH and pK_a. When the pH of the medium equals the pK_a of the drug, 50% of the drug in solution is nonionized and 50% is ionized, as can be shown from the following equations:

(1) For weak acids:

$$pH = pK_a + \log\left(\frac{\text{salt}}{\text{nonionized acid}}\right)$$

(2) For weak bases:

$$pH = pK_a + \log\left(\frac{\text{nonionized base}}{\text{salt}}\right)$$

5. Salt formation

a. The choice of salt form for a drug depends on the desired physical, chemical, or pharmacologic properties. Certain salts are designed to provide slower dissolution, slower bioavailability, and longer duration of action. Other salts are selected for greater stability, less local irritation at the absorption site, or less systemic toxicity.

(1) Some soluble salt forms are less stable than the nonionized form. For example, sodium aspirin is less stable than aspirin in the acid form.

(2) A solid dosage form containing buffering agents may be formulated with the free acid form of the drug (e.g., buffered aspirin).

(a) The buffering agent forms an alkaline medium in the gastrointestinal tract, and the drug dissolves in situ.

(b) The dissolved salt form of the drug diffuses into the bulk fluid of the gastrointestinal tract, forms a fine precipitate that redissolves rapidly, and becomes available for absorption.

b. Effervescent granules or **tablets** containing the acid drug in addition to sodium bicarbonate, tartaric acid, citric acid, or other ingredients are added to water just before oral administration. The excess sodium bicarbonate forms an alkaline

solution in which the drug dissolves. Carbon dioxide is also formed by the decomposition of carbonic acid.

c. For weakly acidic drugs, potassium and sodium salts are more soluble than divalent cation salts (e.g., calcium, magnesium) or trivalent cation salts (e.g., aluminum).

d. For weak bases, common water-soluble salts include the hydrochloride, sulfate, citrate, and gluconate salts. The estolate, napsylate, and stearate salts are less water soluble.

6. Polymorphism is the ability of a drug to exist in more than one crystalline form.

a. Different polymorphs have different physical properties, including melting point and dissolution rate.

b. Amorphous, or **noncrystalline, forms** of a drug have faster dissolution rates than do crystalline forms.

7. Chirality is the ability of a drug to exist as **optically active stereoisomers** or **enantiomers.** Individual enantiomers may not have the same pharmacokinetic and pharmacodynamic activity. Because most chiral drugs are used as racemic mixtures, the results of studies with such mixtures may be misleading because the drug is assumed to behave as a single entity. For example, ibuprofen exists as the *R*- and *S*-enantiomers; only the *S*-enantiomer is pharmacologically active. When the racemic mixture of ibuprofen is taken orally, the *R*-enantiomer undergoes presystemic inversion in the gut to the *S*-enantiomer. Because the rate and extent of inversion are site specific and formulation dependent, ibuprofen activity may vary considerably.

8. Hydrates. Drugs may exist in a **hydrated,** or **solvated, form** or as an **anhydrous molecule.** Dissolution rates differ for hydrated and anhydrous forms. For example, the anhydrous form of ampicillin dissolves faster and is more rapidly absorbed than the hydrated form.

9. Complex formation. A **complex** is a species formed by the reversible or irreversible association of two or more interacting molecules or ions. **Chelates** are complexes that typically involve a ring-like structure formed by the interaction between a partial ring of atoms and a metal. Many biologically important molecules (e.g., hemoglobin, insulin, cyanocobalamin) are chelates. Drugs such as tetracycline form chelates with divalent (e.g., Ca^{++}, Mg^{++}) and trivalent (e.g., Al^{+++}, Bi^{+++}) metal ions. Many drugs adsorb strongly on charcoal or clay (e.g., kaolin, bentonite) particles by forming complexes. Drug complexes with proteins, such as albumin or α_1-acid glycoprotein, often occur.

a. Complex formation usually alters the physical and chemical characteristics of the drug. For example:

(1) The chelate of tetracycline with calcium is less water soluble and is poorly absorbed.

(2) Theophylline complexed with ethylenediamine to form aminophylline is more water soluble and is used for parenteral and rectal administration.

(3) Cyclodextrins are used to form complexes with many drugs to increase their water solubility.

b. Large drug complexes, such as drug-protein complexes, do not cross cell membranes easily. These complexes must dissociate to free the drug for absorption at the absorption site or to permit transport across cell membranes or glomerular filtration before the drug is excreted into the urine.

B. Drug product and delivery system formulation

1. General considerations

a. Design of the appropriate dosage form or **delivery system** depends on the

(1) Physical and chemical properties of the drug

(2) Dose of the drug

(3) Route of administration

(4) Type of drug delivery system desired

(5) Desired therapeutic effect

(6) Physiologic release of the drug from the delivery system

(7) Bioavailability of the drug at the absorption site

(8) Pharmacokinetics and pharmacodynamics of the drug

b. Bioavailability. The more complicated the formulation of the finished drug product (e.g., controlled-release tablet, enteric-coated tablet, transdermal patch), the greater the potential for a bioavailability problem. For example, the **release** of a drug from a peroral dosage form and its subsequent bioavailability depend on a succession of rate processes (Figure 4-2). These processes may include the following:

(1) Attrition, disintegration, or **disaggregation** of the drug product

(2) Dissolution of the drug in an aqueous environment

(3) Convection and **diffusion** of the drug molecules to the absorbing surface

(4) Absorption of the drug across cell membranes into the systemic circulation

c. The **rate-limiting step** in the bioavailability of a drug from a drug product is the slowest step in a series of kinetic processes.

(1) For most conventional solid drug products (e.g., capsules, tablets), the dissolution rate is the slowest, or rate-limiting, step for bioavailability.

(2) For a controlled- or sustained-release drug product, the release of the drug from the delivery system is the rate-limiting step.

2. Solutions are homogeneous mixtures of one or more solutes dispersed molecularly in a dissolving medium (solvent).

a. Compared with other oral and peroral drug formulations, a drug dissolved in an aqueous solution is in the most bioavailable and consistent form. Because the drug is already in

solution, no dissolution step is necessary before systemic absorption occurs. Peroral drug solutions are often used as the reference preparation for solid peroral formulations.

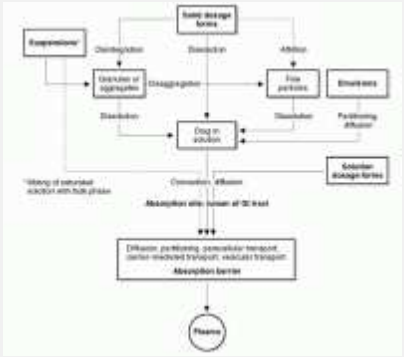

Figure 4-2. The processes involved in drug release from peroral dosage forms. GI, gastrointestinal.

b. A drug dissolved in a hydroalcoholic solution (e.g., elixir) also has good bioavailability. Alcohol aids drug solubility. However, when the drug is diluted by gastrointestinal tract fluid and other gut contents (e.g., food), it may form a finely divided precipitate in the lumen of the gastrointestinal tract. Because of the extensive dispersion and large surface area of such finely divided precipitates, redissolution and subsequent absorption occur rapidly.

c. A viscous drug solution (e.g., syrup) may interfere with dilution and mixing with gastrointestinal tract contents. The solution decreases the gastric emptying rate and the rate of transfer of drug solution to the duodenal region, where absorption is most efficient.

3. Suspensions are dispersions of finely divided solid particles of a drug in a liquid medium in which the drug is not readily soluble. The liquid medium of a suspension comprises a saturated solution of the drug in equilibrium with the solid drug.

a. The bioavailability of the drug from suspensions may be similar to that of a solution because the finely divided particles are dispersed and provide a large surface area for rapid dissolution. On the other hand, a slow dissolution rate decreases the absorption rate.

b. Suspending agents are often hydrophilic colloids (e.g., cellulose derivatives, acacia, xanthan gum) added to suspensions to increase viscosity, inhibit agglomeration, and decrease the rate at which particles settle. Highly viscous suspensions may prolong gastric emptying time, slow drug dissolution, and decrease the absorption rate.

4. Capsules are solid dosage forms with hard or soft gelatin shells that contain drugs, usually admixed with excipients. **Coating** the capsule shell or the drug particles within the capsule can affect bioavailability.

a. Hard gelatin capsules are usually filled with a powder blend that contains the drug. Typically, the powder blend is simpler and less compacted than the blend in a compressed tablet. After ingestion, the gelatin softens, swells, and begins to dissolve in the gastrointestinal tract. Encapsulated drugs are released rapidly and dispersed easily, and bioavailability is good. Hard gelatin capsules are the preferred dosage form for early clinical trials of new drugs.

b. Soft gelatin capsules may contain a nonaqueous solution, a powder, or a drug suspension. The vehicle may be water miscible (e.g., PEG). The cardiac glycoside digoxin, dispersed in a water-miscible vehicle (Lanoxicaps), has better bioavailability than a compressed tablet formulation (Lanoxin). However, a soft gelatin capsule that contains the drug dissolved in a **hydrophobic** vehicle (e.g., vegetable oil) may have poorer bioavailability than a compressed tablet formulation of the drug.

c. **Aging** and **storage conditions** can affect the moisture content of the gelatin component of the capsule shell and the bioavailability of the drug.

(1) At low moisture levels, the capsule shell becomes brittle and is easily ruptured.

(2) At high moisture levels, the capsule shell becomes moist, soft, and distorted. Moisture may be transferred to the capsule contents, particularly if the contents are hygroscopic.

5. Compressed tablets are solid dosage forms in which high pressure is used to compress a powder blend or granulation that contains the drug and other ingredients, or excipients, into a solid mass.

a. Excipients, including diluents (fillers), binders, disintegrants, lubricants, glidants, surfactants, dye, and flavoring agents, have the following properties.

(1) They permit the efficient manufacture of compressed tablets.

(2) They affect the physical and chemical characteristics of the drug.

(3) They affect bioavailability. The higher the ratio of excipient to active drug, the greater the likelihood that the excipients affect bioavailability.

b. Examples

(1) Disintegrants (e.g., starch, croscarmellose, sodium starch glycolate) vary in action, depending on their concentration, the method by which they are mixed with the powder formulation or granulation, and the degree of tablet compaction. Although tablet disintegration is usually not a problem because it often occurs more rapidly than drug dissolution, it is necessary for dissolution in immediate-release formulations. Inability to disintegrate may interfere with bioavailability.

(2) Lubricants are usually hydrophobic, water-insoluble substances such as stearic acid, magnesium stearate, hydrogenated vegetable oil, and talc. They may reduce wetting of the surface of the solid drug particles, slowing the dissolution and bioavailability rates of the drug. Water-soluble lubricants, such as L-leucine, do not interfere with dissolution or bioavailability.

(3) Glidants (e.g., colloidal silicon dioxide) improve the flow properties of a dry powder blend before it is compressed. Rather than posing a potential problem with bioavailability, glidants may reduce tablet-to-tablet variability and improve product efficacy.

(4) Surfactants enhance drug dissolution rates and bioavailability by reducing interfacial tension at the boundary between solid drug and liquid and by improving the wettability (contact) of solid drug particles by the solvent.

c. **Coated compressed tablets** have a sugar coat, a film coat, or an enteric coat with the following properties:
(1) It protects the drug from moisture, light, and air.
(2) It masks the taste or odor of the drug.
(3) It improves the appearance of the tablet.
(4) It may affect the release rate of the drug.
d. In addition, **enteric coatings** minimize contact between the drug and the gastric region by resisting dissolution or attrition and preventing contact between the underlying drug and the gastric contents or gastric mucosa. Some enteric coatings minimize gastric contact because they are insoluble at acidic pHs. Other coatings resist attrition and remain whole long enough for the tablet to leave the gastric area. By resisting dissolution or attrition, enteric coatings may decrease bioavailability. Enteric coatings are used to
(1) Minimize irritation of the gastric mucosa by the drug
(2) Prevent inactivation or degradation of the drug in the stomach
(3) Delay release of the drug until the tablet reaches the small intestine, where conditions for absorption may be optimal
6. Modified-release dosage forms are drug products that alter the rate or timing of drug release. Because modified-release dosage forms are more complex than conventional immediate-release dosage forms, more stringent quality control and bioavailability tests are required. **Dose dumping,** or the abrupt, uncontrolled release of a large amount of drug, is a problem.
a. Extended-release dosage forms include **controlled-release, sustained-action,** and **long-acting drug delivery systems.** These delivery systems allow at least a twofold reduction in dosing frequency compared with conventional immediate-release formulations.
(1) The extended, slow release of controlled-release drug products produces a relatively flat, sustained plasma drug concentration that avoids toxicity (from high drug concentrations) or lack of efficacy (from low drug concentrations).
(2) Extended-release dosage forms provide an immediate (initial) release of the drug, followed by a slower sustained release.
b. Delayed-release dosage forms release active drug at a time other than immediately after administration at a desired site in the gastrointestinal tract. For example, an enteric-coated drug product does not allow for dissolution in the acid environment of the stomach but, rather, in the less acidic environment of the small intestine.
7. Transdermal drug delivery systems, or **patches,** are controlled-release devices that contain the drug for systemic absorption after topical application to the skin surface. Transdermal drug delivery systems are available for a number of drugs (nitroglycerin, nicotine, scopolamine, clonidine, fentanyl, 17-β-estradiol, and testosterone). Although the formulation matrices of these delivery systems differ somewhat, they all differ from conventional topical formulations in the following ways:
a. They have an impermeable **occlusive backing film** that prevents insensible water loss from the skin beneath the patch. This film causes increased hydration

and skin temperature under the patch and enhanced permeation of the skin by the drug.

b. The formulation matrix of the patch maintains the drug concentration gradient within the device after application so that drug delivery to the interface between the patch and the skin is sustained. As a result, drug partitioning and diffusion into the skin persist, and systemic absorption is maintained throughout the dosing interval.

c. Transdermal drug delivery systems are kept in place on the skin surface by an **adhesive layer,** ensuring drug contact with the skin and continued drug delivery.

8. Targeted (site-specific) drug delivery systems are drug carrier systems that place the drug at or near the receptor site. Examples include macromolecular drug carriers (protein drug

carriers), particulate drug delivery systems (e.g., liposomes, nanoparticles), and monoclonal antibodies. With targeted drug delivery, the drug may be delivered to

a. The capillary bed of the active site

b. A special type of cell (e.g., tumor cells) but not to normal cells

c. A specific organ or tissue by complexing with a carrier that recognizes the target

9. Inserts, implants, and **devices** are used to control drug delivery for localized or systemic drug effects. The drug is impregnated into a biodegradable or nonbiodegradable material and is released slowly. The inserts, implants, and devices are inserted into a variety of cavities (e.g., vagina, buccal cavity) or tissues (e.g., skin). For example, the leuprolide acetate implant, Viadur, is inserted beneath the skin of the upper arm. It provides palliative treatment of advanced prostate cancer for 1 year.

STUDY QUESTIONS

Directions: Each question, statement, or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which statement best describes bioavailability?

(A) relation between the physical and the chemical properties of a drug and its systemic absorption

(B) measurement of the rate and amount of therapeutically active drug that reaches the systemic circulation

(C) movement of the drug into body tissues over time

(D) dissolution of the drug in the gastrointestinal tract

(E) amount of drug destroyed by the liver before systemic absorption from the gastrointestinal tract occurs

View Answer***1. The answer is B[see].*****2. The route of drug administration that gives the most rapid onset of the pharmacologic effect is**

(A) intramuscular injection.

(B) intravenous injection.
(C) intradermal injection.
(D) peroral administration.
(E) subcutaneous injection.

View Answer***2. The answer is B[see].*****3. The route of drug administration that provides complete (100%) bioavailability is**

(A) intramuscular injection.
(B) intravenous injection.
(C) intradermal injection.
(D) peroral administration.
(E) subcutaneous injection.

View Answer***3. The answer is B[see].*****4. After peroral administration, drugs generally are absorbed best from the**

(A) buccal cavity.
(B) stomach.
(C) duodenum.
(D) ileum.
(E) rectum.

View Answer***4. The answer is C[see].*****5. The characteristics of an active transport process include all of the following *except* for which one?**

(A) Active transport moves drug molecules against a concentration gradient.
(B) Active transport follows Fick's law of diffusion.
(C) Active transport is a carrier-mediated transport system.
(D) Active transport requires energy.
(E) Active transport of drug molecules may be saturated at high drug concentrations.

View Answer***5. The answer is B[seeand].*****6. The passage of drug molecules from a region of high drug concentration to a region of low drug concentration is known as**

(A) active transport.
(B) bioavailability.
(C) biopharmaceutics.
(D) simple diffusion.
(E) pinocytosis.

View Answer***6. The answer is D[see].*****7. Which equation describes the rate of drug dissolution from a tablet?**

(A) Fick's law
(B) Henderson-Hasselbalch equation
(C) Law of mass action
(D) Michaelis-Menten equation
(E) Noyes-Whitney equation

View Answer***7. The answer is E[see].*****8. Which condition usually increases the rate of drug dissolution from a tablet?**

(A) increase in the particle size of the drug
(B) decrease in the surface area of the drug

(C) use of the free acid or free base form of the drug
(D) use of the ionized, or salt, form of the drug
(E) use of sugar coating around the tablet

View Answer***8. The answer is D[seeand].*****9. Dose dumping is a problem in the formulation of**

(A) compressed tablets.
(B) modified-release drug products.
(C) hard gelatin capsules.
(D) soft gelatin capsules.
(E) suppositories.

View Answer***9. The answer is B[see].*****10. The rate-limiting step in the bioavailability of a lipid-soluble drug formulated as an immediate-release compressed tablet is the rate of**

(A) disintegration of the tablet and release of the drug.
(B) dissolution of the drug.
(C) transport of the drug molecules across the intestinal mucosal cells.
(D) blood flow to the gastrointestinal tract.
(E) biotransformation, or metabolism, of the drug by the liver before systemic absorption occurs.

View Answer***10. The answer is B[see].***P.94

11. The extent of ionization of a weak electrolyte drug depends on the

(A) pH of the media and pK_a of the drug.
(B) oil to water partition coefficient of the drug.
(C) particle size and surface area of the drug.
(D) Noyes-Whitney equation for the drug.
(E) polymorphic form of the drug.

View Answer***11. The answer is A[see].*****12. The rate of drug bioavailability is most rapid when the drug is formulated as a**

(A) controlled-release product.
(B) hard gelatin capsule.
(C) compressed tablet.
(D) solution.
(E) suspension.

View Answer***12. The answer is D[see].*****13. The amount of drug that a transdermal patch (i.e., transdermal drug delivery system) delivers within a 24-hr period depends on the**

(A) patch composition, which includes an occlusive backing and an adhesive film in contact with the skin.
(B) affinity of the drug for the formulation matrix relative to its affinity for the stratum corneum.
(C) rate of drug partitioning and/or diffusion through the patch to the skin surface.
(D) surface area of the patch.
(E) All of the above

View Answer***13. The answer is E[see].***P.95

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* I.A.3*].*

Bioavailability is the measurement of the rate and extent (amount) of therapeutically active drug that reaches the systemic circulation. The relation of the physical and the chemical properties of a drug to its systemic absorption (i.e., bioavailability) is known as its biopharmaceutics. The movement of a drug into body tissues is an aspect of pharmacokinetics, which is the study of drug movement in the body over time. The dissolution of a drug in the gastrointestinal tract is a physicochemical process that affects bioavailability. Significant destruction of a drug by the liver before it is systemically absorbed (known as the first-pass effect because it occurs during the first passage of the drug through the liver) decreases bioavailability.

2. The answer is B *[see* II.B.1.a*].*

When the active form of the drug is given intravenously, it enters the systemic circulation directly. The drug is delivered rapidly to all tissues, including the drug receptor sites. For all other routes of drug administration, except intra-arterial injection, the drug must be systemically absorbed before it is distributed to the drug receptor sites. For this reason, the onset of pharmacologic effects is slower. If the drug is a prodrug that must be converted to an active drug, oral administration, not intravenous injection, may not provide the most rapid onset of activity if conversion to the active form takes place in the gastrointestinal tract or liver.

3. The answer is B *[see* II.C.2*].*

When a drug is given by intravenous injection, the entire dose enters the systemic circulation. With other routes of administration, the drug may be lost before it reaches the systemic circulation. For example, with first-pass effects, a portion of an orally administered drug is eliminated, usually through degradation by liver enzymes, before the drug reaches its receptor sites.

4. The answer is C *[see* II.B.2.b.(4)*].*

Drugs given orally are well absorbed from the duodenum. The duodenum has a large surface area because of the presence of villi and microvilli. In addition, because the duodenum is well perfused by the mesenteric blood vessels, a concentration gradient is maintained between the lumen of the duodenum and the blood.

5. The answer is B *[see* II.A.2 *and* 3*].*

Fick's law of diffusion describes passive diffusion of drug molecules moving from a high concentration to a low concentration. This process is not saturable and does not require energy.

6. The answer is D *[see* II.A.2*].*

The transport of a drug across a cell membrane by passive diffusion follows Fick's law of diffusion: The drug moves with a concentration gradient (i.e., from an area of high concentration to an area of low concentration). In contrast, drugs that are actively transported move against a concentration gradient.

7. The answer is E *[see* III.A.1*].*

The Noyes-Whitney equation describes the rate at which a solid drug dissolves. Fick's law is similar to the Noyes-Whitney equation in that both equations describe drug movement caused by a concentration gradient. Fick's law generally refers to passive diffusion, or passive transport, of drugs. The law of mass action describes the rate of a chemical reaction, the Michaelis-Menten equation involves enzyme kinetics, and the Henderson-Hasselbalch equation gives the pH of a buffer solution.

8. The answer is D *[see* III.A.1 *and* 3*].*

The ionized, or salt, form of a drug has a charge and is generally more water soluble and, therefore, dissolves more rapidly than the nonionized (free acid or free base) form of the drug. The dissolution rate is directly proportional to the surface area and inversely proportional to the particle size. An increase in the particle size or a decrease in the surface area slows the dissolution rate.

9. The answer is B *[see* III.B.6*].*

A modified-release, or controlled-release, drug product contains two or more conventional doses of the drug. An abrupt release of the drug, known as dose dumping, may cause intoxication.

10. The answer is B *[see* III.B.1.c*].*

For lipid-soluble drugs, the rate of dissolution is the slowest (i.e., rate-limiting) step in drug absorption and thus in bioavailability. The disintegration rate of an immediate-release or conventional compressed tablet is usually more rapid than the rate of drug dissolution. Because the cell membrane is a lipoprotein structure, transport of a lipid-soluble drug across the cell membrane is usually rapid.

11. The answer is A *[see* III.A.4.b*].*

The extent of ionization of a weak electrolyte is described by the Henderson-Hasselbalch equation, which relates the pH of the solution to the pK_a of the drug.

12. The answer is D *[see* III.B.2.a*].*

Because a drug in solution is already dissolved, no dissolution is needed before absorption. Consequently, compared with other drug formulations, a drug in solution has a high rate of bioavailability. A drug in aqueous solution has the highest bioavailability rate and is often used as the reference preparation for other formulations. Drugs in hydroalcoholic solution (e.g., elixirs) also have good bioavailability. The rate of drug bioavailability from a hard gelatin capsule, compressed tablet, or suspension may be equal to that of a solution if an optimal formulation is manufactured and the drug is inherently rapidly absorbed.

13. The answer is E *[see* III.B.7*].*

Drug delivery from a transdermal drug delivery system depends on all of the factors cited—that is, on the presence of an occlusive backing (to maintain skin hydration and elevate skin temperature slightly) and an adhesive film to maintain contact of the formulation matrix with the skin to enable drug transfer from the patch into the skin. If the drug's affinity for the formulation matrix is greater than its affinity for the stratum corneum, the drug's escaping tendency from the patch will be reduced, minimizing the gradient for drug transfer into the skin. The microviscosity of the

formulation matrix, the presence of a membrane between the drug reservoir in the patch and the skin surface, and interaction of the drug with the formulation matrix affect the rate and extent of diffusion and/or partitioning of the drug through the patch to the skin surface. Finally, the extent of drug delivery from the patch is directly proportional to the surface area of the patch in contact with the skin surface.

I. INTRODUCTION

A. Definitions

1. Compounding vs manufacturing

2. It is important, but oftentimes difficult, to distinguish between compounding and manufacturing.

3. Compounding has been defined by the National Association of Boards of Pharmacy as the preparation, mixing, assembling, packaging, or labeling of a drug or device (i) as the result of a practitioner's prescription drug order or initiative based on the pharmacist/patient/prescriber relationship in the course of professional practice or (ii) for the purpose of, as an incident to research, teaching, or chemical analysis and not for sale or dispensing. Compounding also includes the preparation of drugs and devices in anticipation of prescription drug orders based on routine, regularly observed patterns.

4. Manufacturing has been defined as the production, preparation, propagation, conversion or processing of a drug or device, either directly or indirectly, by extraction from substances of natural origin or independently by means of chemical or biological synthesis, and includes any packaging or repackaging of the substance(s) or labeling or relabeling of its container, and the promotion and marketing of such drugs or devices. Manufacturing also includes the preparation and promotion of commercially available products from bulk compounds for resale by pharmacies, practitioners, or other persons.

5. The purpose of pharmaceutical compounding is to prepare an individualized drug treatment for a patient based on an order from a duly licensed prescriber. The fundamental difference between compounding and manufacturing is the existence of a pharmacist/prescriber/patient relationship that controls the compounding of the drug preparation. Compounded drugs are not for resale but, rather, are personal and responsive to the patient's immediate needs. They are prepared and administered by the patient, caregiver or patient's healthcare professionals, which allows for the monitoring of patient outcomes. On the other hand, drug manufacturers produce batches consisting of tens or hundreds of thousands of dosage units, such as tablets or capsules, for resale, using many personnel and large-scale manufacturing equipment. These products are distributed through the normal channels of interstate commerce to individuals unknown to the company. Manufacturers are not required to, and do not, provide oversight of individual patients. It is also acceptable and routine practice for pharmacists to compound for “office use” those preparations that are not commercially available. These preparations are “For Office Use Only” and are not for resale or to be given to the patients to take home; they are to be administered at the office.

6. The *United States Pharmacopeia* (USP) uses the term *preparation* to refer to compounded prescriptions and the term *products* to refer to manufactured pharmaceuticals. Also, for stability purposes, compounded preparations are

assigned a “beyond-use” date and manufactured products are assigned an “expiration date.”

B. Regulation

1. Current good manufacturing practices (cGMPs) are the standards of practice used in the pharmaceutical industry and are regulated by the Food and Drug Administration (FDA).

2. Good compounding practices (GCPs) are the standards of practice detailed in the USP, chapter <1075>. Community pharmacists must comply with state board of pharmacy laws, regulations, and guidelines to ensure a quality preparation, which includes using proper materials, weighing equipment, documented techniques, and dispensing and storage instructions.

3. Legal considerations

a. Extemporaneous compounding by the pharmacist or a prescription order from a licensed practitioner, as with the dispensing of any other prescription, is controlled by the state boards of pharmacy.

b. The legal risk (liability) of compounding is no greater than the risk of filling a prescription for a manufactured product because the pharmacist must ensure that the correct drug, dose, and directions are provided. The pharmacist is also responsible for preparing a quality pharmaceutical preparation, providing proper instructions regarding its storage, and advising the patient of any adverse effects.

4. Food and Drug Administration. The FDA has developed a list of preparations that should not be extemporaneously compounded. This list was developed primarily from commercial products that have been removed from the market owing to safety and/or efficacy concerns. This is a lengthy list and must be read carefully because, in some cases, only certain dosage forms of a specific drug are included on the list and others are not. The list is too extensive to include here but can be accessed at www.fda.gov/cder/pharmcomp/pcwd.txt.

C. Stability and quality control of compounded preparations

1. Beyond-use dates. The assignment of a beyond-use date is one of the most difficult tasks required of a compounding pharmacist. Chapters <795> and <797> of the USP provide guidelines for this task. Chapter <795> involves nonsterile preparations, and chapter <797> involves sterile preparations. For nonsterile preparations, current USP criteria for nonaqueous liquids and solid formulations (for which a manufactured drug product is the source of active ingredients) include a beyond-use date not later than 25% of the time remaining until the product's expiration date or 6 months, whichever is earlier. When a USP or *National Formulary* (*NF*) substance is the source of active ingredient, the beyond-use date is not later than 6 months. For water-containing formulations (prepared from ingredients in solid form), the beyond-use date is not later than 14 days when stored at cold temperatures. For all other formulations, the beyond-use date is not later than the intended duration of therapy or 30 days, whichever is earlier. These

beyond-use dates may be exceeded when there is supporting valid scientific stability information that is directly applicable to the specific preparation.
For sterile preparations, if a sterility testing program is not in place, the following can be used provided the preparation is properly packaged and stored.
Low-Risk Level Compounded Sterile Preparations: Not more than 48 hours at controlled room temperature, not more than 14 days at a cold temperature (refrigerator) and for 45 days frozen at -20°C or colder.
Medium-Risk Level Compounded Sterile Preparations: Not more than 30 hours at controlled room temperature, not more than 9 days at cold temperature (refrigerator) and for 45 days frozen at -20°C or colder.
High-Risk Level Compounded Sterile Preparations: Not more than 24 hours at controlled room temperature, not more than 3 days at cold temperature (refrigerator) and for 45 days frozen at -20°C or colder.
If a sterility testing program is in place, the beyond-use dates for nonsterile preparations apply. As in nonsterile compounding, these beyond-use dates for sterile compounding may be exceeded when there is supporting valid scientific stability information that is directly applicable to the specific preparation.
2. Quality control. Quality control is becoming one of the fastest growing aspects of pharmacy compounding. Pharmacists are becoming more involved in the final testing of compounded preparations or are sending them to contract laboratories for testing. For example, the following quality control tests can be considered for the respective compounded dosage forms:

a. Ointments, creams, and gels. Theoretical weight compared to actual weight, pH, specific gravity, active drug assay, physical observations (color, clarity, texture-surface, texture-spatula spread, appearance, feel), and rheological properties.
b. Hard gelatin capsules. Weight overall, average weight, individual weight variation, dissolution of capsule shell, disintegration of capsule contents, active drug assay, physical appearance (color, uniformity, extent of fill, locked), and physical stability (discoloration, changes in appearance).
c. **Special hard gelatin capsules.** Weight overall, average weight, individual weight variation, dissolution of capsule shell, disintegration of capsule contents, active drug assay, physical appearance (color, uniformity of appearance, uniformity of extent of fill, closures), and physical stability (discoloration or other changes).
d. Suppositories, troches, lollipops, and sticks. Weight, specific gravity, active drug assay, physical observations (color, clarity, texture of surface, appearance, feel), melting test, dissolution test, physical stability.
e. Oral and topical liquids. Weight to volume, pH, specific gravity, active drug assay, globule size range, rheological properties/pourability, physical observations (color, clarity), and physical stability (discoloration, foreign materials, gas formation, mold growth).

f. Parenteral preparations. Weight or volume, pH, specific gravity, osmolality, assay, physical observations (color, clarity), particulate matter, sterility, and pyrogenicity.

3. Quality control testing. Pharmacists have the option of doing testing in-house or outsourcing it to laboratories.

a. In-house testing can include measurements such as weight, volume, pH, specific gravity, osmolality, physical observations, sterility and endotoxins.

b. Out-sourced testing can include sterility, endotoxins, potency, and dissolution.

c. **Test results** should be kept on file with the compounding records for the individual compounded preparations.

II. REQUIREMENTS FOR COMPOUNDING

A. Sources for chemicals and drugs. Pharmacists can obtain small quantities of the appropriate chemicals or drugs from wholesalers or chemical supply houses. These suppliers then may also serve as compounding consultants to the pharmacists to aid in ensuring their product's purity and quality.

B. Equipment. The correct equipment is important when compounding. Many state boards of pharmacy have a required minimum list of equipment for compounding prescriptions. Suggested equipment, which varies according to the amount of material needed and the type of compounded prescription (e.g., parenteral), includes the following:

1. Electronic balance and/or class A prescription balance
2. Hot plate
3. Magnetic stirrer
4. Electric mixer
5. Special containers for packaging (e.g., applicator tip bottles, insufflators)
6. Graduated cylinders from 10 mL to 1000 mL
7. Glass, Wedgwood, and porcelain mortars and pestles of various sizes
8. Funnels of various sizes
9. Spatulas of various sizes, including several plastic spatulas
10. Weighing and filter papers
11. Stirring rods (glass)
12. Ointment/pill tile
13. Capsule-filling machine
14. Ointment-filling machine
15. Autoclave
16. Laminar flow clean bench
17. Special suppository, troche and medication-stick molds

18. Record-keeping system (compounding log book)
19. Glass beakers from 50 mL to 1000 mL

C. Location of compounding area. Many pharmacies actively involved in compounding have dedicated a separate area in the pharmacy to this process. The

ideal location is away from heavy foot traffic and is near a sink where there is sufficient space to work and store all chemicals and equipment. For compounding of sterile preparations, a laminar air-flow hood (minimal) and a clean room are current practice, or isolation barrier technology equipment.

III. COMPOUNDING OF SOLUTIONS

A. Definition. USP 30 defines **solutions** as liquid preparations that contain one or more chemical substances dissolved (i.e., molecularly dispersed) in a suitable solvent or mixture of mutually miscible solvents. Although the uniformity of the dosage in a solution can be assumed, the stability, pH, solubility of the drug or chemicals, taste (for oral solutions), and packaging need to be considered.

B. Types of solutions

1. Sterile parenteral and ophthalmic solutions require special consideration for their preparation (see XI).

2. Nonsterile solutions include oral, topical, and otic solutions.

C. Preparation of solutions. Solutions are the easiest of the dosage forms to compound extemporaneously, as long as a few general rules are followed.

1. Each drug or chemical is dissolved in the solvent in which it is most soluble. Thus the solubility characteristics of each drug or chemical must be known.

2. If an alcoholic solution of a poorly water-soluble drug is used, the aqueous solution is added to the alcoholic solution to maintain as high an alcohol concentration as possible.
P.101

3. The salt form of the drug—not the free-acid or base form, which both have poor solubility—is used.
4. Flavoring or sweetening agents are prepared ahead of time.
5. When adding a salt to a syrup, dissolve the salt in a few milliliters of water first; then add the syrup to volume.
6. The proper vehicle (e.g., syrup, elixir, aromatic water, purified water) must be selected.

D. Examples

1. Example 1

a. Medication order

Triamcinolone acetonide	100 mg
Menthol	50 mg
Ethanol	10 mL
Propylene glycol	30 mL
Glycerin	20 mL
Sorbitol 70% solution, qs	100 mL
Sodium saccharin	100 mg
Sodium metabisulfite	20 mg
Disodium EDTA	100 mg
Purified water	5 mL

b. Compounding procedure. Triamcinolone acetonide 0.1% mouthwash solution is prepared by dissolving the triamcinolone acetonide and menthol in the ethanol. Add the propylene glycol, glycerin, and about 10 mL of the 70% sorbitol and mix well.

Dissolve the sodium saccharin, sodium metabisulfite, and disodium EDTA in the purified water. Add the aqueous solution to the drug mixture and mix well. Add sufficient 70% sorbitol solution to volume and mix well.

How much of the triamcinolone base is present in this prescription? The molecular weight of triamcinolone is 394.4 and that of triamcinolone acetonide is 434.5.

$$\frac{394.4}{434.5} \times 100 \text{ mg} = 91 \text{ mg of triamcinolone base}$$

2. Example 2

a. Medication order

Potassium chloride	1 mEq/mL
Preserved flavored, oral vehicle, qs	100 mL

b. Calculations. The molecular weight of potassium chloride is 74.5 (K = 39; Cl = 35.5). One milliequivalent (mEq) weighs 74.5 mg.

100 mL × 74.5 mg/mL = 7450 mg or 7.45 g of KCl required

What is the molar concentration of this prescription?

7.45 g per 100 mL or 74.5 g per 1000 mL

1 mole of KCl weights 74.5 g

It is a 1 molar solution

c. **Compounding procedure.** The solubility of potassium chloride is 1 g in 2.8 mL water. Therefore, dissolve the 7.45 g KCl in 21 mL of purified water. Add sufficient preserved flavored oral vehicle to volume and mix well.

3. Example 3

a. Medication order

Salicylic acid	2%
Lactic acid	6 mL
Flexible collodion, ad	30 mL

b. Compounding procedure. Pharmacists must use caution when preparing this prescription because flexible collodion is extremely flammable. A 1-oz. applicator-tip bottle is calibrated, using ethanol, which is poured out and any remaining alcohol allowed to

evaporate, resulting in a dry bottle. Salicylic acid (0.6 g) is added directly into the bottle, to which is added the 6 mL of lactic acid. The bottle is agitated or a glass stirring rod is used to dissolve the salicylic acid. Flexible collodion is added up to the calibrated 30-mL mark on the applicator-tip bottle.

4. Example 4

a. Medication order

Iodine	2%
Sodium iodide	2.4%
Alcohol, qs	30 mL

b. Compounding procedure. Iodine (0.6 g) and sodium iodide (0.72 g) are dissolved in the alcohol, and the final solution is placed in an amber bottle. A **rubber or plastic spatula** is used because **iodine is corrosive.**

IV. COMPOUNDING OF SUSPENSIONS

A. Definition. Suspensions are defined by USP 30 as liquid preparations that consist of solid particles dispersed throughout a liquid phase in which the particles are not soluble.

B. General characteristics

1. Some suspensions should contain an antimicrobial agent as a preservative.

2. Particles settle in suspensions even when a suspending agent is added; thus suspensions must be well shaken before use to ensure the distribution of particles for a uniform dose.

3. Tight containers are necessary to ensure the stability of the final preparation.

4. Principles to keep in mind when compounding include the following:

a. Insoluble powders should be small and uniform in size to decrease settling.

b. The suspension should be viscous.

c. Topical suspensions should have a smooth, impalpable texture.

d. Oral suspensions should have a pleasant odor and taste.

C. Formation of suspensions. Suspensions are easy to compound; however, physical stability after compounding the final preparation is problematic. The following steps may minimize stability problems.

1. The particle size of all powders used in the formulation should be reduced.

2. A thickening (suspending) agent may be used to increase viscosity. Common thickening agents include alginic acid, bentonite, VEEGUM, methylcellulose, and tragacanth.

3. A levigating agent may aid in the initial dispersion of insoluble particles. Common levigating agents include glycerin, propylene glycol, alcohol, syrups, and water.

4. Flavoring agents and preservatives should be selected and added if the preparation is intended for oral use. Common preservatives include methylparaben, propylparaben, benzoic acid, and sodium benzoate. Flavoring agents may be any flavored syrup or flavor concentrate (Table 5-1).

5. The source of the active ingredients (e.g., bulk powders versus tablets or capsules) must be considered; if commercial dosage forms are used, the inactive ingredients must be considered and only immediate-release tablets or capsules should be used and not modified release.

D. Preparation of suspensions

1. The insoluble powders are triturated to a fine powder.

2. A small portion of liquid is used as a levigating agent, and the powders are triturated until a smooth paste is formed.

3. The vehicle containing the suspending agent is added in divided portions. A high-speed mixer greatly increases the dispersion.

Table 5-1. Selected Flavor Applications

Drug Category	Preferred Flavors
Antibiotics	Cherry, maple, pineapple, orange, raspberry, banana-pineapple, banana-vanilla, butterscotch-maple, coconut custard, strawberry, vanilla, lemon custard, cherry custard, fruit-cinnamon
Antihistamines	Apricot, black currant, cherry, cinnamon, custard, grape, honey, lime, loganberry, peach-orange, peach-rum, raspberry, root beer, wild cherry
Barbiturates	Banana-pineapple, banana-vanilla, black currant, cinnamonpeppermint, grenadine-strawberry, lime, orange, peach-orange, root beer
Decongestants and expectorants	Anise, apricot, black currant, butterscotch, cherry, coconut custard, custard mint-strawberry, grenadine-peach, strawberry, lemon, coriander, orange-peach, pineapple, raspberry, strawberry, tangerine
Electrolyte solutions	Cherry, grape, lemon-lime, raspberry, wild cherry, black currant, grenadine-strawberry, lime, Port wine, Sherry wine, root beer, wild strawberry

4. The preparation is brought to the required volume using the vehicle.

5. The final mixture is transferred to a “tight” bottle for dispensing to the patient.

6. All suspensions are dispensed with a “shake well” label.

7. Suspensions are not filtered.

8. The water-soluble ingredients, including flavoring agents, are mixed in the vehicle before mixing with the insoluble ingredients.

E. Examples

1. Example 1

a. Medication order

Propranolol HCI	4 mg/mL
Disp	30 mL
Sig:	1 mL p.o. t.i.d.

b. Calculations. Propranolol HCl: 4 mg/mL × 30 mL = 120 mg. Propranolol HCl is available as a powder or in immediate-release and extended-release (long-acting) dosage forms. Only the powder or the immediate-release tablets are used for compounding prescriptions; therefore, some combination of propranolol HCl tablets that yields 120 mg active drug (e.g., 3 × 40 mg tablets) may be used.

c. **Compounding procedure.** The propranolol tablets are reduced to a fine powder in a mortar. The powder or the comminuted tablets are levigated to a smooth paste, using a 2% methylcellulose solution. To this mixture, about 10 mL of a suitable flavoring agent is added. The mixture is transferred to a calibrated container and brought to the final volume with purified water or suitable suspending vehicle. A "shake well" label is attached to the prescription container.

2. Example 2

a. Medication order

Zinc oxide	10
Ppt sulfur	10
Bentonite	3.6
Purified water, ad	90 mL
Sig:	Apply t.i.d.

b. Compounding procedure. The powders are reduced to a fine uniform mixture in a mortar. The powders are mixed to form a smooth paste using water and transferred to

a calibrated bottle. The final volume is attained with purified water. A “shake well” label is attached to the prescription container.

3. Example 3

a. Medication order

Rifampin suspension	20 mg/mL
Disp	120 mL
Sig:	u.d.

b. Calculations. Rifampin: 20 mg/mL × 120 mL = 2400 mg. Rifampin is available in 150-mg and 300-mg capsules. Hence, 8 capsules containing 300 mg of rifampin in each capsule or 16 capsules containing 150 mg of rifampin per capsule are needed.

c. **Compounding procedure.** The contents of the appropriate number of rifampin capsules are emptied into a mortar and comminuted with a pestle. This powder is levigated with a small amount of 1% methylcellulose solution. Then 20 mL of simple syrup are added and mixed. The mixture is brought to the final volume with simple syrup. “Shake well” and “refrigerate” labels are attached to the prescription container.

V. EMULSIONS

A. Definition. Emulsions are **two-phase systems** in which one liquid is dispersed throughout another liquid in the form of small droplets (see Chapter 3.VI.D).

B. General characteristics. Emulsions can be used **externally** as lotions and creams or **internally** to mask the taste of medications.

1. The two liquids in an emulsion are immiscible and require the use of an **emulsifying agent.**

2. Emulsions are classified as either **oil-in-water (o/w)** or **water-in-oil (w/o);** there can also be multiple emulsions, such as **oil-in-water-in-oil (o/w/o)** and **water-in-oil-in-water (w/o/w),** as well as emulsion-gels, in which the external phase of an oil in water emulsion is thickened with a gelling agent.

3. Emulsions are **unstable** by nature, and the following steps should be taken to prevent the two phases of an emulsion from separating into two layers after preparation.

a. The correct **proportions** of oil and water should be used during preparation. The internal phase should represent 40%-60% of the total volume.

b. An emulsifying **agent** is needed for emulsion formation.
c. A **hand homogenizer,** which reduces the size of globules of the internal phase, may be used; if small quantities are compounded, two 60-mL syringes attached with a Leur-Lock adapter can be used and the materials pushed back and forth between the two syringes.
d. Preservatives should be added if the preparation is intended to last longer than a few days. Generally, a combination of methylparaben (0.2%) and propylparaben (0.02%) may be used.
e. A **"shake well" label** should be placed on the final preparation.
f. The preparation should be **protected** from light and extreme temperature. Both freezing and heat may have an effect on stability.
C. Emulsifying agents
1. Gums, such as acacia or tragacanth, are used to form o/w emulsions. These emulsifying agents are for general use, especially for emulsions intended for internal administration (Table 5-2).
a. Use 1 g of acacia powder for every 4 mL of fixed oil or 1 g to 2 mL for a volatile oil.
b. If using tragacanth in place of acacia, 0.1 g of tragacanth is used for every 1 g of acacia.
2. Methylcellulose and carboxymethylcellulose are used for o/w emulsions. The concentrations of these agents vary, depending on the grade that is used. Methylcellulose is available in several viscosity grades, ranging from 15 to 4000 and designated by a centipoise number, which is a unit of viscosity.

Table 5-2. Agents Used in Prescription Compounding

Ointments			
Oleaginous or hydrocarbon bases		Hydrous emulsion bases (w/o)	
	Anhydrous		Hydrous
	Nonhydrophilic		Will absorb water
	Insoluble in water		Insoluble in water
	Not water removable (occlusive)		Not water removable (occlusive)

Good vehicles for antibiotics	Examples
Example	Cold cream
Petrolatum	Hydrous lanolin
Absorption bases	Emulsion bases (o/w)
Anhydrous	Hydrous
Will absorb water	Hydrophilic
Insoluble in water	Insoluble in water
Not water removable (occlusive)	Water removable
Examples	Can absorb 30-50% of weight
Hydrophilic petrolatum	Examples
Lanolin USP (anhydrous)	Hydrophilic ointment USP
	Acid mantle cream
	Water soluble
	Anhydrous or hydrous
	Soluble in water
	Water removable
	Hydrophilic

		Example	
			Polyethylene glycol ointment
Suspending Agents			
Acacia 10%		Methylcellulose 1%-7%	
Alginic acid 1%-2%		Sodium alginate 1%-2%	
Bentonite 6%		Tragacanth 1%-3%	
Carboxymethylcellulose 1%-5%		VEEGUM 6%	
Preservatives			
Methylparaben 0.02%-0.2%		Propylparaben 0.01%-0.04%	
Emulsifying Agents			
Hydrophilic colloids		Surfactants, nonionic	
	Acacia	Concentrations used (1-30%)	
	Tragacanth	Tweens (e.g., polysorbate 80)	
	Pectin; favor o/w	Spans	
	Carboxymethylcellulose		
	Methylcellulose		
Proteins		Soaps	
	Gelatin		Triethanolamine
	Egg whites; favor o/w		Stearic acid

Inorganic gels and magmas		Others	
	Milk of magnesia		Sodium lauryl sulfate
	Bentonite; favor o/w		Dioctyl sodium sulfosuccinate
			Cetyl pyridinium chloride

o/w, oil-in-water; *w/o,* water-in-oil

3. Soaps can be used to prepare o/w or w/o emulsions for external preparations.
4. Nonionic emulsifying agents can be used for o/w and w/o emulsions.
D. Formation and preparation of emulsions. The procedure for preparing an emulsion depends on the desired emulsifying agent in the formulation.
1. A **mortar** and **pestle** are frequently all the equipment that is needed.
a. A mortar with a **rough surface** (e.g., Wedgwood) should be used. This rough surface allows maximal dispersion of globules to produce a fine particle size.
b. A **rapid motion** is essential when triturating an emulsion using a mortar and pestle.
c. The mortar should be able to hold at least three times the **quantity** being made. Trituration seldom requires more than 5 min to create the emulsion.
2. Electric mixers and hand homogenizers are useful for producing emulsions after the coarse emulsion is formed in the mortar.
3. The **order** of mixing of ingredients in an emulsion depends on the type of emulsion being prepared (i.e., o/w or w/o) as well as the emulsifying agent chosen. Methods used for compounding include the following:
a. Dry gum (continental) method is used for forming emulsions using natural emulsifying agents and requires a specific order of mixing.
b. Wet gum (English) method is used for forming emulsions using natural emulsifying agents and requires a specific order of mixing.
c. **Bottle method** is used for forming emulsions using natural emulsifying agents and requires a specific order of mixing.
d. Beaker method is used to prepare emulsions using synthetic emulsifying agents and produces a satisfactory preparation regardless of the order of mixing.
4. Preservatives. If the emulsion is kept for an extended period of time, refrigeration is usually sufficient. The preparation should not be frozen. If a preservative is used, it must be soluble in the water phase to be effective.

5. Flavoring agents. If the addition of a flavor is needed to mask the taste of the oil phase, the flavor should be added to the external phase before emulsification (Table 5-3).

E. Examples

1. Example 1

a. Medication order

Mineral oil	18 mL
Acacia	qs
Distilled water, qs ad	90.0 mL
Sig:	1 tablespoon q.d.

b. Compounding procedure. With the dry gum method, an initial emulsion (primary emulsion) is formed, using 4 parts (18 mL) of oil, 2 parts (9 mL) of water, and 1 part (4.5 g) of powdered acacia. The mineral oil is triturated with the acacia in a Wedgwood mortar. The 9 mL of water is added all at once and, with rapid trituration, form the primary emulsion, which is triturated for about 5 min. The remaining water is incorporated in small amounts with trituration. The emulsion is transferred to a 90-mL prescription bottle, and a “shake well” label is attached to the container.

Table 5-3. Flavor Selection Guide

Taste	Masking Flavor
Salt	Butterscotch, maple
Bitter	Wild cherry, walnut, chocolate mint, licorice
Sweet	Fruit, berry, vanilla
Acid	Citrus

2. Example 2

a. Medication order

Olive oil	30 mL
Zinc oxide	8 g
Calamine	8 g
Lime water	30 mL

b. Compounding procedure. The olive oil is placed in a suitably sized beaker. Using an electric mixer, the zinc oxide, the calamine, and the lime water are added in that order. This yields a w/o emulsion. This procedure is known as the nascent soap method. The olive oil reacts with the calcium hydroxide solution (lime water) and forms a soap. For this reaction to occur, fresh lime water (calcium hydroxide solution) is required. A small quantity of oleic acid can also be added to further stabilize the emulsion.

3. Example 3

a. Medication order

Mineral oil	50 mL
Water, qs	100 mL
Sig:	2.5 mL p.o. h.s.

b. Compounding procedure. Using a combination of nonionic emulsifying agents, such as Span 40 and Tween 40, the correct hydrophilic-lipophilic balance (HLB) is obtained. Next, the mineral oil is warmed in a water bath to about 60°C, and the Span 40 is dissolved in the heated mineral oil. The water is warmed to about 65°C, and the Tween 40 is dissolved in the heated water. This mixture is added to the

mineral oil and dissolved Span 40 and stirred until cooled. An “external use only” label is added to the container.

VI. POWDERED DOSAGE FORMS

A. Definition. Powders are intimate mixtures of dry, finely divided drugs and/or chemicals that may be intended for internal (oral powders) or external (topical powders) use. The major types are powder papers, bulk powders, and insufflations.

B. General characteristics

1. Powder dosage forms are used when **drug stability** or **solubility** is a concern. These dosage forms may also be used when the powders are too bulky to make into capsules and when the patient has difficulty swallowing a capsule.

2. Some **disadvantages** to powders include unpleasant-tasting medications and, occasionally, the rapid deterioration of powders.

3. Blending of powders may be accomplished by using trituration in a mortar, stirring with a spatula, and sifting. Geometric dilution should be used if needed. When heavy powders are mixed with lighter ones, the heavier powder should be placed on top of the lighter one and then blended. When mixing two or more powders, each powder should be pulverized separately to about the same particle size before blending together.

a. The mortar and pestle method is preferred when **pulverization** and a thorough mixing of ingredients are desired (geometric dilution). A Wedgwood mortar is preferable, but glass or porcelain may also be used.

b. Light powders are mixed best by using the **sifting method.** The sifting is repeated three to four times to ensure thorough mixing of the powders.

C. Preparation of powder dosage forms

1. Bulk powders, which may be used internally or topically, include dusting powders, douche powders, laxatives, antacids, and insufflation powders.

2. After a bulk powder has been pulverized and blended, it should be dispensed in an appropriate container.

a. Hygroscopic or **effervescent** salts should always be placed in a tight, wide-mouth jar.

b. Dusting powders should be placed in a container with a sifter top.

3. Eutectic mixtures of powders can cause problems because they may liquefy. One remedy is to add an inert powder, such as magnesium oxide, to separate the eutectic materials.

4. Powder papers are also called divided powders.

a. The entire powder is initially blended. Each dose is then individually weighed.

b. The dosage should be weighed, then transferred onto a powder paper and folded. This technique requires practice. Hygroscopic, deliquescent, and effervescent powders require the use of glassine paper as an inside lining. Plastic bags or envelopes with snap-and-seal closures offer a convenient alternative to powder papers.

c. The folded papers are dispensed in a powder box or other suitable container; however, these containers are not child resistant.

D. Examples

1. Example 1

a. Medication order

Camphor	100 mg
Menthol	200 mg
Zinc oxide	800 mg
Talc	1.9 g
M foot powder	
Sig:	Apply to feet b.i.d.

b. Compounding procedure. The camphor and menthol are triturated together in a glass mortar, where a liquid eutectic is formed. The zinc oxide and talc are blended and mixed with the eutectic, using geometric dilution. This mixing results in a dry powder, which is passed through a wire mesh sieve. The final preparation is dispensed in a container with a sifter top.

2. Example 2

a. Medication order

Citric acid	0.3 g
Sodium bicarbonate	0.25 g
Psyllium mucilloid	2 g
Powdered flavor, qs	
M. Ft d.t.d. charts v	

Sig: Empty the contents of one chart into a glass of water and take h.s.

b. Calculations. Calculate for one extra powder paper:

Citric acid 0.3 g × 6 doses	=	1.8 g
Sodium bicarbonate 0.25 g × 6 doses	=	1.5 g
Psyllium mucilloid 2 g × 6 doses	=	12 g
Total wight	=	15.3 g
15.3 g/6 doses	=	2.55 g/dose

Note: Also consider the weight of the powdered flavor.

c. **Compounding procedure.** The ingredients are first pulverized and weighed. The citric acid and sodium bicarbonate are mixed together first; the psyllium mucilloid is then added along with the powdered flavor, using geometric dilution. Each dose (2.55 g) of the resultant mixture is weighed and placed into a powder paper. This preparation is an effervescent powder. When dissolved in water, the citric acid and sodium bicarbonate react to form carbonic acid, which yields carbon dioxide, making the solution more palatable.

VII. CAPSULES

A. Definition. Capsules are solid dosage forms in which the drug is enclosed within either a hard or soft soluble container or shell. The shells are usually made from a suitable gelatin. Hard gelatin capsules may be manually filled for extemporaneous compounding.

Table 5-4. Approximate Amount of Powder Contained in Capsules

Capsule Size	Range of Powder Capacity (mg)
No. 5	60-130
No. 4	95-260
No. 3	130-390
No. 2	195-520
No. 1	225-650
No. 0	325-910
No. 00	390-1300
No. 000	650-2000

B. Capsule sizes

1. A list of capsule sizes and the approximate amount of powder that may be contained in the capsule appear on the side of the capsule box (Table 5-4).

2. Capsule sizes for oral administration in humans range from no. 5, the smallest, to no. 000, the largest.

3. No. 0 is usually the largest oral size suitable for human patients.

4. Capsules for veterinarians are available in no. 10, no. 11, and no. 12, containing approximately 30, 15, and 7.5 g, respectively.

C. Preparation of hard and soft capsules

1. As with the bulk powders, all ingredients are triturated and blended, using geometric dilution.

2. The correct size capsule must be determined by trying different capsule sizes, weighing them, and then choosing the appropriate size.

3. Before filling capsules with the medication, the body and cap of the capsule are separated. Filling is accomplished by using the “punch” method (Alternatively, small capsule machines are commonly used to prepare up to 300 capsules at a time, extemporaneously).

a. The powder formulation is compressed with a spatula on a pill tile or paper sheet with a uniform depth of approximately half the length of the capsule body.

b. The empty capsule body is repeatedly pressed into the powder until full.

c. The capsule is then weighed to ensure an accurate dose. An empty tare capsule of the same size is placed on the pan containing the weights.

4. For a large number of capsules, capsule-filling machines can be used for small-scale use to save time. Most commonly, capsules machines are used capable of preparing 100 to 300 capsules at a time.

5. The capsule is wiped clean of any powder or oil and dispensed in a suitable prescription vial.

D. Examples

1. Example 1

a. Medication order

Rifampin	100 mg
dtd #50	
Sig:	1 cap p.o. q.d.

b. Calculations. Compound this prescription using the commercially available 300-mg capsules as the drug source. Calculate for at least one extra capsule.

51 caps × 100 mg/cap	=	5100 mg rifampin
5100 mg rifampin ÷ 300 mg/cap	=	17 caps

c. **Compounding procedure.** Use 17 rifampin capsules, each containing 300 mg rifampin. The content of each capsule is emptied, and the powder is weighed. The powder equivalent to 100 mg rifampin is placed in a capsule (e.g., if the total contents of one capsule weigh 360 mg; then 100/300 = *x*/360; *x* = 120 mg of active drug powder required from the capsule contents to provide 100 mg active drug) and sufficient lactose added to fill the capsule. The total filled capsule contents weigh 200 mg. The weight of the active drug powder is subtracted from 200 mg to obtain the amount of lactose required per capsule, which is 200 mg - 120 mg = 80 mg. This is multiplied by 51 capsules. Enough lactose (51 capsules × 80 mg/cap = 4.08 g) is added to make a total of 10.2 g of powder. The powders are combined, using geometric dilution, and 50 capsules can be punched out. Each capsule should weigh 200 mg (10.2 g/51 caps).

2. Example 2

a. Medication order. This order is for veterinary use only.

Castor oil	8 mL
Disp	12 caps
Sig:	2 caps p.o. h.s.

b. Calculations. No calculations are necessary.

c. **Compounding procedure.** A no. 11 veterinary capsule is used. Using a calibrated dropper or a pipette, 8 mL of the oil is carefully added to the inside of each capsule body. Next, the lower inside portion of the cap is moistened, using a glass rod or brush. The cap and body are joined together, using a twisting motion, to form a tight seal. The capsules are placed on a piece of filter paper and checked for signs of leakage. The capsules are dispensed in the appropriate size and type of prescription vial. They can be stored in a refrigerator if desired.

VIII. MOLDED TABLETS (TABLET TRITURATES)

A. Definition. Tablet triturates are small, usually cylindrical molded or compressed tablets. They are made of powders created by moistening the powder mixture with alcohol and water or by the process of sintering. They can be used for compounding potent drugs in small doses and for preparation of a rapidly disintegrating/dissolving dosage form.

B. Formulation and preparation of tablet triturates using moistened powders

1. Tablet triturates are made in special molds consisting of a pegboard and a corresponding perforated plate.
2. In addition to the mold, a diluent, usually a mixture of lactose and sucrose (80:20), and a moistening agent, usually a mixture of ethyl alcohol and water (60:40), are required.
3. The diluent is triturated with the active ingredients.
4. A paste is then made, using the alcohol and water mixture.
5. This paste is spread into the mold; the tablets are punched out and remain on the pegs until dry.

C. Example

1. Medication order

Atropine sulfate	0.4 mg
Disp	#500 TT
Sig:	u.d.

2. Calculations. For 500 TT: 500 × 0.4 mg = 200 mg atropine sulfate
3. Compounding procedure. The mold prepares 70-mg tablets. The 200 mg of atropine sulfate, 6.8 g of sucrose, and 28 g of lactose are weighed and mixed by geometric dilution. The powder is wet with a mixture of 40% purified water and 60% ethyl alcohol (95%). The paste that is formed is spread onto the tablet triturate mold; the tablets are then punched out of the mold and allowed to dry on the pegs. This procedure is repeated until the required number of tablet triturates has been prepared.

D. Formulation and preparation of tablet triturates using sintering

1. These tablet triturates are made in special molds consisting of materials that can tolerate heat to about 100°C.
2. In addition to the mold, a diluent, usually a mixture of active drug and diluent, which make up approximately 65% of the tablet weight, are blended together. Mannitol is good to use in combination with lactose for particle sizes of 60-80 mesh fraction.
3. The mixture is triturated with polyethylene glycol 3350 with a particle size of 80-100 mesh fraction.

4. The powder mixture is placed into appropriate molds and lightly tamped.
5. The molds containing the powder are placed in an oven at about 90°C for 10-20 min, removed and allowed to cool. Depending on the molds used, the tablets can be dispensed in the molds or removed from the molds and packaged and labeled.

E. Example

6. Medication order

Homatropine hydrobromide	300 mg
Mannitol	3.5 g
Lactose	3.47 g
Flavor (dry powder type), qs	
Polyethylene glycol 3350	3.5 g

7. Calculations. As presented, this formula is for 100 rapid-dissolving tablet triturates.

8. Compounding procedure. Blend the homatropine hydrobromide, mannitol, lactose, and dry flavor together until fine and uniformly mixed. Separately, reduce the particle size of the polyethylene glycol 3350 to 100-200 mesh fraction. Lightly blend in the polyethylene glycol 3350 into the previously blended powders. Place 100 mg of the powder into the cavities of a mold (some blister packs work well; otherwise, obtain a tablet triturate mold or a special mold for preparing these tablets). Place the mold containing the powder in an oven at 80-90°C for 15-20 min. The time depends on the mold, formulation, oven, etc. Remove from the oven and place in a refrigerator for approximately 5 min. Remove from the refrigerator and let set at room temperature. Package and label.

IX. OINTMENTS, CREAMS, PASTES, AND GELS

A. Definitions

1. Ointments, creams, and pastes are semisolid dosage forms intended for topical application to the skin or mucous membranes. **Ointments** are characterized as being oleaginous in nature; **creams** are generally o/w or w/o emulsions, and **pastes** are characterized by their high content of solids (about 25%).

2. Gels (sometimes called jellies) are semisolid systems consisting of suspensions made up of either small inorganic particles or large organic molecules interpenetrated by a liquid.

B. General characteristics. These dosage forms are semisolid preparations generally applied externally. Semisolid dosage forms may contain active drugs intended to:

1. Act solely on the surface of the skin to produce a local effect (e.g., antifungal agent; topicals)
2. Release the medication, which, in turn, penetrates into the skin (e.g., hydrocortisone cream)
3. Release medication for systemic absorption through the skin (e.g., nitroglycerin; transdermals)

C. Types of ointment bases

1. Hydrophobic bases feel greasy and contain mixtures of fats, oils, and waxes. Hydrophobic bases cannot be washed off using water.

2. Hydrophilic bases are usually emulsion bases. The o/w-type emulsion bases can be easily washed off with water, but the w/o type is slightly more difficult to remove.

D. Preparation of ointments, creams, pastes, and gels

1. Mixing can be done in a mortar or on an ointment slab or tile or using an ointment mill.
2. Liquids are incorporated by gradually adding them to an absorption-type base and mixing.
3. Insoluble powders are reduced to a fine powder and then added to the base, using geometric dilution.
4. Water-soluble substances are dissolved with water and then incorporated into the base.
5. The final preparation should be smooth (impalpable) and free of any abrasive particles.

E. Examples

1. Example 1

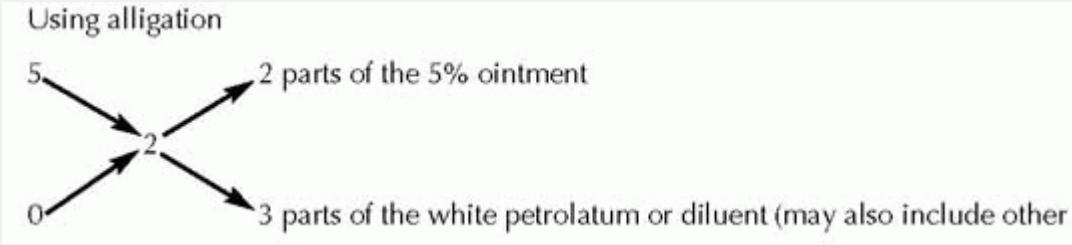
a. Medication order

Sulfur	
Salicylic acid, aa	600 mg
White petrolatum, ad	30 g
Sig:	Apply t.i.d.

b. Compounding procedure. The particle sizes of the sulfur and salicylic acid are reduced separately in a Wedgwood mortar and then blended together. Using a pill tile, the powder mixture is levigated with the base. Using geometric dilution, the

base and powders are blended to the final weight. An ointment jar or plastic tube is used for dispensing, and an “external use only” label is placed on the container.

c. **Alternate method.** Suppose you have sulfur 5% in white petrolatum ointment and a salicylic acid 5% ointment. **How can you prepare the prescription using these and diluting with white petrolatum?**



However, since we are using two different 5% ointments, 2 parts of each, this leaves 1 part for the white petrolatum. A total of 5 parts is to be used to make 30 g (6 g per part): 2 parts (12 g) of the sulfur 5%, 2 parts (12 g) of the salicylic acid 5%, and 1 part (6 g) of the white petrolatum could be used. To check:

12 g × 0.05	=	600 mg of sulfur
12 g × 0.05	=	600 mg of salicylic acid
12 g + 12 g + 6 g	=	30 g

2. Example 2

a. Medication order

Methylparaben	0.25 g
Propylparaben	0.15 g
Sodium lauryl sulfate	10 g
Propylene glycol	120 g
Stearyl alcohol	250 g
White petrolatum	250 g
Purified water	370 g
Disp	60 g
Sig:	Apply u.d.

b. Calculations. The quantity of each ingredient required to prepare 60 g is obtained as follows. The medication order is for 1000 g; therefore, the multiplication factor is 60/1000 = 0.06.

0.25 g × 0.06	=	0.15 g methylparaben
0.15 g × 0.06	=	0.009 g propylparaben
10 g × 0.06	=	0.6 g sodium lauryl sulfate
120 g × 0.06	=	7.2 g propylene glycol
250 g × 0.06	=	15 g stearyl alcohol

250 g × 0.06	=	15 g white petrolatum
370 g × 0.06	=	22.2 g purified water

Since the 0.009 g of propylparaben is too small to accurately weigh, a dilution can be prepared as follows, assuming a minimum weighable quantity of 120 mg. Weigh 120 mg of propylparaben and add to 40 mL of propylene glycol, resulting in a propylparaben concentration of 3 mg/mL. Take 3 mL of this solution to obtain the propylparaben and subtract the 3 mL from the quantity of propylene glycol required in the formula.

c. **Compounding procedure.** The stearyl alcohol and the white petrolatum are melted on a steam bath and heated to about 75°C. The other ingredients, previously dissolved in purified water at about 78°C, are added. The mixture is stirred until it congeals. An ointment jar is used for dispensing, and an “external use only” label is placed on the jar.

3. Example 3

a. Medication order

Scopolamine hydrobromide	0.25%
Soy lecithin	12 g
Isopropyl palmitate	12 g
Pluronic F-127 20% gel, qs	100 mL
Sig:	Apply 0.1 mL t.i.d.

b. Calculations. The quantity of scopolamine hydrobromide required for the prescription will be

0.0025 × 100 mL = 0.25 g or 250 mg

c. **Compounding procedure.** Mix the soy lecithin with the isopropyl palmitate. Dissolve the scopolamine hydrobromide in about 3 mL of purified water and add to about 70 mL of the Pluronic F-127 gel. Add the soy lecithin-isopropyl palmitate mixture, and mix well. Add sufficient Pluronic F-127 gel to volume, and mix well using a shearing technique. Package and label.

X. SUPPOSITORIES

A. General characteristics

1. Suppositories are **solid bodies** of various weights and shapes, adapted for introduction into the rectal, vaginal, or urethral orifices of the human body. They are used to deliver drugs for their local or systemic effects.

2. Suppositories differ in **size** and **shape** and include

a. Rectal

b. Vaginal

c. Urethral

B. Common suppository bases

1. Cocoa butter (theobroma oil), which melts at body temperature, is a fat-soluble mixture of triglycerides that is most often used for rectal suppositories. Witepsol is a synthetic triglyceride. Fatty acid bases include Fattibase.

2. Polyethylene glycol (PEG, carbowax) derivatives are water-soluble bases suitable for vaginal and rectal suppositories. Polybase is an example.

3. Glycerinated gelatin is a water-miscible base often used in vaginal and rectal suppositories.

C. Suppository molds

1. Suppository molds can be made of rubber, plastic, brass, stainless steel, or other suitable material.

2. The formulation and volume of the base depend on the size of the mold used, less the displacement caused by the active ingredient.

D. Methods of preparing and dispensing suppositories

1. Molded suppositories are prepared by first melting the base and then incorporating the medications uniformly into the base. This mixture is then poured into the suppository mold (fusion method).

2. Hand-rolled suppositories require a special technique. With proper technique, it is possible to make a preparation equal in quality to the molded suppositories.

3. Containers for the suppositories are determined by the method and base used in preparation. Hand-rolled and molded suppositories should be dispensed in special boxes that prevent the suppositories from coming in contact with each other. Suppositories made using plastic strip molds are easily dispensed in various types of packages.

4. Storage conditions. If appropriate, a “refrigerate” label should appear on the container. Regardless of the base or medication used in the formulation, the patient should be instructed to store the suppositories in a cool, dry place.

E. Examples

1. Example 1

a. Medication order

Naproxen suppository	500 mg
Disp	#12
Sig:	Insert u.d. into rectum

b. Calculations. Each standard adult suppository should weigh 2 g, but it depends on the mold used and should be calibrated before compounding. Also, the displacement must be determined for the added powder.

2 g (total weight) - 0.540 g (weight of base displaced by the 500-mg tablet) per suppository

=	1.46 g cocoa butter per suppository × 13 suppositories
=	18.98 g cocoa butter

c. **Compounding procedure.** The 13 naproxen 500-mg tablets are triturated to a fine powder, using a Wedgwood or porcelain mortar. The 18.98 g cocoa butter base is melted in a beaker, using a water bath. The temperature of the water bath should not exceed 36°C. The powder is then added and stirred until mixed. The mixture is poured into an appropriate rectal suppository mold (about 2 g per suppository) and placed into a refrigerator until the suppositories congeal. Any excess is scraped from the top of the mold, and a suppository box is used for dispensing. A “refrigerate” label is placed on the box.

2. Example 2

a. Medication order

Progesterone	50 mg
Disp	#14
Sig:	1 per vagina once daily on days 14-28 of cycle

b. Calculations. Total weight of each vaginal suppository is 1.9 g. Assuming 50 mg progesterone displaces 50 mg PEG base:
50 mg progesterone/suppository × 15 = 750 mg progesterone
1.9 g (total weight) - 0.050 g progesterone
= 1.85 g PEG × 15 suppositories
= 27.75 g PEG total

c. **Compounding procedure.** The PEG is melted to 55-57°C, and 750 mg progesterone is added. This mixture is poured into a vaginal suppository mold, allowed to cool, cleaned, and dispensed.

XI. PARENTERAL PREPARATIONS

A. General requirements. The extemporaneous compounding of sterile preparations occurs in many pharmacy environments, including community, home healthcare, hospital, and nuclear. Minimum requirements include
1. Proper equipment and supplies
2. Proper facilities, including a laminar-flow clean bench and a clean room or isolation barrier technology equipment
3. Proper documentation of all preparations made
4. Quality control, including batch sterility testing
5. Proper storage both at the facility and in transport to the patient's home
6. Proper labeling of the prescription preparation
7. Knowledge of product's/preparation's stability and incompatibilities
8. Knowledge of all ancillary equipment involved in compounding or delivery of the medications

B. Compounding of parenteral preparations

1. Compounding of sterile preparations, including intravenous admixtures, requires special skills and training. Compounding parenteral preparations or providing this service without proper training should not be attempted.
2. These preparations must be compounded in a clean environment, using aseptic technique (i.e., working under controlled conditions to minimize contamination).
3. Dry powders of parenteral drugs for reconstitution are used for drug products or preparations that are unstable as solutions. It is important to know the correct diluents that can be used to yield a solution.
4. Solutions of drugs for parenteral administration may also be further diluted before administration. If further dilution is required, then the pharmacist must know the stability and compatibility of the drug in the diluent.

C. Reconstitution of a dry powder from a vial

1. Work takes place in a clean-air environment, observing aseptic technique.
2. The manufacturer's instructions should be checked to determine the required volume of diluent.
3. The appropriate needle size and syringe are chosen, keeping in mind that the capacity of the syringe should be slightly larger than the volume required for reconstitution.
4. Using the correct diluent, the surface of the container is cleaned, using an alcohol prep pad, after which the alcohol is permitted to evaporate.
5. The syringe is filled with the diluent to the proper volume.
6. The surface of the vial containing the sterile powder is cleaned, using an alcohol prep pad, after which it is permitted to dry. The diluent is injected into the vial containing the dry powder.
7. The vial is gently shaken or rolled, and the powder is allowed to dissolve.
8. After the powder has dissolved, the vial is inverted and the desired volume is withdrawn.
9. The vehicle is prepared by swabbing the medication port of the bag or bottle with an alcohol prep pad.

10. The solution in the syringe is injected into the vehicle. If a plastic container is used, care must be taken not to puncture the side walls of the container with the tip of the needle.
11. The container should be shaken or kneaded or rotated to ensure thorough mixing of the contents.
12. The contents of the container should be checked for particulate matter.
13. A sterile seal or cap is applied over the port of the container.
14. All needles and syringes should be properly discarded.
15. The bag is labeled.

D. Removing the fluid contents from an ampule

1. The ampule is held upright to open it, and the top is tapped to remove any solution trapped in this area.
2. The neck of the ampule is swabbed with an alcohol swab.

3. The ampule is grasped on each side of the neck with the thumb and index finger of each hand and quickly snapped open.
4. A 5-µm filter needle is attached to a syringe of the appropriate size.
5. The ampule is tilted, and the needle is inserted.
6. The needle is positioned near the neck of the ampule, and the solution is withdrawn from the ampule.
7. If the solution is for an intravenous push (bolus injection), the filter needle is removed from the syringe and replaced with a cap.
8. If the solution is for an intravenous infusion, then the filter needle is removed and replaced with a new needle of the appropriate size. The drug is injected into the appropriate vehicle.
9. All materials should be discarded properly, and the final product or preparation should be labeled.

E. Removing drug solution from a vial

1. The tab around the rubber closure on the vial is removed, and this surface is swabbed with an alcohol prep pad.
2. An equivalent amount of sterile air is injected into the vial to prevent a negative vacuum from being created and to allow the drug to be removed.
3. Using the appropriate needle size and syringe, the needle is inserted into the rubber closure.
4. The plunger is pushed down, and air is released into the vial; when the plunger is pulled back, the solution is withdrawn.
5. The solution is then injected into the appropriate vehicle.

F. Examples

1. Example 1

a. Medication order

Progesterone	5 g
Benzyl alcohol	10 mL
Sesame oil, qs	100 mL

b. Compounding procedure. Dissolve the progesterone in the benzyl alcohol. Add sufficient sesame oil to make 100 mL. Sterilize by filtration through a sterile 0.2-µm filter or by dry heat (170°C for 1.5 hr). Package in sterile vials and label.

2. Example 2

a. Medication order

Fentanyl (as the citrate)	2 mg
Bupivacaine hydrochloride	125 mg
0.9% sodium chloride injection, qs	100 mL

b. Calculations. Since 157 µg fentanyl citrate is equivalent to 100 µg fentanyl, the quantity of fentanyl citrate required is (157/100) × 2 mg = 3.14 mg fentanyl citrate. This is the quantity of fentanyl citrate that would be required if compounding as a high-risk preparation from bulk powders. It would also require 125 mg bupivacaine, and the remainder is the 0.9% sodium chloride injection. However, commercial products are available so we can calculate how much of each might be required using fentanyl 50 µg/mL injection and bupivacaine hydrochloride 0.5% injection.

$$2 \text{ mg fentanyl} = 2{,}000 \text{ µg}$$

$$\frac{2000 \text{ µg}}{50 \text{ µg/mL}} = 40 \text{ mL of fentanyl injection}$$

Bupivacaine hydrochloride 0.5% injection contains 500 mg/100 mL; therefore,

$$\frac{500}{100} = \frac{125}{x}; \; x = 25 \text{ mL}$$

If 40 mL of fentanyl injection is used, and 25 mL of bupivacaine hydrochloride injection is used, then 40 + 25 = 65 mL; the quantity of 0.9% sodium chloride injection required is 100 mL - 65 mL = 35 mL. Note: **If the order is to be filled in a 20-**mL **pump with delivery for 30 days, what is the delivery rate in** µL**/hr?**

$$\frac{20 \text{ mL}}{30 \text{ days}} = 0.667 \text{ mL/day}$$

$$\frac{0.667 \text{ mL/day}}{24 \text{ hr}} = 0.0277 \text{ mL/hr}$$

$$0.0277 \text{ mL} \times 1000 \text{ µL/mL} = 27.7 \text{ µL/hr}$$

c. **Compounding procedure.** Using commercially available injections, accurately measure the volume of each and fill into a sterile ambulatory pump reservoir. An air bubble can be injected and used to thoroughly mix the solution. Remove the air from the reservoir, and tightly seal/close the outlet. Label.

3. Example 3

a. Medication order

Morphine sulfate	5 g
Citric acid	100 mg
Sodium chloride, qs to isotonic	
Methylparaben	150 mg
Sterile water for injection, qs	100 mL

b. Calculations. Using a sodium chloride equivalent of 0.09 for a 5% morphine sulfate solution, 0.18 for citric acid, 1 for sodium chloride, and ignoring the methylparaben, the calculations can be made as follows:

5 g morphine sulfate is equivalent to 450 mg sodium chloride (5 g × 0.09 = 450 mg).

100 mg citric acid is equivalent to 18 mg sodium chloride (100 mg × 0.18 = 18)

450 mg + 18 mg = 468 mg

To be isotonic, the solution needs the equivalent of 900 mg of sodium chloride in the 100 mL: 900 mg - 468 mg = 432 mg sodium chloride needs to be added.

c. **Compounding procedure.** Dissolve the methylparaben in about 90 mL of sterile water for injection. A small amount of heat may be required. Cool the solution to room temperature; then add the morphine sulfate, citric acid, and sodium chloride. Add sufficient sterile water for injection to volume and mix well. Sterilize by filtration through a sterile 0.2-µm filter into a sterile vial or reservoir. Package and label.

4. Example 4

a. Medication order

Mefoxitin	1 g
Diluent to final concentration of 125 mg/mL	

b. Calculations. A 1-g vial of Mefoxin (cefoxitin for injection) is reconstituted with 10 mL of diluent to provide for approximate withdrawal of 10.5 mL and an approximate average concentration of 95 mg/mL. **What quantity of diluent should be added to provide an approximate average concentration of 125** mg/mL?

$$10.5\ \text{mL} - 10\ \text{mL} = 0.5\ \text{mL occupied by the powder}$$
$$\frac{1000\ \text{mg}}{125\ \text{mg/mL}} = 8\ \text{mL total volume}$$
$$8\ \text{mL} - 0.5\ \text{mL} = 7.5\ \text{mL diluent to be added}$$

c. **Compounding procedure.** Aseptically, withdraw 7.5 mL of diluent and inject into the vial to be reconstituted, using an appropriate vented needle. Gently swirl until dissolved.

P.119

STUDY QUESTIONS

Directions for questions 1-3: Each question or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer. The following medication order is given to the pharmacist by the physician.

Olive oil	60.0 mL
Vitamin A	60,000 units
Water	120.0 mL
Sig:	15 mL t.i.d.

1. The final dosage form of this prescription will be

(A) a solution.

(B) an elixir.

(C) an emulsion.

(D) a suspension.

(E) a lotion.

View Answer***1. The answer is C[see].*****2. When preparing this prescription, the pharmacist needs to add**

(A) Tween 80.

(B) acacia.

(C) glycerin.

(D) alcohol.

(E) propylene glycol.

View Answer***2. The answer is B[see].*****3. Which of the following caution labels should the pharmacist affix to the container when dispensing this preparation?**

(A) Do not refrigerate.

(B) Shake well.

(C) For external use only.

(D) No preservatives added.

View Answer***3. The answer is B[see].For 1-3:*****Directions for questions 4-9:** Each question or statement in this section can be correctly answered or completed by **one or more** of the suggested answers or phrases. Choose the correct answer, A-E:

4. Which statements about the following prescription are correct?

Morphine	1 mg/mL
Flavored vehicle, qs ad	120 mL
Sig:	5-20 mg p.o. q
	3-4 hours prn pain

I. The amount of morphine needed is 240 mg.

II. Powdered morphine alkaloid should be used when compounding this prescription.

III. The final dosage form of this prescription is a solution.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***4. The answer is B[see].*****5. When preparing the following prescription, the pharmacist should**

Podophyllum	5%
Salicylic acid	10%
Acetone	20%
Flexible collodion, ad	30 mL
Sig:	Apply q h.s.

I. triturate 1.5 g **of podophyllum with the 8** mL **of acetone.**
II. add 3 g **of salicylic acid to the collodion with trituration.**
III. affix an "external use only" label to the container.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***5. The answer is B[see].***P.120

6. Which statements about the following prescription are correct?

Sulfur	6 g
Purified water	
Camphor water, aa qs ad	60

I. Precipitated sulfur can be used to prepare this prescription.
II. The sulfur can be triturated with glycerin before mixing with other ingredients.
III. A "shake well" label should be affixed to the bottle.
A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***6. The answer is E[seeand].***7. **Which statements about the following prescription are correct?**

Starch	10%
Menthol	1%
Camphor	2%
Calamine, qs ad	120

I. The powders should be blended together in a mortar, using geometric dilution.

II. The prescription should be prepared by dissolving the camphor in a sufficient amount of 90% alcohol.

III. A eutectic mixture should be avoided.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***7. The answer is A[see].***8. **When preparing the following prescription, the pharmacist should**

Salicylic acid	3 g
Sulfur ppt	7 g
Lanolin	10 g
White petrolatum	10 g

I. reduce the particle size of the powders, using a mortar and pestle or using the pill tile with a spatula.
II. place on an ointment tile and levigate the ingredients, using geometric dilution.
III. package the ointment in an ointment jar or tube.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***8. The answer is E[seeand].*****9. An equal volume of air is injected when removing drug solutions from**
I. vials.
II. ampules.
III. syringes.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***9. The answer is A[see].***P.121

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* V.B.1.*].*
2. The answer is B *[see* V.B.2; V.C.1*].*
3. The answer is B *[see* V.B.3*].*
For 1-3: Because olive oil and water are two immiscible liquids, their incorporation requires a two-phase system in which one liquid is dispersed throughout another liquid in the form of small droplets. To accomplish this, an emulsifying agent is

necessary. Acacia is the most suitable emulsifying agent when forming an oil-in-water emulsion that is intended for internal use.

Emulsions are physically unstable, and they must be protected against the effects of microbial contamination and physical separation. Shaking before use redistributes the two layers of emulsion. Because light, air, and microorganisms also affect the stability of an emulsion, preservatives can be added.

4. The answer is B (III) *[see* III.A.C.3*].*

The concentration of morphine needed for the prescription described in the question is 1 mg/mL, and because 120 mL is the final volume, 120 mg of morphine is needed to compound this prescription. Morphine alkaloid has poor solubility; therefore, one of the salt forms should be used. Because morphine is dissolved in the vehicle, resulting in a liquid preparation, the final dosage form is a solution.

5. The answer is B (III) *[see* III.C.1.; III.C.5; III.D.3*].*

Calculating for the amount of each ingredient of the prescription in the question requires 1.5 g of podophyllum, 3 g of salicylic acid, and 6 mL of acetone. The correct procedure would be to triturate the podophyllum with the acetone, then add the triturated salicylic acid to a calibrated bottle containing the podophyllum and acetone. Flexible collodion is then added up to the 30-mL calibration. An “external use only” label should be affixed to the container.

6. The answer is E (I, II, and III) *[see* IV.B.2; IV.C.5; IV.D.1 *and* 2*].*

While precipitated sulfur can be used to prepare the prescription described in the question, it is difficult to triturate; therefore, it must first be levigated with a suitable levigating agent (e.g., glycerin). All suspensions, owing to their instability, require shaking before use to redistribute the insoluble ingredients.

7. The answer is A (I) *[see* VI.C.3; VI.D.1*].*

The proper procedure for compounding the prescription described in the question is to first form a liquid eutectic. This is done by triturating the menthol and camphor together in a mortar. This eutectic is then blended with the powdered starch and calamine, using geometric dilution.

8. The answer is E (I, II, and III) *[see* IX.D.1 *and* 3; IX.E.1*].*

The proper procedure for preparing the prescription given in the question is to reduce the particle size of each powder and mix them together, using geometric dilution. This ensures the proper blending of the powders. Next, this powdered mixture is incorporated, geometrically, with the petrolatum. Then, the lanolin is added geometrically.

9. The answer is A (I) *[see* XI.E.2*].*

An equal volume of air must be injected when removing a drug solution from a vial. This is done to prevent the formation of a vacuum within the vial. This problem does not occur with ampules and syringes containing drug solutions; therefore, it is unnecessary to inject any air when removing them.

Basic Pharmacokinetics

Riccardo L. Boni

Leon Shargel

I. PHARMACOKINETICS

A. INTRODUCTION

1. Pharmacokinetics is the quantitative measurement of drug absorption, distribution, and elimination (i.e., excretion and metabolism) and includes the rate processes for drug movement into the body, within the body, and out of the body.

2. Commonly used units in pharmacokinetics are tabulated in Table 6-1.

3. Rates and orders of reactions. The **rate** of a chemical reaction or pharmacokinetic process is the velocity with which it occurs. **The order** of a reaction is the way in which the concentration of a drug or reactant in a chemical reaction affects the rate.

a. Zero-order reaction. The drug concentration changes with respect to time at a constant rate, according to the following equation:

$$\frac{dC}{dt} = -k_0$$

Table 6-1. Common Units in Pharmacokinetics

Pharmacokinetic Parameter	Abbreviation	Fundamental Units	Units Example
Area under the curve	AUC	Concentration X time	µg X hr/mL
Total body clearance	Cl_T	Volume/time	Liters/hr
Renal clearance	Cl_R	Volume/time	Liters/hr
Hepatic clearance	Cl_H	Volume/time	Liters/hr
Apparent volume of distribution	V_D	Volume	Liters
Volume of distribution at	Vss	Volume	Liters

steady state			
Peak plasma drug concentration	Cmax	Concentration	mg/L
Plasma drug concentration	Cp	Concentration	mg/L
Steady-state drug concentration	Css or Cav	Concentration	mg/L
Time for peak drug concentration	Tmax	Time	hr
Dose	Do	Mass	mg
Loading dose	D_L	Mass	mg
Maintenance dose	D_M	Mass	mg
Amount of drug in the body	D_B	Mass	mg
Rate of drug infusion	R	Mass/time	mg/hr
First order rate constant for drug absorption	ka	1/time	1/hr or hr^{-1}
Zero order rate constant for drug absorption	ko	Mass/time	mg/hr
First order rate constant for drug absorption	K (sometimes referred to as kel)	1/time	1/hr or hr^{-1}

Elimination half-life	$t_{½}$	Time	hr
Fraction of drug absorbed	F	(no units)	Ranges from 0 to 1 (0 to 100%)

where *C* is the drug concentration and k_0 is the **zero-order rate constant** expressed in units of concentration per time (e.g., milligrams per milliliter per hour). Integration of this equation yields the linear (straight-line) equation:

$C = -k_0 t + C_0$

where k_0 is the slope of the line (see Figure 3-5) and C_0 is the *y* intercept, or drug concentration, when time (*t*) equals zero. The negative sign indicates that the slope is decreasing.

b. First-order reaction. The change in drug concentration with respect to time equals the product of the rate constant and the concentration of drug remaining, according to the following equation:

$$\frac{dC}{dt} = -kC$$

where *k* is the first-order rate constant, expressed in units of reciprocal time, or $time^{-1}$ (e.g., 1/hr or hr^{-1}).

(1) Integration of this equation yields the following mathematically equivalent equations:

$$C = C_0 e^{-kt}$$
$$\ln C = -kt + \ln C_0$$
$$\log C = \frac{-kt}{2.3} + \log C_0$$

(2) A graph of the equation in Figure 6-1 shows the linear relation of the log of the concentration versus time. In Figure 6-1, the slope of the line is equal to $-k/2.3$, and the *y* intercept is C_0. The values for *C* are plotted on logarithmic coordinates, and the values for *t* are shown on linear coordinates.

(3) The **half-life ($t_{1/2}$)** of a reaction or process is the time required for the concentration of a drug to decrease by one half. For a first-order reaction or process, the half-life is a constant and is related to the first-order rate constant, according to the following equation:

$$t_{1/2} = \frac{0.693}{k}$$

2. Models and compartments

a. A **model** is a mathematic description of a biologic system and is used to express quantitative relationships.

b. A **compartment** is a group of tissues with similar blood flow and drug affinity. A compartment is not a real physiologic or anatomic region.

3. Drug distribution

a. Drugs distribute rapidly to tissues with high blood flow and more slowly to tissues with low blood flow.

b. Drugs rapidly cross capillary membranes into tissues because of **passive diffusion** and **hydrostatic pressure. Drug permeability** across capillary membranes varies.

(1) Drugs easily cross the capillaries of the glomerulus of the kidney and the sinusoids of the liver.

(2) The capillaries of the brain are surrounded by glial cells that create a **blood-brain barrier,** which acts as a thick lipid membrane. Polar and ionic hydrophilic drugs cross this barrier slowly.

(3) In disease states, membranes may become more permeable to drugs. For example, in meningitis, the blood brain barrier becomes more permeable to the penetration of drugs into brain.

c. **Drugs may accumulate in tissues** as a result of their physicochemical characteristics or special affinity of the tissue for the drug.

(1) Lipid-soluble drugs may accumulate in adipose (fat) tissue because of partitioning of the drug.

(2) Tetracycline may accumulate in bone because complexes are formed with calcium.

d. Plasma protein binding of drugs affects drug distribution.

(1) A drug bound to a protein forms a complex that is too large to cross cell membranes.

(2) Albumin is the major plasma protein involved in drug protein binding. **α_1-Glycoprotein,** also found in plasma, is important for the binding of such basic drugs as propranolol.

(3) Potent drugs, such as phenytoin, that are highly bound (> 90%) to plasma proteins may be displaced by other highly bound drugs. The displacement of the bound drug results in more free (nonbound) drug, which

rapidly reaches the drug receptors and causes a more intense pharmacologic response.

(4) A few hormonal drugs bind to specific plasma proteins. For example, prednisone binding to transcortin (and albumin) results in dose-dependent pharmacokinetics of prednisone. This nonlinear pharmacokinetics is due to saturable protein binding. Transcortin has high affinity and low capacity while albumin has low affinity and a high capacity.

B. One-compartment model

1. Intravenous bolus injection. The entire drug dose enters the body rapidly, and the rate of absorption is neglected in calculations (Figure 6-1). The entire body acts as a single compartment, and the drug rapidly equilibrates with all of the tissues in the body.

a. Drug elimination is a first-order kinetic process, according to the equations in I.A.1.b.

(1) The first-order elimination rate constant (k or k_{el}) is the sum of the rate constants for removal of drug from the body, including the rate constants for renal excretion and metabolism (**biotransformation**) as described by the following equation:

$$k = k_e + k_m$$

where k_e is the rate constant for renal excretion and k_m is the rate constant for metabolism. This equation assumes that all rates are first-order processes.

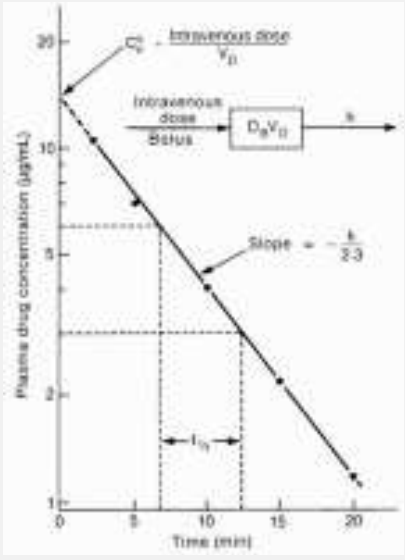


Figure 6-1. Generalized pharmacokinetic model for a drug administered by rapid intravenous bolus injection. , extrapolated drug concentration; V_D, apparent volume of distribution; D_B, amount of drug in the body; k, elimination rate constant; $t_{1/2}$, elimination half-life. [Adapted with permission from Gibaldi M, Perrier D. Pharmacokinetics, 2nd ed. New York, Marcel Dekker, Inc., 1982. Copyright © 1982 Routledge/Taylor & Francis Group, LLC.]

(2) The **elimination half-life ($t_{1/2}$)** is given by the following equation:

$$t_{1/2} = \frac{0.693}{k}$$

b. Apparent volume of distribution (V_D) is the hypothetical volume of body fluid in which the drug is dissolved. This value is not a true anatomic or physical volume.

(1) V_D is needed to estimate the amount of drug in the body relative to the concentration of drug in the plasma, as shown in the following:

$V_D \times C_p = D_B$

where V_D (liters) is the apparent volume of distribution, C_p (mg/liter) is the plasma drug concentration, and D_B (mg) is the amount of drug in the body.

(2) To calculate the V_D after an intravenous bolus injection, the equation is rearranged to give:

$$V_D = \frac{D_B^0}{C_P^0}$$

where is the dose (D_B) of drug given by intravenous bolus and is the extrapolated drug concentration at zero time on the *y* axis, after the drug equilibrates (Figure 6-1).

(3) According to the equation, V_D is increased and is decreased when the drug is distributed more extravascularly into the tissues. When more drug is contained in the vascular space or plasma, is increased and V_D is decreased.

2. Single oral dose. If the drug is given in an oral dosage form (e.g., tablet, capsule), the drug is generally absorbed by first-order kinetics. Elimination of the drug also follows the principles of first-order kinetics (Figure 6-2).

a. The following equation describes the pharmacokinetics of **first-order absorption and elimination:**

$$C_P = \frac{FD_0k_A}{V_D(k_A - k)}(e^{-kt} - e^{-K_At})$$

where k_A is the first-order absorption rate constant and *F* is the fraction of drug bioavailable. Changes in *F,* D_0, V_D, k_A, and *k* affect the plasma drug concentration.

b. The time for maximum, or **peak, drug absorption** is given by the following equations:

$$t_{max} = \frac{2.3 \log (k_A/k)}{k_A - k}$$

where t_{max} depends only on the rate constants k_A and *k,* not on *F,* D_0, or V_D.

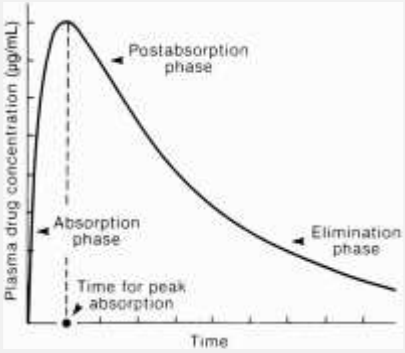

Figure 6-2. Generalized plot for a one-compartment model showing first-order drug absorption and first-order drug elimination. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005.]

c. After t_{max} is obtained, the peak drug concentration (C_{max}) is calculated, using the equation in I.B.2.a and substituting t_{max} for t.

d. The area under the curve (AUC) may be determined by integration of $C_P dt$ using the trapezoidal rule or by the following equation:

$$[AUC]_0^\infty = \int_0^\infty C_P \, dt = \frac{FD_0}{V_D k}$$

changes in F, D_0, k, and V_D affect the AUC. Minor changes in k_A do not affect the AUC.

e. To obtain , obtain the [AUC] from 0 to t by the trapezoidal rule and add on the extrapolated section of AUC, which is the last measurable drug concentration at time t divided by the slope of the terminal elimination curve, as shown in the following equation:

$$[AUC]_0^\infty = [AUC]_0^t + \frac{C_{P,t}}{k}$$

f. Lag time occurs at the beginning of systemic drug absorption. For some individuals, systemic drug absorption is delayed after oral drug administration because of delayed stomach emptying or other factors.

3. Intravenous infusion

a. Intravenous infusion is an example of zero-order absorption and first-order elimination (Figure 6-3).

b. A few oral controlled-release drug products release the drug by zero-order kinetics and have **zero-order systemic absorption.**

c. The plasma drug concentration at any time after the start of an intravenous infusion is given by the following equation:

$$C_p = \frac{R}{V_D k}(1 - e^{-kt})$$

where *R* is the zero-order rate of infusion given in units as milligrams per hour or milligrams per minute.

d. If the intravenous infusion is discontinued, the plasma drug concentration declines by a first-order process. The elimination half-life, or elimination rate constant, *k,* may be obtained from the declining plasma drug concentration versus time curve.

e. As the drug is infused, the plasma drug concentration increases to a plateau, or **steady-state concentration (C_{SS}).**

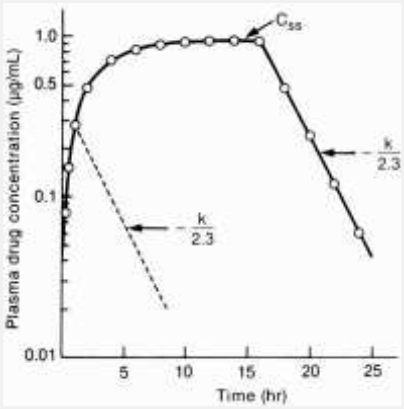

Figure 6-3. Generalized semilogarithmic plot for a drug showing zero-order absorption and first-order elimination. C_{ss}, steady-state concentration; *k,* elimination rate constant. [Adapted with permission from Gibaldi M, Perrier D. Pharmacokinetics, 2nd ed. New York, Marcel Dekker, Inc., 1982. Copyright © 1982 Routledge/Taylor & Francis Group, LLC.]

(1) Under steady-state conditions, the fraction of drug absorbed equals the fraction of drug eliminated from the body.

(2) The plasma concentration at steady state (C_{ss}) is given by the following equation:

$$C_{SS} = \frac{R}{V_D k} = \frac{R}{Cl_T}$$

Where, Cl_T is total body clearance (see Section I.E.)

(3) The rate of drug infusion (R) may be calculated from a rearrangement of the equation if the desired C_{ss}, the V_D, and the k are known. These values can often be obtained from the drug literature. To calculate the rate of infusion, the following equation is used:

$R = C_{ss}\ V_D k = C_{ss}\ Cl_T$

where C_{ss} is the desired (target) plasma drug concentration and Cl_T is total body clearance.

f. A **loading dose (D_L)** is given as an initial intravenous bolus dose to produce the C_{ss} as rapidly as possible. The intravenous infusion is started at the same time as the D_L.

(1) The time to reach C_{ss} depends on the elimination half-life of the drug. Reaching 90%, 95%, or 99% of the C_{ss} without a D_L takes 3.32, 4.32, or 6.65 half-lives, respectively. Thus, for a drug with an elimination $t_{1/2}$ of 8 hr, it will take 3.32 × 8 hr, or 26.56 hr, to reach 90% of C_{ss} if no loading dose is given.

(2) The D_L is the amount of drug that, when dissolved in the apparent V_D, produces the desired C_{ss}. Thus D_L is calculated by the following equation:

$$D_L = C_{ss}V_D \text{ and } D_L = \frac{R}{k}$$

g. An intravenous infusion provides a relatively constant plasma drug concentration and is particularly useful for drugs that have a narrow therapeutic range. The IV infusion keeps the plasma drug concentration between the minimum toxic concentration (MTC) and the minimum effective concentration (MEC).

4. Intermittent intravenous infusions

a. Intermittent intravenous infusions are infusions in which the drug is infused for short periods to prevent accumulation and toxicity.

b. Intermittent intravenous infusions are used for a few drugs, such as the aminoglycosides. For example, gentamicin may be given as a 1-hr infusion every 12 hr. In this case, steady-state drug concentrations are not achieved.

c. The peak drug concentration in the plasma for a drug given by intermittent intravenous infusion may be calculated by the following equation:

$$C_{p,n} = \frac{R(1 - e^{-kt})(1 - e^{-nk\tau})}{Cl(1 - e^{-k\tau})}$$

where $C_{p,n}$ is the peak drug concentration, R is the rate of drug infusion, Cl is total body clearance, k is the dosage interval, n is the number of infusions, t is the time for the infusion, and τ is the dosage interval.

5. Multiple doses. Many drugs are given intermittently in a multiple-dose regimen for continuous or prolonged therapeutic activity. This regimen is often used to treat chronic disease.

a. If drug doses are given frequently before the previous dose is completely eliminated, then plasma drug concentrations accumulate and increase to a steady-state level.

b. At **steady state,** plasma drug concentration fluctuates between a maximum () and a minimum () value (Figure 6-4).

c. When a multiple-dose regimen is calculated, the **superposition principle** assumes that previous drug doses have no effect on subsequent doses. Thus the predicted plasma drug concentration is the total plasma drug concentration obtained by adding the residual drug concentrations found after each previous dose.

d. When a multiple-dose regimen is designed, only the **dosing rate** (D_0/τ) can be adjusted easily.

(1) The dosing rate is based on the **size of the dose** (D_0) and the **interval (τ) between doses,** or the **frequency of dosing.**

P.128

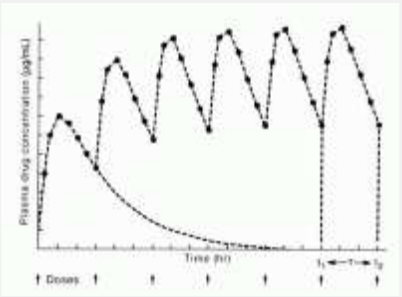

Figure 6-4. Generalized plot showing plasma drug concentration levels after administration of multiple doses and levels of accumulation when equal doses are given at equal time intervals. τ, time interval between doses (*t*), or the frequency of dosing. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005]

(2) The dosing rate is given by the following equation:

$$\text{Dosing rate} = \frac{D_0}{\tau}$$

(3) As long as the dosing rate is the same, the expected **average drug concentration at steady state** () is the same (Figure 6-4).

(a) For example, if a 600-mg dose is given every 12 hr, the dosing rate is 600 mg/12 hr, or 50 mg/hr.

(b) A dose of 300 mg every 6 hr or 200 mg every 4 hr also gives the same dosing rate (50 mg/hr), with the same expected . However, the and values will be different.

(c) For a larger dose given over a longer interval (e.g., 600 mg every 12 hr), the is higher and the lower compared with a smaller dose given more frequently (e.g., 200 mg every 4 hr).

e. Certain antibiotics are given by **multiple rapid intravenous bolus injections.**

(1) The peak, or **maximum, serum drug concentration** at steady state may be estimated by the following equation:

$$C_{max}^{\infty} = \frac{\frac{D_0}{V_D}}{1 - e^{-k\tau}}$$

(2) The **minimum serum drug concentration** () at steady state is the drug concentration after the drug declines one dosage interval. Thus is determined by the following equation:

$$C_{max}^{\infty} = \frac{\frac{D_0}{V_D}}{1 - e^{-k\tau}}$$

(3) The **average drug concentration** () at steady state is estimated with the equation used for multiple oral doses:

$$C_{Av}^{\infty} = \frac{FDo}{kV_D\tau}$$

For intravenous bolus injections, $F = 1$.

P.129

f. Orally administered drugs given in **immediate-release dosage forms** (e.g., solutions, conventional tablets, capsules) by multiple oral doses are usually rapidly absorbed and slowly eliminated ($k_A \geq k$). and for these drugs are approximated by the equations shown in I.B.5.e.(1) and (2).

(1) For more exact calculations of and after multiple oral doses, the following equations are used:

$$C_{max}^{\infty} = \frac{FD_O k_A}{V_D(k_A - k)}\left(\frac{1}{1 - e^{-k\tau}}\right) \text{ and}$$

$$C_{min}^{\infty} = \frac{FD_O k_A}{V_D(k_A - k)}\left(\frac{1}{1 - e^{-k\tau}}\right)e^{-k\tau}$$

(2) The calculation of is the same as for multiple intravenous bolus injections, using the equation shown in I.B.5.e.(3).

(3) The term $1/(1 - e^{-k\tau})$ is known as the **accumulation rate.**

(4) The fraction of drug remaining in the body (f) after a dosage interval is given by the following equation:

$f = e^{-k\tau}$

g. Loading dose. An initial loading dose (D_L) is given to obtain a therapeutic steady-state drug level quickly.

(1) For multiple oral doses, D_L is calculated by:

$$D_L = D_M \frac{1}{1 - e^{-k\tau}}$$

where D_M is the maintenance dose.

(2) If D_M is given at a dosage interval equal to the elimination half-life of the drug, then D_L equals twice the maintenance dose.

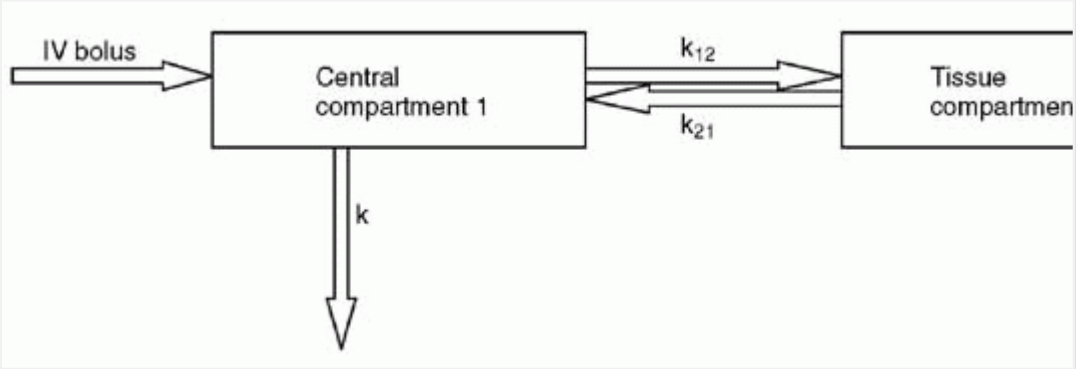
C. Multicompartment models

1. Drugs that exhibit multicompartment pharmacokinetics distribute into different tissue groups at different rates. Tissues with high blood flow equilibrate with a drug more rapidly than tissues with low blood flow. Drug concentration in various tissues depends on the physical and chemical

characteristics of the drug and the nature of the tissue. For example, highly lipid-soluble drugs accumulate slowly in fat (lipid) tissue.

2. Two-compartment model (intravenous bolus injection)

a. After an intravenous bolus injection, the drug distributes and equilibrates rapidly into highly perfused tissues (**central compartment**) and more slowly into peripheral tissues (**tissue compartment**).



b. The initial rapid decline in plasma drug concentration is known as the **distribution phase.** The slower rate of decline in drug concentration after complete equilibration is achieved is known as the **elimination phase** (Figure 6-5).

P.130

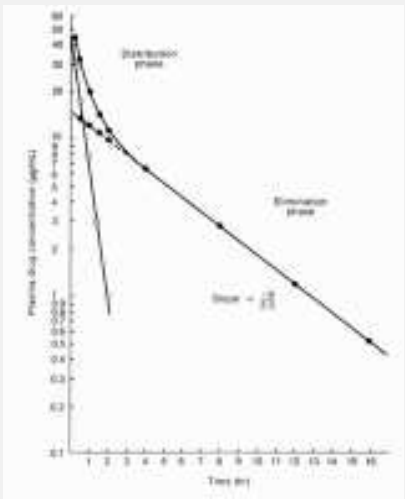


Figure 6-5. Generalized plot showing drug distribution and equilibration for a two-compartment model (intravenous bolus injection). The distribution phase is the initial rapid decline in plasma drug concentration. The elimination phase is the slower rate of decline after complete equilibration of the drug is achieved. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005.]

c. The **plasma drug concentration** at any time is the sum of two first-order processes, as given in the following equation:

$C_p = Ae^{-at} + Be^{-bt}$

where *a* and *b* are hybrid first-order rate constants and *A* and *B* are *y* intercepts.

(1) The **hybrid first-order rate constant *b*** is obtained from the slope of the elimination phase of the curve (Figure 6-5) and represents the first-order elimination of drug from the body after the drug equilibrates with all tissues.

(2) The **hybrid first-order rate constant *a*** is obtained from the slope of the residual line of the distribution phase after the elimination phase is subtracted.

d. The **apparent volume of distribution** depends on the type of pharmacokinetic calculation. Volumes of distribution include the volume of the central compartment (V_p), the volume of distribution at steady state (V_{ss}), and the volume of the tissue compartment (V_t).

3. Two-compartment model (oral drug administration)

a. A drug with a rapid distribution phase may not show two-compartment characteristics after oral administration. As the drug is absorbed, it equilibrates with the tissues so that the elimination half-life of the elimination portion of the curve equals 0.693/*b*.

b. Two-compartment characteristics are seen if the drug is absorbed rapidly and the distribution phase is slower.

4. Models with additional compartments

a. The addition of each new compartment to the model requires an additional first-order plot.

b. The addition of a third compartment suggests that the drug slowly equilibrates into a deep tissue space. If the drug is given at frequent intervals, the drug begins to accumulate into the third compartment.

c. The terminal linear phase generally represents the elimination of the drug from the body after equilibration occurs. The rate constant from the elimination phase is used to calculate dosage regimens.

d. Adequate pharmacokinetic description of multicompartment models is often difficult and depends on proper plasma sampling and determination of drug concentrations.

5. Elimination rate constants

a. The elimination rate constant, *k,* represents drug elimination from the central compartment.

b. The terminal elimination rate constant (λ or *b* in the two-compartment model) represents drug elimination after drug distribution is mostly completed.

D. Nonlinear pharmacokinetics are also known as capacity-limited, dose-dependent, or saturation pharmacokinetics. Nonlinear pharmacokinetics do not follow first-order kinetics as the dose increases (Figure 6-6). Nonlinear

pharmacokinetics may result from the saturation of an enzymeor carrier-mediated system.

1. Characteristics of nonlinear pharmacokinetics include

a. The AUC is not proportional to the dose.

b. The amount of drug excreted in the urine is not proportional to the dose.

c. The elimination half-life may increase at high doses.

d. The ratio of metabolites formed changes with increased dose.

2. Michaelis-Menten kinetics describe the velocity of enzyme reactions. Michaelis-Menten kinetics are used to describe nonlinear pharmacokinetics.

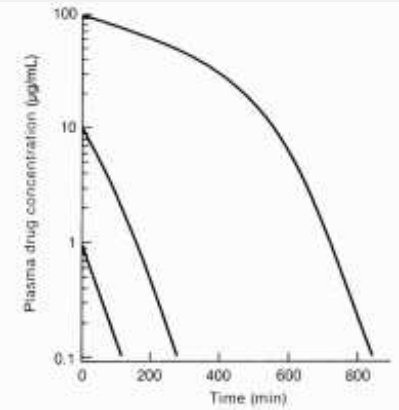

Figure 6-6. Generalized plot showing plasma drug concentration versus time for a drug with Michaelis-Menten (nonlinear) elimination kinetics. For this one-compartment model (intravenous injection), the doses are 1 mg, 10 mg, and 100 mg; and the apparent in vivo rate constant (k_M) is 10 mg. The maximum velocity of the reaction (V_{max}) is 0.2 mg/min. [Adapted with permission from Gibaldi M, Perrier D. Pharmacokinetics, 2nd ed. New York, Marcel Dekker, Inc., 1982. Copyright © 1982 Routledge/Taylor & Francis Group, LLC.]

a. The **Michaelis-Menten equation** describes the rate of change (velocity) of plasma drug concentration after an intravenous bolus injection, as follows:

$$\frac{dC_p}{dt} = \frac{-V_{max}C_p}{k_M + Cp}$$

where V_{max} is the maximum velocity of the reaction, C_p is the substrate or plasma drug concentration, and k_M is the Michaelis constant equal to the C_p at 0.5 V_{max}.

b. At low C_p values, where $C_p << k_M$, this equation reduces to a first-order rate equation because both k_M and V_{max} are constants.

$$\frac{dC_p}{dt} = \frac{-V_{max}C_p}{k_M} = -k'C_p$$

c. At high C_p values, where $C_p >> k_M$, the Michaelis-Menten equation is a zero-order rate equation, as follows:

$$\frac{dC_p}{dt} = -V_{max}$$

3. Drugs that follow nonlinear pharmacokinetics may show zero-order elimination rates at high drug concentrations, fractional-order elimination rates at intermediate drug concentrations, and first-order elimination rates at low drug concentrations (Figure 6-6).

E. Clearance is a measurement of drug elimination from the body. Units for clearance are volume per time (e.g., liters per hour).

1. Total body clearance (Cl_T) is the drug elimination rate divided by the plasma drug concentration. According to the concept of clearance, the body contains an apparent volume of distribution in which the drug is dissolved. A constant portion of this volume is cleared, or removed, from the body per unit time.

a. The following equations express the measurement of total body clearance:

$$Cl_T = \frac{\text{drug elimination}}{\text{plasma drug concentration}} = \frac{(dDe/dt)}{Cp}$$

$$Cl_T = V_D k$$

$$Cl_T = \frac{FD_0}{AUC}$$

b. For drugs that follow first-order (linear) pharmacokinetics, total body clearance is the sum of all the clearances in the body, as shown in the following equation:

$CL_T = CL_R + Cl_{NR}$

where CL_R is renal clearance and Cl_{NR} is nonrenal clearance. Nonrenal clearance, Cl_{NR}, is often equated with hepatic clearance, Cl_H.

c. The relation between Cl_T and $t_{1/2}$ is obtained by substituting $0.693/t_{1/2}$ for k in the equation in I.E.1 a to obtain the following expression:

$$t_{1/2} = \frac{0.693 V_D}{Cl_T}$$

where V_D and Cl_T are considered independent variables, and $t_{1/2}$ is considered a dependent variable.

d. As clearance decreases (e.g., in renal disease), $t_{½}$ increases. Changes in V_D also cause proportional changes in $t_{½}$.

2. Renal drug excretion is the major route of drug elimination for polar drugs, water-soluble drugs, drugs with low molecular weight (< 500), and drugs that are biotransformed slowly. The relation between the drug excretion rate and the plasma drug concentration is shown

in Figure 6-7. Drugs are excreted through the kidney into the urine by glomerular filtration, tubular reabsorption, and active tubular secretion.

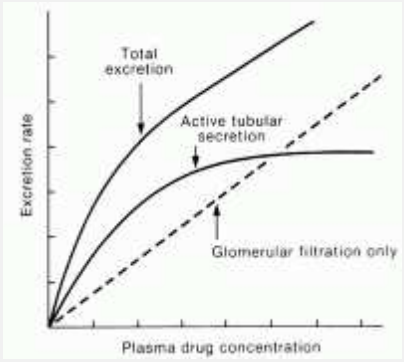

Figure 6-7. Generalized plot showing the excretion rate versus plasma drug concentration for a drug with active tubular secretion and for a drug secreted by glomerular filtration only. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005.]

a. Glomerular filtration is a passive process by which small molecules and drugs are filtered through the glomerulus of the nephron.

(1) Drugs bound to plasma proteins are too large to be filtered at the glomerulus.

(2) Drugs such as **creatinine and inulin** are not actively secreted or reabsorbed. They are used to measure the **glomerular filtration rate (GFR).**

b. Tubular reabsorption is a passive process that follows Fick's law of diffusion.

(1) Lipid-soluble drugs are reabsorbed from the lumen of the nephron back into the systemic circulation.

(2) For weak electrolyte drugs, urine pH affects the ratio of nonionized and ionized drug.

(a) If the drug exists primarily in the nonionized or lipid-soluble form, then it is reabsorbed more easily from the lumen of the nephron.

(b) If the drug exists primarily in the ionized or water-soluble form, then it is excreted more easily in the urine.

(c) Depending on the pK_a of the drug, alteration of urine pH alters the ratio of ionized to nonionized drug and affects the rate of drug excretion. For example, alkalinization of the urine by the administration of sodium bicarbonate increases the excretion of salicylates (weak acids) into the urine.

(3) An increase in urine flow caused by simultaneous administration of a diuretic decreases the time for drug reabsorption. Consequently, more drug is excreted if given with a diuretic.

c. **Active tubular secretion** is a carrier-mediated active transport system that requires energy.

(1) Two active tubular secretion pathways exist in the kidney: one system for weak acids and one system for weak bases.

(2) The active tubular secretion system shows competition effects. For example, **probenecid** (a weak acid) competes for the same system as

penicillin, decreasing the rate of penicillin excretion, resulting in a longer penicillin $t_{1/2}$.

(3) The renal clearance of drugs that are actively secreted, such as ***p*-aminohippurate (PAH),** is used to measure **effective renal blood flow (ERBF).**

3. Renal clearance is the volume of drug contained in the plasma that is removed by the kidney per unit time. **Units for renal clearance** are expressed in volume per time (e.g., milliliters per minute or liters per hour).

a. Renal clearance may be measured by dividing the rate of drug excretion by the plasma drug concentration, as shown in the following equation:

$$Cl_R = \frac{\text{rate of drug excretion}}{C_p} = \frac{\frac{dD_u}{dt}}{C_p}$$

b. Measurement of renal clearance may also be expressed by the following equation:

$Cl_R = k_e V_D$

where k_e is the first-order renal excretion rate constant and

$$Cl_R = \frac{D_u^\infty}{\text{AUC}}$$

where is the total amount of parent (unchanged) drug excreted in the urine.

c. Renal clearance is measured without regard to the physiologic mechanism of renal drug excretion. The probable mechanism for renal clearance is obtained with a **clearance ratio,** which relates drug clearance to inulin clearance (a measure of GFR).

(1) If the clearance ratio is < 1.0, the mechanism for drug clearance may result from filtration plus reabsorption.

(2) If the ratio is 1.0, the mechanism may be filtration only.

(3) If the ratio is > 1.0, the mechanism may be filtration plus active tubular secretion.

4. Hepatic clearance is the volume of plasma containing drug that is cleared by the liver per unit time.

a. Measurement of hepatic clearance. Hepatic clearance is usually measured indirectly, as the difference between total body clearance and renal clearance, as shown in the following equation:

$Cl_H = Cl_T - Cl_R$

where Cl_H is the hepatic clearance. Hepatic clearance is generally considered to be equivalent to Cl_{NR}, or nonrenal drug clearance. Hepatic clearance can also be calculated as the **product of the liver blood flow (*Q*)** and the **extraction ratio (ER),** as shown in the following equation:

$Cl_H = Q(ER)$

(1) The **extraction ratio** is the fraction of drug that is irreversibly removed by an organ or tissue as the plasma-containing drug perfuses that tissue.
(2) The extraction ratio is obtained by measuring the plasma drug concentration entering the liver and the plasma drug concentration exiting the liver:

$$ER = \frac{C_a - C_v}{C_a}$$

where C_a is the arterial plasma drug concentration entering the liver and C_v is the venous plasma drug concentration exiting the liver.
(3) Values for the ER range from 0 to 1. For example, if the ER is 0.9, then 90% of the incoming drug is removed as the plasma perfuses the liver. If the ER is 0, then no drug is removed by the liver.
b. Blood flow, intrinsic clearance, and **protein binding** affect hepatic clearance.
(1) Blood flow to the liver is approximately 1.5 L/min and may be altered by exercise, food, disease, or drugs.
(a) Blood enters the liver through the hepatic portal vein and hepatic artery and leaves through the hepatic vein.
(b) After oral drug administration, the drug is absorbed from the gastrointestinal tract into the mesenteric vessels and proceeds to the hepatic portal vein, liver, and systemic circulation.
(2) Intrinsic clearance, Cl_{int} describes the ability of the liver to remove the drug independently of blood flow.
(a) Intrinsic drug clearance primarily occurs because of the inherent ability of the **biotransformation enzymes** (mixed-function oxidases) to metabolize the drug as it enters the liver.
(b) Normally, basal level mixed-function oxidase enzymes biotransform drugs. Levels of these enzymes may be increased by various drugs (e.g., phenobarbital) and environmental agents (e.g., tobacco smoke). These enzymes may be inhibited by other drugs and environmental agents (e.g., cimetidine, acute lead poisoning).

(3) Protein binding. Drugs that are bound to protein are not easily cleared by the liver or kidney because only the free, or nonplasma protein-bound, drug crosses the cell membrane into the tissue.
(a) The free drug is available to drug-metabolizing enzymes for biotransformation.
(b) A sudden increase in free-drug plasma concentration results in more available drug at pharmacologic receptors, producing a more intense effect in the organs (e.g., kidney, liver) involved in drug removal.

(c) Blood flow (*Q*), intrinsic clearance (Cl_{int}), and fraction of free drug in plasma (***f***) are related to hepatic clearance as shown in the following equation:

$$Cl_H = Q\left(\frac{fCl_{int}}{Q + fCl_{int}}\right)$$

(1) The hepatic clearance of drugs that have high extraction ratios and high Cl_{int} values (e.g., propranolol) is most affected by changes in blood flow and inhibitors of the drug metabolism enzymes.
(2) The hepatic clearance of drugs that have low extraction ratios and low Cl_{int} values (e.g., theophylline) is most affected by changes in Cl_{int} and is affected only slightly by changes in hepatic blood flow.
(3) Only drugs that are highly plasma protein bound (i.e., > 95%) and have a low intrinsic clearance (e.g., phenytoin) are affected by a sudden shift in protein binding. This shift causes an increase in free-drug plasma concentration.
c. **Biliary drug excretion,** an active transport process, is also included in hepatic clearance. Separate active secretion systems exist for weak acids and weak bases.
(1) Drugs that are excreted in bile are usually high molecular weight compounds (i.e., > 500) or polar drugs, such as reserpine, digoxin, and various glucuronide conjugates.
(2) Drugs may be recycled by the **enterohepatic circulation.**
(a) Some drugs are absorbed from the gastrointestinal tract through the mesenteric and hepatic portal veins, proceeding to the liver. The liver may secrete some of the drug (unchanged or as a glucuronide metabolite) into the bile.
(b) The bile and drug are stored in the gallbladder and will empty into the gastrointestinal tract through the bile duct and then may be reabsorbed.
(c) If the drug is a **glucuronide metabolite,** bacteria in the gastrointestinal tract may hydrolyze the glucuronide moiety, allowing the released drug to be reabsorbed.
d. First-pass effects (presystemic elimination) occur with drugs given orally. A portion of the drug is eliminated before systemic absorption occurs.
(1) First-pass effects generally result from rapid drug biotransformation by liver enzymes. Other mechanisms include metabolism of the drug by gastrointestinal mucosal cells, intestinal flora, and biliary secretion.
(2) First-pass effects are usually observed by measuring the **absolute bioavailability** (*F*) of the drug (see Chapter 7). If $F < 1$, then some of the drug was eliminated before systemic drug absorption occurred.
(3) Drugs that have a **high hepatic extraction ratio,** such as propranolol and morphine, show first-pass effects.
(4) To obtain better systemic absorption of a drug that demonstrates high first-pass effects, then either

(a) The drug dose could be increased (e.g., propranolol, penicillin)
(b) The drug could be given by an alternate route of administration (e.g., nitroglycerin sublingual, insulin subcutaneous, estradiol transdermal)
(c) The dosage form could be modified as a delayed-release drug product (e.g., enteric-coated aspirin, mesalamine) so that the drug may be absorbed more distally in the GI tract

F. Noncompartment methods. Some pharmacokinetic parameters for absorption, distribution, and elimination may be estimated with noncompartment methods. These methods usually require comparison of the areas under the curve.

1. Mean residence time

a. Mean residence time (MRT) is the average time for the drug molecules to reside in the body. MRT is also known as the *mean transit time* and *mean sojourn time*.

b. The MRT depends on the route of administration and assumes that the drug is eliminated from the central compartment.

c. The MRT is the total residence time for all molecules in the body divided by the total number of molecules in the body, as shown in the following equation:

$$MRT = \frac{\text{total residence time for all drug molecules in the boc}}{\text{total number of drug molecules}}$$

d. MRT after IV bolus injection

(1) The MRT after a bolus intravenous injection is calculated by the following equation:

$$MRT_{IV} = \frac{AUMC}{AUC_{0-\infty}}$$

where AUMC is the area under the first moment versus time curve from t = 0 to t = infinity and $AUC_{0-\infty}$ is the area under the plasma drug concentration versus time curve from t = 0 to t = infinity. $AUC_{0-\infty}$ is also known as the zero moment curve.

(2) The MRT_{IV} is related to the elimination rate constant by the following expression:

$MRT_{IV} = 1/k$

(3) During MRT_{IV}, 62.3% of the intravenous bolus dose is eliminated.

(4) The MRT for a drug given by a noninstantaneous input is longer than the MRT_{IV}.

2. Mean absorption time (MAT) is the difference between MRT and MRT_{IV} after an extravascular route is used.

$MAT = MRT_{ev} = MRT_{IV}$

When first-order absorption occurs, MAT = 1/*ka*.

3. Clearance is the volume of plasma cleared of drug per unit time and may be calculated without consideration of the compartment model.

$$Cl = \frac{FD_0}{\text{AUC}_{0-\infty}}$$

After an IV dose, $F = 1$.

4. Steady-state volume of distribution (V_{ss})

a. The steady-state volume of distribution is the ratio of the amount of drug in the body at steady state and the average steady-state drug concentration.

b. After an intravenous bolus injection, V_{ss} is calculated by the following equation:

$$Vss = \frac{\text{dose}_{IV}(\text{AUMC})}{\text{AUC}^2}$$

II. Clinical Pharmacokinetics

is the application of pharmacokinetic principles for the rational design of an individualized dosage regimen. The two main objectives are **maintenance of an optimum drug concentration at the receptor site** to produce the desired therapeutic response for a specific period and **minimization of any adverse or toxic effects** of the drug.

III. Toxicokinetics

is the application of pharmacokinetic principles to the design, conduct, and interpretation of drug safety evaluation studies.

A. Toxicokinetics is also used to validate dose-related exposure in animals. Toxicokinetic studies are performed in animals during preclinical drug development to aid in prediction of human drug toxicity. Toxicokinetic (nonclinical) studies may continue after the drug has been tested in humans.

B. Clinical toxicology is the study of adverse effects of drugs and toxic substances (poisons) in the human body. The pharmacokinetics of a drug in an overmedicated (intoxicated) patient may be very different from the pharmacokinetics of the same drug given in therapeutic doses. For example, a very high toxic dose may show nonlinear pharmacokinetics due to saturation kinetics

compared to the drug given at lower therapeutic doses in which the drug levels follow linear pharmacokinetics.

IV. Population Pharmacokinetics

is the study of sources and correlates of variability in drug concentrations among individuals who are the target patient population. Population pharmacokinetics is

most often applied to the clinical patient who is receiving relevant doses of a drug of interest. Both pharmacokinetic and nonpharmacokinetic data may be considered, including gender, age, weight, creatinine clearance, and concomitant disease.

STUDY QUESTIONS

Directions: Each question, statement or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Creatinine clearance is used as a measurement of

(A) renal excretion rate.
(B) glomerular filtration rate (GFR).
(C) active renal secretion.
(D) passive renal absorption.
(E) drug metabolism rate.

View Answer***1. The answer is B[see].*****For questions 2-5:** A new cephalosporin antibiotic was given at a dose of 5 mg/kg by a single intravenous bolus injection to a 58-year-old man who weighed 75 kg. The antibiotic follows the pharmacokinetics of a one-compartment model and has an elimination half-life of 2 hr. The apparent volume of distribution is 0.28 L/kg, and the drug is 35% bound to plasma proteins.

2. What is the initial plasma drug concentration () in this patient?

(A) 0.24 mg/L
(B) 1.80 mg/L
(C) 17.9 mg/L
(D) 56.0 mg/L
(E) 1339 mg/L

View Answer***2. The answer is C[see].*****3. What is the predicted plasma drug concentration (C_p) at 8 hr after the dose?**

(A) 0.73 mg/L
(B) 1.11 mg/L
(C) 2.64 mg/L
(D) 4.02 mg/L
(E) 15.10 mg/L

View Answer***3. The answer is B[see I.A.1.b.(1);].*****4. How much drug remains in the patient's body (D_B) 8 hr after the dose?**

(A) 15.3 mg
(B) 23.3 mg
(C) 84.4 mg
(D) 100.0 mg
(E) 112.0 mg

View Answer***4. The answer is B[see].*****5. How long after the dose is exactly 75% of the drug eliminated from the patient's body?**

(A) 2 hr
(B) 4 hr
(C) 6 hr
(D) 8 hr
(E) 10 hr

View Answer***5. The answer is B[see].CDCVt*****For questions 6-11:** A 35-year-old man who weighs 70 kg and has normal renal function needs an intravenous infusion of the antibiotic carbenicillin. The desired steady-state plasma drug concentration is 15 mg/dL. The physician wants the antibiotic to be infused into the patient for 10 hr. Carbenicillin has an elimination half-life ($t_{1/2}$) of 1 hr and an apparent volume distribution (V_D) of 9 L in this patient.

6. Assuming that no loading dose was given, what rate of intravenous infusion is recommended for this patient?

(A) 93.6 mg/hr
(B) 135.0 mg/hr
(C) 468.0 mg/hr
(D) 936.0 mg/hr
(E) 1350.0 mg/hr

View Answer***6. The answer is D[see].*****7. Assuming that no loading intravenous dose was given, how long after the initiation of the intravenous infusion would the plasma drug concentration reach 95% of the theoretic steady-state drug concentration?**

(A) 1.0 hr
(B) 3.3 hr
(C) 4.3 hr
(D) 6.6 hr
(E) 10.0 hr

View Answer***7. The answer is C[see].***P.139

8. What is the recommended loading dose?

(A) 93.6 mg
(B) 135.0 mg
(C) 468.0 mg
(D) 936.0 mg
(E) 1350.0 mg

View Answer***8. The answer is E[see].*****9. To infuse the antibiotic as a solution containing 10** g **drug in 500** mL **5% dextrose, how many milliliters per hour of the solution would be infused into the patient?**

(A) 10.0 mL/hr
(B) 46.8 mL/hr
(C) 100.0 mL/hr
(D) 936.0 mL/hr
(E) 1141.0 mL/hr

View Answer***9. The answer is B[see].*****10. What is the total body clearance rate for carbenicillin in this patient?**

(A) 100 mL/hr

(B) 936 mL/hr

(C) 4862 mL/hr

(D) 6237 mL/hr

(E) 9000 mL/hr

View Answer***10. The answer is D[see].*****11. If the patient's renal clearance for carbenicillin is 86 mL/min, what is the hepatic clearance for carbenicillin?**

(A) 108 mL/hr

(B) 1077 mL/hr

(C) 3840 mL/hr

(D) 5160 mL/hr

(E) 6844 mL/hr

View Answer***11. The answer is B[see].CRkVCCCCDCICICICICICICICI*****12. The earliest evidence that a drug is stored in tissue is**

(A) an increase in plasma protein binding.

(B) a large apparent volume of distribution (V_D).

(C) a decrease in the rate of formation of metabolites by the liver.

(D) an increase in the number of side effects produced by the drug.

(E) a decrease in the amount of free drug excreted in the urine.

View Answer***12. The answer is B[see].V*****13. The intensity of the pharmacologic action of a drug is most dependent on the**

(A) concentration of the drug at the receptor site.

(B) elimination half-life ($t_{1/2}$) of the drug.

(C) onset time of the drug after oral administration.

(D) minimum toxic concentration (MTC) of the drug in plasma.

(E) minimum effective concentration (MEC) of the drug in the body.

View Answer***13. The answer is A[see].*****14. Drugs that show nonlinear pharmacokinetics have which property?**

(A) A constant ratio of drug metabolites is formed as the administered dose increases.

(B) The elimination half-life ($t_{1/2}$) increases as the administered dose increases.

(C) The area under the plasma drug concentration versus time curve (AUC) increases in direct proportion to an increase in the administered dose.

(D) Both low and high doses follow first-order elimination kinetics.

(E) The steady-state drug concentration increases in direct proportion to the dosing rate.

View Answer***14. The answer is B[see].*****15. The loading dose (D_L) of a drug is usually based on the**

(A) total body clearance (Cl_T) of the drug.

(B) percentage of drug bound to plasma proteins.

(C) fraction of drug excreted unchanged in the urine.

(D) apparent volume of distribution (V_D) and desired drug concentration in plasma.

(E) area under the plasma drug concentration versus time curve (AUC).

View Answer***15. The answer is D[see].DDV*****16. The renal clearance of inulin is used as a measurement of**

(A) effective renal blood flow.

(B) rate of renal drug excretion.

(C) intrinsic enzyme activity.

(D) active renal secretion.

(E) glomerular filtration rate (GFR).

View Answer***16. The answer is E[see].***P.140

17. All of the following statements about plasma protein binding of a drug are true *except* which one?

(A) Displacement of a drug from plasma protein binding sites results in a transient increased volume of distribution (V_D).

(B) Displacement of a drug from plasma protein binding sites makes more free drug available for glomerular filtration.

(C) Displacement of a potent drug that is normally > 95% bound may cause toxicity.

(D) Albumin is the major protein involved in protein binding of drugs.

(E) Drugs that are highly bound to plasma proteins generally have a greater V_D compared with drugs that are highly bound to tissue proteins.

View Answer***17. The answer is E[see].V*****18. The onset time for a drug given orally is the time for the drug to**

(A) reach the peak plasma drug concentration.

(B) reach the minimum effective concentration (MEC).

(C) reach the minimum toxic concentration (MTC).

(D) begin to be eliminated from the body.

(E) begin to be absorbed from the small intestine.

View Answer***18. The answer is B[see].*****19. The initial distribution of a drug into tissue is determined chiefly by the**

(A) rate of blood flow to tissue.

(B) glomerular filtration rate (GFR).

(C) stomach emptying time.

(D) affinity of the drug for tissue.

(E) plasma protein binding of the drug.

View Answer***19. The answer is A[see].*****20. Which tissue has the greatest capacity to biotransform drugs?**

(A) brain

(B) kidney

(C) liver

(D) lung

(E) skin

View Answer***20. The answer is C[see].*****21. The principle of superposition in designing multiple-dose regimens assumes that**

(A) each dose affects the next subsequent dose, causing nonlinear elimination.

(B) each dose of drug is eliminated by zero-order elimination.

(C) steady-state plasma drug concentrations are reached at approximately 10 half-lives.
(D) early doses of drug do not affect subsequent doses.
(E) the fraction of drug absorbed is equal to the fraction of drug eliminated.

View Answer***21. The answer is D[see].CI*****For questions 22-24:** A new cardiac glycoside is developed for oral and intravenous administration. The drug has an elimination half-life ($t_{1/2}$) of 24 hr and an apparent volume of distribution (V_D) of 3 L/kg. The effective drug concentration is 1.5 ng/mL. Toxic effects of the drug are observed at drug concentrations > 4 ng/mL. The drug is bound to plasma proteins at approximately 25%. The drug is 75% bioavailable after an oral dose.

22. What is the oral maintenance dose, if given once a day, for a 68-year-old man who weighs 65 kg and has congestive heart failure (CHF) and normal renal function?

(A) 0.125 mg
(B) 0.180 mg
(C) 0.203 mg
(D) 0.270 mg
(E) 0.333 mg

View Answer***22. The answer is D[see].*****23. What is the loading dose (D_L) for this patient?**

(A) 0.270 mg
(B) 0.293 mg
(C) 0.450 mg
(D) 0.498 mg
(E) 0.540 mg

View Answer***23. The answer is E[see]*****24. If the drug is available in tablets of 0.125** mg **and 0.250** mg**, what is the patient's plasma drug concentration if he has a dosage regimen of 0.125** mg **every 12 hr?**

(A) 1.39 ng/mL
(B) 1.85 ng/mL
(C) 2.78 ng/mL
(D) 3.18 ng/mL
(E) 6.94 ng/mL

View Answer***24. The answer is A[see].DFVkFkVDFDkVCCD***P.141

Directions for question 25: The question in this section can be correctly answered by **one or more** of the suggested answers. Choose the correct answer, A-E.

25. Which equation is true for a zero-order reaction rate of a drug?

$$\text{I. } \frac{dA}{dt} = -k$$

$$\text{II. } t_{1/2} = \frac{0.693}{k}$$

$$\text{III. } A = A_0 e^{-kt}$$

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***25. The answer is A[see].AtkAktAt***P.142

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* I.E.2.a*].*
A substance that is used to measure the GFR must be filtered but not reabsorbed or actively secreted. Although inulin clearance gives an accurate measurement of GFR, creatinine clearance is generally used because no exogenous drug must be given. However, creatinine formation depends on muscle mass and muscle metabolism, which may change with age and various disease conditions.
2. The answer is C *[see* I.B.1.b.(2)*].*
3. The answer is B *[see I.A.1.b.(1);* I.B.1*].*
4. The answer is B *[see* I.B.1.a.(2)*].*
5. The answer is B *[see* I.B.1.a.(2)*].*
Substituting the data for this patient in the equation for the initial plasma drug concentration () gives

$$C_p^0 = \frac{D_0}{V_D} = \frac{5 \text{ mg}}{0.28 \text{ L/kg}} = 17.9 \text{ mg/L}$$

To obtain the patient's plasma drug concentration (C_p) 8 hr after the dose, the following calculation is performed:

$$C_p = C_p^0 e^{-kt}$$

$$k = \frac{0.693}{t_{1/2}} = \frac{0.963}{2} = 0.347 \text{ hr}^{-1}$$

$$C_p = 17.9e^{-(0.347)(8)}$$
$$C_p = (17.9)(0.0623) = 1.11 \text{ mg/L}$$

The amount of drug in the patient's body at 8 hr is calculated as follows:
$D_B = C_p V_D = (1.11)(0.28)(75) = 23.3$ mg
For any first-order elimination process, 50% of the initial amount of drug is eliminated at the end of the first half-life, and 50% of the remaining drug (i.e., 75%

of the original amount) is eliminated at the end of the second half-life. Because the drug in the current case has an elimination half-life ($t_{½}$) of 2 hr, 75% of the dose is eliminated in two half-lives, or 4 hr.

6. The answer is D *[see* I.B.3.e.(3)*].*

7. The answer is C *[see* I.B.3.c*].*

8. The answer is E *[see* I.B.3.f.(2)*].*

9. The answer is B *[see* I.B.3.e.(3)*].*

10. The answer is D *[see* I.B.3.e.(3); I.E.1.a*].*

11. The answer is B *[see* I.E.4.a*].*

The equation for the plasma concentration at steady state (C_{ss}) provides the formula for calculating the rate of an intravenous infusion (R). The equation is

$$C_{SS} = \frac{R}{kV_D}$$

where k is the first-order elimination rate constant and V_D is the apparent volume of distribution. Rearranging the equation and substituting the data for this patient give the following calculations:

$$R = C_{ss}kV_D = \frac{15\text{ mg}}{100\text{ mL}} \times \frac{0.693}{1\text{ hr}} \times 9000\text{ mL}$$

$$R = 936\text{ mg/hr}$$

The time it takes for an infused drug to reach the C_{ss} depends on the elimination half-life of the drug. The time required to reach 95% of the C_{ss} is equal to 4.3 times the half-life, whereas the time required to reach 99% of the C_{ss} is equal to 6.6 times the half-life. Because the half-life in the current case is 1 hr, the time to reach 95% of the C_{ss} is 4.3 × 1 hr, or 4.3 hr.

The loading dose (D_L) is calculated as follows:

$$D_L = C_{ss}V_D = \frac{15\text{ mg}}{100\text{ mL}} \times 9000\text{ mL} = 1350\text{ mg}$$

The answer to question 6 shows that the infusion rate should be 936 mg/hr. Therefore, if a drug solution containing 10 g in 500 mL is used, the required infusion rate is

$$\frac{936\text{ mg}}{1\text{ hr}} \times \frac{500\text{ mL}}{10{,}000\text{ mg}} = 46.8\text{ mL/hr}$$

The patient's total body clearance (Cl_T) is calculated as follows:

$$Cl_T = kV_D$$

$$Cl_T = \frac{0.693}{1} \times 9000\text{ mL} = 6237\text{ mL/hr}$$

The hepatic clearance (Cl_H) is the difference between total clearance (Cl_T) and renal clearance (Cl_R):

$Cl_H = Cl_T - Cl_R$

Cl_H = 6237 - (86 mL/min × 60 min/hr) = 1077 mL/hr

12. The answer is B *[see* I.B.1.b.(1)*].*

A large apparent volume of distribution (V_D) is an early sign that a drug is not concentrated in the plasma, but is distributed widely in tissue. An increase in

plasma protein binding suggests that the drug is located in the plasma rather than in tissue. A decrease in hepatic metabolism, an increase in side effects, or a decrease in urinary excretion of free drug is caused by a decrease in drug elimination.

13. The answer is A *[see* I.A.3.d.(3)*].*

As more drug is concentrated at the receptor site, more receptors interact with the drug to produce a pharmacologic effect. The intensity of the response increases until it reaches a maximum. When all of the available receptors are occupied by drug molecules, additional drug does not produce a more intense response.

14. The answer is B *[see* I.D*].*

Nonlinear pharmacokinetics is a term used to indicate that first-order elimination of a drug does not occur at all drug concentrations. With some drugs, such as phenytoin, as the plasma drug concentration increases, the elimination pathway for metabolism of the drug becomes saturated and the half-life increases. The area under the plasma drug concentration versus time curve (AUC) of the drug is not proportional to the dose; neither is the rate of metabolite formation. The metabolic rate is related to the effects of the drug.

15. The answer is D *[see* I.B.1.b.(2); I.B.5.g.(1)*].*

A loading dose (D_L) of a drug is given to obtain a therapeutic plasma drug level as rapidly as possible. The D_L is calculated on the basis of the apparent volume of distribution (V_D) and the desired plasma level of the drug.

16. The answer is E *[see* I.E.3.c*].*

Inulin is neither reabsorbed nor actively secreted. Therefore, it is excreted by glomerular filtration only. The inulin clearance rate is used as a standard measure of the GFR, a test that is useful both in a clinical situation and in the development of new drugs.

17. The answer is E *[see* I.A.3.d*].*

Drugs that are highly bound to plasma proteins diffuse poorly into tissue and have a low apparent volume of distribution (V_D).

18. The answer is B *[see* I.B.3.g*].*

The onset time is the time from the administration of the drug to the time when absorbed drug reaches

the MEC. The MEC is the drug concentration in the plasma that is proportional, but not necessarily equal, to the minimum drug concentration at the receptor site that elicits a pharmacologic response.

19. The answer is A *[see* I.A.3.a*].*

The initial distribution of a drug is chiefly determined by blood flow, whereas the affinity of the drug for tissue determines whether the drug concentrates at that site. The GFR affects the renal clearance of a drug, not its initial distribution. The gastric emptying time and degree of plasma protein binding affect drug distribution but are less important than the rate of blood flow to tissue.

20. The answer is C *[see* I.E.4.b.(2)*].*

The kidney, lung, skin, and intestine all have some capacity to biotransform, or metabolize, drugs; but the brain has little capacity for drug metabolism. The liver has the highest capacity for drug metabolism.

21. The answer is D *[see* I.B.5.c*].*

The superposition principle, which underlies the design of multiple-dose regimens, assumes that earlier drug doses do not affect subsequent doses. If the elimination rate constant or total body clearance of the drug changes during multiple dosing, then the superposition principle is no longer valid. Changes in the total body clearance (Cl_T) may be caused by enzyme induction, enzyme inhibition, or saturation of an elimination pathway. Any of these changes would cause nonlinear pharmacokinetics.

22. The answer is D *[see* I.B.5.e.(3)*].*

23. The answer is E *[see* I.B.5.g.(1)*]*

24. The answer is A *[see* I.B.5.d.(2); I.B.5.e.(3)*].*

The oral maintenance dose (D_o) should maintain the patient's average drug concentration at the effective drug concentration. The bioavailability of the drug (F), the apparent volume of distribution (V_D), the dosage interval (τ), and the excretion rate constant (k) must be considered in calculating the dose. The equation used is

$$C_{AV}^{\infty} = FD_0 / kV_D\tau$$

For this drug, F = 0.75, k = 0.693/24 hr, V_D = 3 L/kg × 65 kg, τ = 24 hr, and = 1.5 ng/mL, or 1.5 µg/L. Therefore, by substitution, D_o = 270 µg, or 0.270 mg. When the maintenance dose is given at a dosage frequency equal to the half-life, then the loading dose is equal to twice the maintenance dose, in this case 540 µg, or 0.540 mg. To determine the plasma drug concentration for a dosage regimen of 0.125 mg every 12 hr, the formula is used. This time, F = 0.75, D_o = 0.125 mg, k = 0.693/24 hr, V_D = 3 L/kg × 65 kg, and τ = 12 hr. Therefore, = 1.39 ng/mL. For cardiac glycosides, the peak (C_{max}) and trough (C_{min}) concentrations are calculated, and plasma drug concentrations are monitored after dosing. The loading dose (D_L) may be given in small increments over a specified period, according to the dosage regimen suggested by the manufacturer.

25. The answer is A (I) *[see* I.A.1.a*].*

The first equation in the question describes a zero-order reaction (dA/dt) in which the reaction rate increases or decreases at a constant rate (k). A zero-order reaction produces a graph of a straight line with the equation of $A = -kt + A_o$ when A is plotted against time (t). The other equations in the question represent first-order reactions.

7
Bioavailability and Bioequivalence

Leon Shargel

I. BACKGROUND

A. Bioavailability and bioequivalence studies are important for the development of both new drug products (new drug application [NDA]) and generic drug products (abbreviated new drug application [ANDA])

B. Bioavailability studies are used for establishing dosage regimens of new drug products

C. Bioequivalence studies can be useful during the investigational new drug (IND) development or NDA development period to establish links between

1. Early and late clinical trial formulations

2. Formulations used in clinical trial and stability studies, if different

3. Clinical trial formulations and to-be-marketed drug product

D. Bioequivalence studies are a critical component of ANDA submissions

1. The purpose of these studies is to demonstrate bioequivalence between a pharmaceutically equivalent generic drug product and the corresponding reference listed drug (usually the brand drug product).

2. Together with the determination of pharmaceutical equivalence, establishing bioequivalence allows a regulatory conclusion of therapeutic equivalence.

E. *Scale-up and post-approval changes* (SUPAC)—After market approval, a drug product may make a manufacturing change. A bioequivalence study may be needed to show that the new formulation or new method of manufacture (test product) and the prior formulation or method of manufacture (reference product) are equivalent.

II. DEFINITIONS[1]

A. Bioavailability is a measurement of the rate and extent (amount) to which the active ingredient or active moiety becomes available at the site of action. Bioavailability is also considered a measure of the rate and extent of therapeutically active drug that is systemically absorbed. For drug products that are not intended to be absorbed into the bloodstream, bioavailability may be assessed by measurements intended to reflect the rate and extent to which the active ingredient or active moiety becomes available at the site of action.

B. Bioequivalent drug products. A generic drug product is considered bioequivalent to the **reference listed drug (RDL) product** if both products are pharmaceutical equivalents and the generic drug product's rate and extent of systemic drug absorption (bioavailability) do not show a statistically significant difference when administered in the same molar dose of the active ingredient, in the same chemical form, in a similar dosage form, by the same route of administration, and under the same experimental conditions. The RDL is generally the brand product.

C. Generic drug product

1. The generic drug product requires an **abbreviated new drug application** (ANDA) for approval by the U.S. Food and Drug Administration (FDA) and may be marketed after patent expiration of the reference drug product (see Chapter 1).

2. The generic drug product must be a **therapeutic equivalent** to the reference drug product but may differ in certain characteristics, including shape, scoring configuration, packaging, and excipients (such as colors, flavors, preservatives, expiration date, and minor aspects of labeling).

3. FDA believes that products classified as therapeutically equivalent can be substituted with the full expectation that the substituted product will produce the same clinical effect and safety profile as the prescribed product.

D. Pharmaceutical equivalents are drug products that contain the same therapeutically active drug ingredient(s); contain the same salt, ester, or chemical form; are of the same dosage form; and are identical in strength, concentration, and route of administration. Pharmaceutical equivalents may differ in characteristics such as shape, scoring configuration, release mechanisms, packaging, and excipients (including colors, flavoring, and preservatives).

E. The reference listed drug product is usually the currently marketed, brand-name product with a full **new drug application (NDA)** approved by the FDA. The RLD is the reference drug product identified by FDA (see “Electronic Orange Book” at www.fda.gov/cder/ob/default.htm).

F. Therapeutic equivalent drug products are pharmaceutical equivalents that can be expected to have the same clinical effect and safety profile when administered to patients under the same conditions specified in the labeling. Therapeutic equivalent drug products have the following criteria:

1. The products are safe and effective.

2. The products are pharmaceutical equivalents that contain the same active drug ingredient in the same dosage form, given by the same route of administration; meet compendial or other applicable standards of strength, quality, purity, and identity; and meet an acceptable in vitro standard.

3. The drug products are bioequivalent in that they do not present a known potential problem and are shown to meet an appropriate bioequivalence standard.

4. The drug products are adequately labeled.

5. The drug products are manufactured in compliance with current good manufacturing practice regulations.

G. Pharmaceutical alternatives are drug products that contain the same therapeutic moiety but are different salts, esters, or complexes (e.g., tetracycline hydrochloride versus tetracycline phosphate) or are different dosage forms (e.g., tablet versus capsule; immediate-release dosage form versus controlled-release dosage form) or strengths.

III. BIOAVAILABILITY AND BIOEQUIVALENCE.

These may be determined directly using pharmacokinetic studies (e.g., plasma drug concentration versus time profiles, urinary drug excretion studies), measurements of an acute pharmacodynamic effect, comparative clinical studies, or in vitro studies.

The choice of study used is based on the site of action of the drug and the ability of the study design to compare drug delivered to that site by the two products.

A. Acute pharmacodynamic effects, such as changes in heart rate, blood pressure, electrocardiogram (ECG), clotting time, or forced expiratory volume in 1 sec (FEV_1) can be used to measure bioavailability when no assay for plasma drug concentration is available or when the plasma drug concentration does not relate to the pharmacological response (e.g., a bronchodilator

such as albuterol given by inhalation). Quantitation of the pharmacological effect versus time profile can be used as a measure of bioavailability and/or bioequivalence (Figure 7-1).

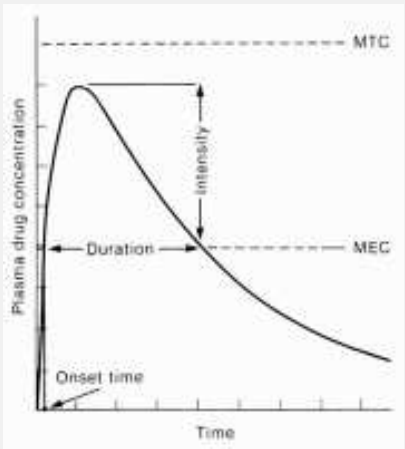

Figure 7-1. Generalized plasma drug concentration versus time curve after oral drug administration. *MEC,* minimum effective concentration; *MTC,* minimum toxic concentration. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC: Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005, p. 6.]

1. Onset time. As the drug is systemically absorbed, the drug concentration at the receptor rises to a **minimum effective concentration** (MEC) and a pharmacological response is initiated. The time from drug administration to the MEC is known as the onset time.

2. Intensity. The intensity of the pharmacological effect is proportional to the number of receptors occupied by the drug up to a *maximum* pharmacological effect. The maximum pharmacological effect may occur before, after, or at peak drug absorption.

3. Duration of action. As long as the drug concentration remains above the MEC, pharmacological activity is observed. The duration of action is the time for which the drug concentration remains above the MEC.

4. Therapeutic window. As the drug concentration increases, other receptors may combine with the drug to exert a toxic or adverse response. This drug concentration is the **minimum toxic concentration** (MTC). The drug concentration range between the MEC and the MTC is the therapeutic window.

B. Plasma drug concentration. The plasma drug concentration versus time curve is most often used to measure the systemic bioavailability of a drug from a drug product (Figure 7-2).

1. Time for peak plasma drug concentration (T_{max}) relates to the rate constants for systemic drug absorption and elimination. If two oral drug products contain the same amount of active drug but different excipients, the dosage form that yields the faster rate of drug absorption has the shorter T_{max}.

2. Peak plasma drug concentration (C_{max}). The plasma drug concentration at T_{max} relates to the intensity of the pharmacological response. Ideally, C_{max} should be within the therapeutic window.

3. Area under the plasma drug concentration versus time curve (AUC) relates to the amount or extent of drug absorption. The amount of systemic drug absorption is directly related to the AUC. The AUC is usually calculated by the **trapezoidal rule** and is expressed in units of concentration multiplied by time (e.g.,).

C. Urinary drug excretion. Measurement of urinary drug excretion can determine bioavailability from a drug product. This method is most accurate if the active therapeutic moiety is excreted unchanged in significant quantity in the urine (Figure 7-3).

P.148

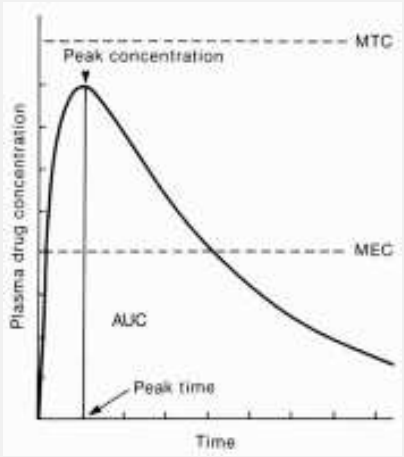

Figure 7-2. Generalized plasma drug concentration versus time curve, showing peak time and peak concentration. *AUC,* area under the curve; *MEC,* minimum effective concentration; *MTC,* minimum toxic concentration. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC: Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005, p. 7.]

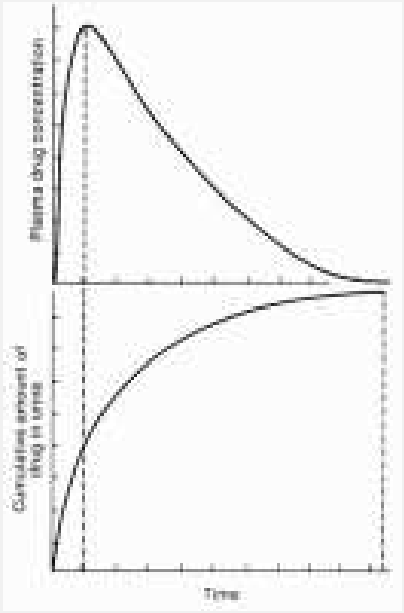

Figure 7-3. These corresponding plots show the relationship of the plasma drug concentration versus time curve to the cumulative amount of drug in the urine versus time curve. [Adapted with permission from Shargel L, Wu-Pong S, Yu ABC: Applied Biopharmaceutics and Pharmacokinetics, 5th ed. New York, McGraw-Hill, 2005, p. 463.]

P.149

1. The cumulative amount of active drug excreted in the urine () is directly related to the extent of systemic drug absorption.

2. The rate of drug excretion in the urine (dD_U/dt) is directly related to the rate of systemic drug absorption.

3. The time for the drug to be completely excreted (t^{∞}) corresponds to the total time for the drug to be systemically absorbed and completely excreted after administration.

D. Comparative clinical trials to a drug can be used to measure bioavailability quantitatively. Clinical studies are highly variable and less precise than other methods because of individual differences in drug pharmacodynamics and subjective measurements.

E. In vitro measurements of bioequivalence. Bioequivalence may sometimes be demonstrated using an in vitro bioequivalence standard, especially when such an in vitro test has been correlated with human in vivo bioavailability data. For example, the rate of drug dissolution in vitro for certain drug products correlates with drug bioavailability in vivo. If the dissolution test in vitro is considered statistically adequate to predict drug bioavailability, then, in some cases, dissolution may be used in place of an in vivo bioavailability study.

IV. RELATIVE AND ABSOLUTE BIOAVAILABILITY

A. Relative bioavailability (RBA) is the systemic availability of the drug from a dosage form as compared to a reference standard given by the same route of administration. Relative bioavailability is calculated as the ratio of the AUC for the dosage form to the AUC for the reference dosage form given in the same dose. A relative bioavailability of 1 (or 100%) implies that drug bioavailability from both dosage forms is the same but does not indicate the completeness of systemic drug

absorption. The determination of relative bioavailability is important in generic drug studies (e.g., bioequivalence studies). Bioequivalence is a relative bioavailability study.

$$RBA = \frac{[AUC]_{0\ oral TEST}^{\infty} / Dose_{oral TEST}}{[AUC]_{0\ oral REF}^{\infty} / Dose_{oral REF}}$$

B. Absolute bioavailability (*F*) is the fraction of drug systemically absorbed from the dosage form. *F* is calculated as the ratio of the AUC for the dosage form given orally to the AUC obtained after intravenous (IV) drug administration (adjusted for dose). A parenteral drug solution given by IV administration is considered to have 100% systemic absorption (i.e., *F* = 1). An *F* value of 0.80 (or 80%) indicates that only 80% of the drug was systemically available from the oral dosage form.

$$F = \frac{[AUC]_{0\ oral}^{\infty} / Dose_{oral}}{[AUC]_{0\ iv}^{\infty} / Dose_{iv}}$$

V. BIOEQUIVALENCE STUDIES FOR SOLID ORAL DRUG PRODUCTS

A. Objective of bioequivalence studies. The objective of a bioequivalence study is to measure and compare formulation performance between two or more pharmaceutically equivalent drug products.

B. Design of bioequivalence studies

1. The FDA's Division of Bioequivalence, Office of Generic Drugs provides guidance for the performance of in vitro dissolution and in vivo bioequivalence studies. These guidances are available at www.fda.gov/cder/guidances.

2. Fasting study. Bioequivalence studies are usually evaluated by a single-dose, two-period, two-treatment, two-sequence, open-label, randomized crossover design, comparing equal doses of the test (generic) and reference (brand) products in fasted, adult, healthy subjects.

a. Both men and women may be used in the study.

b. Blood sampling is performed just before the dose (zero time) and at appropriate intervals after the dose to obtain an adequate description of the plasma drug concentration versus time profile.

3. Food intervention study. If the bioavailability of the active drug ingredient is known to be affected by food, the generic drug manufacturer must include a single-dose, randomized, crossover, food effects study comparing equal doses of the test product and reference products given immediately after a standard high-fat-content breakfast.

4. Other study designs. Crossover studies may not be practical in drugs with a long half-life in the body, and a parallel study design may be used instead. Alternate study methods, such as in vitro studies or equivalence studies with clinical or pharmacodynamic end points, are used for drug products where plasma

concentrations are not useful to determine delivery of the drug substance to the site of activity (such as inhalers, nasal sprays, and topical products applied to the skin).

5. Waiver of an in vivo bioequivalence study (Biowaiver)

a. A comparative in vitro dissolution (drug-release) study between the test and the reference products may be used in lieu of an in vivo bioequivalence study for some immediate-release (conventional) oral drug products.

b. No bioequivalence study is required for certain drug products given as a solution such as oral, parenteral, ophthalmic, or other solutions because bioequivalence is self-evident. In this case, the drug is in a pure aqueous solution and there is no drug dissolution rate consideration.

c. Immediate release (IR) solid oral drug products that meet biopharmaceutic classification (BCS) system class 1 drugs, i.e., highly water soluble, rapidly dissolving, and rapid permeation of cellular membranes may obtain a biowaiver.

d. Drug products containing a lower dose strength (e.g., 200 mg, 100 mg, and 50 mg IR tablets). The drug product must be in the same dosage form, lower strength, and is proportionately similar in its active and inactive ingredients.

B. Pharmacokinetic evaluation of the data. Pharmacokinetic analysis includes calculation for each subject of the AUC to the last quantifiable concentration (AUC_{0-t}) and to infinity ($AUC_{0-\infty}$), T_{max}, and C_{max}. In addition, the elimination rate constant (k), the elimination half-life ($t_{1\backslash 2}$), and other parameters may be estimated.

C. Statistical evaluation of the data

1. The statistical methodology for analyzing bioequivalence studies is called the two one-sided test procedure. Two situations are tested with this statistical methodology.

a. The first of the two one-sided tests determines whether a generic product (test), when substituted for a brand-name product (reference) is significantly less bioavailable.

b. The second of the two one-sided tests determines whether a brand-name product (reference) when substituted for a generic product (test) is significantly less bioavailable.

c. Based on the opinions of FDA medical experts, a difference of > 20% for each of the above tests was determined to be significant and, therefore, undesirable for all drug products.

2. An analysis of variance (ANOVA) should be performed on the log transformed AUC and C_{max} values obtained from each subject. The 90% confidence intervals for both pharmacokinetic parameters, AUC and C_{max}, must be entirely within the 80% to 125% boundaries based on log transformation of the data. The ratio of the means of the study data (test to reference) should lie in the center of the 90% confidence interval, or close to 100% (equivalent to a test to reference ratio of 1) (Table 7-1).

3. Different statistical criteria are sometimes used when bioequivalence is demonstrated through comparative clinical trials, pharmacodynamic studies, or comparative in vitro methodology.

4. The bioequivalence methodology and criteria described above simultaneously control for both differences in the average response between test and reference products as well as the precision with which the average response in the population

is estimated. This precision depends on the within-subject (normal volunteer or patient) variability in the pharmacokinetic parameters (AUC and C_{max}) of the two products and on the number of subjects in the study. The width of the 90% confidence interval is a reflection in part of the within-subject variability of the test and reference products in the bioequivalence study.

P.151

Table 7-1. Bioavailability Comparison of a Generic (TEST) and Brand (Reference) Drug Product

LN-Transformed Data								
		Geometric Mean			90 % Confidence Interval			
PK Variable	**Units**	**Test**	**Reference**	**% Ratio T/R**	**(Lower Limit, Upper Limit)**	**P-values for Product Effects**	**Power of ANOVA**	**ANOVA % CV**
C_{max}	ng/mL	344.79	356.81	96.6	(89.5, 112)	0.3586	0.8791	17.90%
AUC$_{0-t}$	ng hr/mL	2659.12	2674.92	99.4	(95.1, 104)	0.8172	1.0000	12.60%
AUC$_{inf}$	ng hr/mL	2708.63	2718.52	99.6	(95.4, 103)	0.8865	1.0000	12.20%
T_{max}	hr	4.29	4.24	101				
k_{elim}	1/hr	0.0961	0.0980	98.1				

$t_{1/2}$	hr	8.47	8.33	10 1.7				

AUC, area under the curve; C_{max}, peak plasma drug concentration; T_{max}, time for peak plasma drug concentration.

The results were obtained from a two-way crossover, single-dose, fasting study in 36 healthy adult volunteers. Mean values are reported. No statistical differences were observed between AUC and Cmax values for the test and reference products.

VI. BIOEQUIVALENCE ISSUES

A. Problems in determining bioequivalence include lack of an adequate study design; inability to accurately measure the drug analytes, including metabolites and enantiomers (chiral drugs); and lack of systemic drug absorption (Table 7-2.)

B. Bioequivalence studies for which objective blood drug concentrations cannot be obtained require either a pharmacodynamic study, a clinical trial, or an in vitro study that has been correlated with human in vivo bioavailability data.

1. Pharmacodynamic measurements are more difficult to obtain, and the data tend to be variable, requiring a larger number of subjects compared to the bioequivalence studies for systemically absorbed drugs.

a. A bioequivalence study using pharmacodynamic measurements tries to obtain a pharmacodynamic effect versus time profile for the drug in each subject.

b. The area under the effect versus time profile, peak effect, and time for peak effect are obtained for the test and reference products and are then statistically analyzed.

2. Comparative clinical trials are more difficult to run, do not have easily quantifiable observations, and are quite costly.

3. In vitro studies may require the development of a reliable surrogate marker that may be correlated with human in vivo bioavailability data. For example, the penetration of drug into layers of skin with respect to time (*dermatopharmacokinetics*) has been suggested as a method for measuring the bioequivalence of topical drug products intended for local activity.

VII. DRUG PRODUCTION SELECTION

A. Generic drug substitution

1. Generic drug substitution is the process of dispensing a generic drug product in place of the prescribed drug product (e.g., generic product for brand-name product, generic product for another generic product, brand-name product for generic

product). The substituted product must be a therapeutic equivalent to the prescribed product.

2. Generic drug products that are classified as therapeutic equivalents by the FDA are expected to produce the same clinical effect and safety profile as the prescribed drug.

Table 7-2. Problem Issues in the Determination of Bioequivalence

Problem Issues	Example
Drugs with highly variable bioavailability[a]	Propranolol, verapamil
Drugs with active metabolites	Selegiline
Chiral drugs	Ibuprofen, albuterol
Drugs with nonlinear pharmacokinetics	Phenytoin
Orally administered drugs that are not systemically absorbed	Cholestyramine resin, sucralfate
Drugs with long elimination half-lives	Probucol
Variable-dosage forms	Dyazide, conjugated estrogens
Nonoral drug delivery	
Topical drugs	Steroids, antifungals
Transdermal delivery systems	Estrogen patch
Drugs given by inhalation aerosols	Bronchodilators, steroids
Intranasal drugs	Intranasal steroids
Biotechnology derived drugs	Erythropoietin, interferon

Bioavailable drugs that should not reach peak drug levels	Potassium supplements, hormone replacement therapy
Target population used in the bioequivalence studies	Pediatric patients; renal disease

[a] These drugs have high intrasubject variability.

3. Prescribability refers to the measurement of average bioequivalence in which the comparison of population means of the test and reference products falls within acceptable statistical criteria. Prescribability is the current basis for FDA approval of therapeutic equivalent generic drug products.

4. Switchability refers to the measurement of individual bioequivalence, which requires knowledge of individual variability (intrasubject variability) and subject-by-formulation effects. Switchability ensures that the substituted generic drug product produces the same response in the individual patient.

B. Therapeutic substitution

1. Therapeutic substitution is the process of dispensing a therapeutic alternative in place of the prescribed drug product. For example, amoxicillin is dispensed for ampicillin.

2. The substituted drug product is usually in the same therapeutic class (e.g., calcium channel blocker) and is expected to have a similar clinical profile.

C. Formulary issues

1. A **formulary** is a list of drugs. A **positive** formulary lists all the drugs that may be substituted, whereas a **negative** formulary lists drugs for which the pharmacist may not substitute. A **restrictive** formulary lists only those drugs that may be reimbursed without justification by the prescriber; for drugs not listed in the restrictive formulary, the prescriber must justify the need for the nonlisted drug.

2. Many states have legal requirements that address the issue of drug product selection. States may provide information and guidance in drug product selection through positive, negative, or restrictive formularies.

3. The FDA annually publishes *Approved Drug Products with Therapeutic Equivalence Evaluations* (the "Orange Book"). This publication is also reproduced in the *United States Pharmacopeia* (USP), DI Vol. III, *Approved Drug Products and Legal Requirements,* published annually by the USP Convention. The "Electronic Orange Book" may be found at http://www.fda.gov/cder/ob/default.htm.

a. The “Orange Book” provides therapeutic evaluation codes for drug products (Table 7-3).

Table 7-3. Therapeutic Equivalence Evaluation Codes

A Codes	Drug products that are considered to be therapeutically equivalent to other pharmaceutically equivalent products
AA	Products in conventional dosage forms not presenting bioequivalence problems
AB	Products meeting bioequivalence requirements
AN	Solutions and powders for aerosolization
AO	Injectable oil solutions
AP	Injectable aqueous solutions
AT	Topical products
B Codes	**Drug products that the FDA does not at this time consider to be therapeutically equivalent to other pharmaceutically equivalent products**
BC	Extended-release tablets, extended-release capsules, and extended-release injectables
BD	Active ingredients and dosage forms with documented bioequivalence problems
BE	Delayed-release oral dosage forms
BN	Products in aerosol-nebulizer drug delivery systems
BP	Active ingredients and dosage forms with potential bioequivalence problems
BR	Suppositories or enemas for systemic use
BS	Products with drug standard deficiencies

BT	Topical products with bioequivalence issues
BX	Insufficient data

FDA, U.S. Food and Drug Administration.

P.154

(1) "A-"rated" drug products are drug products that contain active ingredients and dosage forms that are *not* regarded as presenting either actual or potential bioequivalence problems or drug quality standards issues. However, all oral dosage forms must meet an appropriate in vitro bioequivalence standard that is acceptable to the FDA to be approved as therapeutically equivalent and may be interchanged.
(2) "B"-rated" drug products are drug products for which actual or potential bioequivalence problems have not been resolved by adequate evidence of bioequivalence. These products often have specific dosage form problems rather than a problem with the active ingredients (e.g., two different nicotine patches). "B-"rated" drug products are *not* considered therapeutically equivalent to other pharmaceutically equivalent products and are *not* interchangeable.
(3) Certain products present special situations that deserve a more complete explanation than can be provided by the two-codes used in the "Orange Book." These drugs have particular problems with standards of identity, analytical methodology, or bioequivalence that are considered individually. For these drugs, consult the "Orange Book."
b. For some drug products, bioequivalence has not been established or no generic product is currently available.
4. Various hospitals, institutions, insurance plans, health maintenance organizations (HMOs), and other third-party plans may have a formulary that provides guidance for drug product substitution.
P.155

STUDY QUESTIONS

Directions for questions 1-3: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The parameters used to describe bioavailability are

(A) C_{max}, AUC_{0-t}, and $AUC_{0-\infty}$.

(B) C_{max}, AUC_{0-t}, $AUC_{0-\infty}$, and T_{max}.

(C) C_{max}, AUC_{0-t}, $AUC_{0-\infty}$, and $t_{1\backslash 2}$.

(D) C_{max} and AUC_{0-t}.

(E) C_{max}, AUC_{0-t}, $AUC_{0-\infty}$, and T_{max}, and $t_{1\backslash 2}$.

View Answer***1. The answer is B[see].CTt2.*** **To determine the absolute bioavailability of a drug given as an oral extended-release tablet, the bioavailability of the drug must be compared to the bioavailability of the drug from**

(A) an immediate-release oral tablet containing the same amount of active ingredient.

(B) an oral solution of the drug in the same dose.

(C) a parenteral solution of the drug given by intravenous (IV) bolus or IV infusion.

(D) a reference (brand) extended-release tablet that is a pharmaceutical equivalent.

(E) an immediate-release hard gelatin capsule containing the same amount of active drug and lactose.

View Answer***2. The answer is C[see].F3.*** **A single-dose, two-way crossover, fasting, comparative bioavailability study was performed in 24 healthy, adult male subjects. Plasma drug concentrations were obtained for each subject, and the results shown in** Table 7-Q3 **were obtained. The relative bioavailability of the drug from the generic tablet compared to the reference tablet is**

Table 7-Q3

Drug Product	Dose (mg)	C_{max} (µg/mL)	T_{max} (hr)	$AUC_{0-\infty}$ (µg hr/mL)
IV bolus injection	100			1714
Oral solution	200	21.3	1.2	3143
Generic tablet	200	17.0	2.1	2822
Reference tablet	200	16.5	1.9	2715

IV, intravenous.

(A) 82.3%.

(B) 69.8%.

(C) 91.7%.

(D) 96.2%.
(E) 103.9%

View Answer***3. The answer is E[see].*****Directions for questions 4-6:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**
P.156

4. For two drug products, generic (test) and brand (reference), to be considered bioequivalent
I. there should be no statistical difference between the extent of bioavailability of the drug from the test product compared to the reference product.
II. the 90% confidence intervals about the ratio of the means of the C_{max} and AUC values for the test product to reference product must be within 80%-125% of the reference product.
III. there should be no statistical differences between the mean C_{max} and AUC values for the test product compared to the reference product.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***4. The answer is E[see].TC*****5. For which of the following products is measuring plasma drug concentrations not appropriate for estimating bioequivalence?**
I. metered-dose inhaler containing a bronchodilator
II. antifungal agent for the treatment of a vaginal infection
III. enteric-coated tablet containing a nonsteroidal anti-inflammatory agent
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***5. The answer is C[see].*****6. Bioequivalence studies compare the bioavailability**
I. of the generic drug product to the brand drug product.
II. of a reformulated brand drug product to the original formulation of the brand product.
III. of a to-be-marketed brand product to the drug product used in the clinical trials.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***6. The answer is E[seeand].***P.157

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* III.B*].*

AUC relates to the extent of drug absorption. C_{max} and T_{max} relate to the rate of drug absorption. The elimination $t_{1/2}$ of the drug is usually independent of the route of drug administration and is not used as a measure of bioavailability. For the FDA, only the C_{max} and AUC parameters must meet 90% confidence intervals of 80-125% of the reference (brand) product (Table 7.1).

2. The answer is C *[see* IV.B*].*

After an IV bolus injection or IV infusion, all the dose is absorbed into the body. The ratio of the AUC of the drug given orally to the AUC of the drug given by IV injection is used to obtain the absolute bioavailability (*F*) of the drug.

3. The answer is E *[see* IV.A*].*

The relative bioavailability is determined from the ratio of the AUC of the generic (test) product to the AUC of the reference standard. Thus the relative bioavailability can exceed 100%, whereas the absolute bioavailability cannot exceed 100%.

4. The answer is E *[see* V.C*].*

Although T_{max} is an indication of rate of drug absorption, it is a discrete measurement and usually too variable to use for statistical comparisons in bioequivalence studies. Statistical comparisons use AUC and C_{max} values from test and reference drug products as the basis of bioequivalence.

5. The answer is C *[see* V.A*].*

Although some systemic absorption may be demonstrated after administering a metered dose inhaler containing a bronchodilator or a vaginal antifungal agent, bioequivalence can be determined only by using a clinical response measurement.

6. The answer is E *[see* I.A, B, C, D *and* E*].*

Bioequivalence studies compare the bioavailability of a drug from one drug product to another drug product containing the same active ingredient. Drug products such as capsules that are used in clinical trials should be bioequivalent to the marketed drug product which may be a tablet. Generic drug products and the corresponding brand drug product must be bioequivalent. For any change a formulation, the manufacturer (brand or generic) must demonstrate that the formulation change does not affect the bioavailability compared to the original product.

8

Functional Group Chemistry and Biochemistry

Marc W. Harrold

I. FUNCTIONAL GROUP CHEMISTRY

A. Introduction. Drug molecules can be viewed as a collection of functional groups (i.e., groups of atoms present within the drug that confer specific chemical and physical properties [Figure 8-1]). Functional groups determine such characteristics as ionization, solubility in aqueous and lipid environments (aka polarity), reactivity, chemical stability, and in vivo metabolic stability. Additionally, these functional groups are **capable of forming specific bonds** (primarily noncovalent) with their receptors and are thus extremely important in drug activity and potency.

1. Functional groups that impart **hydrophilicity** are likely to increase the drug's water solubility, while functional groups that impart **lipophilicity** (hydrophobicity) are likely to increase the drug's tendency to cross cellular membranes through passive diffusion. See Chapter 12 VIII B 1 for a further discussion of water and lipid solubility.

a. Acidic and basic functional groups allow for **drug ionization** and, in most cases, impart enhanced water solubility to the molecule. One notable exception to this is seen in **amphoteric drugs** (i.e., those compounds possessing both acidic and basic functional groups). As exemplified by ampicillin in Figure 8-2, amphoteric compounds can form **zwitterions,** or **internal salts.** Since the zwitterion form of ampicillin has a net overall charge of zero, it has difficulty dissolving in aqueous environments such as the gastrointestinal (GI) tract.

b. Neutral functional groups (i.e., those that are incapable of ionization) can enhance either water or lipid solubility depending on their ability to form **hydrogen bonds with water.** Hydrogen bonding is the primary mechanism for increasing the water solubility of nonelectrolytes (i.e., compounds that do not possess acidic, basic, or quaternary ammonium functional groups).

2. Functional group **reactivity** affects **drug shelf life, stability,** and **storage.** There are a number of functional groups that will degrade, primarily through air oxidation and hydrolysis, under **normal environmental conditions.** Two examples of this latter concern are seen with aspirin and nitroglycerin. Both compounds are subject to rapid hydrolysis if exposed to moist environments.

3. Functional groups also affect **in vivo stability** and the duration of drug action. The susceptibility of a given drug to metabolic biotransformation depends in part upon the functional groups that are present (see Chapter 17 II, III).

a. Drugs that contain a large number or percentage of hydrophilic functional groups are often eliminated from the body unchanged or with minimal metabolism.

b. Drugs that contain a large number or percentage of lipophilic functional groups often require extensive metabolism.

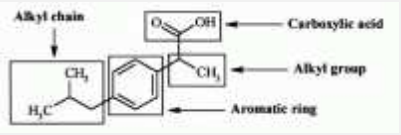

Figure 8-1. Ibuprofen, a nonsteroidal anti-inflammatory agent, is comprised of an ionizable, hydrophilic carboxylic acid and three hydrophobic functional groups: an isobutyl alkyl chain, an ethyl alkyl group, and an aromatic ring.

P.159

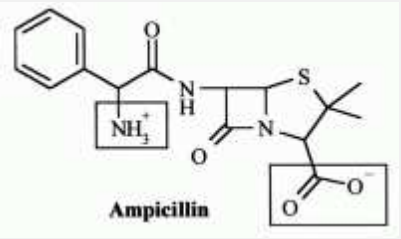

Figure 8-2. Ampicillin is an amphoteric compound. It contains an acidic carboxylic acid and a basic amine and exists in vivo as a zwitterion. The proton from the carboxylic acid binds to the basic amine, producing a molecule with an overall net charge equal to zero.

B. Acidic functional groups

1. Types. Shown in Figure 8-3 are examples of the six most common acidic functional groups. In general, carboxylic acids tend to be more acidic than any of the other five functional groups. The tetrazole ring provides the best charge delocalization since resonance allows the charge to be equally shared among all five atoms in the ring.

2. Common attributes

a. Acidic functional groups impart **hydrophilicity** to a drug molecule due to their potential for ionization.

b. Acidic functional groups can form **ionic, ion-dipole, and hydrogen bonds** with receptors, enzymes, transport proteins, and other macromolecules.

c. Acidic functional groups can form **salts when combined with bases.**

d. Carboxylic acids are often **esterified** for the purposes of prodrug formation (see Chapter 17, section VI for additional information). They can also undergo acid- or enzymecatalyzed **decarboxylation** reactions.

e. Metabolism. Acidic functional groups can undergo **conjugation** with glucuronic acid, glycine, and glutamine.

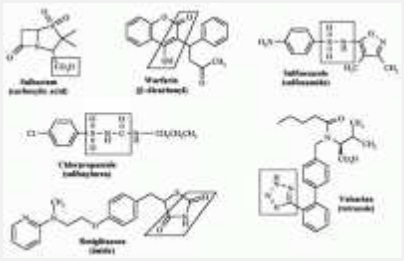

Figure 8-3. Examples of drugs that contain an acidic functional group as part of their chemical structure.

C. Basic functional groups

1. Types

a. Aliphatic and alicyclic amines are the most common basic functional groups. As shown in Figure 8-4, these amines can be **primary, secondary, or tertiary,** depending on the number of substituents attached to the nitrogen.

b. Aromatic amines, such as that seen in procainamide (Figure 8-4), are much less basic and for all intents and purposes can be considered neutral.

c. **Aromatic, heterocyclic nitrogens** vary in their basicity, but in general are much less basic than aliphatic and alicyclic amines (Figure 8-5).

d. Additional basic functional groups include **imines, hydrazines, amidines,** and **guanidines** (Figure 8-6). Imines tend to be less basic than aliphatic and alicyclic amines, whereas guanidines tend to be much more basic. The basicity of the other two functional groups lies somewhere in between.

2. Common attributes

a. Basic functional groups impart **hydrophilicity** to a drug molecule due to their potential for ionization and their ability to form hydrogen bonds.

b. Basic functional groups can form **ionic, ion-dipole, and hydrogen bonds** with receptors, enzymes, transport proteins, and other macromolecules.

c. Basic functional groups can form **salts when combined with acids.**

d. Metabolism. Common metabolic pathways for primary amines are **oxidative deamination, acetylation, and N-oxidation.** Common pathways for secondary and tertiary amines are **acetylation** (secondary amines only), **oxidative N-dealkylation,** and **N-oxidation.** Aromatic amines can be **acetylated,** while aromatic heterocyclic

nitrogens can undergo **N-oxidation or N-dealkylation.** Imine, hydrazine, amidine, and guanidine groups can undergo similar reactions as those listed for primary, secondary, and tertiary amines. Additionally, amines can be **glucuronidated, sulfated,** and **methylated** by **phase II conjugation** reactions.

D. Additional hydrophilic functional groups

1. Similar to amines, **hydroxyl groups (or alcohols)** may be classified as **primary, secondary, or tertiary,** depending on the number of substituents attached to their respective carbons. A good example of this is seen with the glucocorticoid fludrocortisone (Figure 8-7).

a. Hydroxyl groups can form **ion-dipole and hydrogen bonds** with receptors, enzymes, transport proteins, and other macromolecules.

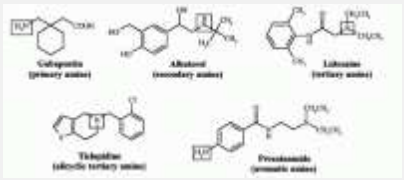

Figure 8-4. Examples of drugs that contain a primary, secondary, tertiary, or aromatic amine as part of their chemical structure. Whenever an amine is part of a nonaromatic ring (e.g., ticlopidine), it is referred to as an alicyclic amine. Whenever an amine amino is part of a side chain or is attached to a nonaromatic ring, it is referred to as an aliphatic or alkyl amine. Whenever an amine is directly attached to an aromatic ring (e.g., procainamide), it is referred to as an aromatic amine.

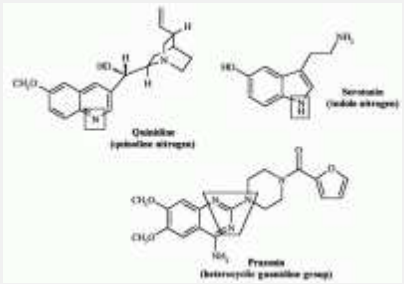

Figure 8-5. Examples of drugs that contain aromatic, heterocyclic nitrogens as part of their chemical structure.

b. Hydroxyl groups **enhance water solubility** due to their ability to form hydrogen bonds with water.

c. Hydroxyl groups are often **esterified** in order to produce prodrugs. See Chapter 17 VI for additional information on prodrugs.

d. Metabolism. Primary hydroxyl groups are initially **oxidized to aldehydes** and then to **carboxylic acids.** Secondary hydroxyl groups are **oxidized to ketones,** while tertiary hydroxyl groups are not usually oxidized. Hydroxyl groups may also undergo **phase II glucuronide or sulfate conjugation.**

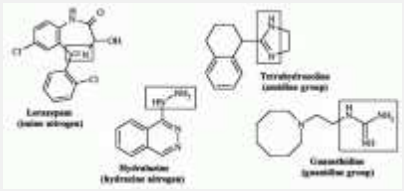

Figure 8-6. Examples of drugs that contain a basic imine, hydrazine, amidine, or guanidine functional group as part of their chemical structure.

P.162

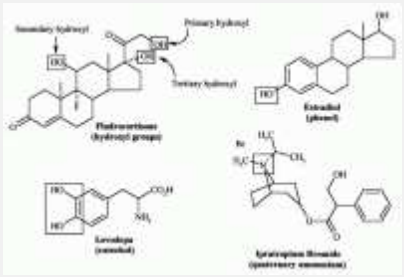

Figure 8-7. Examples of drugs that contain a hydroxyl group, phenol, catechol, or quaternary ammonium functional group as part of their chemical structure. Fludrocortisone contains a primary, secondary, and tertiary hydroxyl group. This designation is similar to that used for amines and depends on the number of substituents attached to the respective carbons. As illustrated with levodopa, a catechol is simply two phenol groups that are *ortho* to one another.

2. Phenols, as exemplified by estradiol (Figure 8-7), are hydroxyl groups that are directly attached to an aromatic ring.

a. Due to resonance stabilization of the aromatic ring, phenols can be ionized in basic environments; however, most phenols are **primarily unionized** at physiological pH and as such should be treated as **neutral,** nonionizable functional groups.

b. Similar to alcohols, phenols primarily form **ion-dipole and hydrogen bonds.** They can also **enhance water solubility** and be esterified to form prodrugs (see Chapter 17 VI).

c. Drug molecules containing phenols or **catechols** (see **levodopa** in Figure 8-7) are susceptible to **air oxidation** and to **oxidation on contact with ferric ions.**

d. Metabolism. Phenols undergo **sulfation, glucuronidation, aromatic hydroxylation,** and ***O*-methylation.**

3. Quaternary ammonium salts, as exemplified by ipratropium bromide (Figure 8-7), are neither acidic nor basic but contain a **permanent positive charge.**

a. These salts **enhance water solubility;** however, due to the permanence of the positive charge, compounds containing this functional group often have **difficulty passing through lipid membranes.**

b. Similar to amines, quaternary ammonium salts can participate in **ionic** and **ion-dipole bonds.**

c. Quaternary ammonium salts are generally not metabolized; however, **N-dealkylation** could occur in some cases.

E. Functional groups with intermediate polarity

1. Ketones are less prevalent than alcohols and phenols in the structures of drug molecules. One example is seen in the oral hypoglycemic agent, acetohexamide, shown in Figure 8-8.

a. Ketones are primarily lipid soluble; however, they are able to form **hydrogen bonds** with alcohols and certain amines. They can also form **ion-dipole** bonds.

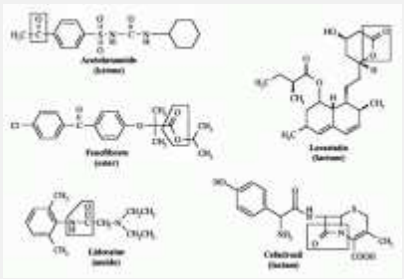

Figure 8-8. Examples of drugs that contain a ketone, ester, amide, lactone, or lactam as part of their chemical structure.

b. Metabolism. Ketones are very stable. Their primary route of metabolism is **reduction to an alcohol.**

2. Compounds containing **esters, amides** and their respective cyclic forms, **lactones, and lactams** can be seen in Figure 8-8.

a. These functional groups are capable of forming **hydrogen bonds** with receptors, enzymes, transport proteins, other macromolecules, and water. Similar to ketones,

esters and lactones can function as **hydrogen-bond acceptors,** while amides and lactams can function as either **hydrogen-bond donors or acceptors.**

b. Metabolism. Enzymatic **hydrolysis** is the primary route of metabolism for these functional groups. Esters and lactones are hydrolyzed to alcohols and carboxylic acids, while amides and lactams are hydrolyzed to amines and carboxylic acids. Esters and lactones are more susceptible to hydrolysis than are amides and lactams. Additionally, some lactams may undergo **N-dealkylation** prior to or in place of hydrolytic cleavage.

F. Lipophilic functional groups

1. Alkyl groups are **saturated hydrocarbon chains, links, and rings** that can vary in size from single-carbon **methyl** and **methylene** groups to large chains. Similar to the designations previously given for amines, the designation **alicyclic** refers to alkyl groups that are part of a nonaromatic ring, while the designation **aliphatic** refers to those that are part of a side chain or that function to connect, or bridge, other functional groups. Examples of alkyl groups are illustrated in Figure 8-9.

a. Alkyl groups can participate in **van der Waals interactions** (i.e., induced dipole-induced dipole bonds) and **hydrophobic bonding.**

b. Metabolism. Oxidation is the major route of metabolism. Alkyl side chains are usually oxidized at either the **terminal** (ω) or **penultimate (ω-1)** carbon atoms.

2. Alkenes, also known as **olefins,** are **unsaturated** analogs of alkyl groups (see Figure 8-9).

a. The binding ability of alkenes is similar to that of saturated alkyl groups.

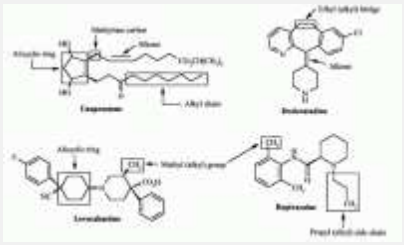

Figure 8-9. Examples of drugs that contain alkyl groups and alkenes as part of their chemical structure. For the sake of clarity, only certain functional groups have been highlighted.

b. Metabolism. Alkenes are somewhat more reactive than alkyl groups and are subject to metabolic **hydration, epoxidation, peroxidation,** and **reduction.**

3. Most **aromatic hydrocarbons** are analogs of either **benzene** or **naphthalene** (see Figure 8-10 for examples). When attached to a drug molecule, benzene is referred to as a **phenyl group.**

a. Similar to alkyl groups and alkenes, aromatic hydrocarbons can participate in **van der Waals interactions** and **hydrophobic bonding.** Additionally, aromatic rings can participate in **charge-transfer interactions.** Electron-rich aromatic rings (i.e., those with electron-donating groups) can form dipole-like interactions with electron-poor aromatic rings (i.e., those with electron-withdrawing groups).

b. Metabolism. Oxidation is the primary route of metabolism for aromatic hydrocarbons, with **hydroxylation, epoxidation,** and **diol formation** comprising the three most common pathways.

4. Ether functional groups contain an oxygen atom bound on both sides by either alkyl or aromatic carbons. They can be present as either a terminal functional group, such as the **methoxy group** of naproxen, or as part of a central chain/backbone, such as that seen in gemfibrozil (Figure 8-10).

a. The contribution of ethers to drug binding is minimal; however, these functional groups can participate in **dipole-induced dipole interactions** and can serve as **hydrogen-bond acceptors.**

b. Metabolism. Methyl and ethyl ethers can undergo ***O*-dealkylation,** while those larger do not generally undergo metabolism. While ethers used as organic solvents (e.g., diethylether) can form **peroxides and may explode,** this property is generally not present in drug molecules.

5. Alkyl and aromatic halides are **electron-withdrawing** functional groups. They are often used to "lock" a drug molecule in a desired conformation and/or to decrease aromatic oxidation of the drug. Fluorine is the smallest halogen, with its size very similar to that of hydrogen. Chlorine is the second smallest, followed by bromine and iodine, respectively. See Figure 8-10 for specific examples.

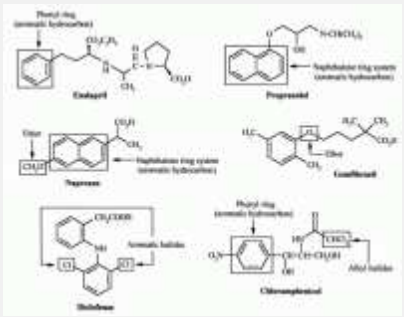

Figure 8-10. Examples of drugs that contain an aromatic hydrocarbon, ether, and/or alkyl or aromatic halide as part of their chemical structure. For the sake of clarity, only certain functional groups have been highlighted.

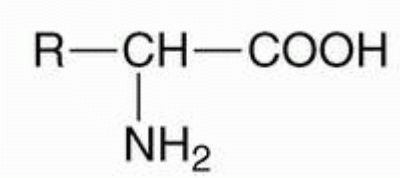
a. With the exception of fluorine, which can serve as a hydrogen-bond acceptor, halides do not directly participate in the binding of drugs to their receptors or other macromolecules.

b. Metabolism. Aromatic halides are not normally metabolized. Alkyl halides can undergo **oxidative dehalogenation** to form aldehydes.

II. BIOCHEMISTRY

A. Introduction. Biochemistry is the study of chemical principles that support life processes. It influences drug metabolism, therapeutic effectiveness, and biotransformation. Biochemically significant molecules include amino acids, carbohydrates, lipids, pyrimidines, purines, and biopolymers—proteins and enzymes, which are built from amino acids; polysaccharides, which are built from carbohydrates; and nucleic acids, which are built from pyrimidines and purines.

B. Amino acids are the monomeric units of proteins and enzymes and have the following general formula:



1. With the exception of glycine, naturally occurring amino acids are L, α-amino acids. Proteins are made up of the 20 different amino acids, which differ in the side chain (R) attached to

the α-carbon. The 20 different side chains vary in size, shape, charge, hydrogen-bonding capacity, and chemical reactivity. A protein can be hydrolyzed into its component α-amino acids by acids, bases, or enzymes.

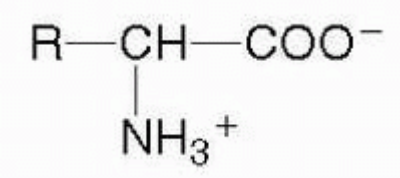
a. Amino acids with **acidic side chains** include aspartic acid and glutamic acid.

b. Amino acids with **basic side chains** include arginine, lysine, and histamine.

c. Amino acids with **polar, nonionic side chains** include glycine, serine, cysteine, threonine, tyrosine, asparagine, and glutamine.

d. Amino acids with **nonpolar, hydrophobic side chains** include alanine, valine, leucine, isoleucine, phenylalanine, methionine, proline, and tryptophan.

2. Amino acids have a **zwitterion structure,** which accounts for their high melting point and low water solubility. Amino acids in solution have the following general formula:



3. Ionization of amino acids to the zwitterion form or other forms depends on pH (Figure 8-11).

C. Carbohydrates. These are polyhydroxy aldehydes or ketones. Three major classes of carbohydrates exist.

1. Monosaccharides (simple sugars), such as glucose or fructose, consist of a single polyhydroxy aldehyde or ketone unit.

a. Aldehydic monosaccharides are reducing sugars.

b. Monosaccharides can be linked together by **glycosidic bonds,** which are hydrolyzed by acids but not by bases.

2. Oligosaccharides, such as sucrose, maltose, and lactose, consist of short chains of monosaccharides joined covalently.

a. Sucrose cannot be absorbed by the intestine until it is converted by sucrase into its components, glucose and fructose.

b. Maltose is hydrolyzed by maltase into two molecules of glucose.

c. **Lactose** (or milk sugar) cannot be absorbed by the intestine until it is converted by lactase into its components, galactose and glucose.

3. Polysaccharides, such as **cellulose** and **glycogen,** consist of long chains of monosaccharides.

D. Pyrimidines and purines. These are bases that, when bonded with ribose, form nucleosides, which when subsequently bonded to phosphoric acid form nucleotides—the structural building blocks of nucleic acids.

1. Pyrimidine bases include:

a. Cytosine (C), found in deoxyribonucleic acid (DNA) and ribonucleic acid (RNA)

b. Uracil (U), found in RNA only

c. **Thymine** (T), found in DNA only

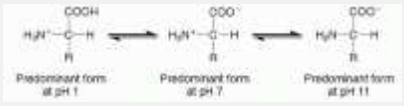


Figure 8-11. Amino acid ionization in solution. The carboxyl and amino groups are either in ionized or unionized form depending on the pH of the solution.

2. Purine bases include:

a. Adenine (A), found in DNA and RNA

b. Guanine (G), found in DNA and RNA

3. Pyrimidines and purines exhibit **tautomerism** (a form of stereoisomerism) and can exist in either **keto** (lactam) or **enol** (lactim) forms.

E. Biopolymers

1. Proteins are polymers of amino acids that are linked together by **peptide bonds** (i.e., links between carbonyl carbons and amino nitrogens [Figure 8-12]). Proteins have four structural levels.

a. Primary structure refers to the sequence of amino acids and location of disulfide bonds in the protein.
b. Secondary structure refers to the spatial arrangement of sequenced amino acids (for example, α-conformation [helical coil] or β-conformation [pleated sheet]).
c. **Tertiary** structure refers to the three-dimensional structure of a single protein.
d. Quaternary structure refers to the arrangement of individual subunit chains into complex molecules.
2. Enzymes are proteins capable of acting as catalysts for biologic reactions. They may be simple or complex and may require cofactors or coenzymes for biologic activity.
a. An enzyme enhances the rate of a specific chemical reaction by lowering the **activation energy** of the reaction. It does not change the reaction's equilibrium point, and it is not used up or permanently changed by the reaction.
b. A cofactor may be an **inorganic component** (usually a metal ion) or a **nonprotein organic molecule.** A cofactor may be biologically inactive without an apoenzyme (the protein portion of a complex enzyme). A cofactor firmly bound to the apoenzyme is called a **prosthetic group.** An organic cofactor that is not firmly bound but is actively involved during catalysis is called a **coenzyme.**
c. A complete, catalytically active enzyme system is referred to as a **holoenzyme.**
d. Enzymes fall into six major classes.
(1) Oxidoreductases (e.g., dehydrogenases, oxidases, peroxidases) are important in the oxidative metabolism of drugs.
(2) Transferases catalyze the transfer of groups, such as phosphate and amino groups.
(3) Hydrolases (e.g., proteolytic enzymes, amylases, esterases) hydrolyze their substrates.
(4) Lyases (e.g., decarboxylases, deaminases) catalyze the removal of functional groups by means other than hydrolysis.
(5) Ligases (e.g., DNA ligase, which binds nucleotides together during DNA synthesis) catalyze the coupling of two molecules.
(6) Isomerases catalyze various isomerizations, such as the change from D to L forms or the change from cisisomers to transisomers.
3. Polysaccharides (also called glycans) are long-chain polymers of carbohydrates and may be linear or branched. They are classified as homopolysaccharides or heteropolysaccharides.
a. Homopolysaccharides (e.g., starch, glycogen, cellulose) contain only one type of monomeric unit.
(1) Starch (a reserve food material of plants) is composed of two glucose polymers—amylose (linear and water soluble) and amylopectin (highly branched and water insoluble). It yields mainly maltose (a glucose disaccharide) after enzymatic hydrolysis with salivary or pancreatic amylase; only glucose after complete hydrolysis by strong acids.

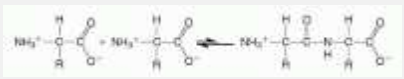

Figure 8-12. Peptide bond formation occurs as a result of the condensation of the carboxyl group of one amino acid with the amino group of another. Water is eliminated during this process.

(2) Glycogen, like amylopectin, is a highly branched, compact chain of D-glucose. The main storage polysaccharide of animal cells, it is found mostly in liver and muscle and can be hydrolyzed by salivary or pancreatic amylase into maltose and D-glucose.

(3) Cellulose (a water-insoluble structural polysaccharide found in plant cell walls) is a linear, unbranched chain of D-glucose. It cannot be digested by humans because the human intestinal tract secretes no enzyme capable of hydrolyzing it.

b. Heteropolysaccharides (e.g., heparin, hyaluronic acid) contain two or more types of monomeric units.

(1) Heparin (an acid mucopolysaccharide) consists of sulfate derivatives of D-glucuronate, D-glucosamine and L-iduronate. It can be isolated from lung tissue and is used medically to prevent blood clot formation.

(2) Hyaluronic acid, a component of bacterial cell walls as well as of the vitreous humor and synovial fluid, consists of alternating units of *N*-acetyl-D-glucosamine and *N*-acetyl-muramic acid.

4. Nucleic acids are linear polymers of nucleotides—pyrimidine and purine bases linked to ribose or deoxyribose sugars (nucleosides) and bound to phosphate groups. The backbone of the nucleic acid consists of alternating phosphate and pentose units with a purine or pyrimidine base attached to each.

a. Nucleic acids are closely associated with **cellular cations** and such basic proteins as **histones** and **protamines.**

b. The two main types of nucleic acids are **DNA** and **RNA.** RNA exists in three forms.

(1) Ribosomal RNA (rRNA) functions as a framework to bind both messenger and transfer RNA. It is comprised of numerous subunits with the 40S and 60S being the most well known.

(2) Messenger RNA (mRNA) serves as the template for protein synthesis and specifies a polypeptide's amino acid sequence.

(3) Transfer RNA (tRNA) carries activated amino acids to the ribosomes, where the amino acids are incorporated into the growing polypeptide chain.

c. In both DNA and RNA, the successive nucleotides are joined by **phosphodiester bonds** between the 5′-hydroxy group of one nucleotide's pentose and the 3′-hydroxy group of the next nucleotide's pentose.

d. DNA differs from RNA in that it **lacks a hydroxyl group** at the pentose's C_2' position, and it contains T rather than U.

e. DNA structure consists of two α-helical DNA strands coiled around the same axis to form a double helix. The strands are antiparallel—the 5′, 3′-internucleotide phosphodiester links run in opposite directions.

(1) Hydrogen bonding between specific base pairs A-T and C-G holds the two DNA strands together. The strands are complementary (the base sequence of one strand determines the base sequence of the other).

(2) The **hydrophobic bases** are on the inside of the helix; the hydrophilic deoxyribose-phosphate backbone is on the outside.

III. BIOCHEMICAL METABOLISM

A. Overview. Biochemical metabolism is the review of pathways that lead to the synthesis or breakdown of compounds important to the life of an organism.

1. Control of metabolism. Metabolism is controlled by substrate concentration, enzymes (constitutive or induced), allosteric (regulatory) enzymes, hormones, and compartmentation.

2. Catabolism is the sum of degradation reactions that usually release energy for useful work (e.g., mechanical, osmotic, biosynthetic).

3. Anabolism is the sum of biosynthetic (build-up) reactions that consume energy to form new biochemical compounds (metabolites).

4. Amphibolic pathways are those that may be used for both catabolic as well as anabolic purposes. **Krebs cycle** breaks down metabolites primarily to release 90% of the total energy of an organism. It also draws off metabolites to form compounds such as amino acids (e.g., aspartic, glutamic, alanine). Hemoglobin has its heme moiety formed from succinyl coenzyme A (succinyl CoA) and glycine followed by a complex set of reactions.

B. Bioenergetics

1. Substrate level phosphorylation entails the formation of one unit of adenosine triphosphate (ATP) per unit of metabolite transformed (e.g., succinyl CoA to succinate, phosphoenolpyruvate to pyruvate). These reactions do not need oxygen.

2. Oxidative phosphorylation entails the formation of one-and-a-half or two-and-a-half units of ATP per unit of metabolite transformed by oxidoreductase enzymes (e.g., dehydrogenases); these enzymes use flavin A dinucleotide (FAD) formed from the vitamin riboflavin, or nicotinamide A dinucleotide (NAD^+) from the vitamin nicotinamide as cofactors. The reactions are coupled to the electron transport system, and the energy released is used to form ATP in the mitochondria.

C. Carbohydrate metabolism

1. Catabolism. This process releases stored energy from carbohydrates.

a. Glycogenolysis is the breakdown of glycogen into glucose phosphate in the liver and skeletal muscle. It is controlled by the hormones glucagon and epinephrine.

b. Glycolysis is the breakdown of sugar phosphates (e.g., glucose, fructose, glycerol) into pyruvate (aerobically) or lactate (anaerobically).

2. Anabolism. This process consumes energy to build up complex molecules from simpler molecules.

a. Glycogenesis is the formation of glycogen in the liver and muscles from glucose consumed in the diet; its synthesis is controlled by the pancreatic hormone insulin.

b. Gluconeogenesis is the formation of glucose from noncarbohydrate sources, such as lactate, alanine, pyruvate, and Krebs cycle metabolites; fatty acids cannot form glucose.

D. Krebs cycle. This pathway is also known as the citric acid cycle, serves both breakdown and synthetic purposes, and occurs in the mitochondrial compartment.

1. Catabolism. This pathway converts pyruvate (glycolysis), acetyl CoA (fatty acid degradation), and amino acids to carbon dioxide and water with a release of energy. The cycle is strictly oxygen-dependent (aerobic). Mature red blood cells lack mitochondria; hence, there is no Krebs cycle activity.

2. Anabolism. This pathway forms amino acids such as aspartate and glutamate from cycle intermediates; also, the porphyrin ring of heme (e.g., hemoglobin, myoglobin, cytochromes) is formed from a cycle intermediate.

3. Anaplerotic reactions. Because metabolites are used to make amino acids or heme (e.g., succinyl CoA), the metabolite must be replaced by intermediates from other sources (e.g., glutamate from the breakdown of protein forms α-ketoglutarate).

4. Electron transport. The electron transport system accepts electrons and hydrogen from the oxidation of Krebs cycle metabolites and couples the energy released to synthesize ATP in the mitochondria.

E. Lipid metabolism

1. Catabolism. Triglycerides (triacylglycerols) stored in fat cells (adipocytes) are hydrolyzed by hormone-sensitive lipases into three fatty acids and glycerol.

a. Fatty acids are broken down by beta oxidation to acetyl CoA (two carbon units), which enter the Krebs cycle to complete the oxidation to carbon dioxide and water with release of considerable energy. Too rapid breakdown of fatty acids leads to ketone bodies (ketogenesis) as in diabetes mellitus.

b. Glycerol enters glycolysis and is oxidized to pyruvate and, via the Krebs cycle, to carbon dioxide and water.

c. **Steroids** may be converted to other compounds such as bile acids, vitamin D, or steroidal hormones (e.g., cortisone, estrogens, androgens); they are not broken down completely.

2. Anabolism. Biosynthesis forms fatty acids, steroids, and other terpene-related metabolites.

a. Fatty acids are formed in the cytoplasm, and unsaturation occurs in the mitochondria

or endoplasmic reticulum. Humans cannot make linoleic acid; thus, it is important that it be included in the diet (essential fatty acid).

b. Terpene compounds are derived from acetyl CoA via mevalonate and include:

(1) Cholesterol and other steroids

(2) Fat-soluble vitamins (i.e., A, D, E, K)

(3) Bile acids

c. **Sphingolipids** contain sphingenine formed from palmitoyl CoA and serine. Sphingenine forms a ceramide backbone when joined to fatty acids. The addition of sugars, sialic acid, or choline phosphate forms compounds such as cerebrosides, gangliosides, or sphingomyelin found in nerve tissues and membranes.

d. Phosphatidyl compounds, such as phosphatidyl choline (lecithin), phosphatidyl serine, or ethanolamine, are also important parts of membranes.

F. Nitrogen metabolism. Nitrogen metabolism involves amino acid metabolism and nucleic acid metabolism (see Chapter 9 for a discussion of the nucleic acid role in cell activity).

1. Catabolism

a. Amino acids. The amino group is removed by a transaminase enzyme. The carbon skeleton is broken down to acetyl CoA (ketogenic amino acids) or to citric acid cycle intermediates (glycogenic amino acids) and oxidized to carbon dioxide and water for energy. Glycogenic amino acids form glucose as needed via gluconeogenesis; some amino acids are both ketogenic and glycogenic (e.g., tyrosine).

b. Purines are salvaged (90%), and the remaining 10% are degraded in a sequence that includes xanthine oxidase forming uric acid in humans.

c. **Pyrimidines** are catabolized to β-alanine, ammonia, and carbon dioxide.

2. Anabolism

a. Amino acids are formed from the citric acid cycle intermediates (see III D 2); others must be eaten daily in dietary proteins. The latter are called essential amino acids (phenylalanine, valine, tryptophan [PVT]; threonine, isoleucine, methionine [TIM]; histidine, arginine in infants, lysine, leucine [HALL]).

b. Purines are formed by complex reactions using carbamoyl phosphate, aspartate, glutamine, glycine, carbon dioxide, and formyl tetrahydrofolate.

c. **Pyrimidines** are formed from aspartate and carbamoyl phosphate in a multistep process.

G. Nitrogen excretion. Excess nitrogen must be eliminated because it is toxic. Humans primarily excrete urea but also excrete uric acid.

1. Urea synthesis. The **Krebs-Henseleit pathway** is used to form urea principally in the liver. The ammonia is removed from amino acids by amino acid transferases (transaminases) that use pyridoxal phosphate (vitamin B_6) as a coenzyme.

Glutamine is formed from glutamate (an intermediate) and ammonia; glutamine and carbon dioxide form carbamoyl phosphate, which enters the urea cycle and after several steps forms urea.

2. Uric acid synthesis. Although most purines are salvaged, humans excrete the remaining purines as uric acid.

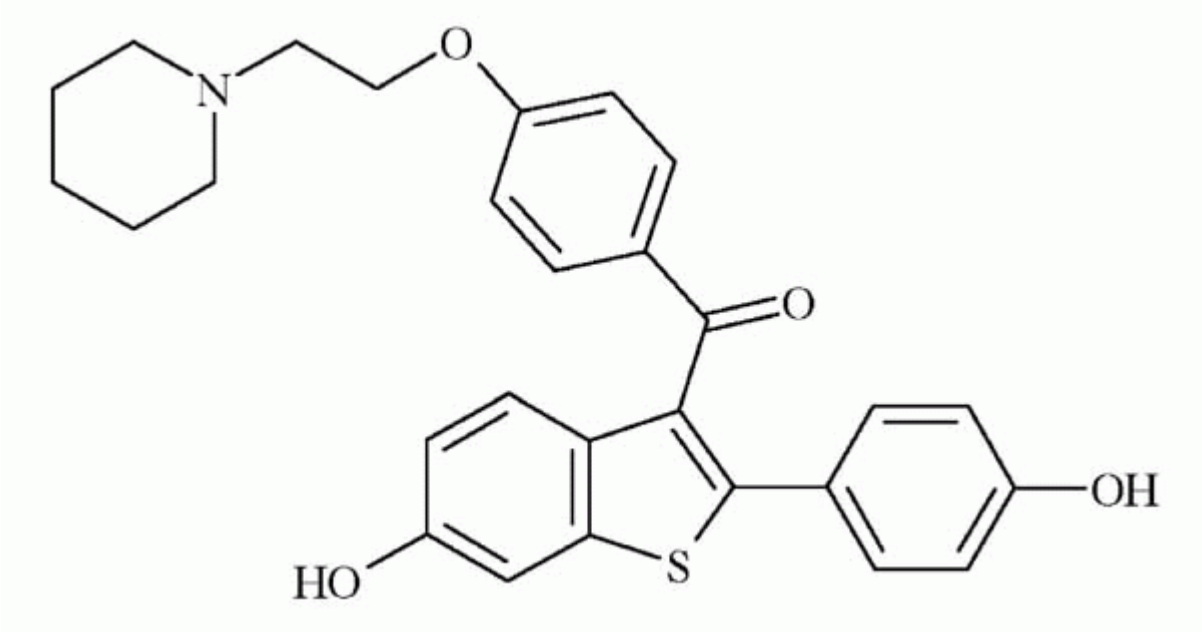
STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. Which of the following functional groups can react with hydrochloric acid to form a salt?

(A) Tertiary amines
(B) Carboxylic acids
(C) Amides
(D) Ethers
(E) Secondary alcohols

View Answer***1. The answer is A[].***2. **The compound shown contains all of the following functional groups EXCEPT:**



(A) a phenol
(B) a substituted phenyl ring
(C) an ester
(D) an alicyclic nitrogen
(E) a ketone

View Answer***2. The answer is C[].***3. **Which of the following functional groups is most susceptible to hydrolysis?**

(A) R—CO—R
(B) R—COOR
(C) R—O—R
(D) R—NH—CH_3
(E) R—COOH

View Answer*3. The answer is B[].*4. **Monomer units of proteins are known as**

(A) monosaccharides

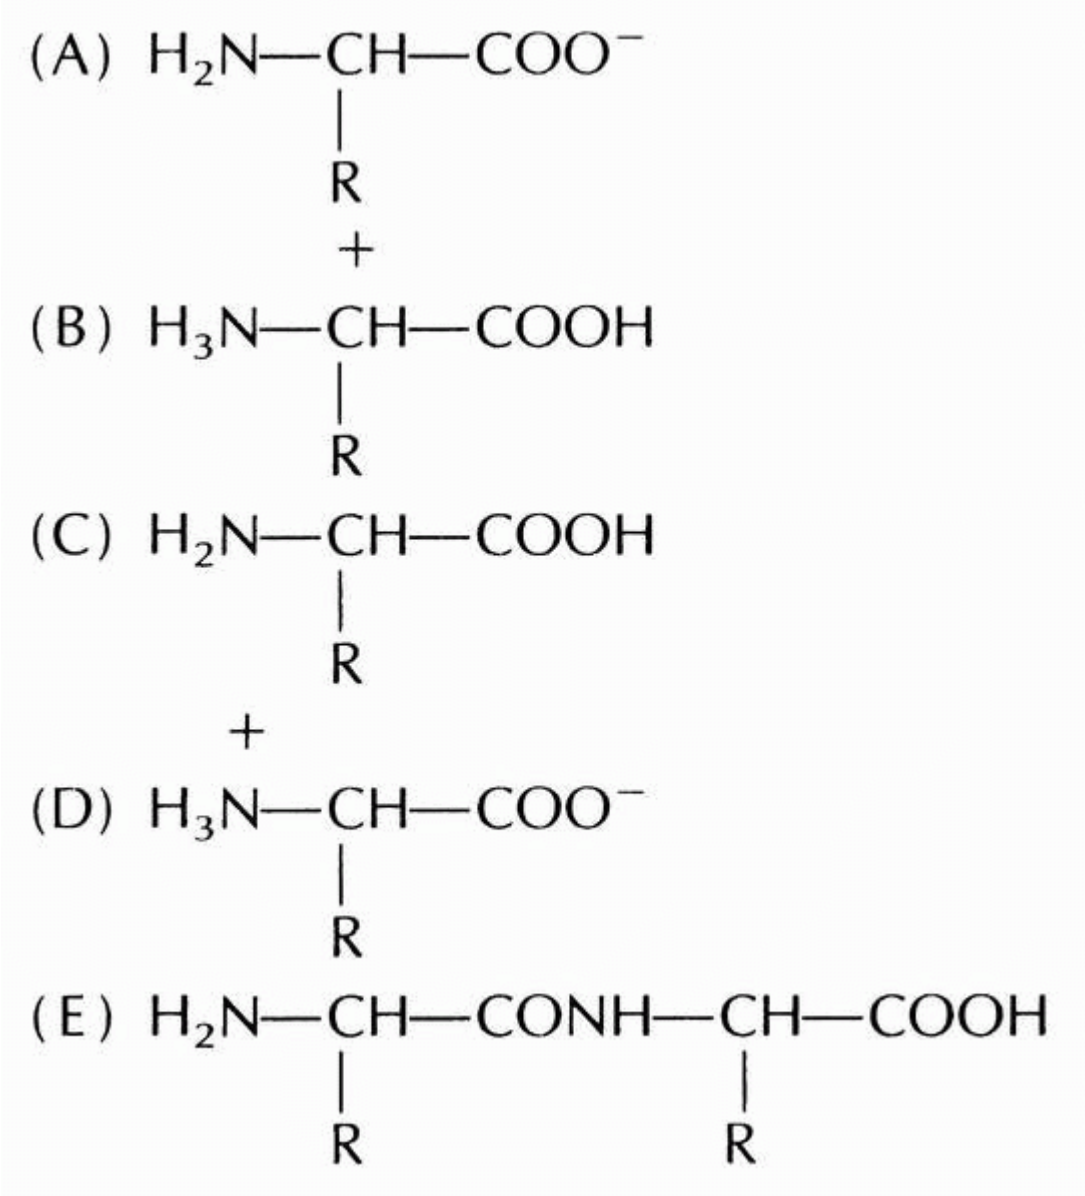
(B) prosthetic groups

(C) amino acids

(D) purines

(E) nucleosides

View Answer*4. The answer is C[].*5. **Which of the following formulas represents the zwitterion form of an amino acid?**



View Answer*5. The answer is D[].*6. **Glucose is a carbohydrate that cannot be hydrolyzed into a simpler substance. It is best described as**

(A) a sugar

(B) a monosaccharide

(C) a disaccharide

(D) a polysaccharide

(E) an oligosaccharide

View Answer***6. The answer is B[].***7. **All of the following carbohydrates are considered to be polysaccharides EXCEPT**

(A) heparin

(B) starch

(C) glycogen

(D) maltose

(E) cellulose

View Answer***7. The answer is D[].***8. **Which of the following compounds are considered the building blocks of nucleic acids?**

(A) Nucleotides

(B) Nucleosides

(C) Monosaccharides

(D) Purines

(E) Amino acids

View Answer***8. The answer is A[].***P.172

9. Which of the following terms best describes a cofactor that is firmly bound to an apoenzyme?

(A) Holoenzyme

(B) Prosthetic group

(C) Coenzyme

(D) Transferase

(E) Heteropolysaccharide

View Answer***9. The answer is B[and].O***10. **Enzymes that uncouple peptide linkages are best classified as**

(A) hydrolases

(B) ligases

(C) oxidoreductases

(D) transferases

(E) isomerases

View Answer***10. The answer is A[].***11. **The sugar that is inherent in the nucleic acids RNA and DNA is**

(A) glucose

(B) sucrose

(C) ribose

(D) digitoxose

(E) maltose

View Answer***11. The answer is C[].*****Directions:** Each item below contains three suggested answers of which **one or more** is correct. Choose the answer.

12. Which of the following functional groups can form a hydrogen bond?

I. An aromatic amine

II. A tertiary hydroxyl

III. An aromatic hydrocarbon

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***12. The answer is C[].***13. **Which of the following functional groups commonly undergoes conjugation with glucuronic acid?**

I. A carboxylic acid

II. A primary amine

III. A phenol

A if **I only** is correct

B if **III only** is correct

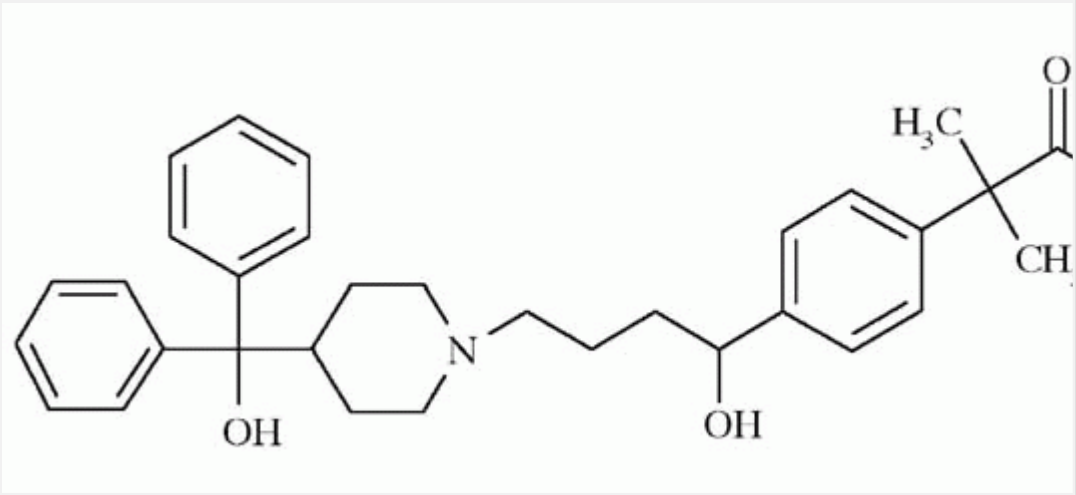
C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***13. The answer is E[].***Questions 14-16

The following questions refer to the drug molecule shown below.



14. The functional groups that enhance this compound's ability to cross cell membranes include:

I. the phenyl rings

II. the central alkyl chain

III. the secondary and tertiary hydroxyls

A if I only is correct

B if III only is correct

C if I and II are correct

D if II and III are correct

E if I, II, and III are correct

15. Based upon the functional groups present, this drug would be expected to be able to form:

I. van der Waals interactions

II. ionic bonds
III. hydrogen bonds
A if I only is correct
B if III only is correct
C if I and II are correct
D if II and III are correct
E if I, II, and III are correct
16. Possible metabolic pathways for this drug include:
I. reduction of the carboxylic acid
II. hydrolytic cleavage
III. aromatic oxidation
A if I only is correct
B if III only is correct
C if I and II are correct
D if II and III are correct
E if I, II, and III are correct

View Answer***14-16. The answers are: 14-C[],15-E (I, II, and III)[],16-B (III)[].***P.173

ANSWERS AND EXPLANATIONS

1. The answer is A *[*I C 2 c*].*
Substances that react with acids to form salts must be bases. Only organic compounds that contain the nitrogen-containing amine group are bases. While amides contain nitrogen, the adjacent carbonyl group decreases the basicity; therefore, they are essentially neutral.
2. The answer is C *[*Figures 8-4, 8-7, 8-8, 8-10*].*
As shown in Figure 8-8, esters have a carbonyl atom directly bonded to an oxygen atom. This structural feature is not present in this compound. However, the compound does have three substituted phenyl rings, two phenols, a tertiary alicyclic nitrogen, a ketone, and an ether.
3. The answer is B *[*I E 2 b*].*
Hydrolysis is a double decomposition reaction in which water is one of the reactants. Esters, particularly simple esters, commonly undergo hydrolysis. Certain types of ethers such as glycosides also undergo hydrolysis, but they usually require strongly alkaline conditions or a catalyst such as an enzyme. Ketones, amines, or carboxylic acids do not undergo hydrolysis.
4. The answer is C *[*II B 1, II E 1*].*
Proteins are large molecules with molecular weights ranging from 5000 to more than 1 million daltons. All proteins are composed of chains of amino acids and can be hydrolyzed to yield a mixture of their respective amino acids. There are 20 α-amino acids, which are commonly found in proteins. All the naturally occurring amino acids in proteins are L-enantiomers, with the exception of glycine. All have at least one amino group and one carboxyl group. The amino acids are linked together through

the amino group of one amino acid and the carboxyl group of another amino acid with the splitting out of a water molecule to form an amide linkage, which in a protein is referred to as a peptide. Monosaccharides are simple, nonhydrolyzable sugars. Purines and pyrimidines are organic bases, while a prosthetic group is a cofactor that is firmly bound to an apoenzyme.

5. The answer is D *[*I A 1 a, II B 2, 3, II E 1, Figures 8-2, 8-11, 8-12*].*

A zwitterion is a single species containing both negative and positive charges. It sometimes is referred to as an internal salt. Amino acids have an amino group and a carboxyl group in the same molecule. The amino group, which is basic, attracts the proton from the carboxyl group and becomes positively charged, while the carboxyl group becomes negatively charged when it donates its proton to the amino group. Amino acids exist as zwitterions at near neutral pH such as occurs within a cell or in the bloodstream.

6. The answer is B *[*II C 1*].*

While glucose is a sugar, it is more specifically a simple sugar that cannot be hydrolyzed into more simple sugars—thus, it is classified as a monosaccharide. Sugars may be simple, such as glucose, or complex, such as sucrose, and are classified as disaccharides or oligosaccharides, respectively. Polysaccharides consist of long chains of monosaccharides such as cellulose and glycogen.

7. The answer is D *[*II C 2 b, 3, E 3 a, b*].*

Polysaccharides are long-chain polymers of sugars. As the prefix “poly” indicates, there are many sugar units in the molecule. Maltose is composed of two molecules of glucose and is classified as a disaccharide or an oligosaccharide.

8. The answer is A *[*II D, E 4*].*

Nucleic acids are linear polymers of nucleotides that consist of three different molecules that are covalently linked to form one unit: (1) an organic base of either a purine or a pyrimidine; (2) a 5-carbon sugar (e.g., pentose); and (3) a phosphoric acid group. A nucleoside consists of the organic base and the pentose. A monosaccharide is a simple nonhydrolyzable carbohydrate, which may be considered a building block of polysaccharides. Purines are heterocyclic bases. Adenine and guanine are the two purines found in deoxyribonucleic acid (DNA) and ribonucleic acid (RNA). Amino acids are the building blocks of protein.

9. The answer is B *[*II E 2 b, c *and* d*].*

Complex, or conjugated, enzymes contain a nonprotein group called a cofactor, which is required for biologic activity. In many cases, the cofactor is quite firmly bound to the protein. In others, the binding occurs only during the reaction that the enzyme catalyzes. Cofactors that are firmly bound to the protein are known as prosthetic groups, whereas those that are actively bound to the protein only during catalysis are referred to as coenzymes.

A holoenzyme is a complete, catalytically active enzyme system. A transferase is an enzyme that catalyzes the transfer of groups from one substance to another, such as catechol-*O*-methyl transferase (COMT). A heteropolysaccharide is a

polysaccharide that contains two or more different monomeric units, such as heparin.

10. The answer is A *[*II E 2 d*].*

A peptide linkage is an amide functional group formed from the loss of a molecule of water from two amino acids. Uncoupling this linkage is the reverse of this reaction, a hydrolysis reaction. A hydrolase is an enzyme that catalyzes hydrolysis reactions. More specific terms for an enzyme that catalyzes the hydrolysis of proteins are amidase or peptidase. A ligase catalyzes the coupling of two molecules. An oxidoreductase catalyzes oxidation reactions. A transferase catalyzes the transfer of groups from one substance to another. An isomerase catalyzes the interconversion of one isomer to another.

11. The answer is C *[*II E 4*].*

Nucleic acids are biopolymers consisting of long chains of nucleotides. Nucleotides contain a pentose monosaccharide as one of their three constituents. RNA contains, as the name suggests, the monosaccharide ribose, whereas DNA contains deoxyribose. The only difference between these two sugars is the absence of oxygen in the 2 position of the ribose ring. Glucose, also known as dextrose, is a hexose. Digitoxose is a deoxyhexose present in the digitalis glycosides. Sucrose and maltose are disaccharides.

12. The answer is C (I, II) *[*I C 2 b, D 1 a, F 3 a*].*

Hydrogen bonds are a specialized type of dipole bond in which a hydrogen atom serves as a bridge between two electronegative atoms. Hydrogen-bond donors include hydroxyl groups, phenols, amines, and amides. Hydrogen-bond acceptors include hydroxyl groups, phenols, unionized nitrogen atoms, ketones, and ethers. Hydrocarbons, regardless if they are aliphatic, alicyclic, or aromatic, are not capable of forming hydrogen bonds.

13. The answer is E (I, II, and III) *[*I B 2 e, C 2 d, D 2 d*].*

Glucuronide conjugation is the most common phase II metabolic pathway for two reasons: (1) The body has a readily available supply of glucuronic acid, and (2) there are a large number of functional groups that can react with this compound. Included among these functional groups are carboxylic acids, primary, secondary and tertiary amines, and phenols.

14-16. The answers are: 14-C (I, II) *[*I A 1, D 1 b, F 1, 3*],* **15-E (I, II, and III)** *[*I B 2 b, C 2 b, D 1 a, F 1 a, 3 a*],* **16-B (III)** *[*I B 2 e, E 2 b, F 3 b*].*

Lipophilic functional groups increase a drug's ability to cross cell membranes. The three aromatic phenyl rings, as well as the aliphatic butyl chain connecting the central phenyl ring to the nitrogen of the piperadine ring, are all lipophilic (i.e., hydrophobic) and contribute to the drug's passage through cell membranes. The hydroxyl groups, as well as the acidic carboxylic acid and the basic alicyclic amine, are all hydrophilic and enhance the overall water solubility of the compound.

The phenyl rings, as well as the central alkyl chain and the methyl groups, are capable of forming van der Waals interactions with aromatic and aliphatic hydrocarbon regions on receptor molecules. The carboxylic acid and the basic nitrogen are capable of forming both ionic and hydrogen bonds, while the hydroxyl groups are also capable of forming hydrogen bonds.

Of the metabolic pathways listed, aromatic oxidation is the only plausible choice. The two unsubstituted phenyl rings are very susceptible to hydroxylation, epoxidation, and/or diol formation. Carboxylic acids are not normally reduced, but rather conjugated with either glucuronic acid, glycine or glutamine. Esters, amides and their cyclic derivatives, lactones and lactams, are the primary functional groups that undergo hydrolysis. None of these functional groups are present in the compound shown.

9

Microbiology

Gail Goodman-Snitkoff

I. SCOPE OF MICROBIOLOGY.

Microbiology is the study of organisms from three domains as well as acellular entities that are not considered to be living in the biological sense.

A. Domains of living organisms

1. Archaea include prokaryotes with cell walls that are biochemically different from bacteria and that inhabit extreme environments of heat, cold, pH, or salts. Archaea are not a medically important domain of microorganisms.

2. Eukarya contains some microorganisms—for example, fungi (yeasts and molds), protozoa, and algae—along with macroscopic organisms such as mushrooms, plants, and animals. **Dimorphic fungi** are those that can exist in either the unicellular (yeast) or the filamentous (mold) phase, depending on the incubation temperature (e.g., *Histoplasma* and *Blastomyces*).

a. Fungi are classified into phyla based on the type of reproductive structures observed or the lack of observable sexual reproductive structures.

(1) Ascomycota (ascus) (e.g., *Candida* and *Histoplasma*)

(2) Basidiomycota (basidium) (e.g., *Cryptococcus*)

(3) Zygomycota (zygote) (e.g., *Rhizopus*)

(4) Deuteromycota (asexual, also called fungi imperfecti) (e.g., *Coccidioides*). Recently, some sexual reproductive states have been identified in fungi classified as belonging to Deuteromycota.

b. Protozoa, unicellular, nonphotosynthetic eukaryotes characterized by mode of motility, include the following:

(1) Mastigophora (flagellates) (e.g., *Giardia*)

(2) Sarcodina (amoebae) (e.g., *Entamoeba*)

(3) Ciliophora (ciliates) (e.g., *Balantidium*)

(4) Sporozoa (nonmotile) (e.g., *Plasmodium*)

3. Bacteria contain a wide variety of prokaryotes, including gram-positive and gram-negative bacteria. Sections II-VII characterize bacteria in more detail.

B. Nonliving, but medically significant entities are the following

1. Viruses (see VIII), which are classified by:

a. Capsid structure, which is the protein coating around the nucleic acid

b. Type and strandedness of nucleic acid, which could be DNA or RNA, either single or double stranded

c. Presence or absence of a **lipid envelope** surrounding the protein capsid

d. Presence of **enzymes,** which may be either incorporated into the lipid envelope or found in the capsid near the nucleic acid

2. Prions, infectious proteins, are implicated in some spongiform encephalopathies (e.g., mad cow disease, Creutzfeldt-Jakob disease, and kuru).

II. TAXONOMY AND NOMENCLATURE OF BACTERIA

A. Taxonomy is classification or ordering into groups based on degree of relatedness. Bacteria are **prokaryotes** that belong to the Bacteria domain and the Eubacteria kingdom and are grouped and named primarily by morphology, biochemical and metabolic differences, and immunologic and genetic relationships. DNA technology has led to the reclassification of some organisms based on DNA sequences and homology. Bacteria are named using the **Linnaean** or **binomial** system as a genus and species (e.g., *Homo sapiens* is the genus and species for humans).
P.176

B. Morphology is the classification of bacteria by shape and structure.
1. Cultural morphology is based on the size, shape, and texture of colonies that are grown in pure culture on an agar plate. Each colony originates from a **colony-forming unit (CFU),** consisting of a single cell or group of adherent cells.
2. Microscopic morphology describes bacteria on the basis of the size, shape, and arrangement of the cells (see II.C and D).
C. Stains. Because of their small size and relative transparency, bacteria must be stained to be visible under the light microscope. Staining is also used as a classification system. The major types of staining reactions are the following:
1. Simple stain. A single dye (e.g., Gentian violet, safranin) that colors the cells.
2. Gram stain. A differential staining procedure that divides bacterial cells into either gram-positive (purple) or gram-negative (pink).
3. Acid-fast stain. A procedure that stains cells that have an outer layer of a waxy lipid (acidfast) but not cells that lack that layer (non-acid-fast).
4. Spore stain. A procedure that uses heat to help dye enter the spore.
5. Capsule stain. Two dyes are used to stain the cell and the background, allowing visualization of the unstained capsular material.
D. Bacterial cell shape and arrangement
1. Cocci are spherical and exist in chains (*Streptococcus pyogenes*), pairs or diplococci (*Streptococcus pneumoniae, Neisseria gonorrhoeae*), clusters (staphylococci), and packets of four or eight (sarcinae).
2. Bacilli are cylindrical and rod-shaped organisms (pseudomonads, *Escherichia*).
3. Coccobacilli are short rounded rods (*Brucella*).
4. Spirochetes and spirilla are helical, like a corkscrew (*Treponema pallidum*); spirilla are rigid helices, whereas spirochetes are flexible helices.
5. Fusobacteria have tapered ends and are slightly curved (i.e., fusiform; *Fusobacterium mortiferum*).
6. Filamentous organisms are branching organisms and are associated with mold-like bacteria (*Actinomyces bovis*).
7. Vibrios are comma shaped rods (*Vibrio cholerae*).
8. Pleomorphic organisms exist in varied forms (*Haemophilus, Legionella, Corynebacteria*).
E. Other classification parameters
1. Presence or absence of

a. Spores used for survival (*Bacillus anthracis*).
b. Capsules or **slime layers** used for adherence. Capsules are also antiphagocytic (*Streptococcus pneumoniae, Neisseria meningitidis*).
2. Motility and the type of **flagella**
a. Monotrichous. A single flagellum
b. Lophotrichous. A tuft of flagella at one pole
c. **Amphitrichous.** A flagellum at both poles
d. Peritrichous. Flagella distributed evenly over the entire cell
e. Axial filaments. Periplasmic flagella wrapped around spirochetes
f. Gliding motility. As demonstrated by slime molds
P.177

III. STRUCTURE OF THE PROKARYOTIC CELL

A. Overview. Prokaryotic cells (bacteria) are **small** and relatively **simple** (Figure 9-1). They have the following characteristics:
1. Contain no internal membrane bound organelles but have complex cell wall structures
2. Lack a true nucleus, a nuclear membrane, and intracytoplasmic membranous organelles (e.g., plastids, endoplasmic reticulum, vacuoles)
3. Multiply asexually by **binary fission** rather than by mitosis or meiosis
4. Protein synthesis is mediated by 70s rather than by 80s ribosomes.
5. Bacterial genetic information is arranged on a single supercoiled circular strand of double-stranded DNA; the **nucleoid** is the area of the cell containing the tightly coiled chromosome.
6. Some bacteria contain storage granules, or inclusion bodies, the staining of these granules may also be useful in identifying the bacteria.
B. External structures
1. Capsule and slime layer
a. The **capsule** is an adherent, surface coat made up of long chain repeats of carbohydrates or peptides. The capsule differs in composition among bacteria of different genus and species. Antigenic differences among capsules can be used to identify strains within a single species of bacteria (*Streptococcus pneumoniae*). Capsules are usually polysaccharide in nature; however, the capsule of *Bacillus* is polypeptide. The capsule has several functions:
(1) Increases the **virulence** (degree of organism pathogenicity) of a microorganism
(2) Prevents **phagocytosis** of the organism by macrophages and neutrophils
(3) Aids in **adherence** of the organism to host cells
b. If the polysaccharide is nonadherent, it is called a **slime layer.**

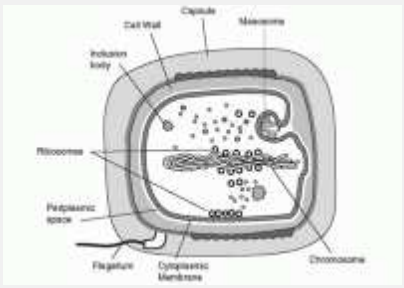


Figure 9-1. Structure of a procaryote cell. [Adapted with permission from Winn WC Jr, Allen SD, Janda WM, et al. Koneman's Color Atlas and Textbook of Diagnostic Microbiology, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2006.]

c. **Transformation** from smooth to rough colonies on media indicates **capsule loss.** Concurrently, there is a loss of virulence. This capsular material is immunogenic, thereby inducing the production of **antibodies,** which act as opsonins to enhance phagocytosis (**opsonization**).

2. Flagella are proteinaceous, helically coiled organs used for movement that extend outward from the cytoplasm through the cell wall into the environment (Figure 9-2). Flagella rotate either clockwise or counterclockwise, allowing a series of runs and tumbles in response to chemicals in the environment. The direction of movement is controlled by a complex mechanism involving chemoreceptors and an intracellular cascade of methylation and phosphorylation reactions, causing bacteria to move toward nutrient chemoattractants and away from repellants.

a. Structure

(1) Flagella are composed of **flagellin,** a protein called **Hantigen,** which is antigenically distinct from other flagella in eucaryotes.

(2) Flagella have **three parts:**

(a) Basal body

(i) Attaches the flagella to the cytoplasmic membrane and cell wall

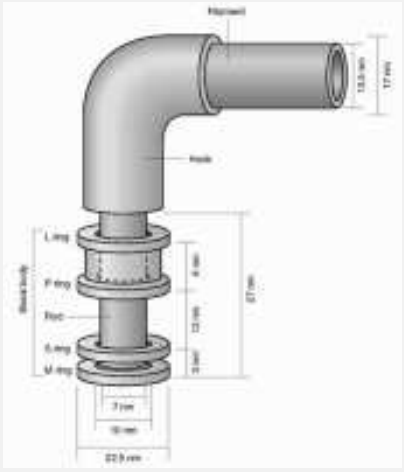

Figure 9-2. Structure of a procaryote flagella from a Gram-negative organism. [Adapted with permission from Winn WC Jr, Allen SD, Janda WM, et al. Koneman's Color Atlas and Textbook of Diagnostic Microbiology, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2006.]

P.179

(ii) The number of rings that make up the basal body differ in gram-positive (two) and gram-negative (four) organisms. The L and P rings are absent in Gram-positive organisms.

(b) Hook

(c) Filament

b. Periplasmic flagella, also called **axial filaments,** occur in spirochetes and are embedded into the cell wall's outer membrane. Because they cause a corkscrew type of motion on contraction, these organisms are not hindered by the viscosity of media.

3. Pili (**fimbriae**) are proteinaceous, hair-like extensions that are shorter than flagella and composed of regularly arranged protein subunits called **pilin** or **fimbrilin.** They are more common in gram-negative organisms but can be found in gram-positive organisms. There are two morphological and functional varieties:

a. Common (attachment) pili

(1) Appear in greater numbers than sex pili

(2) Have adhesive properties, which are important in the formation of biofilms

(3) Are lectins, which are responsible for trophism, the ability of the organism to bind to specific receptors on host cells

b. Sex (conjugative or F) pili

(1) Are longer than common pili

(2) Form in groups of < 10

(3) Are involved in the transport of DNA between donor and recipient cells

C. The cell wall, periplasmic space, and cytoplasmic membrane

1. The **cell wall** is rigid. Although it provides the general shape of the cell, its function is to protect the cell from osmotic shock. If the cell wall is destroyed, the bacterial cells are susceptible to alterations in the tonicity of the environment. The wall is composed of a basic **peptidoglycan layer,** which in turn is composed of repeating disaccharide units (a polymer of ***N*-acetylglucosamine** and ***N*-**

acetylmuramic acid), with a four-amino-acid side chain that is covalently linked to amino acids from neighboring disaccharide units, forming a stable cross-linked structure. Most bacteria are designated as either gram-positive or gram-negative, based on fundamental differences in the components of the cell wall. Owing to the uniqueness and the importance of the cell wall to bacterial viability, it is the target of many antibiotic agents.

a. Gram-positive organisms have a thick cell wall, which is 90% peptidoglycan, with extensive cross-linking that is approximately 40 layers thick and forms a layered network around the cytoplasmic membrane. Within the cell wall, a variety of elements serve to stabilize the cell wall, maintain its association with the cytoplasmic membrane, and act as receptors and antigenic determinants. These elements include proteins, polysaccharides and teichoic acid (glycerol or ribitol phosphodiesters).

(1) Teichoic acids (glycerol or ribitol phosphodiesters)

(a) Membrane-associated teichoic acids (lipoteichoic acid) are covalently linked to glycolipids of the cytoplasmic membrane.

(b) Wall-associated teichoic acids are covalently linked to the glycan chain of peptidoglycan.

b. Gram-negative organisms' cell walls are multilayered with a thin peptidoglycan layer that has no teichoic acids. External to this is the **outer membrane,** a complex cell wall layer, which is linked to the peptidoglycan layer by the **lipoprotein** layer. The outer membrane acts as a hydrophobic diffusion barrier and consists of

(1) Phospholipid, a bi layer similar to the cytoplasmic membrane with protein channels, called **porins,** for nutrient transport. The phospholipid layer of the outer membrane faces the cytoplasmic membrane.

(2) The **lipopolysaccharide (LPS)** component projects from the cell surface and is both toxic and antigenic (**O antigen**). In a gram-negative organism, the LPS **blocks diffusion** of low molecular weight substances into the cell, so antibiotics and chemicals that attack the cell wall (e.g., lysozyme, penicillin) cannot easily pass through. LPS, also known as **endotoxin,** is toxic to humans and is composed of three parts:

(a) Lipid A: toxic portion that can either slough off intact cells or be released into circulation upon lysis of the cell, causing nonspecific inflammation, including diarrhea, fever, and septic shock

(b) Core polysaccharide: similar within genera

(c) O-specific side chain: species specific

(3) Protein

2. The **periplasmic space,** an area between the cell wall and the cytoplasmic membrane, contains a gel of several types of molecules (e.g., hydrolytic enzymes, periplasmic-binding proteins) that process molecules before they enter the cytoplasm. It also contains proteins that act as chemoreceptors for chemotaxis,

others that act as carriers of nutrients (similar to carriers in the cytoplasmic membrane), and antibiotic-inactivating enzymes.

3. The **cytoplasmic membrane** is a phospholipid bilayer matrix of a fatty acid core (hydrophobic) and glycerol phosphate (hydrophilic). In the presence of proteins embedded in the matrix, these membranes are actively and passively engaged in several **cellular functions.**

a. Transportation of nutrients through

(1) Passive diffusion

(2) Facilitated diffusion

(3) Active transport (this method is the only one that actively uses energy because molecules are moving into the cell against a concentration gradient)

b. The site of **respiration proteins** used for **electron transport** and energy formation

c. **Enzymes** involved in the assembly of the cell wall components

d. Secretion of exotoxins and other substances for the breakdown of macromolecules

D. Internal structures

1. Storage granules are inclusion bodies used for food or energy storage (e.g., polyphosphate complexes, carbohydrate).

2. Ribosomes are cellular units that synthesize protein by the translation of messenger RNA (mRNA) base sequences into amino acid protein sequences. These ribosomes, unlike those in eukaryotic cells, are 70s units and are not associated with membranes such as mitochondria or rough endoplasmic reticulum.

3. The **nuclear region** of bacteria is a condensed area (a nucleoid) containing the bacterial chromosome, which lacks a nuclear membrane and consists of a long, double-stranded, supercoiled, circular DNA molecule.

4. Some organisms contain **plasmids,** circular double-stranded pieces of DNA that are found outside of the bacterial chromosome. These structures are autonomous (not controlled by the bacterial chromosome), contain information for heavy metal and antibiotic resistance, are conjunctive, and carry genetic elements called **transposons.**

IV. MICROBIAL PHYSIOLOGY

A. Nutritional types

1. Autotrophs use carbon dioxide as their sole or main carbon source.

a. Photoautotrophs use light as an energy source.

b. Chemoautotrophs oxidize organic or inorganic compounds to produce energy.

2. Heterotrophs use organic compounds as their main carbon source.

a. Photoheterotrophs use light as an energy source.

b. Chemoheterotrophs oxidize organic and inorganic compounds to produce energy.

3. Prototrophs are parent cells that have no special nutritional requirements. They require the same nutrients as the major number of the natural members of the species.

4. Auxotrophs are mutated so that they cannot synthesize the same essential nutrients (usually amino acids) as their parent cell.

5. Subsets

a. Holophytic. Organisms whose nutrients must be in a soluble, diffusible form

b. Holozoic. Organisms that need complex nutrients, often solid materials that are ingested and then broken down

c. **Saprophytic.** Organisms whose nutrients are obtained from dead or decaying organic matter

d. Parasitic. Organisms whose nutrients are obtained from and at the expense of a living organism (human pathogens)

B. Nutritional requirements. Bacteria use a wide variety of nutrients to obtain energy and to construct new cellular components. The six elements used as the main components of carbohydrates, lipids, proteins, and nucleic acids are carbon, oxygen, hydrogen, nitrogen, phosphorus, and sulfur. Several minor and trace elements as well as cations play various roles in the microorganisms.

C. Temperature relations

1. Psychrophile, an organism that grows well at 0°C, has optimal growth at 15°C or less, and a maximum growth temperature of 20°C

2. Mesophile: an organism with optimal growth at 20°-45°C, minimum growth temperatures between 15° and 20°C, and a maximum growth temperature of approximately 45°C (human pathogens)

3. Thermophile: an organism that can grow at 55°C or greater, with a minimum growth temperature of approximately 45°C.

D. Oxygen requirements. How organisms use oxygen can be a major factor in their classification.

1. Aerobes have the ability to grow in the presence of atmospheric oxygen.

a. Obligate aerobes depend completely on oxygen for growth. Oxygen serves as terminal electron acceptor in aerobic respiration.

b. Facultative aerobes have the ability to grow with or without molecular oxygen.

2. Anaerobes have the ability to grow without oxygen.

a. Obligate anaerobes do not tolerate oxygen at all and die in its presence. Many strains lack catalase and superoxide dismutase, which protect cells from the destructive oxidizing capabilities of hydrogen peroxide and superoxide ions, which are normally produced under aerobic conditions.

b. Facultative anaerobes do not require oxygen but grow better in its presence.

3. Microaerophiles require oxygen levels below normal atmospheric pressures for growth (e.g., *Helicobacter pylori*)

4. Capnophiles require higher levels of carbon dioxide than are found at normal atmospheric pressures for growth (e.g., *Neisseria* sp. and *Streptococcus pneumoniae*).

E. Bacterial growth curve. Bacterial growth is defined as an increase in the number of cells present. Because bacteria reproduce by **binary fission,** growth can

be plotted as the log of the cell number versus time to produce a curve with four distinct phases (Figure 9-3).

1. Lag phase. A transition period during which the bacteria are replicating DNA and the enzymes needed for the new environment are being induced. The cells are increasing in size but not in number. During this phase of growth, the cells are most permeable.

2. Logarithmic (log) phase. Division occurs at constant and maximal rate, and the number of cells increases in a geometric progression. The generation time, which varies among species, is usually 15-20 minutes (*Escherichia*), but may be hours (*Mycobacterium*). Because the cell wall is being synthesized so rapidly, bacterial cells are most susceptible to cell wall inhibitors during this phase.

3. Stationary phase. The growth rate tapers off and growth and death rates are nearly equal. A fairly constant population of viable cells results. During this phase, cellular metabolites are polluting the environment.

4. Death phase. When the concentration of viable cells decreases because of the accumulation of toxic wastes and autolytic enzymes.

V. METABOLISM AND ENERGY PRODUCTION.

Microorganisms derive energy from nutrients by a series of chemical reactions by which the energy stored in chemical bonds is transferred to newly formed chemical bonds to provide energy storage in a useful form, such as adenosine triphosphate (ATP).

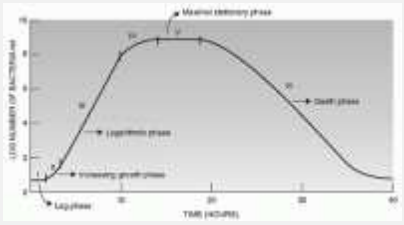

Figure 9-3. Growth curve of bacterial culture. [Reprinted with permission from Winn WC Jr, Allen SD, Janda WM, et al. Koneman's Color Atlas and Textbook of Diagnostic Microbiology, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2006.]

A. ATP generation

1. Substrate-level phosphorylation releases energy through direct transfer of high-energy phosphate groups from an intermediate metabolic compound to adenosine diphosphate (ADP). No molecular oxygen or other inorganic final electron acceptor is required.

2. Oxidative phosphorylation removes electrons from organic compounds and passes these electrons through a series of electron acceptors along an electron transport chain, with molecular oxygen or some other inorganic compound as the final acceptor.

B. Fermentation refers to energy-producing oxidative sequences, in which organic compounds serve as both electron donors and acceptors. This process occurs in the absence of external electron acceptors.

1. Glycolysis is the first step in fermentation and respiration and causes the oxidation of glucose to pyruvic acid with a yield of two moles of ATP. There are different pathways for pyruvic acid production in microorganisms:

a. The **Embden-Meyerhof (glycolytic) pathway** is the major pathway.

b. The **Entner-Doudoroff pathway** is an alternate.

c. The **hexose monophosphate shunt** used with the glycolytic pathway is an alternative.

2. Secondary fermentation process. Many bacteria use pyruvate to oxidize **reduced nicotinamide adenine dinucleotide (NADH),** produced in glycolysis, to manufacture a variety of final products.

a. Lactic acid fermentation. The simplest process, which converts pyruvate to lactate (*Lactobacillus, Streptococcus*).

b. Alcohol fermentation. Pyruvate is converted to ethanol and carbon dioxide (*Saccharomyces*).

c. **Mixed acid fermentation.** A combination of lactic, formic, and acetic acids is produced with ethanol, hydrogen, and carbon dioxide (*Escherichia coli*).

d. Butanediol fermentation. Pyruvate is converted to acetoin, which is reduced to 2,3-butanediol (*Enterobacter*).

e. Butyric acid fermentation. Butanol, isopropanol, and acetone are produced (*Clostridium*).

f. Propionic acid fermentation. Pyruvate is converted to oxaloacetate with the addition of carbon dioxide and then to propionic acid (*Propionibacterium*).

C. Respiration refers to energy-producing oxidative sequences, in which inorganic compounds act as the last electron acceptor in a series of reactions. This process includes **glycolysis,** the **tricarboxylic acid (TCA) cycle,** and the **electron transport system,** which yields ATP when coupled with oxidative phosphorylation.

1. Aerobic respiration. Oxygen serves as the final electron acceptor.

a. Pyruvate is converted to **acetyl coenzyme A** and carbon dioxide and water through the **TCA cycle.**

b. The **electron transport system** plays a role in the transport of electrons along a series of carriers found in the cytoplasmic membrane, each with successively higher oxidation potentials. Major components of the electron transport system include

(1) Cytochromes

(2) Flavoproteins

(3) Ubiquinones

2. Anaerobic respiration. An inorganic electron acceptor other than oxygen (e.g., nitrate, sulfate, carbonate) serves as the final electron acceptor.

VI. GENETICS

A. Definition and terms. Genetics is the study of what genes are, how they carry information, and how they are replicated and passed on.

1. Chromosomes are bodies composed of DNA that contain genetic information. Bacteria have only one chromosome—a single, continuous (closed), double-stranded, circular piece of DNA.

a. Duplication occurs by semiconservative replication, in which the two strands of the helix separate (**origin**) and at this point (**two replication forks**) new strands are synthesized, bidirectionally, with the originals serving as templates.

b. Structure. The cell membrane is attached to the chromosome; as the cell grows, it separates the daughter chromosomes. Therefore, each daughter cell has one original and one new strand.

2. Genes are DNA segments that are processed in two steps to produce various proteins. A normal bacterial cell is **haploid.**

B. Regulation and expression of genetic information

1. DNA has many **functions.**

a. It is **duplicated** for transfer to progeny during cell division.

b. It is **transcribed** into RNA, which can be translated into a protein.

c. It contains **control signals,** which ultimately control the synthesis of protein.

d. It can be **mutated** to alter specific characteristics encoded by genes.

e. It can be duplicated and transferred to **other bacterial cells** in processes other than cell division (e.g., conjugation).

2. DNA replication, transcription, and **translation** affect cellular growth and development.

a. Bacterial **replication** involves accurate duplication of chromosomal DNA, which enables the formation of two identical daughter cells.

b. Transcription of information from DNA to RNA is the first of two steps needed to produce necessary proteins. One gene can be transcribed into many copies of RNA. Simplistically, RNA polymerase locates the beginning of the gene (promotor), and this area undergoes localized unwinding to allow RNA polymerase to **transcribe** RNA (called **mRNA**) from the DNA template. The RNA is not processed, as in eukaryotes. There are no introns and exons, no capping of the 5′ end, and no polyadenine tails added to the 3′ end.

c. **Translation** is the processing of genetic information to synthesize proteins. Before transcription is completed, a ribosome will attach to the 5′ end of the message. The 70s

bacterial **ribosome** is composed of two subunits, 30s and 50s. The ribosome **translates** the message into protein by reading the **triplet codon** (three nucleotides) which code for a specific amino acid. This amino acid is carried to the site by **transfer RNA (tRNA)** and pairs with the codon by an **anticodon.** Amino

acids are joined, and the ribosome moves to the next codon. This continues until the complete protein is synthesized.

3. Regulation. The products of cellular growth must be produced in correct proportions for the cell to live and function. The two most common mechanisms of metabolic and genetic regulation are as follows:

a. Feedback inhibition of enzyme activity (metabolic regulation) inhibits the synthesis of the cell growth product. The product binds with an allosteric site on the enzyme, thereby inactivating the active site.

b. Repression of enzyme activity (genetic regulation) inhibits the synthesis of the enzyme at the transcriptional level.

c. **Induction** of enzyme activity activates the synthesis of the enzyme at the transcription level.

C. Other methods of DNA transfer. Microorganisms can change their genetic constitution by the transfer of genetic material from a donor chromosome to a recipient chromosome (recombination). Recombination occurs between homologous segments (those that have similar nucleotide sequences). There are three general mechanisms:

1. Transformation involves the recipient cell taking up cell-free, fragmented (i.e., naked) DNA and recombining genetic elements.

a. This process is **primitive** and occurs naturally within only a few genera.

b. Requirements include competent recipient cells (exhibiting DNA receptors) or a **"leaky" bacterial cell wall,** so that DNA can be introduced into the cell.

c. It is generally associated with **recombinant DNA technology** or **cloning,** a technique to amplify a specific gene in preparation for analysis. In this process, the bacterial cell walls are made leaky by chemical treatment.

(1) Cloning involves splicing a gene into a plasmid DNA (**vector**). All vectors share several common characteristics:

(a) Typically small, well-characterized molecules of DNA

(b) Contain at least one replicon and can be replicated within the host even when the vectors contain foreign DNA

(c) Code for a phenotypic trait that can be used to detect the presence of foreign DNA, which can often be used to distinguish parental from recombinant vectors

(2) Selectable markers are used to find cells that contain these vectors.

(3) Plasmids cannot maintain stability unless they are beneficial to the host, so the plasmid should contain a gene essential for cellular survival—either an enzyme required in a metabolic pathway or a gene that resists certain antibiotics (see III.D.4).

2. Conjugation is an important means of gene transfer, particularly among gram-negative organisms. This process involves two mating types—the donor ($\mathbf{F^+}$) and recipient ($\mathbf{F^-}$) cells—and the extrachromosomal piece known as the sex or fertility factor (**F factor**). The F factor (e.g., F plasmid or episome) is not under the control of the chromosome and can replicate autonomously. Plasmid-mediated exchange of genetic information can occur only through the expression of transfer genes. The genes encoded on the plasmid result in the transfer of a single strand of DNA through the sex pilus into the recipient cell. The F factor has several genes that

code for formation and aid in donor attachment of sex pili. During this process, a copy is made, a single strand is transferred, and the recipient becomes F^+. R plasmids also exist, which encode for resistance to certain antibiotics or heavy metals. When an F plasmid integrates into the cellular chromosome, the bacterial strain is said to be a **high-frequency recombination (Hfr)** strain. During the conjugal transfer involving an Hfr strain, depending on the amount of time, the whole bacterial chromosome may be transferred. Antibiotic-resistance genes are often parts of **transposons** (see III.D.4), which are responsible for additions, deletions, and inversions of large (4-80 kilobases) sequences. When different transposons "jump" into transferable plasmids, contagious resistance to multiple antibiotics can occur.

3. Transduction is the transfer of genetic material by **bacteriophages** (viruses that infect bacteria). Such viruses can be classified into two groups:

a. Lytic phages enter the cell, replicate, and package their DNA; they then lyse the cell to release mature infective virions.

b. Lysogenic (temperate) phages can alternate between two pathways:

(1) The lytic pathway

(2) The lysogenic pathway-integrating into the host DNA and remaining dormant

(a) The viral DNA does not replicate but is integrated into the host genome and is known as **prophage.**

(b) The prophage suppresses the lytic state by synthesizing a protein known as a repressor, which protects the cell from further infection by a virus.

(c) Some prophages can change the cell's phenotype (**phage** or **lysogenic conversion**), which allows the organism to elaborate materials (exotoxins or virulence factors) that are detrimental to the human host. Lysogenic conversion thereby increases the virulence or the symptoms of a specific pathogen—for example, *Corynebacterium diphtheriae* (diphtheria toxin), *Streptococcus pyogenes* (erythrogenic toxin in scarlet fever), and *Clostridium tetani* (tetanus toxin).

VII. EXAMPLES OF UNIQUE BACTERIA

A. *Chlamydia* are obligate intracellular parasites that

1. Lack the ability to generate ATP; hence they must obtain it from the host cell

2. Have a **two-phase life cycle**

a. The infectious form, or **elementary body,** is a dense, nonreplicating cell that is resistant to drying in the environment.

b. The **reticulate body** forms from engulfed elementary body and undergoes binary fission. After multiple divisions, the reticulate bodies become the dense, elementary bodies, which are released from the host cell (e.g., *Chlamydia trachomatis,* which causes blindness and sexually transmitted diseases).

B. *Rickettsia,* obligate intracellular parasites transmitted by arthropods, appear to have the ability to generate ATP, but instead **use the host cell products, including**

ATP, amino acids, nicotinamide adenine dinucleotide (NAD), and coenzyme A (e.g., *Rickettsia rickettsii,* which causes Rocky Mountain spotted fever).

C. *Mycoplasma,* the smallest bacteria, are unique in that

1. They **lack a cell wall.**

2. The plasma membrane contains **sterols** for added strength (e.g., *Mycoplasma pneumonia,* which causes an atypical or walking pneumonia).

VIII. VIRUSES

A. Viral structure

1. The basic structure of a virus is the **virion** or **nucleocapsid.** This structure is composed of a protein coat, which surrounds the viral genome. The shape of the nucleocapsid is one component that determines the classification of the virus. As noted in I.B.1.b, the viral genome is composed of either RNA or DNA and may be single or double stranded. The nucleocapsid of viruses that infect humans has two basic shapes.

a. Icosahedral. A regular **geometric** structure with 12 or more faces; resembles a soccer ball

b. Helical. The proteins that make up the structure wrap in a helical fashion. Helical capsids often have cone or bullet shapes.

Table 9-1. The Multiplication of Animal Viruses

Number	Step	Action(s)
1	Attachment (adsorption)	Virus attaches to a protein or polysaccharide molecule (receptor) on the surface of a cell
2	Penetration	Entire virus enters the cell, in some cases because it was phagocytized by the cell
3	Uncoating	Viral nucleic acid escapes from the capsid
4	Biosynthesis	Viral genes are expressed, resulting in the production of pieces or parts of viruses (i.e., viral DNA and viral proteins)
5	Assembly	Viral pieces are assembled to create complete virions
6	Release	Complete virions escape from the bacterial

		cell by lysis or budding

Reprinted by permission from Burton GRW, Engelkirk PG. Microbiology for the Health Sciences, 7th ed. Philadelphia: Lippincott Williams & Wilkins, 2004.

2. The virion may have a **lipid envelope,** which is produced when the virus buds from the host cell. The envelope is composed of the host cell plasma membrane and virally coded glycoproteins.

B. Viral replication. Viruses are nonliving entities that must enter a host cell to **replicate.** Once in the host cell, the virus is able to replicate its genome and produce more viruses, which will infect other cells. The steps in the multiplication of animal viruses are outlined in Table 9-1 and involve:

1. The virus attaches (**attachment**) to the host cell using viral proteins or glycoproteins, which bind to receptors on the host cell surface.

2. The virion then **enters (penetration)** the host cell. Entry may be accomplished by fusion of a viral envelope with the cell membrane or by uptake of the virion into an endocytic vesicle. If the virus enters the cell through an endocytic vesicle, there are several ways for it to leave the endocytic vesicle and enter the cytoplasm of the host cell.

3. Once in the host cell, the virus **uncoats,** and the nucleic acid is released from the capsid. The free nucleic acid then is able to begin the process of reproduction.

4. Protein synthesis occurs in two stages. **Early proteins** are necessary for the synthesis of a new viral genome and are synthesized immediately after infection. **Late proteins** are synthesized after the viral genome has been copied; these are the proteins necessary for the assembly of the capsid, glycoproteins for the envelope, and any enzymes included in the nucleocapsid.

a. For viruses with a **single-stranded RNA genome,** the RNA may be a plus (+) strand or a minus (-) strand. Plus-strand RNA genomes are mRNAs and are translated directly to proteins. Minus-strand RNA genomes have an RNA-dependent RNA polymerase that copies the genome into a strand of mRNA for transcription.

b. Double-stranded RNA genomes use an RNA-dependent RNA polymerase to transcribe the minus strand of RNA into a message for translation.

c. Some plus-strand RNA viruses are members of the **retrovirus** family (e.g., human immunodeficiency virus). These viruses have an enzyme called reverse polymerase, which transcribes the RNA to double-stranded DNA. The double-stranded DNA is integrated into the host cell chromosome (a **provirus**) and then transcribed to

mRNA using host cell enzymes. The viral mRNA is then translated into viral proteins.

d. In viruses with a **DNA genome,** the DNA may be double stranded or single stranded. In either case, the DNA is transcribed to mRNA and then translated into proteins.

5. After genome and protein synthesis, the virus is **assembled** into new virions.

6. After assembly, the virions are **released** from the host cell. For nonenveloped viruses, the virions are released when the host cell lyses. Enveloped viruses are released from the host cells by budding out of the host cell membrane.

P.187

IX. TRANSMISSION OF INFECTIOUS AGENTS

A. Infectious agents are found in a number of different environments, called **reservoirs.**

1. Humans are **reservoirs** for diseases that are obligate human pathogens, which include almost all viral infections and many bacterial diseases. When humans are the reservoir for the disease, they are said to be **carriers.**

a. Asymptomatic carriers harbor an infection but have no symptoms. Some asymptomatic carriers carry the infectious agent as part of their normal flora (*Streptococcus pyogenes*).

b. Symptomatic carriers have obvious signs and symptoms of disease.

2. An **animal reservoir** exists when the primary host is an animal. Such animals may be wild (e.g., foxes, raccoons) or domesticated (livestock and pets).

3. Environmental reservoirs include soil, lakes, and plants.

B. The **transmission of infectious agents** depends on the source of infection. For diseases with human reservoirs, the mechanisms of transmission include

1. Contact

a. Direct contact requires physical contact between an infected individual and a susceptible individual (sexually transmitted diseases).

b. Indirect contact involves a susceptible individual coming in contact with a contaminated surface (many viruses and bacteria). **Fomites** are surfaces that can be and frequently are contaminated with microorganisms (door knobs, counters and other surfaces, computer keyboards, toys).

2. Droplet transmission. Infected droplets are formed when an infected individual coughs or sneezes. The infected droplets transmit the disease to a susceptible individual when they come in contact with the mucous membranes of the individual's nose, mouth, or eyes (measles).

3. Airborne transmission. When small contaminated dust particles or the residue from dried droplets (droplet nuclei) remain suspended in the air for long periods of time, they can transmit disease (influenza, pneumonia, tuberculosis). These small nuclei can infect both the upper and the lower respiratory tract.

4. Food and water contamination. Food or water contaminated with bacteria from human or animal feces leads to transmission of disease through the fecal-oral route.

C. Vectors are animals capable of transmitting diseases. The most common vector for disease is the mosquito (malaria), but other insects (fleas, ticks and flies) are also vectors (Rocky Mountain spotted fever). In addition, mammals (dogs, mice and rats) can be vectors for disease.

D. Entry into a host. Bacteria can enter a host through ingestion of food or water, inhalation of droplets or dust particles, injection by an insect vector, or by contamination of a wound.

X. MECHANISMS OF PATHOGENICITY

A. Microorganisms cause disease in different ways. Although signs and symptoms of the disease are often the result of the host response, microorganisms can damage tissue through the production of exotoxins and endotoxins, and by direct effects. In addition, microbial virulence factors contribute to the ability of a microorganism to infect a host and cause disease.

1. Virulence factors are the characteristics of an organism that allow it to either damage the host or evade host defenses.

a. Exotoxins are toxins that are secreted by the microorganism either into the environment or after colonization of a host.

(1) Exotoxins secreted into food or water that are then ingested by a host cause intoxication (botulism and staphylococcal food poisoning).

(2) Exotoxins produced after infection and colonization interfere with cell function or physically damage the cell (*Bordetella pertussis, Corynebacterium diphtheriae, Vibrio cholera*).

Table 9-2. Important Human Pathogens and Their Diseases

Infectious Agent	Typical Infection
Bacteria	
Gram-positive cocci	
Staphylococcus aureus	Abscess, skin infections, toxic shock
Streptococcus pyogenes	Strep throat, erysipelas, rheumatic fever
Streptococcus pneumoniae	Pneumonia

	Gram-positive rods		
		Bacillus	Anthrax
		Clostridium	Gas gangrene, tetanus
		Corynebacterium	Diphtheria
	Acid-fast rods		
		Mycobacterium tuberculosis	Tuberculosis
		Mycobacterium leprae	Leprosy
		Nocardia	Nocardiosis
	Gram-negative cocci		
		Neisseria gonorrhoeae	Gonorrhea
		Neisseria meningitidis	Meningitis
	Gram-negative rods		
		Bordetella	Pertussis
		Brucella	Brucellosis
		Escherichia coli	Sepsis, diarrhea, urinary tract infection
		Haemophilus influenzae	Meningitis
		Legionella	Legionnaires disease

		Pseudomonas	Opportunistic lung and burn infections
		Salmonella	Typhoid fever, salmonellosis
		Shigella	Dysentery
		Vibrio cholerae	Cholera
		Yersinia pestis	Plague
	Spirochetes		
		Borrelia	Lyme disease
		Treponema pallidum	Syphilis
	Mycoplasma		Pneumonia, urinary infections
	Rickettsia		Rocky Mountain spotted fever
	Chlamydia		Urethritis, vaginitis
Fungi			
	Systemic mycoses		
		Aspergillus	Aspergillosis
		Blastomyces	Blastomycosis
		Candida albicans	Candidiasis
		Coccidioides immitis	Valley fever

		Cryptococcus neoformans	Cryptococcosis
		Pneumocystis (carinii) jiroveci	Pneumonia (PCP)
		Sporothrix schenckii	Sporotrichosis
	Protozoa		
		Entamoeba histolytica	Amoebiasis
		Giardia lamblia	Giardiasis
		Plasmodium	Malaria
		Toxoplasma gondii	Toxoplasmosis
		Trichomonas vaginalis	Trichomoniasis
		Trypanosoma brucei	Sleeping sickness
	Helminths		
		Ascaris	Acariosis
		Cestodes	Tapeworm
		Schistosoma	Schistosomiasis
		Various fluke infections	
		Various roundworm infections

Table 9-3. Important Human Virus Families and Their Diseases

Family	Virus	Disease
DNA viruses		
Poxviridae	Variola and vaccinia	Smallpox, cowpox
Herpesviridae	Herpes simplex 1 virus (HSV-1)	Fever blister, cold sores
	Herpes simplex 2 virus (HSV-2)	Genital herpes
	Varicella zoster virus (VZV)	Chickenpox, shingles
	Human cytomegalovirus (CMV)	CMV infections
Adenoviridae	Human adenoviruses	Adenovirus infection

	Papovaviridae	Human papillomavirus (HPV)	Several types of warts
		JC virus (JCV)	Progressive multifocal leukoencephalopathy (PML)
	Hepadnaviridae	Hepatitis B virus (HBV; of Dane particle)	Serum hepatitis
	Parvoviridae	Parvovirus B19	Erythema infectiosum
RNA viruses			
	Picornaviridae	Poliovirus	Poliomyelitis
		Coxsackievirus	Hand-foot-mouth disease
		Hepatitis A virus (HAV)	Short-term hepatitis
		Human rhinovirus	Common cold, bronchitis
	Calciviridae	Norwalk virus	Viral diarrhea, Norwalk virus syndrome
	Togaviridae	Eastern equine encephalitis virus	Eastern equine encephalitis (EEE)
		Western equine encephalitis virus	Western equine encephalitis (WEE)

		Yellow fever virus	Yellow fever
		St. Louis encephalitis virus	St. Louis encephalitis
		Rubella virus	Rubella (German measles)
	Flaviviridae	Dengue fever virus	Dengue fever
		West Nile fever virus	West Nile fever
	Bunyaviridae	Bunyamwera viruses	California encephalitis
		Sin Nombre virus	Respiratory distress syndrom
		Rift Valley fever virus	Rift Valley fever
		Crimean-Congo hemorrhagic fever virus (CCHF)	Crimean-Congo hemorrhagic fever
	Filoviridae	Ebola, Marburg virus	Ebola fever
	Reoviridae	Colorado tick fever virus	Colorado tick fever
		Human rotavirus	Rotavirus gastroenteritis
	Orthomyxoviridae	Influenza virus, type A (Asian,	Influenza, flu

		Hong Kong, swine)	
	Paramyxoviridae	Parainfluenza virus, types 1-5	Parainfluenza
		Mumps virus	Mumps
		Measles virus	Measles (red)
		Respiratory syncytial virus (RSV)	Common cold syndrome
	Rhabdoviridae	Rabies virus	Rabies (hydrophobia)
	Retroviridae	Human T-cell leukemia virus (HTLV)	T-cell leukemia
		HIV (1 and 2)	AIDS
	Arenaviridae	Lassa virus	Lassa fever
	Coronaviridae	Infectious bronchitis virus (IBV)	Bronchitis
		Enteric corona virus	Coronavirus enteritis
		SARS virus	Severe acute respiratory syndrome

Adapted with permission from Cowan MK, Talaro KP. Microbiology: A Systems Approach. 1st ed.: McGraw-Hill, 2005. With permission of The McGraw-Hill Companies, Inc.

b. Endotoxins (see III.C.1.b) are integral parts of the outer membrane of gram-negative bacteria. During an infection, endotoxins are able to induce fever and shock in the host.

c. **Capsules** (see III. B.1) are used for adherence to host surfaces and help the bacteria evade phagocytosis by the host cells.

2. Mechanisms of disease. There are three main patterns by which microorganisms cause disease:

a. Intoxication [see X.A.1.a.(1)]

b. Infection is sufficient to cause disease for some microorganisms, especially for diseases such as pneumonia, in which the capsule surrounding the bacteria stimulates a strong inflammatory response. This response is responsible for many of the symptoms of the disease. In some cases, infection may be followed by toxin production (see X.A.1.a.(2)), as in diphtheria.

c. **Invasion of host tissues** and then growth in the tissue is the mechanism of disease infection by viruses and bacteria such as *Mycobacteria*. Some bacteria (e.g., *Shigella* sp.) are able to produce toxins after the invasion of host tissue.

XI. DISEASES CAUSED BY INFECTIOUS AGENTS

A. Diseases caused by bacteria, fungi, protozoa, and helminths (Table 9-2)

B. Diseases caused by viruses (Table 9-3)

P.191

STUDY QUESTIONS

Directions for questions 1-12: Each question, statement, or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Cell walls of both gram-positive and gram-negative bacteria are composed of complex macromolecules. Which of the following statements describes both types of cell walls?

(A) They contain significant amounts of teichoic acid.

(B) They contain pores made from proteins.

(C) Their antigenic specificity is determined by the polysaccharide O antigen.

(D) They contain peptidoglycan.

View Answer***1. The answer is D[see].*****2. Which of the following descriptions best characterizes sex pili?**

(A) They enable DNA transport between bacteria during conjugation.

(B) They play a role in the adhesion of bacteria to their target cells.

(C) They are numerous on the bacterial cell surface.

(D) They are found only on gram-positive organisms.

View Answer***2. The answer is A[see].*****3. The mode of gene transfer in which naked DNA is taken up is called**

(A) transformation.

(B) transduction.

(C) conjugation.

(D) cell fusion.

View Answer***3. The answer is A[see].*****4. Bacteria that make either a fermentative or respiratory set of enzymes are known as**

(A) obligate anaerobes.

(B) obligate aerobes.

(C) microaerophiles.

(D) facultative organisms.

View Answer***4. The answer is D[see].*****5. Which of the following statements describes plasmids?**

(A) They are single-stranded DNA molecules.

(B) They carry optional genes.

(C) They carry genes essential for growth.

(D) They are always found in linear form.

View Answer***5. The answer is B[see].*****6. All of the following statements describe the nuclear body *except* which one?**

(A) It is referred to as nucleoid.

(B) It is free of ribosomes.

(C) It is composed of ribosomes.

(D) It lacks a nuclear membrane.

View Answer***6. The answer is C[seeand].*****7. Bacteria that grow at temperatures as high as 55°C are known as**

(A) psychrophiles.

(B) thermophiles.

(C) mesophiles.

(D) auxotrophs.

View Answer***7. The answer is B[seeand].*****8. Which of the following organisms can use only molecular oxygen as the final acceptor?**

(A) obligate anaerobes

(B) facultative anaerobes

(C) obligate aerobes

(D) strict anaerobes

View Answer***8. The answer is C[seeand].*****9. Viruses are classified by all of the following *except* by**

(A) structure of capsid.

(B) type of nucleic acid.

(C) oxygen requirements.

(D) presence of lipid envelope.

View Answer***9. The answer is C[see].*****10. Protozoa are classified by**

(A) shape.

(B) cell wall type.

(C) sexual reproductive structures.

(D) mode of motility.

View Answer***10. The answer is D[see].*****11. Which of the following is *not* part of the viruse's infectious cycle?**

(A) attachment

(B) unwinding

(C) replication of the genome

(D) protein synthesis

(E) release

View Answer***11. The answer is B[seeand].***P.192

12. Infectious agents are transmitted to people from reservoirs. These reservoirs include

(A) droplets.

(B) animals.

(C) fomites.

(D) contaminated food.

View Answer***12. The answer is B[seeand].*****Directions for questions 13-20:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the correct answer, A-D.

13. Gram-negative and gram-positive cell walls share which of the following characteristics?

I. peptide cross-links between polysaccharides

II. hydrolysis by lysozyme

III. rigid polysaccharide framework

A if **I** only is correct

B if **III** only is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II and III** are correct

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* III.C.1*].*

The cell wall of gram-positive bacteria is a thick layer of peptidoglycan with a large amount of teichoic acids (surface antigens). Gram-negative bacteria have only a small amount of peptidoglycan, no teichoic acid, and an outer membrane composed of lipoprotein and lipopolysaccharide, of which the polysaccharide makes up the O antigen.

2. The answer is A *[see* III.B.3.b*].*

Sex pili are found only on gram-negative organisms and in very small numbers (< 10). They act as fragile transport tubes for DNA exchange. Common pili are adhesions.

3. The answer is A *[see* VI.C.1*].*

Of the three methods of DNA transfer, only transformation takes up DNA without an intermediary.

4. The answer is D *[see* IV.D.1.b*].*

Facultative organisms can grow without air and make either a fermentative or a respiratory set of enzymes, depending on the conditions.

5. The answer is B *[see* III.D.4; VI.C.2*].*

The chromosome carries all of the genes essential for growth, whereas plasmids are extrachromosomal, double-stranded, circular pieces of DNA that carry optional genes that add extra properties.

6. The answer is C *[see* III.D.2 *and* 3*].*

Ribosomes are found in the cytoplasm, not in the nucleoid (a long, circular, double-stranded DNA without a nuclear membrane).

7. The answer is B *[see* IV.C.1, 2 *and* 3*].*
Thermophiles grow at 55°C and are found in hot springs and compost piles. Mesophiles grow at approximately 37°C, psychrophiles grow at 15°C and lower, and auxotrophs are mutant organisms.
8. The answer is C *[see* IV.D.1 *and* 2*].*
Obligate aerobes require oxygen and lack an alternative fermentative pathway. Obligate anaerobes are strict anaerobes that cannot live in the presence of oxygen. Facultative anaerobes can use oxygen as the final acceptor or to provide an alternate fermentative pathway.
9. The answer is C *[see* I.B.1; VIII.A*].*
Viruses are classified by the structure of the capsid, the type and strandedness of the nucleic acid, the presence of a lipid envelope, and the presence of enzymes. Viruses do not generate their own energy, hence there is no need for oxygen. Viruses use the energy in the host cell.
10. The answer is D *[see* I.A.2.b*].*
Protozoa are unicellular, nonphotosynthetic eukaryotes that are classified by their mode of motility or lack of motility. The types of motility are flagella, cilia, and amoeboid movement.
11. The answer is B *[see* VIII.B.1, 2, 3, 4, 5 *and* 6*].*
The viral infectious cycle consists of attachment, entry, uncoating (not unwinding), protein synthesis, genome replication, assembly, and release.
12. The answer is B *[see* IX.A.1, 2 *and* 3*].*
Infectious agents can be found in many different environments, including people, animals, and the natural environment. Animals are a resevoir; fomites, droplets and contaminated food or water are mechanisms of transmission.
13. The answer is E (I, II, III) *[see* III.C.1 *and* 2*].*
Peptidoglycan is the basic layer of the cell wall in both gram-positive and gram-negative organisms. It provides a rigid framework that is susceptible to the action of lysozyme. Gram-positive cells are deficient in lipids; however, gram-negative cells are rich in complex lipids (e.g., lipopolysaccharide). Both types of cell walls have cross-links between polysaccharides.

14. The answer is B (III) *[see* IV.E.1, 2, 3 *and* 4*].*
During the lag phase, the cells prepare for growth, so there is no actual growth. Growth is maximal during the exponential phase and levels out during the stationary phase with no net increase in cell number. There is a decline in organism number during the death phase because there are more organisms dying than are being produced.
15. The answer is D (II, III) *[see* III.C.1*].*
The cell wall of both gram-positive and gram-negative organisms is composed of repeating disaccharide units. These units contain *N*-acetylglucosamine and *N*-acetylmuramic acid, to which tetrapeptide chains are cross-linked. Only gram-positive organisms have teichoic acid.

16. The answer is C (I, III) *[see* I.B.1 *and* 2*].*
Viruses are basically proteins and nucleic acids, whereas prions are proteins, neither of which are cells. Bacteria are prokaryotic cells, and fungi are eukaryotic cells.
17. The answer is C (I, III) *[see* I.A.2.a.(1), (2), (3) *and* (4)*].*
Dimorphic fungi like *Blastomyces, Coccidioides,* and *Histoplasma* can be grown in either a yeast (unicellular) or mold (filamentous) phase, depending on the temperature of incubation. Fungi are placed in phyla based on the type of sexual reproduction observed: either ascus, basidium, or zygote. Fungi imperfecti consist of species without observable sexual reproductive structures.
18. The answer is B (III) *[see* IX.B.1, 2, 3 *and* 4*].*
The fecal-oral route of transmission involves contamination of food or water with animal feces.
19. The answer is E (I, II, III) *[see* X.A.1*].*
Capsules act as virulence factors by inhibiting phagocytosis and acting to attach microorganisms to host surfaces. Exotoxins are secreted by microorganisms and either alter cell functions or cause cell death. Endotoxins induce shock in mammalian hosts through the lipid A component of the molecule. Peptidoglycan is the backbone of the bacterial cell wall.
20. The answer is B (III) *[see* X.A.1.a.(1); X.A.2*].*
Staphylococcus aureus can produce an exotoxin, which results in gastrointestinal disease. When there is disease in the absence of infection or invasion of the tissues by a live organism, the disease is called an intoxication.

Immunology

Gail Goodman-Snitkoff

I. THE PHYSIOLOGY OF THE IMMUNE SYSTEM

A. Immunogens, antigens, and haptens

1. Immunogens are chemical compounds that cause a specific immune response.

2. Antigens are chemical compounds that bind to products of an immune response. When the antigens are recognized by antibody or activated cells, they can be eliminated by a specific immune response.

3. Immunogen-antigens. Compounds associated with or secreted by parasitic bacteria, protozoa, fungi, and viruses and of molecular weight (mol wt) > 5000 daltons may act as both immunogens and antigens.

a. Molecular complexity is as important as molecular weight in determining the status of a compound as an immunogen. For a molecule to be immunogenic, it must contain protein or peptide. Therefore, proteins, glycoproteins, lipoproteins, and nucleoproteins are the most potent immunogen-antigens.

b. Drugs of sufficient molecular weight (e.g., insulin) can act as immunogen-antigens. The cells of another individual and the cells of one's own body (see III) can act as immunogen-antigens. Immunogen-antigens can be contacted environmentally (e.g., pollens).

4. Haptens are low molecular weight compounds that act as immunogens after covalently binding to a larger molecule or cell surface. After they stimulate the immune system in this complex, these compounds can act as antigens in the unbound or bound state.

a. Haptens may be present in the environment (e.g., pentadecacatechol of poison ivy).

b. Several types of drugs act as haptens (e.g., penicillin).

5. Tolerogens are chemical compounds that elicit specific nonresponsiveness. This specific nonresponsiveness may be caused by the ability of the compound to be broken down by the body or by the route of administration of the compound (e.g., oral administration often causes specific nonresponsiveness).

6. In this chapter, the term *antigen* is used for compounds and cells that are both immunogens and antigens.

B. Cells of the immune system

1. B lymphocytes and T **lymphocytes** are the primary cells of specific immune responses. All B and T lymphocytes are antigen specific because they have specific antigen receptors embedded in their plasma membranes. In this chapter, the terms *B cell* and *T cell* are used instead of B lymphocyte and T lymphocyte.

2. Antigen receptors of B cells are antibody molecules.

a. B cells have thousands of identical antibodies in their membranes that allow them to bind to a small group of chemically related antigens. This group defines the antigen specificity of each B cell. Different B cells have different antigen specificities, but each B cell has only one specificity. B cells that recognize specific antigens divide to form new B cells (**memory B cells**) and **plasma cells (antibody-forming cells),** which secrete free, soluble (humoral) antibody molecules into extracellular fluids (Figure 10-1).

b. Virgin B cells have not responded to an antigen since their release into the circulation from bone marrow. Their membrane antibodies are of the immunoglobulin M (IgM) and D (IgD) classes (see I.D).

c. Memory B cells are derived by cell division from another B cell that has responded to an antigen. Their membrane antibodies are of immunoglobulin classes A (IgA), E (IgE), or G (IgG; see I.D).

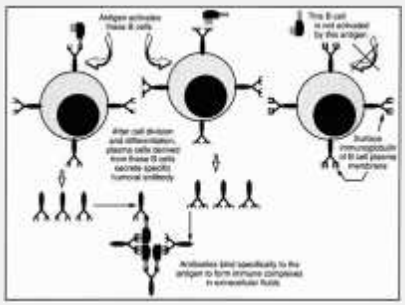

Figure 10-1. B cells: antigen specificity and activation.

3. Antigen receptors of T **cells** have two membrane proteins (α and β or γ and δ), which define the antigen specificity of each T cell, and several other integral membrane proteins known as **CD3 complex.** Therefore, T cells are **$CD3^+$.** Each T cell has thousands of identical antigen receptors in its membrane. Different T cells of different antigen specificities differ in the conformation of their antigen receptors.

a. Major histocompatibility complex (MHC) proteins. The antigen receptors of T cells do not recognize antigens alone. Rather, they normally recognize **peptide epitopes** (fragments of antigen) that are chemically combined with MHC proteins on the surface of other body cells (Figure 10-2). MHC proteins are divided into **two major classes:**

(1) Class I proteins, which are present on the surfaces of almost all body cells

(2) Class II proteins, which are present only on the surfaces of special **antigen-presenting cells (APCs)**

b. Thymus gland. T cells do not enter the circulation directly from bone marrow but first enter the thymus gland to mature. Most developing T cells die in the thymus. The cells that die either do not recognize normal self-antigens or produce a response against normal self-antigens.

(1) T cells that are released from the thymus into the circulation are **virgin** T **cells.**

(2) T cells that originate through cell division from the responses of other T cells are **memory** T **cells or effector** T **cells.**

c. **Glycoproteins.** Most T cells can be classified by the presence of a membrane glycoprotein known as **CD4**—the **helper,** or **T_H cell**—or the presence of **CD8**—the **cytotoxic** T **lymphocyte (CTL),** or **T_C cell.**

(1) T_H cells can be divided into two functional groups: **T_H1** and **T_H2.** These cells have different functions in the immune response and regulate immune responses through the production of interleukins (IL; also called lymphokines), which are proteins that act on cells in an autocrine, paracrine, or endocrine manner.

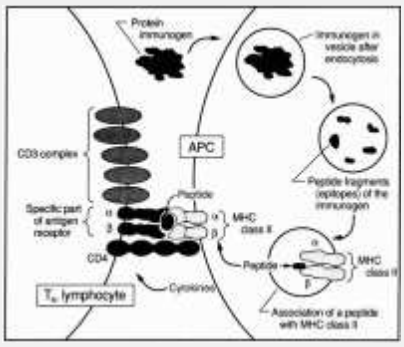

Figure 10-2. Helper T cell (T_H cell) antigen recognition. *MHC,* major histocompatibility complex; *APC,* antigen-presenting cell.

(a) T_H1 cells activate other cells, including some T_H cells, T_C cells, and macrophages. In addition, they can decrease antibody (Ab) production by inhibiting the formation of T_H2 cells.

(b) T_H2 cells activate B cells to divide and produce Ab. They can also inhibit the formation of T_H1 cells.

(2) T_C cells are able to kill cells that are infected by viruses. They do this through direct binding with the infected cell or through the release of cytotoxins.

(3) T_r cells, or T regulatory cells, have recently been described. Most of these cells are $CD4^+$, although there is a $CD8^+$ subset as well. All of these cells suppress immune responses through the secretion of IL-10 and transforming growth factor β (TGF-β); in addition, cells designated $CD4^+CD25^+$ are also able to inhibit other T cells through direct contact.

(4) Interleukins are part of a larger network of regulatory **cytokines.** This network includes secretions of other cell types in addition to those of lymphocytes. Table 10-1 lists the sources and actions of important cytokines that regulate the immune system and inflammation.

4. Natural killer (NK) cells are large, granular lymphocytes without a specific T or B cell antigen receptor. Their cytotoxicity is similar to that of CTL (T_C) cells. NK cells recognize and destroy tumors, and are important for controlling viral infections prior to the development of adaptive immunity.

5. APCs are essential for most immune responses and are found in the sites at which these responses originate.

a. The best understood APCs are the **macrophages** and **dendritic cells** of the **lymph nodes, spleen,** and **other lymphoid tissue.** Most immune responses within these organs begin when these cells present epitopes bound to their surface MHC class II molecules to T_H cells and secrete cytokines as accessory signals (Figure 10-2).

APCs, especially macrophages, are able to control the type of immune response generated. They do this by secreting different cytokines in response to different types of pathogens (e.g., extracellular bacteria, intracellular bacteria, viruses).

Table 10-1. Major Cytokines and Their Actions

Cytokine	Sources of Secretion[a]	Major Actions
IL-1	Macrophages, APCs, others	T and B cell activation, pyrogenic, proinflammatory
TNF-α, TNF-β	Macrophages, T_H1 cells, T_C cells	Similar to IL-1, but including cytotoxicity
IL-2	T_H0 cells, T_H1 cells	T cell, B cell, and NK cell activation
IFN-γ	T_H1 cells	Induction of MHC, activation of macrophages and NK cells, formation of memory B cells, antiviral
IFN-α, IFN-β	Leukocytes, fibroblasts	Induction of MHC, antiviral, and growth inhibition
IL-3	Macrophages, T_H cells	Proliferation of multilineage marrow stem cells
IL-4	T_H2 cells	B cell activation and memory B cell formation, increased mast cell precursors, activation of mast cells
IL-5	T_H2 cells	Memory B cell formation, eosinophil production
IL-6	T_H2 cell, other types	Plasma cell maturation, others similar to IL-1

IL-7	Bone marrow stroma	Lymphocyte maturation
IL-8 (CXCL8)	Monocytes, macrophages, endothelial, fibroblasts cells	Chemokine, attraction and activation of neutrophils, attraction of T cells
IL-9	T_H1 cells	Proliferation and differentiation of bone marrow cells and thymocytes
IL-10	Macrophages, T_H2 cells $CD8^+$ T cells, B cells	Increased humoral (antibody) immunity, decreased cell-mediated immunity, mast cell growth
IL-11	Bone marrow stroma	Proliferation and differentiation of bone marrow cells and thrombocytes
IL-12	Macrophages, B cells	Promotion of cell-mediated immunity, activation of T_C and NK cells, suppression of humoral immunity
IL-13	T_H cells	IL-4-like effects on B cells, inhibition of production of inflammatory cytokines by monocytes
IL-14	T_H cells	Important for the generation of B memory cells
IL-15	Endothelial cells, epithelial monocytes, muscle cells	IL-2-like effects
GM-CSF	T_H1 cells, macrophages	Marrow proliferation of myeloid precursors

G-CSF	Fibroblasts, endothelial cells	Proliferation and survival of neutrophil precursors
M-CSF	Fibroblasts, endothelial cells	Survival of monocyte macrophages

APC, antigen-presenting cell; *G-CSF,* granulocyte colony-stimulating factor; *GM-CSF,* granulocyte-macrophage colony-stimulating factor; *IFN,* interferon; *IL,* interleukin; *M-CSF,* macrophage colony-stimulating factor; *MHC,* major histocompatibility complex; *NK cell,* natural killer cell; *$T_C$cell,* T cytotoxic cell; *$T_H$cell,* T helper cell; *TNF,* tumor necrosis factor.

[a] Not all sources are listed.

b. Any cell in the body can act as an APC for immune responses involving CTL cells. Nucleated cells can present fragments of antigens bound to their surface MHC class I molecules to T_c ($CD8^+$) lymphocytes.

c. Both T and B cells continually circulate from the blood through the lymph nodes, spleen, and other secondary lymphoid tissue and then back into the blood. If there is antigen present in the secondary lymphoid tissue that binds specifically to the receptor on the T or B cell, then an immune response can begin.

6. Neutrophils, macrophages, eosinophils, basophils, platelets, and **mast cells** assist in eliminating antigens from the body. Their functions may be phagocytic, proinflammatory, cytotoxic, regulatory, or a combination of these.

C. Humoral immunity: primary and memory responses that produce antibodies

1. Overview. In most humoral immune responses, antigens are recognized by antigen-specific B cells and T_H cells (non-antigen-specific B and T_H cells do not respond). Initially, B and T_H2 cells divide to increase their cell numbers. Responding B cells produce both memory B cells and plasma cells, aided by cytokines secreted by T_H2 cells. **T-independent responses** to certain bacterial polysaccharide antigens do not require T_H cells. During T-independent responses, a subclass of B cells (B1 B cells) responds alone and produces plasma cells that secrete IgM antibodies, but no memory B cells are produced.

2. Primary immune response. The first time a specific antigen is encountered, only **virgin B cells** and **virgin T_H cells** are present to respond to the antigen. Initially, the T_H cells become T_H effector cells, and the B cells produce plasma cells that secrete IgM antibody. Later in the immune response, plasma cells producing other classes of antibody develop. The primary immune response is detected in the serum after 4 days and peaks in 7-11 days. In a primary immune response, IgM is produced first and is followed by IgG. Memory B and T_H2 cells are also produced. Memory B cells can also be activated to produce the other classes of antibody in subsequent immune responses.

3. Memory immune responses. The second or subsequent encounter with the same antigen or a closely related antigen produces responses by memory B cells and memory T_H2 cells. These responses are more rapid because memory cells require less antigen for stimulation and are of greater magnitude because there are more antigen-specific B and T cells to respond. Most serum antibody produced is IgG, with smaller amounts of IgA and IgE. Significant amounts of antibodies are produced as rapidly as 2-3 days after the reencounter with antigen, and the absolute amount of antibody (measured in milligrams per deciliter of serum) is greater than in primary immune responses. The duration of memory varies among antigens and probably among individuals. Some, but not all, memory is lifelong.

4. Major roles of antibodies

a. The first function of an antibody is to act as an **antigen receptor** for B cells so that the B cells can recognize and respond to antigens.

b. The second function of an antibody is to aid in the **elimination of antigen.** Elimination occurs through nonspecific functions, such as phagocytosis or complement activation. The mechanism of elimination depends on the class of antibody involved.

c. The third function of an antibody is **neutralization of toxins.** Neutralization occurs when an antibody binds to the toxin and prevents it from reaching the target cell or receptor.

D. Immunoglobulins: antigen binding and class-specific functions. The terms *antibody* and *immunoglobulin* are used interchangeably.

1. Structure. The standard immunoglobulin unit has four polypeptide chains: two identical light (L) polypeptide chains and two identical heavy (H) polypeptide chains. The structure is represented as H_2L_2. Each chain can be divided into a **C-terminal constant region** and an **N-terminal variable region** of amino acids (Figure 10-3). The N-terminal variable region formed from the H and L variable domains is responsible for antigen binding by the

immunoglobulin. The C-terminal constant regions of the H chain determine the class of the immunoglobulin.

2. Class. There are five general heavy-chain, constant-region amino acid sequences. These determine the **five general classes of immunoglobulins: IgM, IgG, IgE, IgA,** and **IgD.** Within some classes, variants of the heavy-chain sequence yield subclasses: IgM1-2, IgG1-4, and IgA1-2. The class of an immunoglobulin defines its nonspecific antigen elimination or inflammatory function. These functions are activated only after antigen-antibody complexes are formed, not by unbound antibodies.

a. IgM is the first immunoglobulin secreted during primary immune responses. It plays a minor role in memory responses. It does not leave the blood in significant amounts because of its pentameric structure and large size (mol wt 900,000 daltons). It accounts for approximately 20% of the adult serum immunoglobulin. IgM is the most potent **activator of the complement system** (see I.E.2). Its serum half-life is 9-11 days.

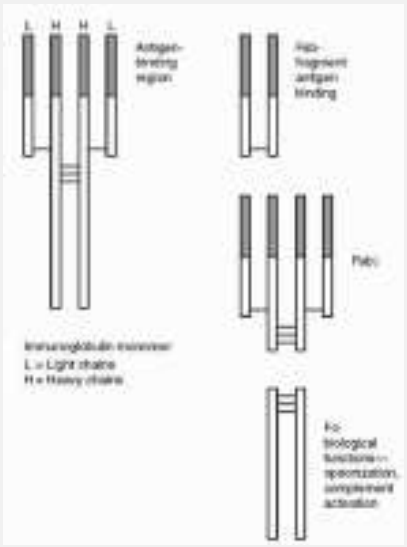

Figure 10-3. Immunoglobulin molecule. *Fc,* fragment, crystallizable.

b. IgG is the predominant serum immunoglobulin secreted at the end of the primary immune responses and during memory responses. It can diffuse from blood into other extracellular fluids, particularly in inflamed microvasculature, and it crosses the placenta to enter the fetal circulation. It accounts for approximately 70% of adult serum immunoglobulin. It **opsonizes antigens** for **phagocytosis and activates the complement system.** Its serum half-life is 25-35 days.

c. **IgE** is secreted during memory responses and may also be secreted late during a primary response. It normally accounts for < 1% of serum immunoglobulin. It **binds to IgE receptors located on the cell surfaces of**

blood basophils and on mucosal and connective tissue mast cells to trigger the secretion of inflammatory mediators from these cells in the presence of specific antigens. IgE mediates allergic reactions. Its serum half-life is 2-3 days, but its mast cell-bound half-life is several months to years.

d. IgA is secreted during memory responses and may also be secreted late during a primary response. It accounts for 10% of serum immunoglobulin. However, it is **secreted in large quantities across mucosal surfaces into gastrointestinal, respiratory, lachrymal, mammary, and genitourinary secretions, where it protects mucosa from colonization** by bacteria and other microorganisms. Its serum half-life is approximately 5 days.

e. IgD accounts for < 1% of serum immunoglobulin and has no known function as a secreted immunoglobulin.

3. Specificity. The specificity of each immunoglobulin for antigen binding resides in the two identical antigen-binding sites, each formed by the combination of the variable regions of heavy and light chains. IgG, IgE, and IgD as well as serum IgA have two antigen-binding sites. IgM antibodies have 10 identical antigen-binding sites through the combination of

five H_2L_2 units with a joining polypeptide chain to form a pentamer. Likewise, secreted IgA typically exists as a dimer with four binding sites.

4. Quantitation of immunoglobulin: antigen binding and cross-reactivity. Between 10^8 and 10^{11} unique immunoglobulins with different antigen-binding specificities are formed by the immune system.

a. Each immunoglobulin specificity can bind to several different, but closely structurally related, antigens. This ability illustrates the phenomenon of cross-reactivity of a single antibody for multiple antigens. Each immunoglobulin-antigen interaction is quantitated by its **association constant (K_a).**

b. Cross-reactivity may also occur through the sharing of some, but not all, antigens by two strains of bacteria, viruses, or other microorganisms.

c. Because each microorganism has several antigens, each elicits the production of multiple antibodies with unique specificities by the immune system. This response is known as a **polyclonal response** and results in a combination of antibodies known as a **polyclonal antiserum** and defines the serotype of the immunizing organism.

5. Fragments of immunoglobulin for clinical use. Immunoglobulins can be enzymatically cleaved into fragments—for example, **Fab** and **$F(ab')_2$** (antigen-binding fragments), **Fc** (crystallizable fragment), and **Fv** (variable region fragment). Fab and $F(ab')_2$ fragments are clinically useful because they retain antigen specificity, but not class-specific (e.g., inflammatory) functions, and are readily excreted renally. Conversely, this characteristic limits their effectiveness in certain situations.

E. Antigen elimination and acute inflammatory mechanisms of humoral immunity

1. Opsonization is the preparation of any extracellular antigen for phagocytosis through binding of antibody. Neutrophils and macrophages have a variety of receptors for the constant region of IgG antibodies ($F_C\gamma R$), which bind antigen-antibody complexes. When the antigen is soluble, the immune complexes must be sufficiently large to induce this reaction. This binding triggers phagocytosis of the antigen-antibody complex and activates the metabolism of the phagocyte, shifting it toward the production of bactericidal oxygen radicals (e.g., superoxide anion, hydrogen peroxide).

2. Complement is a group of approximately 20 serum proteins that, when activated, form a proteolytic cascade similar to the clotting and fibrinolytic sequence. Within this complex of proteins, there are some that inhibit complement activation. Complement is responsible for increasing the inflammatory response, phagocytosis of antigen, lysis of cells (usually pathogens), and clearance of immune complexes.

a. In the **classic activation pathway,** immune complexes of IgM or IgG antibodies bound to antigen bind subunits of complement component 1 (C1) and trigger an initial series of proteolytic cleavages.

b. In the **alternative activation pathway,** the cell walls of certain microorganisms (e.g., gram-negative bacteria) are able to bind C3b and other complement proteins that initiate a different sequence of proteolytic cleavages, leading to the same end point as the classic activation pathway.

c. In the **mannose-binding pathway,** mannose-binding protein (MBP) is produced by the liver during the acute-phase response. MBP binds to mannose on the surface of bacteria and, in conjunction with associated serum proteases, triggers proteolytic cleavages identical to those seen in the classic pathway of complement.

d. C3b, C4b, and associated degradation products provide opsonization, via complement receptors on cells such as macrophages and neutrophils, in addition to that provided by IgG in immune complexes.

e. Proinflammatory fragments of certain complement proteins act both by **direct activity on the microvasculature,** promoting arteriole dilation and increased vascular permeability, and by triggering the release of histamine and other proinflammatory mediators from mast cells and basophils.

f. A complex of complement proteins known as the **membrane attack complex (MAC)** can insert into any lipid bilayer membrane, forming a large channel through which ions and water diffuse. Many bacteria, enveloped viruses, and some human or mammalian cells are subject to this osmotic lysis.

3. Circulating basophils and connective tissue mast cells are mainly proinflammatory cells that rapidly initiate acute inflammation. Triggers of

secretion include mechanical and thermal trauma and immunologic triggers, complement, and IgE.

a. IgE antibodies, regardless of antigen specificity, equilibrate between serum and binding noncovalently to high-affinity IgE receptors on mast cell and basophil surfaces. This activity arms the mast cells and basophils, but the triggering of secretion by these cells requires that antigen bind to and cross-link antigen-specific IgE molecules already affixed to their receptors.

b. Mast cells and basophils, when triggered, immediately secrete the contents of their storage granules, including histamine, tumor necrosis factor α (TNF-α), proteases, and chemotactic proteins for neutrophils and eosinophils. In addition, activation of phospholipase A_2 releases arachidonic acid from membrane phospholipids and results in the synthesis of various leukotrienes, prostaglandins, and thromboxanes. The primary effects of these mediators are

(1) Vascular dilation

(2) Increased vascular permeability

(3) Contraction of respiratory and gastrointestinal smooth muscle

(4) Neutrophil and eosinophil chemotaxis

4. Antibody-dependent cell-mediated cytotoxicity is mediated by cells with cytotoxic potential as well as receptors for IgG. These cells, NK cells, macrophages, and some T_C cells, bind to and lyse target cells coated with IgG.

5. Acute inflammation allows increased ease of movement of crucial components of the blood into the tissues, including phagocytes (especially neutrophils), IgG antibodies, complement, clotting proteins, and kinins. The adaptive result is the isolation and removal of invading microorganisms and necrotic tissues, followed by tissue repair and regeneration.

F. Cell-mediated immune responses (**cell-mediated immunity**) are those in which **antibody is not involved in the elimination of antigen.**

1. Nonviral intracellular parasites of macrophages, such as *Mycobacteria, Listeria,* and certain protozoa, are primarily eliminated by T cell-macrophage immunity. $CD4^+$ T_H1 cells recognize infected macrophages and secrete lymphokines, particularly interferon γ (IFN-γ). These lymphokines activate macrophages to produce more bactericidal oxygen radicals (e.g., superoxide anion, hydrogen peroxide) and also to increase the secretory function of the macrophages and inhibit phagocytosis, enabling the macrophages to kill the parasites in the **extracellular** environment.

2. Viruses must be eliminated from both extracellular sites and infected cells.

a. Antibodies opsonize virus particles in blood and tissue fluids for phagocytosis, but antibodies are generally ineffective against infected cells.

b. CTL cells recognize infected cells and directly kill them in an antigen-specific manner, secreting lymphokines, such as TNF-β as well as granzymes and granulysins. In addition, CTL can induce apoptosis via FAS ligand binding to FAS on the target cells. Often, the cells are killed before

infectious virus particles are assembled. When killed cells release infectious viral particles, they may be opsonized by an antibody. Cell-mediated immunity and humoral immunity must function in concert to provide optimal antiviral defenses.

c. **NK cells** kill infected (and tumor) cells in a non-antigen-specific manner, binding to MHC-like molecules using a variety of receptors. NK cells kill their target cells using mechanisms similar to those used by CTLs.

d. IFN-γ (secreted by CTL, NK, and T_H1 cells) and **IFN-α** and **IFN-β** (secreted by fibroblasts and other cells) provide additional antiviral immunity by binding to receptors on other cells and inducing synthesis of kinases and endonucleases (i.e., antiviral proteins), which inhibit viral and cellular growth. Interferons also upregulate class I MHC proteins, which make infected cells more visible to CTL cells.

3. Tumors are modified host cells and must be eliminated by the immune system, usually by cell-mediated immunity.

a. NK cells are primarily responsible for killing tumor cells. They act by recognizing changes in cell-surface proteins or by **antibody-dependent cell-mediated cytotoxicity.**

b. CTL cells recognize tumor cells in an antigen-specific manner and kill them by secreting lymphokines, such as TNF-β, and by inducing apoptosis through the binding of FAS and FAS-ligand.

c. **Macrophages** also kill tumor cells in a nonspecific manner, through the release of TNF-α.

4. Graft rejection (see V)

II. Hypersensitivity Reactions are exaggerated, inappropriate, or prolonged immune responses that cause damage to otherwise normal tissue.

Four types of hypersensitivity reactions are recognized, primarily on the basis of the mechanisms of pathogenesis (Figure 10-4). Many different diseases are included within each type. **Allergens** are broadly defined as antigens or haptens that induce hypersensitivity reactions, and they are usually nonpathogenic, nontoxic agents.

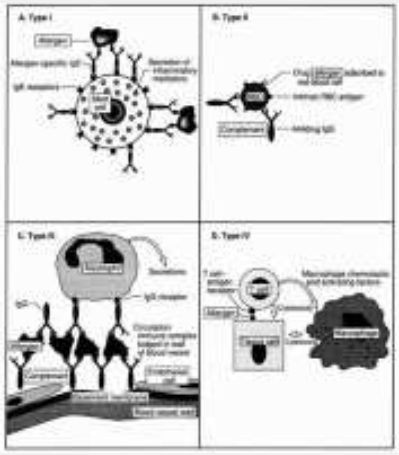

Figure 10-4. The four main types of hypersensitivity reactions. *RBC,* red blood cell.

A. IgE-mediated type I hypersensitivity reaction (immediate hypersensitivity)

1. A type I hypersensitivity reaction is caused by **inappropriate production and hypersecretion of IgE** to specific allergens plus auxiliary factors, such as increased mucosal permeability to irritants (e.g., SO_2, NO_2, diesel fumes). The **tendency to hypersecrete IgE is inheritable;** a child's probability of being a hypersecretor is 50% if one parent is a hypersecretor and 75% if both parents are hypersecretors. These individuals are considered to be atopic.

a. IgE is produced locally after nonsystemic exposure to an antigen.

(1) In normosecretors (1-10 µg/dL of IgE), arming of local mast cells occurs (see I.B.6).

(2) In hypersecretors (typically 100 µg-1 mg/dL of IgE), IgE spillover occurs, arming basophils and nonlocal mast cells and causing increased occupancy of mast cell and basophil IgE receptors by IgE.

b. Because there is a lag period for IgE synthesis and cell arming, a type I reaction usually does not occur on the first (or first seasonal) exposure to a specific allergen.

2. Common allergens

a. Respiratory allergens include pollens of various plants (e.g., ragweed, grasses, trees), fungi, animal fur, carpet mites, and other shed allergens.

b. Gastrointestinal allergens include dairy products, shellfish, tree nuts, and peanuts.

c. **Skin and mouth allergens** include topically applied drugs (e.g., procaine).

d. Intravenous allergens include insect venoms and drugs that act as cell or plasma protein-bound haptens (e.g., penicillin, cephalosporins,

vaccines). These drugs may cause type II or III hypersensitivity reactions in people who do not hypersecrete IgE in response to these drugs.

3. Activation of mast cell and basophil secretion by an allergen requires two or more receptor-bound IgE molecules to be cross-linked by a specific allergen. Hapten-size drugs that provoke this reaction both sensitize the immune system and trigger mast cells when the drug is bound to a larger molecule (e.g., a protein). Activation leads to a transient increase in the cyclic adenosine monophosphate (cAMP) level, followed by an increase in the level of cyclic guanosine monophosphate (cGMP) relative to cAMP. This is followed by phospholipase C producing second messengers, which lead to a rapid increase in cytoplasmic calcium ions (Ca^{++}). With the increase in cytoplasmic Ca^{++}, there is immediate fusion of vesicles containing inflammatory mediators with the cell membrane and release of these mediators into the extracellular milieu. In addition, after degranulation, mast cells produce additional cytokines, leukotrienes, and prostaglandins. These activate the late-phase response, which further activates the local inflammatory response. Prolonged increases in cAMP levels inhibit mast cell activation.

4. Effects of mediators secreted from mast cells and basophils

a. Vasodilation and increased capillary permeability are caused by histamine; the leukotrienes C4, D4, and E4; and prostaglandin D_2 (PGD_2) secreted by mast cells.

b. Gastrointestinal and respiratory smooth muscle constriction is caused primarily by histamine, the leukotrienes C4, D4, and E4; PGD_2; and platelet-activating factor secreted by mast cells and other leukocytes.

c. Eosinophil and neutrophil infiltration is caused by chemotactic factors secreted by mast cells.

5. Local symptoms of pathogenesis include inflammation of the upper (rhinitis) and lower respiratory tract (asthma), gastrointestinal tract, and skin.

a. Common clinical symptoms include urticaria, pruritus (itching), nasal congestion, bronchoconstriction, mucus and lachrymal hypersecretion, laryngeal edema, vomiting, and diarrhea.

b. Symptoms may be confined to the portal of allergen entry (e.g., respiratory allergen: respiratory symptoms) or may be more widespread as a result of allergen spillover into the circulation (e.g., food allergen: gastrointestinal, skin, respiratory symptoms).

c. **Atopic dermatitis** typically includes severe pruritic dermatitis, and may also include rhinitis or asthma, food allergies, and changes in the cell-mediated immune system.

d. The local introduction of allergen sometimes leads to anaphylaxis.

e. Approximately 50% of patients with asthma hypersecrete IgE. This tendency is probably contributory, but ancillary, to the underlying bronchial hyperreactivity present in these patients (see Chapter 48).

6. Systemic anaphylactic manifestations of pathogenesis. In sensitized individuals, intravenous injection of an allergen (e.g., bee venom) or absorption across the mucous membranes (e.g., peanuts) can cause systemic edema and hypovolemic shock, with cardiac arrhythmia, asphyxiation as a result of bronchoconstriction and mucous hypersecretion, and urticaria. Death usually occurs because of asphyxiation. While other sensitized individuals may have only mild local symptoms upon encountering the allergen, these results demonstrate differing host responses to identical proteins.

7. Time course. Immediate hypersensitivity reactions have two phases. The **early reaction,** resulting from mediator secretion by mast cells, begins within 1-2 min after allergen contact and peaks within 1-2 hr. The **late-phase reaction** begins 6-12 hr after contact with the allergen and lasts for several hours. The late-phase reactions are initiated by newly synthesized leukotrienes and prostaglandins along with cytokines, chemokines, and other inflammatory mediators. The late-phase reaction is characterized by increased numbers of eosinophils and is maintained by the products of these cells.

8. Diagnosis. In scratch tests, a variety of allergens are injected intradermally to screen for the presence of a wheal and flare (i.e., edema and erythema) response in the skin. **Radioallergosorbent (RAST)** and **radioimmunosorbent (RIST) assays** use radiolabeled reagents to detect serum IgE concentrations. The results of these assays do not always agree with each other or with clinical manifestations of type I hypersensitivity.

9. Prophylaxis

a. Identifying and avoiding allergens is the most important form of prophylaxis.

b. Hyposensitization (desensitization) is performed by injecting weekly, increasing doses of allergen intramuscularly to elicit an allergen-specific IgG response and decrease the allergen-specific IgE. Once desensitization has been achieved, monthly injections are used to maintain the IgG levels. IgG is able to bind to the allergen and inhibit its binding to the mast-cell bound IgE.

10. Therapy

a. Competitive H_1-antagonists of histamine are useful in local forms but do not completely reverse the inflammation because histamine is not the only inflammatory mediator in the reaction. Competitive H_1-antagonists have little effect on anaphylaxis.

b. Epinephrine reverses anaphylaxis through its α-agonist and β-agonist effects. Patients with systemic allergies are given epinephrine self-administration kits. β_2-agonists (e.g., albuterol) are able to promote bronchodilation, and α_1-agonists (e.g., phenylpropanolamine) decrease nasal congestion.

c. **Cromolyn sodium** (cromoglycate) is a locally administered inhibitor of mast cell degranulation. **Glucocorticoids** are able to block the late phase of the reaction but are less effective during the early phase.
Antileukotriene therapies are also able to block the late phase of the reaction.
d. Topical steroids inhibit inflammation and immune responses. Topical application via spray or inhaler limits the side effects seen when glucocorticoids are administered systemically. In addition to using topical steroids alone, they are also combined with long-acting β_2-agonists as therapy for asthma.
e. Anti-IgE therapy is composed of a high-affinity monoclonal antibody to the Fc region of IgE. It is able to bind IgE and prevent sensitization of mast cells and basophils. This therapy is useful in highly atopic individuals and is used for individuals with severe asthma for whom other therapies have proven ineffective.
B. Non-IgE-mediated type I hypersensitivity reactions are probably the result of several poorly understood causes and are sometimes called **anaphylactoid reactions.** The following factors may contribute to and exacerbate non-IgE-mediated type I reactions.
1. Respiratory β_2-receptor unresponsiveness, which leads to a diminished bronchodilatory effect of the sympathetic nervous system.
2. Hyperreactivity of mast cells through H_2-receptor unresponsiveness. This decreases the negative feedback of histamine on the activation of mast cells.

C. Type II hypersensitivity reactions
1. Pathogenesis. Antibody-mediated cytotoxicity occurs through the production of IgM and IgG. These antibodies are able to bind to specific allergens located on cell surfaces.
a. These allergens may be intrinsic to the cell (i.e., natural cell-surface components) or extrinsic compounds (i.e., drugs) adsorbed to the cell surface.
b. Cytotoxicity may result from activation of complement, phagocytosis of the IgG opsonized cell, or both.
c. A third cytotoxic mechanism, known as antibody-dependent, cell-mediated cytotoxicity, involves the direct killing of antibody-coated cells by NK cells, macrophages, or eosinophils.
d. Type II reactions may exhibit anaphylactic signs and symptoms if enough complement is activated; however, they usually do not progress to this stage.
2. Common allergens. Type II allergens are diverse. It is the pathogenic mechanism that is common to all the reactions.

a. Foreign blood surface antigens may act as allergens to produce **transfusion mismatches** or **Rh disease.**

b. Drug allergens (or drug metabolite allergens) acting as haptens are the **leading cause of hemolytic anemia.**

(1) These allergens may directly adsorb to cell surfaces and be specifically bound by antibodies (e.g., penicillins, cephalosporins, quinidine).

(2) Alternately, they may form serum-phase immune complexes, which adsorb nonspecifically to blood cell surfaces. This makes the cell susceptible to lysis owing to the "innocent bystander" effect (e.g., rifampin, sulfonamides, chlorpromazine).

c. **Self-antigens** are the allergen in certain autoimmune diseases (e.g. myasthenia gravis, autoimmune hemolytic anemia; see III) Autoimmune hemolytic anemia is sometimes associated with administration of α-methyldopa, which induces autoantibodies against the red blood cell surface.

d. Hyperacute rejection of transplanted tissue (see V)

3. Chemical mediators. Complement proteins produce cytotoxicity and inflammation, which stimulate **macrophages and granulocytes** to secrete cytokines and enzymes, which in turn enhance inflammation.

4. Clinical symptoms depend on the type of antigen or allergen involved (see II.D.2). Hemolytic anemia and thrombocytopenia are the major clinical signs of type II hypersensitivity reactions. In hyperacute graft rejection, the transplanted tissue does not successfully perfuse because of antibody-mediated cytotoxicity to the transplanted vasculature.

5. Time course

a. In the first sensitization to a drug allergen, the blood cell lysis and inflammation begin 7-10 days after initiation of drug therapy. The second exposure to the drug causes symptoms within 3 days.

b. Transfusion mismatch. Hemolysis begins 1-2 hr after transfusion. Peak effects occur after approximately 12 hr.

c. **Rh disease** does not occur in the first RhD^+ pregnancy of an RhD^- mother. Maternal IgG is produced in the second and subsequent pregnancies after transplacental maternal sensitization to the RhD^+ fetal red blood cells. This sensitization usually takes place in the third trimester. Maternal anti-RhD IgG crosses the placenta, binds to the fetal red blood cells, and activates the fetal complement system prenatally, which leads to perinatal hemolytic anemia.

6. Prophylaxis and therapy. In drug-induced hypersensitivity reactions, withdrawing the drug usually reverses the lysis. Preventing recontact is the best prophylaxis. In Rh disease, anti-RhD is administered during pregnancy and within 72 hr postpartum for each Rh^+ pregnancy. The simplest explanation for the efficacy of anti-RhD is that this passive immunization (see VI.B.2.d) binds to fetal red blood cells in the maternal circulation and prevents sensitization of the maternal immune system.

D. Type III hypersensitivity reactions involve the persistence of immune complexes in the circulation or at local tissue sites when they are not removed after production of specific antibodies and antigen-antibody complexes. The subtypes of type III hypersensitivity reactions have diverse causes, and only the pathogenic mechanism is common to them all.

1. Pathogenesis. Immune complexes activate complement, cause inflammation, and induce positive chemotaxis in neutrophils. Persistence of immune complexes may be caused by the following:

a. A **high concentration of antigen or antibody,** which leads to a disparity in the molar ratio of antigen to antibody and the production of small immune complexes.

b. Chronic formation of immune complexes in the circulation as a result of **persistence of antigen** as with some chronic infections.

c. Other factors that cause insoluble immune complexes to form and precipitate intravascularly or on basement membranes.

2. Common allergens

a. Self-antigens in most non-organ-specific (rheumatologic) **autoimmune disorders** (e.g., systemic lupus erythematosus, rheumatoid arthritis)

b. Bacterial or protozoan antigens in persistent or chronic infections and in the initial stages of viremia for certain viral infections (e.g., prodrome of hepatitis B virus infection).

c. **Drugs** (e.g., penicillin, sulfonamides, thiouracil).

d. Antisera from another species (e.g., horse), can cause serum sickness when used for passive immunization.

e. Fungal and bacterial spores in the local respiratory form of the reaction

3. Chemical mediators. Complement proteins cause inflammation and **stimulate mast cell and basophil secretions,** which enhance inflammation. The increased vascular permeability allows immune complexes to leave the circulation and attach to basement membranes, which underlay the endothelial lining of blood vessels. The kidney glomerulus and small arteries are particularly susceptible. Complement and mast cell proteins attract neutrophils; these cells can phagocytize immune complexes and release enzymes that damage local tissue, thus intensifying inflammation. In addition, platelet aggregation and microthrombus formation may occur.

4. Clinical symptoms depend on the severity and systemic or local nature of immune complex deposition and persistence.

a. The first symptoms of systemic reactions are lymphadenopathy, splenomegaly, fever, and rash. These are common in drug-induced and viremia-induced type III hypersensitivity reactions.

b. More serious symptoms include vasculitis and glomerulonephritis, both of which may become necrotizing. These symptoms often occur with systemic

lupus erythematosus (SLE). Arthralgia and arthritis occur in both systemic and local reactions.

c. The most common types of local type III hypersensitivity reactions are pneumonitis from inhaled fungi and bacteria to which the patient is occupationally exposed (e.g., moldy hay in **farmer's lung**) and reactions to spores borne in aerosol microdroplets from dirty ultrasonic humidifiers (e.g., **humidifier lung**). The cause of these diseases is not completely understood, but both IgE and IgG are involved. IgE causes the initial inflammation and trapping of antigen, and IgG is responsible for the long-term effects. Symptoms include

(1) Nasal congestion and bronchoconstriction

(2) Joint pain and inflammation of rheumatoid arthritis caused by joint-localized immune complexes involving rheumatoid factor and neutrophil phagocytosis (see Chapter 49)

5. Time course

a. Systemic. In patients with no prior exposure to the allergen, the symptoms appear in 1-2 weeks (possibly longer) after exposure. In patients with preexisting antibodies, symptoms appear within several hours to 1 day after exposure. Severe symptoms, such as glomerulonephritis, usually require 2 weeks or more to appear.

b. Local. In patients with preexisting antibodies, hypersensitivity pneumonitis symptoms appear 6-8 hr after exposure to the antigen.

6. Prophylaxis and therapy. In drug-induced reactions, **withdrawing the drug** usually reverses the reaction. Treatment includes antihistamines or corticosteroids. Transient infectious forms resolve spontaneously as immune complexes are removed by phagocytes.

E. Type IV hypersensitivity reactions

1. Pathogenesis. Type IV reactions include prolonged inappropriate and appropriate immune responses mediated by antigen-specific T_H1 cells in concert with activated macrophages.

The T_H1 cells infiltrate tissues in which the antigen is presented and recruit and activate macrophages. The release of enzymes and cytokines by these cells results in inflammation and disruption of tissue structure in the absence of antibody.

a. Reactions to infections involve a T_H1 response against specific intracellular bacterial (e.g., *Mycobacteria*) and protozoan parasites. When the response is prolonged and ineffective, granuloma formation will occur.

b. Contact dermatitis is an inappropriate skin reaction to haptens (e.g., pentadecacatechols of poison ivy), which bind to epidermal cell surfaces and elicit a CTL and T_H1 cell response.

c. **Tuberculin reaction** is observed in the dermis and is an appropriate reaction to mycobacterial antigens. This reaction indicates a state of active T_H1 immunity (owing to an active infection) or T cell memory to the

organism. (In patients who had a positive tuberculin reaction, a subsequent negative reaction would indicate immunologic anergy or unresponsiveness.)

2. Common antigens

a. Infectious agents include *Mycobacterium tuberculosis, M. leprae, Listeria monocytogenes, trypanosomes,* and viruses.

b. Hapten allergens, such as pentadecacatechols from poison ivy, poison oak, chromates, nickel ions (leached from watch backs and other jewelry), acrylates, hair dyes that contain *p*-phenylene diamine, para-aminobenzoic acid, and certain antibiotic ointments (e.g., topical neomycin), may induce **contact dermatitis.**

c. Antigens that induce a tuberculin reaction include purified protein derivative (PPD), tuberculin (Mantoux reaction), *Candida,* mumps, and other antigens from microorganisms.

3. Chemical mediators are important in type IV reactions. These mediators are cytokines produced by activated T_H1 cells. The cytokines attract and activate macrophages to the site(s) where the pathogen/allergen is located. In turn, the activated macrophages secrete cytokines, which are responsible for inflammation and cytotoxicity (e.g., TNF-α).

4. Clinical symptoms depend on the subtype of reaction.

a. Granulomas are local aggregations of T_H1 cells, macrophages, and giant epithelioid cells (derived from fusion of activated macrophages). They occur at sites of chronic infection and serve to restrict the spread of the infection.

b. In contact sensitivity, cellular infiltration of the epidermis by CTL, T_H1 cells, and macrophages produces microvesicle formation with spongiosis.

c. Tuberculin tests cause erythema and induration as a result of cellular infiltration of the dermis, but no epidermal spongiosis is observed.

5. Time course

a. Granulomas form at various times after the onset of a chronic immune response but generally require a minimum of 2 weeks.

b. Contact sensitivity may not occur with the first transient exposure. However, in a sensitized individual, skin inflammation will appear 12-24 hr after contact with the antigen and peaks between 48 and 72 hr after exposure.

c. Tuberculin reactions follow the same time course as contact sensitivity. This reaction is often called **delayed cutaneous hypersensitivity,** or delayed-type hypersensitivity.

6. Prophylaxis and therapy. Treatment of granulomas depends on the organism involved. Proper treatment to resolve the infection will also aid in resolving the chronic immune response. For contact sensitivity, it is necessary to identify the antigen/allergen involved. Removal and avoidance of the allergen is important for prophylaxis. For treatment, topical corticosteroids suppress T cell and macrophage function. In severe cases, oral corticosteroid therapy may be required.

III. Autoimmunity

is a tissue-damaging immune response directed specifically and inappropriately against one or more self-antigens.

A. The **origin** of autoreactive immune responses is not generally known, but it requires loss of self-tolerance and deregulation of the control networks that normally prevent development of autoimmune disease. Such deregulation may include lack of regulation of T_H and T_C cells,

cross-reactivity with antigens from microorganisms, loss of self-tolerance or failure to develop tolerance, and aberrant presentation of self-antigen on specific HLA molecules.

B. Epidemiology

1. Familial clustering is evident for many, if not most, autoimmune reactions representing a complex inherited predisposition toward autoimmunity. In most cases, this predisposition is associated with specific MHC types, usually class II molecules (e.g., rheumatoid arthritis with the MHC class II molecule HLA-DR4).

2. These reactions are more common in women. The female-to-male ratio in myasthenia gravis is approximately 2:1 and in SLE is approximately 10:1. In contrast, Sjögren's disease and Goodpasture syndrome are more common in men than in women.

C. Pathogenesis

1. Overview. In a specific autoimmune disorder, the primary pathogenic mechanism may be humoral (mediated by antibodies with or without a contribution by complement), T cell mediated, or involve both humoral and cell-mediated components. These diseases are commonly associated with exacerbation and remission of the disease.

2. Environmental factors are thought to contribute to pathogenesis. However, specific associations have been found in only a few cases; these include *Streptococcus* group A pharyngitis, rheumatic fever, exposure to organic solvents, Goodpasture syndrome, ultraviolet irradiation, and SLE. It is likely that environmental factors act in concert with genetic predisposition to induce disease.

3. Organ-specific and systemic (non-organ-specific) disorders

a. Organ-specific disorders (e.g., antithyroid autoimmunity) are limited to and directed specifically against self-antigen in a single organ. Lesions and clinical symptoms are limited primarily to that organ. Cellular damage may be mediated through antibody-mediated and complement-mediated cytotoxicity (type II hypersensitivity) and/or through cell-mediated cytotoxicity (type IV hypersensitivity).

b. Systemic disorders (e.g., SLE)

(1) These disorders are also known as connective tissue, collagen vascular, or rheumatologic disorders. Autoantibodies are formed against antigens

found in most or all tissues, especially those located in the nuclei of cells and containing DNA, RNA, or nuclear-associated proteins (**antinuclear antibodies**). Pathologic changes occur systematically, primarily in the connective tissue and are at least partially caused by type III hypersensitivity reactions. Symptoms may be seen in the blood vessels, kidney glomeruli, skin, joints, and serous membranes.

(2) Non-organ-specific disorders are sometimes difficult to distinguish from one another because of the similarities in autoantigens and pathogenesis. For example, most patients with SLE have circulating antinuclear antibodies; however, these also occur in 50-65% of patients with Sjögren's syndrome and rheumatoid arthritis as well as in a small percentage of clinically normal individuals. By contrast, rheumatoid factor (anti-IgG) is seen in 75-90% of patients with rheumatoid arthritis or Sjögren's syndrome as well as in 35% of patients with SLE. The synovitis of rheumatoid arthritis is often a clinical finding in SLE, and the vasculitis of SLE is found in rheumatoid arthritis (see Chapter 49).

D. Organ-specific autoimmunities

1. Rheumatic fever is not technically an autoimmune response because antibodies are produced against group A streptococci and cross-react with cardiac muscle fibers that are damaged by complement. Increased risk is related to a strong immune response to streptococcal M antigen.

2. Antithyroid autoimmunities (see Chapter 52). Aspects of several subtypes may occur in the same patient. Increased risk is associated with MHC class II types DR3 and DR5.

a. Primary autoimmune myxedema. Antibodies against the thyroid-stimulating hormone (TSH) receptor on thyroid follicle cells act as antagonists to the stimulation of growth of the follicle cells normally provoked by TSH. The result is thyroid atrophy with hypothyroidism.

b. Hashimoto's thyroiditis. Antibodies against thyroid peroxidase on follicle cells cause cytotoxicity and inflammation through the activation of complement. Antibodies against thyroglobulin (colloid) also may be present. Cell-mediated immunity may cause some cytotoxic damage. The resulting hypothyroidism is treated with synthetic thyroid hormone.

c. **Grave's disease.** Antibodies act as agonists of TSH, binding to the TSH receptor and stimulating hypersecretion of thyroid hormone (thyroid-stimulating immunoglobulins). The result is hyperthyroidism, which is treated by antithyroid drugs (e.g., propylthiouracil) or thyroid ablation with surgery or radiation.

3. Myasthenia gravis

a. Pathogenesis. Antibodies against the nicotinic acetylcholine receptor on skeletal muscle plasma membrane at neuromuscular junctions act as competitive antagonists of **acetylcholine** binding. This activity causes

weakness and fatigue in skeletal muscles. In addition to this direct blockage of neuromuscular transmission, down regulation of receptors and complement damage to muscle fibers occur. Many patients have swallowing and respiratory muscle dysfunction that may be caused by penicillamine therapy. Increased risk is associated with MHC class I type B8.

b. Therapy. Anticholinesterase therapy (e.g., neostigmine) increases acetylcholine synaptic concentrations (preservation of endogenous acetylcholine). Immunosuppression with corticosteroids is used in severe cases; plasmapheresis to remove autoreactive antibodies from the blood is also helpful. Thymectomy helps many patients.

4. Autoimmune pernicious anemia

a. Pathogenesis. Antibodies against intrinsic factor are secreted into the stomach lumen, where they inhibit the association of intrinsic factor with vitamin B_{12}. Thus the absorption of vitamin B_{12} is decreased. This condition also can result from antibodies against gastrin receptors on parietal cells of the stomach mucosa that block stimulation of the cells by gastrin and decrease their secretion of intrinsic factor.

b. Therapy is intramuscular injection of cyanocobalamin or oral administration of concentrated intrinsic factor preparations.

5. Goodpasture's syndrome

a. Pathogenesis. Antibodies against **glomerular capillary basement membrane (GBM)** activate complement and neutrophil-mediated damage. This activation leads to glomerulonephritis, with rapid deterioration of renal function. These antibodies cross-react with pulmonary capillary basement membrane, producing pulmonary hemorrhage in smokers. Increased risk is associated with MHC class II type DR2.

b. Therapy. Immunosuppressive therapy includes corticosteroids, with plasmapheresis to remove autoreactive antibodies.

6. Autoimmune hemolytic anemia (red blood cell), thrombocytopenia (platelet), neutropenia (neutrophil), and lymphopenia (lymphocyte)

a. Pathogenesis. Antibodies against membrane antigens of one or more of the indicated cell types may activate complement and opsonize the cells for rapid splenic phagocytosis. It may also occur as part of the spectrum of autoimmunity in non-organ-specific disorders, particularly SLE. These autoimmune varieties must be distinguished from those precipitated by responses to external antigens (e.g., drugs) but the clinical effects are similar.

b. Therapy. These disorders are often acute and self-limiting, but therapy is required when they are chronic. In adults, treatment begins with corticosteroids. Additional options are cyclophosphamide, chlorambucil, and intravenous immune globulin (IVIG).

7. Insulin-dependent diabetes mellitus (IDDM; see Chapter 51). Progressive and ultimately complete destruction of pancreatic B-islet cells occurs in diabetes. Although they are predictively useful, antibodies against insulin and surface cytoplasmic antigens of the B-islet cell are present

before clinical onset. The main cytotoxic mechanisms appear to be mediated by T cells and macrophages. This view is supported by the beneficial effects of cyclosporine therapy in patients with early-stage IDDM at levels that have little effect on antibody production. Increased risk is associated with MHC class II types DR3 and DR4, and DQ2 and DQ8.

8. Multiple sclerosis (MS)

a. Pathogenesis. T cells and macrophages, which are thought to be cytocidal for oligodendrocytes, infiltrate the central nervous system (CNS) and **attack the basic protein of**

myelin as an autoantigen. The immunologic component may be secondary to other, unknown initiating agents. **CNS demyelination with sclerotic plaques** leads to spasticity. Increased risk is associated with MHC class II type DR2. Guillain-Barré syndrome is a related condition that involves peripheral nervous system (PNS) demyelination that, unlike MS, can be acute.

b. Therapy. Spasticity is treated with **baclofen** with variable effectiveness. The peripheral skeletal muscle relaxant **dantrolene** is effective in some patients. **Adrenocorticotropic hormone (ACTH),** rather than corticosteroids, is the favored immunosuppressive therapy. Recombinant IFN-β-1b (Betaseron), IFN-β-1a, and glatiramer acetate are approved by the U.S. Food and Drug Administration (FDA) as a treatment for MS.

E. Non-organ-specific autoimmunities. The similarities and differences in this class of disorders are shown by a comparison of Sjögren's syndrome and SLE. Rheumatoid arthritis is discussed in Chapter 48.

1. Sjögren's syndrome

a. Diagnosis is usually based on lymphocytic infiltration and the presence of autoantibodies against salivary gland antigens and exocrine glands of the eyes, gastrointestinal and respiratory systems, and vagina. Hypergammaglobulinemia (50%) as a result of hyperactive B cells, antinuclear antibodies (50-65%), and rheumatoid factors (anti-IgG; 75-90%) are present in the indicated percentages of patients.

b. Pathogenesis. Primary symptoms include **inhibition of exocrine gland secretion,** with dryness of the eyes, mouth, and gastrointestinal, respiratory, and vaginal mucous membranes; and pain and edema in the salivary glands. Patients with hypergammaglobulinemia often have type III hypersensitivity reactions (e.g., vasculitis with CNS involvement and kidney disease; see II.D).

c. **Therapy.** Mild cases are treated with **artificial tears** and frequent drinking of water. For more serious cases (e.g., vasculitis), treatment is similar to that for SLE (**systemic corticosteroids**).

2. SLE (Systemic Lupus Erythematosus)

a. Diagnosis is complicated and depends on the presence of 4 or more of 11 criteria. The most useful criterion is a high concentration of antinuclear

antibodies directed against double-stranded DNA and the Smith (Sm) nuclear antigen, both of which are considered specific for SLE. Other diagnostic criteria include the presence of the lupus erythematosus cell (a neutrophil that has phagocytosed nuclei); a discoid erythematous facial rash; photosensitivity; oral ulcers; arthritis; persistent proteinuria; and anticardiolipin, antierythrocyte, or antileukocyte antibodies.

b. Pathogenesis is that of **type III hypersensitivity.** Patients have **hyperactivity of B cells** of unknown origin. This hyperreactivity causes hypergammaglobulinemia, with circulating immune complexes of DNA and other nuclear antigens that precipitate onto vascular basement membranes and activate complement.

(1) Mild arthritis, fever, rash, and fatigue occur.

(2) Progressive necrotizing vasculitis with CNS involvement and glomerulonephritis are the most serious consequences, occurring in approximately 50% of patients.

(3) Hypertension may develop secondary to kidney disease.

(4) Hemolytic anemia and thrombocytopenia are common.

(5) Behavioral changes occur in approximately 25% of patients.

(6) Several drugs (e.g., **procainamide, hydralazine, quinidine, methyldopa, isoniazid, phenytoin, chlorpromazine**) provoke a lupus-like syndrome that usually resolves when the drug is withdrawn. The basis for this syndrome is not understood. No renal disorder occurs in drug-induced SLE.

c. **Therapy.** Mild disease (e.g., low-grade fever, arthritis) is managed with nonsteroidal anti-inflammatory drugs (NSAIDs). Therapy for patients with severe symptoms is usually oral methylprednisolone. Cyclophosphamide may also be used, and plasmapheresis to remove circulating immune complexes may be helpful.

F. Prospects for more specific immunologic therapies. Current therapies involve approaches that suppress all immune responses; however, current clinical trials seek to suppress only lymphocytes that are activated—for example:

1. Feeding autoantigens to patients to induce immunologic suppression

2. Vaccination with autoreactive T **cells** to induce immunologic suppression

3. Administration of **anti-T_H** monoclonal antibodies (particularly anti-CD4) to eliminate autoreactive T cells

4. Administration of **conjugates of IL-2 and toxins** from plants or bacteria to eliminate autoreactive T cells without generalized T cell suppression

IV. Immunodeficiency

is either primary or secondary. **Primary immunodeficiencies** are either **hereditary** or **congenital,** and at least one element basic to the immune system does not function properly or is absent. **Secondary immunodeficiencies** are the **result of another systemic** disorder or are **iatrogenic in patients given immunosuppressive therapy.** They usually develop in patients who previously showed normal immune function. The expected clinical outcome of an immunodeficiency is governed by the specific portion of the immune system that is affected (e.g., B and T cells, phagocytic cells, and complement).

A. Primary immunodeficiencies are, with one exception, rare. Examples are the following:

1. X-linked agammaglobulinemia (hypogammaglobulinemia) is an inherited deficiency in antibody production (humoral immunity) in which T cell function is relatively normal, but B cells do not fully mature because of a failure of B cell signaling. Serum immunoglobulin levels are low. Because this disorder is linked to the X chromosome, it occurs primarily in men.

a. Pathogenesis occurs 6-9 months after birth and represents situations in which antibody function is deficient but T-cell function is intact, such as recurrent infections with extracellular pyogenic bacteria (e.g., streptococci, pneumococci, *Haemophilus*). Immunity to fungi and most viruses is generally functional.

b. Clinical symptoms include pneumonia, sinusitis, otitis, meningitis, and septicemia.

c. **Therapy** is **passive immunization with human intravenous immunoglobulin** (IVIG; see VI.B.1.c).

2. Common variable immunodeficiency is an acquired deficiency of B cell maturation to plasma cells. It can occur at any age and in either sex. Symptoms and treatment are similar to those for X-linked agammaglobulinemia; the pathogenesis and origin vary significantly.

3. Selective IgA deficiency is the most common primary immunodeficiency, affecting approximately 0.5% of the U.S. population. It appears to be inherited. The low secretory IgA (sIgA) concentration predisposes patients to extracellular bacterial infections of the mucosal surfaces, leading to respiratory, urogenital, and gastrointestinal infections. Some affected individuals are asymptomatic for unknown reasons. Certain autoimmunities may be more prevalent. There is no specific immunologic therapy.

4. DiGeorge syndrome results from developmental failure of the thymus and parathyroid glands, accompanied by cardiovascular and other developmental anomalies. Patients have a decrease in total T cell numbers but relatively normal immunoglobulin levels.

a. Pathogenesis in severe cases (i.e., little functional thymic tissue) represents conditions involving T cell deficiency, such as recurrent infections of the skin, lungs, genitourinary tract, and blood with opportunistic pathogens, particularly viruses (e.g., herpes viruses), fungi (e.g., *Candida*), and protozoa (e.g., *Pneumocystis carinii*); increased

incidence of certain cancers; graft-versus-host (GVH) disease (see V.C) after transfusion of whole blood; and death in infancy or early childhood.
b. Therapy for severe T cell deficiencies is bone marrow transplantation, although thymus grafts may be attempted in DiGeorge syndrome (see V.C).
5. Nezelof syndrome is probably inherited and causes lymphopenia and thymic abnormalities but normal or elevated serum immunoglobulin levels. Gram-negative sepsis may occur in addition to the opportunistic infections associated with T cell deficiency.
6. Severe combined immunodeficiency disorders (SCIDs) are a heterogeneous group of inherited disorders with deficiencies in T cells, B cells (variable), and serum immunoglobulin. Infections with opportunistic organisms occur in the first few months postnatally, and survival for longer than 1 year is rare without successful bone marrow transplantation. Three forms involve failure of DNA biosynthesis or repair, and a fourth defect is the result of deficiency of the γ chain of the IL-2 receptor.

7. Chronic granulomatous disease (CGD) is a defect in the ability of phagocytes to kill bacteria. The disease is caused by a genetic defect in the production of oxygen radicals that are important for intracellular and extracellular killing of bacteria. The defect can occur in any of the four proteins essential for producing oxygen radicals, but the most common defect is X-linked. CGD is characterized by chronic infection with organisms such as *Staphylococcus aureus* and is usually fatal.
8. Leukocyte adhesion deficiency (LAD) is associated with a defect in the phagocytic cells. These cells lack intercellular adhesion molecules, the proteins necessary for binding to the endothelial cells of the blood vessels and other cell membranes. This defect leads to an inability of phagocytic cells to exit the blood and enter the tissues. In addition, the phagocytes have a decreased ability to bind to activated components of complement on a bacterial surface, leading to a decrease in phagocytosis. Patients have severe bacterial infections, especially in the mouth and gastrointestinal tract.
9. Chédiak-Higashi syndrome is a deficiency in the fusion of lysosomes with phagocytic vesicles. The cause is unknown, but this syndrome leads to bacterial survival in the phagocyte, with an increase in bacterial infections.
10. Defects in complement may be the result of defects in the activation pathways, membrane attack complex, or regulatory proteins. Defects in the activation pathways and in the membrane attack complex are associated with increased infections owing to pyogenic bacteria and with increased rates of immune complex diseases, such as SLE. Defects in regulation can be observed as angioneurotic edema and nocturnal paroxsysmal hemoglobinuria.

B. Secondary immunodeficiencies involve decreased immunologic responsiveness.

1. Cytotoxic drugs prevent the division of responding lymphocytes, suppress the production of blood cells in bone marrow, and may directly kill cells. Patients who receive chemotherapy and exhibit a significant loss of neutrophils may be treated with filgrastim or recombinant granulocyte colony-stimulating factor (G-CSF; Neupogen), to restore the white blood cell count to normal levels. Treatment to increase neutrophil levels in these patients results in decreased morbidity rates from bacterial infection. Corticosteroids broadly suppress immune system cells, including decreased division, cytokine secretion, and chemotaxis (emigration from the blood into tissues).

2. Leukemias, lymphomas, and myelomas are associated with decreased immune responsiveness, at least some of which results from destruction of the architecture of lymphoid organs (e.g., spleen, lymph nodes). Malignancy-related immunodeficiency also occurs in other cancers.

3. Protein-calorie malnutrition significantly decreases immune competence, particularly in children.

4. Aging is associated with decreased immunologic competence.

5. Acute infections produce a transient immunodeficiency.

6. AIDS is a secondary immunodeficiency that is usually persistent and is an indirect consequence of infection by **HIV-1** or **HIV-2.** HIV-1 is the more common subtype in the United States and western Europe.

a. Pathogenesis. The viral envelope glycoprotein 120 (gp120) has a strong affinity for CD4 (see I.B.3.c), allowing the virus to directly infect TH cells. In addition, these proteins use one of two chemokine receptors: CCR5 to gain entry to macrophages and dendritic cells and CXCR4 to gain entry into $CD4^+$ T cells. Because it is a retrovirus, viral entry and uncoating release the viral RNA genome and the associated reverse transcriptase enzyme, which synthesizes a double-stranded DNA copy of the genome (provirus). The proviral copy is integrated into the genome of the infected cell, and the virus enters a period of latency, during which it is essentially hidden from the immune system.

(1) During **initial infection,** there may be an acute illness that lasts an average of 3 weeks and resembles mononucleosis; some individuals have no symptoms.

(2) Seroconversion (i.e., the appearance of antiviral antibodies) occurs 3 weeks to 6 months after the initial exposure to HIV-1. A period of **asymptomatic infection** typically follows seroconversion.

(3) Infected T_H cells are killed when **viral genes are reactivated from latency** and viruses bud from the cell. In addition, infected T_H cells may fuse to form syncytia. This fusion may hasten the spread of virus to

uninfected T_H cells and contribute to cell killing. A **progressive depletion of T_H** cells occurs (normal count: 800-1000/mm^3). However, even before an obvious loss of $CD4^+$ T cells occurs, there is evidence of a defect in $CD4^+$ T cell function. The functional defect is a failure of these cells to respond to antigens to which they were previously sensitized (e.g., tetanus toxoid). The defect in responsiveness may be a function of the $CD4^+$ T cells, the APCs, or both.

(4) Macrophages may produce new virus without being killed and may spread the virus to uninfected T_H cells and other cell types. $CD4^+$ cell lines that are susceptible to HIV infection include neurons, liver, and fibroblasts. In direct cell-to-cell transfer of the virus, minimal exposure to the extracellular immune system (e.g., antibody) may occur.

(5) APCs are also affected by the infection. There is a loss of follicular dendritic cells and interdigitating cells in the lymphoid tissue. This loss leads to decreased antigen presentation to the $CD4^+$ T cells. In addition, the cytokines produced by the APCs may produce $CD4^+$ T cells that increase B cell activation but do not produce the appropriate cytokines for T cell proliferation. This activity changes the T_H cell ratios.

b. Clinical symptoms

(1) Persistent generalized lymphadenopathy (extrainguinal) is an indicator of impending progression to full disease. Unexplained fever, night sweats, diarrhea, and other symptoms known as **AIDS-related complex (ARC)** may occur.

(2) Progression to full-blown AIDS may occur 8 years or longer after the initial infection. Depletion of the T_H cell level to < 200/mm^3 and oral candidiasis suggest imminent disease. Because $CD8^+$ T cells are not significantly affected, the ratio of circulating $CD4^+$ to $CD8^+$ cells is inverted. In addition, the number of virgin T_H cells relative to memory T_H cells increases. TH cells are lost, and memory T_H cells are lost in relatively larger numbers. There is also a shift in the type of T_H cell help being generated.

(3) A diagnosis of AIDS involves the occurrence of **opportunistic infections** or **neoplasms as a result of the progressive immunodeficiency** caused by severe depletion of T_H cell (CD4) function. Also included in this diagnosis are the HIV wasting syndrome and encephalopathy.

(a) Opportunistic infections are the major consequence of AIDS, particularly by *P. carinii* (as many as 80% of patients), *Candida albicans, Mycobacterium avium-intracellulare,* herpes simplex virus (HSV), cytomegalovirus (CMV), and others. Tuberculosis occurs as a reactivation of a latent infection in carriers. Cumulatively, **these opportunistic infections are the primary cause of death.**

(b) Kaposi sarcoma, an otherwise rare cancer, occurs in fewer than one half of patients with AIDS. Non-Hodgkin lymphoma is also more common in these individuals than in the general population.

(4) HIV-associated dementia complex (HADC) affects more than one half of patients with AIDS. In HADC, macrophages infiltrate the brain and are the most productively infected cell in comparison to neurons or glia. Some patients show demyelination.
(5) Other immune system abnormalities include polyclonal B cell activation and hypergammaglobulinemia with a concomitant decreased ability to mount humoral immune responses to specific antigens. Chemotaxis, cytokine secretion, and cytotoxic ability of monocyte-macrophages are all diminished. These problems are consequences of impaired T cell regulation.
c. **Therapy**
(1) Current therapy includes prophylactic use of antibiotics and antifungal agents. Optimal anti-HIV therapy is combination therapy with three antiretroviral drugs. At present, there are four classes of antiretroviral drugs approved by the FDA. These are nucleoside reverse-transcriptase inhibitors (NRTIs; e.g., zidovudine-AZT, lamivudine, stavudine, zalcitabine-ddC, didanosine-ddI, and abacavir), nonnucleoside reverse-transcriptase inhibitors (NNRTIs; e.g., nevirapine, delavirdine, efavirenz), protease inhibitors (e.g., saquinavir, indinavir, ritonavir, nelfinavir) and integrase inhibitors (e.g., raltegravir). IFN-α is recommended for the treatment of Kaposi sarcoma. Other drugs and immunomodulators are currently under development and testing.

(2) An effective active vaccine is necessary to limit the spread of HIV infection. Because of viral antigenic variation, cell-to-cell transmission, and the uncertain role of antibodies in protection, the process of vaccine development is difficult. A live, attenuated vaccine (see VI.C.2) is considered too great a risk. Trials of subunit vaccines are under way.

V. GRAFT REJECTION

A. Overview. Individual differences in the molecular structures of cells and tissues occur, except in identical twins, because of the genetic variation inherent in humans. Because of these molecular differences, transplanted tissues or organs (i.e., grafts) are likely to be antigenically different from the recipient and therefore may stimulate an immune response.
1. Although MHC class I and II glycoproteins play an essential role in all T cell immune responses (see I.B.3.a), these molecules are particularly antigenic and variant in structure among different humans (polymorphic).
2. Each person's set of MHC glycoproteins is called his or her **human leukocyte antigen (HLA),** or **histocompatibility type.** Class I glycoproteins are known as HLA-A, -B, and -C antigens. Class II glycoproteins are known as HLA-DR, -DP, and -DQ antigens. Each person

receives one set of genes (a haplotype) encoding these protein antigens from each parent.

3. Identical twins have the same histocompatibility type. For other siblings, the probability is approximately 25% (0.25) that two siblings with the same parents are HLA identical, or matched, and approximately 50% that they are one half HLA matched, or haploidentical. Parents and children are almost always haploidentical. Some transplanted tissues are rejected because of HLA incompatibility. In other cases, the reason for rejection is the result of minor histocompatibility antigens or is unknown. HLA matching is not always a factor in rejection.

B. Common solid-organ transplants are kidney, heart, liver, heart-lung, and pancreas. Organs are obtained from cadavers or living donors. The probability of an exact HLA match in a cadaver graft is approximately 1 in 10 million.

1. HLA matching

a. The primary problem with organ donation is rejection of the transplanted organ by the host's immune response. Donation of an organ by an HLA-matched sibling is the best way to avoid this problem.

b. Although HLA-DR and HLA-B matching decreases the rejection reaction in renal and cardiac grafts, rejection does occur in HLA-matched situations. HLA matching is not important in liver transplantation.

2. Types of rejection of organ grafts

a. Hyperacute rejection is mediated by preexisting antibody in the recipient, usually against ABO mismatches. Complement is activated, clotting occurs, and the vasculature of the transplanted organ is occluded. Rejection occurs within 2 days after transplantation. An ABO-mismatched graft is rarely attempted. Rejection is essentially untreatable.

b. Acute rejection is a T cell-macrophage-mediated attack on the graft based on HLA and other tissue antigen mismatches. T cells and macrophages infiltrate the graft and, in 10-14 days, cause cellular necrosis and inflammation perivascularly. The entire graft begins to necrose if untreated.

c. **Chronic rejection** occurs several months to several years after transplantation. It causes fibrosis and occlusion of small arteries and arterioles in the kidneys and atherosclerosis in the heart. It is controlled by immunologic injury and mediated primarily by antibody and includes the release of inflammatory cytokines by macrophages. Despite the high success rate of MHC-matched, pharmacologically treated grafts in the first year after transplantation (85-90% kidney grafts), the rejection rate after 5 years is nearly 50%. This form of rejection is relatively resistant to therapy, although treatment with corticosteroids can be helpful.

C. Bone marrow transplantation is sometimes attempted in patients with immunodeficiency diseases, aplastic anemias, some leukemias, and certain genetic diseases. The graft contains a

high proportion of donor lymphocytes that respond to the host HLA and other antigens. This response causes graft-versus-host (GVH) disease.

1. Graft T cell recognition of the host is important in GVH disease, as shown by the decreased incidence of GVH disease after procedures that purge mature T cells from the donor marrow.

2. Clinical symptoms of GVH disease are seen in the skin (e.g., rash, desquamation), gastrointestinal tract (e.g., pain, vomiting, intestinal bleeding), and liver (e.g., necrosis indicated by increased serum bilirubin levels). Death commonly occurs.

3. HLA matching is important in bone marrow transplantation, but the failure rate even of matched grafts as a result of GVH disease is high.

4. Because the recipient of the marrow (host) is immunosuppressed, owing to primary immunodeficiency or by drugs or radiation, host rejection of transplanted bone marrow is less important.

D. Prophylaxis and treatment of graft rejection

1. Immunosuppression of the graft recipient

a. Corticosteroids (e.g., methylprednisolone, prednisone) are administered just before transplantation and rapidly tapered because of their side effects. Corticosteroids are used in combination with azathioprine, cyclosporine, or **antilymphocyte globulins/antithymocyte globulins (ALGs/ATGs).**

b. Azathioprine is given before transplantation. Maintenance doses are given afterward.

c. **Methotrexate** is used primarily for bone marrow transplantation in combination with ALG/ATG. It is administered either a few days before or at the time of transplantation.

2. Specific suppression of T **cells**

a. Cyclosporine A (cyclosporin) binds to an intracellular protein known as cyclophilin and blocks the transcription of cytokine genes in a T cell that has recognized antigens. In this way, it inhibits T_H cell secretion of IL-2 and production of the high-affinity IL-2 receptor and prevents complete T cell activation. It is administered prophylactically because it is more effective if it is present before rejection begins. Cyclosporine A is commonly combined with other agents. The major side effect is nephrotoxicity.

b. Tacrolimus (FK-506) is an immunosuppressive agent that inhibits TH cell function in the same way as cyclosporine A. Both drugs function through the same pathway and are not used together.

c. **Rapamycin** (sirolimus) inhibits T_H cell response to IL-2 and prevents T_H cell activation. It works through a different pathway than either cyclosporine or tacrolimus and is especially effective in combination with the other drugs.

d. ALG and **ATG** are antisera derived from animals. They contain a variety of antibody specificities against T cell antigens. They are used both

prophylactically and therapeutically in bone marrow and organ transplantation.

e. Muromonab-CD3 (OKT3) is a mouse monoclonal antibody specific for the CD3 antigen, which is present on all peripheral T cells. OKT3 is used therapeutically to halt and reverse acute rejection as soon as it is diagnosed.

(1) Its main action is the opsonization of T cells for enhanced phagocytosis. It is administered daily for 10-14 days. Only one course is typically used because it causes an immune response against the foreign mouse antibody.

(2) Acute side effects are common, probably because of nonspecific T cell activation that causes the release of cytokines. Side effects include high fever, chills, blood pressure changes, vomiting, diarrhea, and respiratory distress. OKT3 is contraindicated in patients who have fluid overload because it may cause fatal pulmonary edema.

(3) OKT3 may also be used in vitro to purge donor bone marrow of T cells to reduce the risk of GVH disease.

3. Investigational agents being tested to prevent or reverse graft rejection include anti-T cell immunotoxins (see VII.C.1), conjugates of IL-2 and a toxin, and other monoclonals that prevent T cells from adhering to foreign graft cells. These agents are administered to the graft recipient. In addition, monoclonal antibodies are used to mask HLA antigens on the graft tissue before it is transplanted into the recipient.

VI. VACCINATION

A. Overview

1. Passive vaccination is the intramuscular or intravenous injection of antibody preparations to enhance a patient's immune competence. Protection depends on the serum half-life of the injected antibody and is limited to several weeks to several months for each administration of human sera.

2. Active vaccination is the intramuscular, subcutaneous, or oral introduction of one or more antigens designed to stimulate the immune system to produce a specific immune response. This response generates antibody, activated T cells, and specific memory. Protection through memory varies with the vaccine, but immunity is long lasting.

B. Passive vaccination (Table 10-2)

1. Preparations. Doses of intramuscular preparations are sometimes given in units per kilogram and sometimes in milliliters per kilogram. The dose varies with the vaccine and patient population. Intravenous preparations are commonly used in high doses.

a. Standard human serum immunoglobulin for intramuscular vaccination is a polyclonal antiserum prepared from pooled plasma of donors. It contains 165 mg/mL human immunoglobulin,

predominantly the four subclasses of IgG. Side effects are rare, minimal, and usually confined to minor inflammation and pain at the site of injection. This preparation is unsuitable for intravenous injection because antibody aggregates form and may activate complement and platelets.

Table 10-2. Passive Vaccines

Illness	Vaccine	Rationale
Intramuscular		
Hepatitis B (HBV)	Hepatitis B immunoglobulin (HBIG)	Prophylaxis
Hepatitis A (HAV)	Immunoglobulin, intramuscular (IGIM)	Prophylaxis
Non-A, non-B hepatitis	IGIM	Prophylaxis, therapy
Measles	IGIM	Prophylaxis, therapy
Rabies	Rabies immunoglobulin (RIG)	Prophylaxis
Rubella	IGIM	Fetal prophylaxis in exposed mother
Varicella	Varicella zoster immunoglobulin (VZIG)	Prophylaxis and therapy in immunocompromised individual
Tetanus	Tetanus immunoglobulin	Prophylaxis

	(TIG)	
Hypogammaglobulinemia	IGIM	Therapy for antibody deficiency
Rh disease	Rho (D) immunoglobulin (RhoGAM)	Prophylaxis during pregnancy and after delivery of Rh^+ fetus by Rh^- mother
Botulism	Botulism antiserum (equine)	Prophylaxis, therapy
Snakebite	Polyvalent antivenin (equine)	Prophylaxis, therapy
Black widow bite	Black widow antivenin (equine)	Prophylaxis, therapy
Intravenous[a]		
Hypogammaglobulinemia	Intravenous immunoglobulin (IVIG)	Therapy for antibody deficiency
Idiopathic thrombocytopenic purpura (ITP)	IVIg	Therapy
Chronic lymphocytic leukemia	IVIg	Therapy for antibody deficiency
Cytomegalovirus (CMV) infection	CMV IVIG	Therapy in renal transplant patients

Acute renal rejection	Muromonab-CD3 (murine)	Reversal of acute rejection

[a] U.S. Food and Drug Administration-approved uses; many others currently in trials result from vaccine preparation in cells of nonhuman origin. The valence of a vaccine indicates the number of strains of organism included (e.g., trivalent polio vaccine includes three strains of poliovirus).

b. Special intramuscular immunoglobulins (IGIMs) are individual sera prepared from plasma lots of subjects actively immunized against or recovering from specific diseases. Each serum is enriched for antibodies of the desired specificity (e.g., tetanus immunoglobulin contains more antibodies against tetanus toxin than would be found in IGIM).

c. **IVIGs** are prepared from pooled human serum and modified to minimize antibody aggregation. Chills, nausea, and abdominal pain occur in approximately 10% of patients. Side effects are diminished by reducing the rate of intravenous infusion. Premedication with corticosteroids is recommended, and intravenous epinephrine is used if anaphylaxis occurs.

d. Animal antisera. Equine (horse) antisera are used in certain situations (Table 10-2). Mouse monoclonal antibody (muromonab-CD3) is used in acute renal rejection (see V.D.2.e). The half-lives of animal antibodies are shorter in humans.

2. Rationales for passive vaccination

a. Prophylaxis of infectious disease. Antibodies are given prophylactically to prevent clinical symptoms of a viral or bacterial infectious process, particularly in a patient without previous exposure and therefore without immunologic memory. The vaccine protects the recipient during the incubation period for infection. For example:

(1) *Clostridium tetani* infection has an incubation period of approximately 5 days before significant quantities of tetanus toxin are produced. A primary immune response of 7-10 days is too slow. Passive vaccination with tetanus immunoglobulin (TIG) binds the toxin and prevents disease.

(2) Hepatitis B immunoglobulin (HBIG) is administered to individuals as soon as possible after exposure to prevent viral infection.

b. Prophylaxis or therapy prevents or attenuates the effects of infection in special populations. Examples are the use of **varicella zoster immunoglobulin (VZIG)** in immunocompromised patients and the use of IGIM in pregnant women who are exposed to rubella and have not been actively vaccinated.

c. **Treatment of antibody deficiency.** Individuals who are deficient in antibody production, either because of primary immunodeficiency (see IV) or as a result of chronic lymphocytic leukemia, receive intravenous immunoglobulin (IVIG) or IGIM every 2-4 weeks to maintain humoral immunity. IVIG is preferred.

d. Other situations. IVIG is used for idiopathic (autoimmune) thrombocytopenia purpura. Intramuscular Rh_o(D) immunoglobulin (RhoGAM) is used prophylactically for Rh disease (see II.C.5.c). Muromonab-CD3 (see V.D.2.e) is used for acute renal graft rejection.

C. Active vaccination (Table 10-3) is used for prophylaxis.

1. Overview

a. Contents. Active vaccines contain one or more subunits of a pathogen or whole pathogenic organisms but may also contain preservatives, low doses of antibiotics, and other compounds that do not affect the immune response.

b. Administration. Active vaccines are administered subcutaneously, intramuscularly, intradermally, orally, or intranasally. Some are introduced adsorbed to aluminum hydroxide or aluminum phosphate adjuvants. An adjuvant increases the antigenicity of the vaccine.

c. **Seroconversion.** For most active vaccines, the success of the series of vaccinations is indicated by seroconversion of the patient. Seroconversion indicates that a person who previously did not have specific serum antibodies (i.e., seronegative) now has these antibodies (i.e., seropositive). Seroconversion does not indicate established immunity for certain vaccines (e.g., bacillus Calmette-Guérin vaccine for tuberculosis).

d. A schedule of active vaccination is recommended for infants and children (Table 10-3). The first vaccination is given after the infant is 6 weeks old because responses are normally inadequate in newborns and because maternal antibodies remain in the newborn circulation; some vaccines (e.g., hepatitis B virus; HBV), however, may be given immediately after birth. Some vaccines are intended for use primarily in noninfant populations.

Table 10-3. Commonly Administered U.S. Food and Drug Administration-Approved Active Vaccines

Vaccine	Target Population[a]	Number of Vaccinations	Schedule	Notes
Live, attenuated viral				
Oral polio (OPV; trivalent)	Infants, children, healthcare and daycare workers	4	2, 4, 15-18 months; 1 at school entry	Approximately 1 in 2.6 million risk of vaccine-induced paralysis; no longer recommended because of risks; substitute killed vaccine
Measles, mumps, rubella (MMR)	Infants, children	2	15 months (< 12 months if high risk); 1 at school entry	Generally affords lifelong immunity
Rubella	Adolescent girls not previously vaccinated	1	Postpuberty	Protects future fetus from congenital rubella injury
Varicella	Children, other at-risk individuals	1 (if ≥ 13 years old, 2)	1 between 12 and 18 months or 2-3 years; after 13 years old,	Duration of immunity or effect on developm

			2-4 weeks apart	ent of shingles unknown
Influenza (trivalent)	Individuals between 5 and 59 years old at risk for infection	1 per year	Annually for maximum protection	Administered intranasally
Bacterial				
BCG tuberculosis	Individuals exposed to sputum-positive tuberculosis patients	Varies	Depends on success or initial vaccination	Unpredictable effectiveness; induces cell-mediated immunity
Killed, inactivated viral or viral subunit				
Influenza (trivalent or polyvalent)	Geriatric patients, healthcare workers, individuals at risk for complications	1 per year	Annually for maximum protection	Variant strains may appear each year; vaccine must be updated annually
Hepatitis B (HBV)	All	3	Between 1 and 2 months, 2 and 3 months,	Recombinant, subunit

			after 6 months	
Inactivated polio (IPV; trivalent)	All children; as booster in healthcare and day-care workers	4	2, 4, 15-18 months; 1 at school entry	No sIgA; thus reduced protection; no paralysis risk
Killed, inactivated viral or viral subunit				
Rabies (HDCV)	Animal-care workers	4 or 5[b], with boosters	7 days apart; boosters as required to maintain immunoglobulin	Two doses to exposed, already immune individual
Bacterial, subunit				
Diphtheria, tetanus, pertussis (DTP)	Infants, children	4, with boosters	2,4, 15-18 months; 1 at school entry	Tetanus toxoid (Td) booster every 10 years or on exposure through a wound
Tetanus and diphtheria	Children ≥ 7 years old; adults with no	3, with boosters	Second dose in 4-8 weeks;	Td booster every 10

toxoids (Td)	vaccination		third dose 6 months later	years or on exposure through a wound if more than 10 years or vaccine history unavailable
Haemophilus b (Hib)	Infants, children, HIV-infected adults	Depends on formulation	Depends on formulation	Polysaccharide capsule is poor antigen; conjugate vaccines enhance potency
Pneumococcus (polyvalent)	At-risk adults or children ≥ 2 years old (e.g., immunocompromised patients, geriatric patients)	1 or 1 per year	As necessary in at-risk patients; not given during active infection; 1 per year in geriatric patients	Poor response to polysaccharide antigen in children < 5 years old
Meningococcus (quadrivalent A, C Y, W-135)	College freshmen living in dormitories; high-risk adults or children ≥ 2 years old, including individuals	1, subcutaneously	As necessary in at-risk individuals at 3- to 5-year intervals	Polysaccharide vaccine give poor response in children < 2 years old; does not

	with complement component deficiencies or anatomic or functional asplenia			protect against serotype B, which accounts for 46% of cases

BCG, bacille Calmette-Guérin; *HDCV,* human diploid cell vaccine; *slgA,* secretory immunoglobulin A.

[a] Entire target population is not listed in all cases.

[b] Five doses to already exposed individuals.

e. Most vaccines require **a series of vaccinations;** others are effective with a single vaccination. For those that require a series, intervals between vaccinations greater than those recommended do not generally diminish protection. The duration of memory varies with each vaccine, and **booster vaccinations** are often necessary.

f. Side effects include inflammation at the site of vaccination, malaise, mild fever, chills, headache, myalgia, and arthralgia. More severe side effects include febrile illness, somnolence, seizures, or anaphylactic hypersensitivity to vaccine antigens or accessory components (e.g., antibiotic, chicken protein). Severe reactions contraindicate continuation of a series. A person with severe febrile illness should not be actively vaccinated until the illness resolves.

2. Types of active vaccines

a. Live, attenuated vaccines consist of whole organisms (usually viruses). These organisms multiply after vaccination, but are attenuated to reduce their pathogenicity.

(1) A small dose produces a strong immune response because the antigen concentration increases when the organism multiplies. Some vaccines elicit lifelong immunity in two doses—for example, the measles, mumps, rubella (MMR) vaccine. Because of their relative genetic instability, viruses can revert to virulence and cause the disease against which the patient is vaccinated. This is a particular problem with one of the serotypes of the oral polio vaccine (OPV).

(2) Live, attenuated viral vaccines are not recommended for pregnant women or those intending to become pregnant within 3 months of

vaccination. Live, attenuated viral or bacterial vaccines are not given to immunocompromised individuals.

b. Killed, inactivated vaccines may contain whole killed cells (e.g., phenol-killed *Bordetella pertussis*) or any antigenic fraction isolated from the organism. They are usually given adsorbed to adjuvant.

c. Some isolated antigens (**subunit vaccines**) may require inactivation before they are used in a vaccine —for example, formaldehyde-modified toxin of *Clostridium tetani,* known as **tetanus toxoid (Td)** after modification. Inactivation eliminates pathogenicity, but preserves some antigenicity. Other subunit vaccines include proteins and glycoproteins of an organism that are produced by recombinant DNA technology in bacteria, yeast, or mammalian cells and are then used as the antigens for vaccination. The HBV vaccine contains proteins produced by recombinant genetic technologies and is approved by the FDA for use in humans.

(1) Because no live organisms are present, reversion to pathogenicity is not a problem. However, doses of cells or antigens must be higher than in live, attenuated vaccines, and hypersensitivity reactions to vaccine components are more common. Minimum effective doses are usually measured in numbers of cells or micrograms of antigen.

(2) Vaccines in which the antigenic fragment is a polysaccharide (e.g., *Haemophilus* b) are usually poor at eliciting immune responses and memory, probably because they do not evoke T cell activation. These vaccines have been improved by conjugating the polysaccharide to another antigenic compound (e.g., Td). These are known as **conjugate vaccines.**

4. Experimental vaccines include other subunit vaccines; peptides produced by chemical, cell-free synthesis; recombinant DNA viruses containing genes for the antigens of multiple organisms; and anti-idiotype antibodies used for active vaccination.

5. Specific vaccines in common use and recommended administration schedules are listed in Table 10-3.

D. Simultaneous administration of active and passive vaccines. Sometimes active and passive vaccines against a pathogenic organism are administered simultaneously to maximize postexposure prophylaxis. The immunoglobulin offers immediate protection, and the active vaccine stimulates an immune response. These vaccines are given at separate sites to prevent antibody (passive) and antigen (active) from reacting and inactivating one another.

1. Infants with **HBV** who are born to mothers who have the hepatitis B surface antigen (HBsAg) are significantly protected from becoming chronic carriers by this combined prophylaxis.

2. Rabies. Postexposure prophylaxis typically includes the combined use of active and passive vaccines because of the lethal nature of the unchecked infection. The exception is patients with a previous active vaccination who have sufficient existing serum antibody concentration.

3. Tetanus. Combined prophylaxis is sometimes used, depending on the type of wound and the patient's history of active vaccination. Recommended guidelines are as follows:

a. A tetanus-prone wound is one that produces anaerobic conditions (e.g., deep puncture) or one in which exposure to *Clostridium* or its spores is probable (e.g., contaminated with animal feces). If the patient's history of active vaccination is uncertain or includes fewer than three doses, both TIG and Td are administered. The patient returns to complete the toxoid series.

(1) If the wound is tetanus-prone but the patient received a full series of active vaccination, no treatment is necessary if the last Td dose was received within the last 5 years.

(2) If the last dose was received more than 10 years ago, Td, but not TIG, is given to boost memory immunity and antibody production.

b. For a **clean, minor wound,** if the patient's history of active vaccination is uncertain or includes fewer than three doses, Td is administered.

(1) If the patient received a full series of active vaccinations, no treatment is necessary if the last Td dose was received within 10 years.

(2) If the last dose was received more than 10 years ago, Td, but not TIG, is given to boost memory immunity and antibody production.

VII. PROSPECTS FOR IMMUNOMODULATION

A. Fab antidigoxin antibody preparations obtained from sheep are approved for the reversal of toxicity associated with toxic digoxin serum levels. The antibody binds digoxin and prevents it from binding to its normal receptor site. The Fab-digoxin complex is excreted renally.

B. Monoclonal antibodies are generally produced through the in vitro fusion of a cancerous plasma cell (myeloma) with an activated mouse B cell. The resulting **hybridoma** secretes murine (mouse) antibodies of a single defined specificity and has the immortality characteristic of the myeloma. Techniques for the production of human monoclonal antibodies and a variety of hybrid mouse-human monoclonal antibodies are also available.

1. Monoclonal antibodies—for example, whole antibodies or Fab or $F(ab')_2$ fragments—are routinely used for in vitro diagnostic tests (e.g., blood group and tissue typing for HLA), screening for cancer-related antigens (e.g., carcinoembryonic antigen; CEA), urine testing for drugs and metabolites, and testing for HIV infection. In these and many other diagnostic applications, monoclonal antibodies are often conjugated to enzymes, radioisotopes, or fluorescent dyes.

2. Muromonab-CD3 is used to treat acute graft rejection. Other monoclonal antibodies are used for treatment of breast cancer and leukemia.

3. In clinical trials, the use of **monoclonal antibodies against** T **cells** causes improvement in certain autoimmune disorders.

4. Monoclonal antibodies against neoplastic cells show some success, and are useful in treating certain leukemias and lymphomas, as well as breast and colon cancers.

C. Monoclonal antibodies are conjugated to enzymes, drugs, prodrugs, radioisotopes, or plant and bacterial toxins to provide specific delivery of the conjugated agent to one or more focused in vivo sites of action. Several problems are associated with the use of these agents.

1. Immunotoxins are usually produced by the conjugation of a monoclonal antibody to a biologic polypeptide toxin (e.g., diphtheria toxin) that is modified to reduce nonspecific toxicity.

2. Although they are being tested for graft rejection and autoimmunity, immunotoxins are primarily used as antineoplastic agents. Clinical trials show moderate success in treating leukemia and lymphoma, with lower success rates against tumors such as breast carcinoma.

3. Monoclonal antibodies conjugated to radioisotopes (e.g., ^{90}Y) cause remissions in patients with Hodgkin disease and acute T cell leukemia.

4. Monoclonal antibodies conjugated to enzymes that activate a prodrug to the active drug at a specific tissue site (e.g., neoplastic cell surface) are in human trials.

D. Immunostimulation has been attempted with a variety of compounds, ranging from cytokines to bacterial products (Table 10-1).

1. IFN-α has many subtypes. Two are currently FDA approved. Because it inhibits cell growth, it is used to treat hairy cell leukemia, Kaposi sarcoma in patients with AIDS, and genital warts. At low doses, interferons stimulate immune cellular function (e.g., T cells, NK cells, macrophages), but at high doses, they are immunosuppressive. The use of IFN-α against other cancers produces variable results.

2. IFN-γ provides greater immunostimulation in the intact immune system, but its effects depend on dose and timing. The combined use of IFN-α and IFN-γ yields better results. The most common side effects of interferon therapy are influenza-like symptoms. IFN-γ is approved for use as a macrophage-activating factor in chronic granulomatous disease.

3. Several protocols using **IL-2** show promising results, with apparently complete remissions in some patients with melanoma. With this technique, known as adoptive immunotherapy, a patient's peripheral blood lymphocytes, or tumor-infiltrating lymphocytes, are removed. They are cultured with IL-2 and reinfused with additional IL-2. These IL-2-responsive cells are likely T cells and NK cells. Severe capillary leakage syndrome, occasionally leading to death, is a problematic side effect.

4. Hormones of the thymus that induce T cell maturation and other functions are used to increase certain cell-mediated immune functions, with variable results.

5. Sulfur-containing compounds, such as **levamisole** (a phenylimidothiazole anthelmintic) and diethyldithiocarbamate (**Imuthiol**), have immunostimulatory activity. Their effect is greater on cell-mediated immunity than on humoral immunity. Levamisole is approved as an oral agent for use in colon cancer in combination with fluorouracil.

6. Inosine pranobex is licensed for use in many countries as an immunostimulant. It induces T cell differentiation and augments cell-mediated immune functions, with minimal toxicity.

7. As a component of mycobacterial cell walls, **muramyl dipeptide (MDP)** stimulates macrophage activation and may be used as an adjuvant, given with antigen (see I), or given alone as an immunostimulant.

STUDY QUESTIONS

Directions: Each question, statement, or item or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A man has symptoms of a viral infection of about 4 days' duration. To confirm the diagnosis, the physician draws a blood sample and requests the antibody titer (level) for the suspected agent. The first blood sample shows a low titer of antibody. A week later, another blood sample is drawn, and the titer against the virus is much higher. This situation is an example of

(A) an inflammatory response to the viral infection.

(B) a primary immune response to the viral infection.

(C) a secondary immune response to the viral infection.

(D) a cellular response to the viral infection.

View Answer***1. The answer is B[seeand].*****2. Which class of antibody has the longest serum half-life and opsonizes antigens for phagocytosis through two different pathways?**

(A) Immunoglobulin G (IgG)

(B) Immunoglobulin M (IgM)

(C) Immunoglobulin A (IgA)

(D) Immunoglobulin E (IgE)

View Answer***2. The answer is A[see].*****3. Urticaria that appears rapidly after the ingestion of food usually indicates which type of hypersensitivity reaction?**

(A) Type I

(B) Type II

(C) Type III

(D) Type IV

View Answer***3. The answer is A[seeand].*****4. In which autoimmune disorder is the mechanism of pathogenesis classified as type II hypersensitivity?**

(A) Systemic lupus erythematosus (SLE)

(B) Insulin-dependent diabetes mellitus (IDDM)

(C) Grave's disease

(D) Hashimoto's thyroiditis

View Answer***4. The answer is C[seeand].*****5. A patient receives long-term, high-dose therapy with a sulfonamide. After approximately 3 weeks of therapy, the patient has a low-grade fever, rash, and muscle and joint pain. Which type of hypersensitivity accounts for these symptoms?**

(A) Type I

(B) Type II

(C) Type III

(D) Type IV

View Answer***5. The answer is C[seeand].*****6. In which type IV hypersensitivity reaction is the tissue-damaging disorder considered an inappropriate response by the immune system?**

(A) Poison ivy dermatitis

(B) Chronic tuberculosis

(C) Acute graft rejection

(D) Tuberculin test

View Answer***6. The answer is A[see].Mycobacterium.*****7. Which agent is commonly used to treat multiple sclerosis (MS)?**

(A) Neostigmine

(B) Cyanocobalamin

(C) IFN-β-1b

(D) Propylthiouracil

View Answer***7. The answer is C[see].*****8. The therapeutic role of muromonab-CD3 in acute renal graft rejection is probably based on**

(A) activation of T cell function and secretion of cytokines.

(B) destruction of T cells by complement.

(C) opsonization of T cells for phagocytosis.

(D) selective inhibition of T_H cell function.

View Answer***8. The answer is C[see].*****9. Which is a current clinical application of intravenous human immunoglobulin (IVIG)?**

(A) Prophylaxis after hepatitis B virus (HBV) exposure

(B) Treatment of humoral immunodeficiency

(C) Prophylactic infant immunization for polio

(D) Prophylaxis for Rh disease by infant immunization

View Answer***9. The answer is B[see].*****10. Which cytokine is approved for the treatment of certain forms of cancer?**

(A) Interleukin 2 (IL-2)

(B) Interferon α (IFN-α)

(C) Interferon γ (IFN-γ)

(D) Imuthiol

View Answer***10. The answer is B[see].***P.225

For questions 11 and 12: A 6-year-old child has a deep puncture wound. The parent is unsure of the child's history of vaccination.

11. If no other information is available, what should the physician recommend?

(A) No vaccination

(B) Tetanus immunoglobulin (TIG)

(C) Tetanus toxoid (Td)

(D) Both TIG and Td at separate sites

View Answer***11. The answer is D[see].*****12. If the child received a full series of diphtheria, pertussis, tetanus (DPT) vaccinations, the last at entry into school, what should the physician recommend?**

(A) No vaccination

(B) Tetanus immunoglobulin (TIG)

(C) Tetanus toxoid (Td)

(D) Both TIG and Td at separate sites

View Answer***12. The answer is A[see].*****13. Persistent infections by opportunistic pathogens, such as *Candida albicans* and *Pneumocystis carinii,* could indicate all of the following *except***

(A) inherited T cell immunodeficiency.

(B) humoral immunodeficiency.

(C) AIDS.

(D) combined immunodeficiency.

View Answer***13. The answer is B[see].*****14. Which statement about HIV infection is *not* correct?**

(A) Individuals who become infected with HIV-1 always show overt symptoms shortly after infection.

(B) Seroconversion to positive status for anti-HIV-1 antibodies is the primary criterion for diagnosis of a viral carrier.

(C) The incubation period for the pathogenesis of AIDS is believed to be 8 years or longer after the initial infection with HIV.

(D) $CD4^+$ T cells and macrophages may be able to spread HIV to uninfected $CD4^+$ cells without releasing any extracellular virus particles.

View Answer***14. The answer is A[see].*****Directions:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, A-E.

15. Which statements about the currently approved sheep Fab fragment used to counteract digoxin overdose are true?

I. It is obtained by the immunization of sheep with a digoxin-protein conjugate and subsequent proteolytic cleavage of the collected antibody.
II. It specifically binds digoxin, preventing its activity.
III. It has a serum half-life of approximately 3 weeks.

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***15. The answer is C[see].***16. **CD4$^+$ T cells specifically recognize antigens in which form?**
I. Bound to major histocompatibility (MHC) class I molecules on the surface of any body cell
II. In free, soluble form in extracellular fluids
III. Bound to MHC class II molecules on the surface of special antigen-presenting cells (APCs)

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***16. The answer is B[see].***17. **What is a normal outcome of the activation of the complement system by either the classic or alternative pathway?**
I. Acute inflammation
II. Opsonization of immune complexes
III. Cytolytic action

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***17. The answer is E[see].***18. **In antiviral immunity, what directly recognizes and kills viral-infected cells?**
I. Cytotoxic T cells (CTLs)
II. Antiviral antibodies
III. Interferons

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***18. The answer is A[see].***P.226

19. A patient is treated with penicillin and produces antibodies against the drug. They are still mostly present. An emergency situation requires administration of an intravenous dose of penicillin. If the patient has a type I penicillin hypersensitivity reaction, which pathologic consequence would be expected, and within what time course of clinical onset?

I. Hemolytic anemia, with an onset of 1-2 hr after the intravenous dose

II. Anaphylaxis, with an onset of a few minutes after the intravenous dose

III. Cutaneous urticaria and pruritus, with an onset of a few minutes after the intravenous dose

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***19. The answer is D[seeand].*****20. Which situation occurs in all type IV hypersensitivity reactions?**

I. Infiltration of the affected tissue by mononuclear cells

II. A delay of 12 hr or longer in the onset of clinical symptoms after allergen contact

III. Significant beneficial effect of the administration of H_1-antagonists

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***20. The answer is C[seeand].*****21. Which immunologic finding is *not* unique to systemic lupus erythematosus (SLE)?**

I. Hypergammaglobulinemia

II. The presence of circulating antinuclear antibodies

III. The presence of circulating rheumatoid factors

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***21. The answer is E[see].*****22. An organ donor who is human leukocyte antigen (HLA) matched with the recipient of a graft is sought. Which individual is at least somewhat likely to provide a total HLA match?**

I. A sibling of the graft recipient

II. A parent of the graft recipient

III. A cadaver

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***22. The answer is A[see].***23. Graft-versus-host (GVH) disease is associated primarily with which type of transplantation?

I. Kidney

II. Heart

III. Bone marrow

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***23. The answer is B[see].***24. The prophylactic use of cyclosporine in graft rejection is probably based on its ability to

I. inhibit synthesis of antibodies, thereby preventing hyperacute rejection.

II. inhibit activation of T **cells, thereby preventing acute rejection.**

III. block transcription of the interleukin 2 (IL-2) gene and synthesis or secretion of IL-2.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***24. The answer is D[see].***25. Which is a valid comparison of live, attenuated and killed, inactivated active vaccines?

I. Replication of the organisms in a live, attenuated vaccine increases the stimulation of the immune system and a lower dose is often required.

II. Attenuated vaccines often require multiple doses.

III. A killed, inactivated vaccine probably produces lifelong immunity in one or two doses.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***25. The answer is A[seeand].***26. Which active vaccine is recommended for healthcare workers but is not routinely given to infants?

I. Measles, mumps, rubella (MMR) vaccine

II. Influenza polyvalent

III. Tetanus toxoid (Td)

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***26. The answer is D[see].*****27. Which statement about pneumococcus and meningococcus vaccines is true?**

I. They are composed of purified polysaccharides.

II. They are recommended for children < 2 years of age.

III. The vaccines protect against all serotypes of disease causing pneumococcus or meningococcus.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***27. The answer is A[see].***P.227

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* I.C.2 *and* 3*].*

A primary immune response to an infection is characterized by the initial production of IgM, beginning about 4 days after antigen is encountered. A switch to a different immunoglobulin isotype (i.e., IgG, IgE, or IgA) occurs before the peak of antibody production is reached. The peak primary immune response occurs 10-14 days after the antigen is encountered, and the serum contains both IgM and IgG.

2. The answer is A *[see* I.D.2.b; I.E*].*

IgG has a serum half-life of 25-35 days, longer than that of any other class, although mast cell-bound IgE has the longest half-life. In general, immune complexes containing IgG are opsonized for phagocytosis through binding to the IgG receptors on neutrophils and macrophages and additionally through the activation of complement. IgM also opsonizes, but only through the activation of complement.

3. The answer is A *[see* II.A.5.a *and* b*].*

Food allergies are usually type I reactions. In a patient with preexisting hypersecreted IgE specific to a food allergen and bound to mast cells, the allergic response usually occurs shortly after ingestion. Mast cell secretions lead to vomiting. Systemic spillover of allergen into the circulation may lead to milder effects in other tissues (e.g., urticaria).

4. The answer is C *[see* II.C.1 *and* 2.c; III.D.2.b*].*

In Graves' disease, an antibody acting as a TSH agonist hyperstimulates the thyroid. In SLE, persistent circulating immune complexes are responsible for much of the pathogenesis (type III). In IDDM, T cell cytotoxicity to beta islet cells is probably responsible for the major pathogenesis (type IV). In Hashimoto's thyroiditis, antibodies to thyroid peroxidase may initiate inflammation but T_H1 cells and macrophages infiltrate the organ (Type IV).

5. The answer is C *[see* II.D.2.c; II.D.4.a *and* b; II.D.5.a*].*

One of the most common causes of type III hypersensitivity is the response to drugs. This type of reaction is often seen after long-term, high-dose therapy. The treatment of choice is to discontinue treatment and substitute an unrelated drug.

6. The answer is A *[see* II.E.1*].*

Poison ivy contains a hapten, pentadecyl catechol, which is not known to be toxic. Therefore, its capacity to elicit an immune response is inappropriate because it serves no useful function. In chronic tuberculosis, the immune response is attempting, although unsuccessfully, to eliminate the mycobacterial pathogen. Acute graft rejection is also appropriate, but unfortunate, because it is a response against foreign tissue. A tuberculin test is an appropriate manifestation of the existence of active immunity or memory to *Mycobacterium.*

7. The answer is C *[see* III.D.8.b*].*

Treatment with IFN-β-1b lowers the frequency of attacks by 33-50% at 2 years in MS patients. Neostigmine is used as an anticholinergic agent in myasthenia gravis. Cyanocobalamin is administered in autoimmune pernicious anemia to replace nonabsorbed vitamin B_{12}. Propylthiouracil is used as an antithyroid in Graves' disease.

8. The answer is C *[see* V.D.2.e*].*

Muromonab-CD3 is a mouse anti-CD3 monoclonal antibody that binds to all T cells because CD3 is a constant part of the antigen receptor of each T cell. The binding of muromonab-CD3 opsonizes the T cells for phagocytosis. Therefore, the total number of T cells is reduced. Mouse antibodies are inefficient at activating human complement. Some T cell activation with cytokine secretion occurs, but it is an undesirable side effect of muromonab-CD3 administration.

9. The answer is B *[see* VI.B.1.c; Table 10-2*].*

IVIGs are used to replace antibody in immunodeficient individuals. Hepatitis B immunoglobulin (HBIG) is administered intramuscularly. Anti-Rh antibody is also administered intramuscularly to the mother immediately postpartum (sometimes during pregnancy), but not to the infant. Prophylactic infant immunization for polio is provided through active, not passive, vaccination.

10. The answer is B *[see* VII.D*].*

IFN-α is approved for use in patients with hairy cell leukemia and in patients with AIDS and Kaposi sarcoma. Some of its beneficial effects probably derive from its ability to inhibit growth. The other cytokines are in various stages of clinical trials as antineoplastic therapies, although IFN-γ is approved for use in patients with chronic granulomatous disease. Imuthiol is not a cytokine but a synthetic drug.

11. The answer is D *[see* VI.D.3.a; Table 10-3*].*

A patient with an uncertain history of vaccination and a tetanus-prone wound requires both active and passive vaccination. TIG provides immediate protection if the individual does not have memory. Td begins the series that leads to the establishment of memory. A tetanus-prone wound in an individual with a full series of active vaccinations requires no treatment if the last vaccination in the series was administered less than 5 years earlier. These recommendations are general guidelines.

12. The answer is A *[see* VI.D.3.a; Table 10-3*].*

13. The answer is B *[see* IV.A; IV.B.6*].*

Opportunistic infections by fungi, viruses, and parasites other than extracellular pyogenic bacteria suggest a deficiency of T cell function. Inherited T cell immunodeficiency and AIDS are inherited and acquired T cell deficiencies, respectively. Combined immunodeficiency includes both humoral and T cell deficiency. Only humoral immunodeficiency is a primarily humoral deficiency in which the expected signs are recurrent infections by extracellular pyogenic bacteria.

14. The answer is A *[see* IV.B.6.a.(1)*].*

It is not known what percentage of individuals shows overt symptoms after initial infection. Those who do, however, generally show mononucleosis-like symptoms for approximately 3 weeks. Some individuals display no overt symptoms.

15. The answer is C (I, II) *[see* I.A.4; I.D.2; I.D.5; VII.A*].*

Digoxin is a hapten, a molecule that is too small to stimulate responses (be an immunogen) in its free form, but can be recognized by antibodies. To obtain sheep antidigoxin antibodies, the sheep is immunized with digoxin that has been coupled to a larger molecule, in this case, a protein. The antibodies obtained from the sheep are cleaved with proteolytic enzymes to yield the Fab fragment. This fragment is specific to and can bind digoxin, blocking its biologic activity. Animal antibodies have a shorter serum half-life when injected into humans, and all Fab fragments, even human, have a short half-life compared to complete antibody molecules. Only complete human IgG has a half-life of approximately 1 month.

16. The answer is B (III) *[see* I.B.3; I.B.5*].*

$CD4^+$, or helper, T cells have receptors that recognize fragments (epitopes) of immunizing antigens (immunogens) only when the fragments are bound to an MHC class II molecule on the surface of APCs. As a result, T cells cannot be activated inappropriately by soluble antigens. $CD8^+$ T cells recognize fragments bound to MHC class I molecules.

17. The answer is E (I, II, III) *[see* I.E.2*].*
When complement is activated, different proteins of the complement sequence have functions that lead to all three actions. Acute inflammation allows greater movement of plasma proteins and phagocytes from blood to tissue. Opsonization of immune complexes enhances their phagocytosis. Cytolysis of microorganisms often results in their killing.
18. The answer is A (I) *[see* I.F.2*].*
Antiviral antibodies are probably most important in extracellular immunity to viruses, binding virus particles for opsonization and preventing additional infection of cells. Interferons are secreted from viral-infected and other cells (e.g., macrophages, T cells) and, after binding to receptors, induce the appearance of antiviral proteins in other cells. CTLs recognize viral-infected cells and cause direct cytotoxicity.

19. The answer is D (II, III) *[see* II.A.2.d; II.A.6 *and* 7; II.C.1.b; II.C.5*].*
If the patient produced antibodies that are still present and the hypersensitivity reaction is type I, these antibodies are IgE, mostly bound to mast cell and basophil IgE receptors. Their half-life is several months to years. Intravenous introduction of penicillin causes rapid activation of and secretion by blood basophils. Symptoms of type I hypersensitivity occur within minutes. These symptoms may be severe (anaphylaxis) or less severe (cutaneous, gastrointestinal, or respiratory), depending on the individual. Hemolytic anemia is an expected result of a type II hypersensitivity reaction to penicillin, based on the presence of IgM or IgG antibodies in the serum. The onset is delayed by a few hours in a patient with preexisting antibodies.
20. The answer is C (I, II) *[see* II.E.3, 4, 5 *and* 6*].*
Type IV hypersensitivity reactions are delayed after the introduction of allergen because allergen-specific T cells become activated and attract other cells, such as macrophages, to the site of allergen introduction (e.g., the epidermis of the skin in contact sensitivity, the lungs in tuberculosis). These sites are infiltrated by mononuclear cells. Inflammation is primarily caused by tissue disruption and necrosis as well as by secretion of cytokines by the infiltrating cells. Although histamine secretion can also occur from local mast cells, H_1-antagonists of histamine usually do not have significant effects because T cell and macrophage activation, migration, and secretion are not greatly affected by these drugs.
21. The answer is E (I, II, III) *[see* III.C.3.b*].*
All three findings are common to more than one non-organ-specific autoimmune disorder, but they occur in different percentages of patients with specific disorders. For example, antinuclear antibodies are probably present in all patients with SLE but are found in only a fraction of patients with rheumatoid arthritis and Sjögren's syndrome. Rheumatoid factors are

more common in rheumatoid arthritis than in SLE or Sjögren's syndrome, and hypergammaglobulinemia is more prevalent in SLE than in Sjögren's syndrome.

22. The answer is A (I) *[see* V.A.3; V.B*].*

Parents and children are rarely HLA matched but are usually half matched. An HLA match from a cadaver-derived organ is unlikely. The probability that two siblings are HLA matched is 25%; the probability that they are half matched is 50%.

23. The answer is B (III) *[see* V.C.1*].*

In bone marrow transplantation, marrow containing competent lymphocytes is transplanted to a generally immunosuppressed host. The greatest problem is an immune response by the graft against HLAs and other tissue antigens of the host. In renal and cardiac transplantation, the greatest problem is rejection of the foreign organ by the immune system of the host (HVG disease).

24. The answer is D (II, III) *[see* V.B.2; V.D.2.a*].*

Cell-mediated immune mechanisms are thought to be more important in acute graft rejection, and the inhibition of T cell activation appears to be the key element in immunosuppression. Responding T cells require signaling from IL-2 to reach full activation and progress to cell division. IL-2 is produced by activated T cells and can act in an autocrine manner. Cyclosporine blocks transcription of the IL-2 gene during T cell activation, inhibits the synthesis of IL-2, and prevents full T cell activation and division. Its effects are limited to activated T cells. Because it has no direct effect on antibody synthesis, it is not useful in the hyperacute rejection phenomena that are based on antibody-mediated mechanisms. Hyperacute rejection is essentially untreatable because it depends on the presence of antibodies in the graft recipient.

25. The answer is A (I) *[see* VI.C.2.a *and* b*].*

Live, attenuated vaccines introduce organisms that are competent to replicate. This replication stimulates the immune response. For this and probably other reasons, a live, attenuated vaccine (but not a killed, inactivated vaccine) probably provides lifelong immunity in one or two doses.

26. The answer is D (II, III) *[see* VI.C.1.d; Table 10-3*].*

The MMR vaccine is administered to infants within or shortly after the 1st year of life. A second dose is recommended at school entry. Influenza active vaccine is targeted toward specific adult populations. Healthcare workers are included in this target population, as are infants and children at risk; however, the vaccine is not routinely administered to infants. Td is not routinely administered to infants, who instead receive DTP. Td is used primarily for initial vaccinations in adults who were not previously vaccinated and for 10-year booster vaccinations in all individuals, including healthcare workers.

27. The answer is A (I) *[see* VI.C.2; Table 10-3*].*
The pneumococcal and meningococcal vaccines are multivalent and contain purified polysaccharide from a number of different serotypes. However, these vaccines do not contain polysaccharide from all the relevant infectious agents. Purified polysaccharides do not stimulate immune responses in children younger than 2 years of age. For polysaccharide vaccines to be effective in young children, the polysaccharide must be conjugated to a protein as in the Hib vaccine.

Biotechnology Drug Products
Godwin W. Fong
Charles Lee
I. INTRODUCTION.
Advances in biotechnology have made many formerly unstable or difficult-to-produce biologic products available for therapeutic use. Some life-threatening diseases are now treated with biotechnology products.
A. Interferon (INF) is an example of a drug that was genetically engineered to inhibit certain types of cancer cells and some viruses.
B. Cellular hormones known as interleukins, lymphotoxins, and tumor necrosis factor are now used to treat cancer and immunodeficiency diseases.
C. Monoclonal antibodies (MAbs) can deliver toxins specifically to cancer cells and destroy them. MAbs are also used with radioisotopes to diagnose and visualize cancer cells. Monoclonal antibodies have been developed to target signaling pathways associated with immune response and are being used to treat various immunological disorders, such as rheumatoid arthritis, inflammatory bowel disease, psoriasis, and moderate to severe asthma.
D. Many biopharmaceutical products derived from the body tissues (through cell lines) are now produced on a large scale. Modified natural products also may be further improved.
E. A synthetic analogue of thyrotropin-releasing hormone prevents paralysis after spinal cord injuries in animal studies.
F. Superoxide dismutase may be useful in preventing damage to tissues that are deprived of oxygen.
G. New biotechnologic treatments have been developed for emphysema, congestive heart failure, ulcers, atherosclerosis, and an increasing number of medical conditions.
Table 11-1 lists the biotechnology products that are approved for human use.
II. BASIC TERMINOLOGY
A. An antigen is a substance that stimulates the production of antibodies.
B. An antibody is an immunoglobulin produced by the body in response to stimulation from an antigen.
C. Antisense DNA is a complementary strand of DNA that is specifically synthesized to attach to the sense DNA and prevent genetic transcription. The sense DNA that carries the information that affects the disease process is usually elucidated before an antisense drug is designed.
D. Colony-stimulating factors (CSFs) are a class of glycoprotein hormones. CSFs regulate the differentiation and formation of blood cells from precursor cells.
E. Cytokines are a group of special proteins (nonantibodies) released by cells to trigger action in other cells.
F. DNA is the molecule that contains the genetic instructions of a cell. DNA consists of deoxyribose, phosphate, and repeating bases as building blocks. The four bases are adenine, guanine, thymine, and cytosine.

Table 11-1. Approved Recombinant Therapeutics and Vaccines

Drug (Trade Name)	Indication(s)	Company; Year Introduced
Human insulin (Humulin)	Diabetes	Eli Lilly, Genentech; 1982
Somatrem for injection (Protropin)	Human growth hormone deficiency in children	Genentech; 1985
Interferon α-2a (Roferon-A)	Hairy cell leukemia	Hoffmann-La Roche; 1986
Interferon α-2b (Intron A)	Hairy cell leukemia	Schering-Plough, Biogen; 1986
	Extension of therapy for chronic hepatitis C from 6 months to 18-24 months	1997
	Follicular lymphoma in conjunction with chemotherapy	1997
Hepatitis B vaccine recombinant (Recombivax HB)	Prevention of hepatitis B	Merck, Chiron; 1986
Muromonab-CD3 (Orthoclone OKT3)	Reversal of acute kidney transplant rejection	Ortho Biotech; 1986
Somatropin for injection (Humatrope)	Human growth hormone deficiency in children	Eli Lilly; 1987
Alteplase (Activase)	Acute myocardial infarction	Genentech; 1987
	Acute pulmonary embolism	1990
	Restoration of function to central venous access devices (as assessed by the ability to withdraw blood)	2001
Interferon α-2a (Roferon-A)	AIDS-related Kaposi sarcoma	Hoffmann-La Roche; 1988

Interferon α-2b (Intron A)	AIDS-related Kaposi sarcoma	Schering-Plough, Biogen; 1988
	Genital warts Hepatitis C	1991
Interferon n3 (Alferon N injection)	Genital warts	Interferon Sciences; 1989
Hepatitis B vaccine (Engerix-B)	Hepatitis B prevention	SmithKline Beecham, Biogen; 1989
	Chronic hepatitis C infection	1998
Erythropoietin (Epogen)	Anemia associated with chronic renal failure	Amgen, Johnson & Johnson, Kirin; 1989
Erythropoietin (Procrit)	Anemia associated with AIDS or zidovudine administration	Amgen, Ortho Biotech; 1990
	Anemia associated with chronic renal failure	1990
	Chemotherapy-associated anemia in patients with nonmyloid malignancy	1993
	Anemia associated with cancer and chemotherapy	1993
PEG-adenosine (ADAGEN)	ADA-deficient severe combined immunodeficiency	Enzon, Eastman Kodak; 1990
Interferon γ-1b (Actimmune)	Management of chronic granulomatous disease	Genentech; 1990
	Delaying time to disease progression in patients with severe, malignant osteopetrosis	InterMune Pharmaceuticals (2000)
CMV immunoglobulin (CytoGam)	Prevention of CMV in kidney transplant recipients	Medimmune; 1990
Filgrastim; G-CSF	Chemotherapy-induced neutropenia	Amgen; 1991
	Acute myeloid leukemia	1998
Glucocerebrosidase (Ceredase)	Type I Gaucher disease[a]	Genzyme; 1991
Glucocerebrosidase (Cerezyme)	Type I Gaucher disease[a]	Genzyme; 1994
Sargramostim (GM-CSF) (Prokine)	Autologous bone marrow transplantation	Hoechst-Roussel, Immunex; 1991
Sargramostim (GM-CSF) (Leukine)	Neutrophil recovery after bone marrow transplantation	Immunex, Hoechst-Roussel; 1991
Antihemophilic factor (Mononine)	Hemophilia B	Armour; 1992
Antihemophilic factor (Recombinate)	Hemophilia A	Genetics Institute, Baxter Healthcare; 1992
Interleukin 2 (Proleukin)	Renal cell carcinoma	Chiron; 1992
	Metastatic melanoma	1998
^{111}Indium-labeled antibody (OncoScint CR103)	Detection, staging, and follow-up of colorectal cancer	Cytogen, Knoll; 1992

^{111}Indium-labeled antibody (OncoScint OV103)	Detection, staging, and follow-up of ovarian cancer	1992
Interferon β-1b (Betaseron)	Relapsing/remitting multiple sclerosis	Chiron, Berlex; 1993
DNase alfa (Pulmozyme)	Cystic fibrosis	Genentech; 1993
Factor VIII (Kogenate)	Hemophilia A	Genentech, Miles; 1993
Filgrastim (G-CSF) (Neupogen)	Bone marrow transplant	Amgen; 1994
PEG-l-asparaginase (Oncaspar)	Refractory childhood acute lymphoblastic leukemia	Enzon; 1994
Human growth hormone (Nutropin)	Short stature caused by human growth hormone deficiency	Genentech; 1994
Abciximab (ReoPro)	Antiplatelet prevention of blood clots Treatment of a broader range of patients undergoing percutaneous coronary intervention; revised dosage and patient management to reduce bleeding Unstable angina that does not respond to conventional medical therapy when percutaneous coronary intervention is planned within 24 hr	Centocor; 1994
Live varicella virus vaccine (Varivax)	Active immunization of persons 12 months of age and older	Merck; 1995
RSV immunoglobulin (RespiGam)	Prevention of serious lower respiratory tract infection in children younger than 24 months old	Massachusetts Public Health Biologic Labs; 1996
Inactivated hepatitis A vaccine (Vaqta)	Immunization against hepatitis A in children older than 6 years of age	Merck; 1996
Interferon β-1a (Avonex)	Multiple sclerosis	Biogen; 1996
Human antihemophilic factor	Hemophilia A	Centeon; 1996
Haemophilus b conjugate (meningococcal protein conjugate) and hepatitis B (recombinant vaccine) (Comvax)	Immunization of individuals 6 weeks to 15 months of age born of HBsAg-negative mothers	Merck; 1996
Cryoprecipitated antihemophilic factor A	Control of bleeding associated with Factor VIII deficiency	Blood Bank of the Redwoods; 1996
Reteplase (Retavase)	Acute myocardial infarction in adults	Boehringer Mannheim; 1996
DTaP vaccine (Infanrix)	Primary and booster immunization of infants and children except as a fifth dose in children who previously received four doses of DTaP	SmithKline Beecham; 1997
Recombinant coagulation Factor IX (BeneFix)	Control and prevention of hemorrhagic episodes in patients with hemophilia B,	Genetics Institute; 1997

	including perioperative management of patients with hemophilia B who are undergoing surgery	
Autologous cultured chondrocytes (Carticel SM Service)	Repair of clinically significant, symptomatic, cartilaginous defects of the femoral condyle (medial, lateral, or trochlear) caused by acute or repetitive trauma	Genzyme Tissue Repair; 1997
Interferon alfacon-1 (Infergen)	Treatment of chronic HCV infection in patients 18 years of age or older who have compensated liver disease and anti-HCV serum antibodies or HCV RNA	Amgen; 1997
	Subsequent treatment of HCV-infected patients who tolerated an initial course of interferon therapy	1997
Rabies vaccine (RabAvert)	Preexposure and postexposure immunization of children and adults	Chiron; 1997
Oprelvekin (Neumega)	Prevention of severe thrombocytopenia and reduction of the need for platelet transfusions after myelosuppressive chemotherapy in patients with nonmyeloid malignancies who are at high risk for severe thrombocytopenia	Genetics Institute; 1997
Rituximab (Rituxan)	Treatment of patients with relapsed or refractory low-grade or follicular B cell non-Hodgkin lymphoma	Genentech; 1997
Daclizumab (Zenapax)	Prophylaxis of acute organ rejection in patients receiving renal transplants; part of an immunosuppressive regimen that includes cyclosporine and corticosteroids	Hoffman-La Roche; 1997
Becaplermin (Regranex)	Lower-extremity diabetic neuropathic ulcers that extend into the subcutaneous tissue or beyond and have an adequate blood supply	OMJ Pharmaceuticals; 1997
HTLV-I and -II (Vironostika HTLV-I and -II MicroELISA System)	Detection of antibodies to HTLV-I and -II in human serum or plasma	Organon Teknika; 1998
Fibrin sealant (Tisseel VH kit)	Adjunct to hemostasis in surgeries that involve cardiopulmonary bypass	Osterreichisches Institut fur Haemoderivate; 1998
	Treatment of splenic injuries caused by blunt or penetrating trauma to the abdomen when control of bleeding by conventional surgical techniques, including suture, ligature, and cautery, is ineffective or impractical	
	Closure of colostomies	

Pooled plasma, solvent detergent treated (VIPLAS/SD)	Documented deficiencies of coagulation factors for which there are no concentrate preparations available, including congenital single-factor deficiencies of Factors I, V, VII, XI, and XIII and acquired multiple coagulation factor deficiencies Reversals of warfarin effect Thrombotic thrombocytopenic purpura	V.I. Technologies; 1998
Basiliximab (Simulect)	Prophylaxis of acute organ rejection in patients undergoing renal transplantation Part of an immunosuppressive regimen that includes cyclosporine and corticosteroids	Novartis; 1998
	Use in renal transplantation in combination with triple immunosuppressive therapy Use in pediatric renal transplantation Use of an IV bolus injection	2001
Palivizumab (Synagis)	Prophylaxis of serious lower respiratory tract disease caused by RSV in pediatric patients at high risk of RSV disease	Medimmune; 1998
Sacrosidase (Sucraid)	Congenital sucrose isomaltase deficiency	Orphan Medical; 1998
Eptifibatide (Integrilin)	Acute coronary syndrome	COR Therapeutics; 1998
	Treatment of patients undergoing percutaneous coronary intervention	
Diphtheria and tetanus toxoids and acellular pertussis vaccine adsorbed (Certiva)	Active immunization of individuals 6 weeks to 7 years of age (before the 7th birthday)	North American Vaccine; 1998
Infliximab (Remicade)	Treatment of moderately to severely active Crohn disease to reduce the signs and symptoms in patients who have an inadequate response to conventional therapies Treatment of patients with fistulizing Crohn disease to reduce the number of draining enterocutaneous fistula(s)	Centocor; 1998
	For reduction in signs and symptoms of rheumatoid arthritis in patients who have had an inadequate response to methotrexate	1999
	Inhibition of progression of structural damage in patients with rheumatoid arthritis who have had an inadequate response to methotrexate	2000

	Improving physical function in patients with moderately to severely active rheumatoid arthritis who have had an inadequate response to methotrexate	2002
	Reducing signs and symptoms, and inducing and maintaining clinical remission in patients with moderately to severely active Crohn disease who have had an inadequate response to conventional therapy	2002
	Reducing the number of draining enterocutaneous and rectovaginal fistulas and maintaining fistula closure in patients with fistulizing Crohn disease	2003
	Improving physical function in patients with moderately to severely active rheumatoid arthritis who have had an inadequate response to methotrexate	2003
Rotavirus vaccine, live, oral, tetravalent (RotaShield)	Primary immunization of infants at 2, 4, and 6 months of age	Wyeth-Ayerst Laboratories; 1998
Trastuzumab (Herceptin)	Metastatic breast cancer in patients whose tumors overexpress the HER-2 protein and who have received one or more chemotherapy regimens for metastatic disease	Genentech; 1998
	Median survival	2001
(Etanercept) Enbrel	Reduction in signs and symptoms of moderately to severely active rheumatoid arthritis in patients who have had an inadequate response to one or more DMARDs	Immunex; 1998
	Reducing the signs and symptoms and delaying structural damage in patients with moderately to severely active rheumatoid arthritis, including those who have not previously failed treatment with a DMARD	2000
	Reducing signs and symptoms of active arthritis in patients with psoriatic arthritis	2002
Recombinant OspA (LYMErix)	Active immunization against Lyme disease in people 15-70 years old	SmithKline Beecham; 1998
Vitravene (Fomivirsen)	Local treatment of CMV retinitis in patients with AIDS who are intolerant of or have a contraindication to other treatments for CMV retinitis or who were insufficiently responsive to previous treatments	Isis Pharmaceuticals, Ciba Vision; 1998

Antithymocyte globulin (Thymoglobulin)	Acute rejection in renal transplant patients	Pasteur-Mérieux Serums et Vaccines—France; 1998
Denileukin diftitox (Ontak)	Treatment of patients with persistent or recurrent cutaneous T cell lymphoma whose malignant cells express the CD25 component of the interleukin 2 receptor	Seragen; 1999
Hepatitis B immunoglobulin (Nabi-HB)	Treatment of acute exposure to HBsAg, perinatal exposure of infants born to HBsAg-positive mothers Sexual exposure to HBsAg-positive individuals Household exposure of infants to people with acute hepatitis B virus infection	Nabi; 1999
Recombinant coagulation factor VIIa (NovoSeven)	Treatment of bleeding episodes in hemophilia A or B with inhibitors to Factor VIII or Factor IX	Novo Nordisk A/S— Denmark; 1999
Interferon α-n1, lymphoblastoid (Wellferon)	Chronic HCV infection in patients 18 years of age or older who do not have decompensated liver disease	GlaxoWellcome; 1999
Antihemophilic factor/von Willebrand factor complex (Humate-P)	Used in adult patients for treatment and prevention of bleeding hemophilia A (classic hemophilia) Used in adult and pediatric patients for treatment of spontaneous and trauma-induced bleeding episodes in severe von Willebrand disease Used in mild and moderate von Willebrand disease when use of desmopressin is known or suspected to be inadequate	Centeon Pharma—Germany; 1999
Hetastarch (Hextend)	Plasma volume expander for treatment of hypovolemia during surgery	BioTime; 1999
Pneumococcal 7-valent conjugate vaccine (diphtheria CRM197 protein) (Prevnar)	Immunization of infants 2, 4, 6, and 12-15 months of age to prevent invasive pneumococcal disease Immunization of infants and toddlers against otitis media caused by vaccine serotypes	Lederle Laboratories Division American Cyanamid; 2000 2002
Antihemophilic factor (recombinant) (ReFacto)	Control and prevention of hemorrhagic episodes and for short-term routine and surgical prophylaxis in patients with hemophilia A	Genetics Institute; 2000
BCG, live (PACIS)	Treatment of CIS in the absence of associated invasive cancer of the bladder	BioChem Pharma—Canada; 2000

Tenecteplase (TNKase)	Reduction of mortality associated with AMI	Genentech; 2000
Crotalidae polyvalent immune Fab (ovine) (CroFab)	Treatment of minimal and moderate North American Crotalidae envenomation	Protherics; 2000
Botulinum toxin type B (MYOBLOC)	Treatment of cervical dystonia to reduce the severity of abnormal head position and neck pain	Elan Pharmaceuticals; 2000
Botulinum toxin type A (BOTOX or BOTOX COSMETIC)	Treatment of cervical dystonia	Allergan; 2002
	Temporary improvement in the appearance of moderate to severe glabellar lines associated with corrugator and/or procerus muscle activity in adult patients ≥ 65 years of age	
Peginterferon α-2b (PEG-Intron)	Treatment of chronic hepatitis C in patients not previously treated with interferon-α who have compensated liver disease and are at least 18 years of age	Schering; 2001
Alemtuzumab (Campath)	Treatment of patients with B cell chronic lymphocytic leukemia who have been treated with alkylating agents and who have failed fludarabine therapy	Millennium and ILEX Partners; 2001
Hepatitis A inactivated and hepatitis B (recombinant) vaccine (TWINRIX)	Active immunization of people 18 years of age or older against disease caused by hepatitis A virus and infection by all known subtypes of hepatitis B virus	SmithKline Beecham Biologicals; 2001
Digoxin immune Fab (ovine) (DigiFab)	Treatment of patients with life-threatening or potentially life-threatening digoxin toxicity or overdose	Protherics; 2001
Darbepoetin α (Aranesp)	Treatment of anemia associated with chronic renal failure, including patients on dialysis and patients not on dialysis	Amgen; 2001
	Treatment of anemia in patients with nonmyeloid malignancies when anemia is the result of the effect of concomitantly administered chemotherapy	2002
Hepatitis B immunoglobulin (human) (Nabi-HB)	Treatment of acute exposure to HBsAg after acute exposure to blood containing HBsAg, perinatal exposure of infants born to HBsAg-positive mothers, sexual exposure to HBsAg-positive persons, and household	Nabi; 2001

	exposure of infants to people with acute hepatitis B virus infection	
Anakinra (Kineret)	Reduction in signs and symptoms of moderately to severely active rheumatoid arthritis, in patients 18 years of age or older who have failed one or more DMARD	Amgen; 2001
Drotrecogin α (activated) (Xigris)	Reduction of mortality in adult patients with severe sepsis (sepsis associated with acute organ dysfunction) who have a high risk of dying from sepsis, as measured by a scoring system based on their general health and the severity of their illness (e.g., by APACHE II)	Eli Lilly; 2001
Pegfilgrastim (Neulasta)	To decrease the incidence of infection, as manifested by febrile neutropenia, in patients with nonmyeloid malignancies receiving myelosuppressive anticancer drugs associated with a clinically significant incidence of febrile neutropenia	Amgen; 2002
Ibritumomab tiuxetan (Zevalin)	Treatment of patients with relapsed or refractory low-grade, follicular, or transformed B-cell non-Hodgkin lymphoma, including patients with rituximab (Rituxan) refractory follicular non-Hodgkin lymphoma The therapeutic regimen includes rituximab, ^{111}indium ibritumomab tiuxetan, and ^{90}yttrium ibritumomab tiuxetan	IDEC Pharmaceuticals; 2002
Interferon β-1a (Rebif)	Treatment of patients with relapsing forms of multiple sclerosis to decrease the frequency of clinical exacerbations and delay the accumulation of physical disability	Serono; 2002
DTaP vaccine adsorbed (DAPTACEL)	Active immunization of infants and toddlers at 2, 4, 6, and 17-20 months of age against diphtheria, tetanus, and pertussis	Aventis Pasteur—Canada; 2002
Rasburicase (Elitek)	Initial management of plasma uric acid levels in pediatric patients with leukemia, lymphoma, and solid tumor malignancies who are receiving anticancer therapy expected to result in tumor lysis and subsequent elevation of plasma uric acid	Sanofi-Synthelabo; 2002
Peginterferon α-2a (PEGASYS)	Treatment of adults with chronic hepatitis C who have compensated liver disease and who have not been	Hoffman-La Roche; 2002

	previously treated with interferon α	
	Combination therapy with ribavirin, USP (Copegus), for the treatment of chronic HCV infection	2002
Peginterferon α-2a co-packaged with ribavirin (Pegasys Copegus Combination Pack)	Prefilled syringes of Pegasys (peginterferon α-2a) for the treatment of chronic hepatitis C, as a subcutaneous injection taken once a week	2004
Urokinase (Abbokinase)	For adults for the lysis of acute massive pulmonary emboli, defined as obstruction of blood flow to a lobe or multiple segments For the lysis of pulmonary emboli accompanied by unstable hemodynamics (i.e., failure to maintain blood pressure without supportive measures)	Abbott Laboratories; 2001
Adalimumab (Humira)	For reducing signs and symptoms and inhibiting the progression of structural damage in adult patients with moderately to severely active rheumatoid arthritis who have had an inadequate response to one or more DMARDs Can be used alone or in combination with methotrexate (MTX) or other DMARDs	Abbott Laboratories; 2002
Laronidase (Aldurazyme)	For patients with Hurler and Hurler-Scheie forms of MPS-I and for patients with the Scheie form who have moderate to severe symptoms	Biomarin Pharmaceutical; 2003
Alefacept (Amevive)	Treatment of adult patients with moderate to severe chronic plaque psoriasis who are candidates for systemic therapy or phototherapy	Biogen; 2003
Agalsidase beta (Fabrazyme)	For use in patients with Fabry disease to reduce GL-3 deposition in capillary endothelium of the kidney and certain other cell types	Genzyme; 2003
Tositumomab and ^{131}iodine tositumomab (Bexxar)	Treatment of patients with CD20 positive, follicular, non-Hodgkin lymphoma, with and without transformation, whose disease is refractory to rituximab and has relapsed after chemotherapy	Corixa; 2004
Omalizumab (Xolair)	For adults and adolescents (≥ 12 years of age) with moderate to severe persistent asthma who have a positive skin test or in vitro reactivity to a	Genentech; 2004

	perennial aeroallergen and whose symptoms are inadequately controlled with inhaled corticosteroids	
Bevacizumab (Avastin)	First-line treatment for patients with metastatic colorectal cancer	Genentech; 2004
Cetuximab (Erbitux)	A monoclonal antibody that targets the protein EGFR	Imclone Systems; 2004
^{99m}Technetium fanolesomab (NeutroSpec)	For scintigraphic imaging of patients with equivocal signs and symptoms of appendicitis aged 5 years or older	Palatin Technologies; 2004
Natalizumab (Tysabri)	Treatment of patients with relapsing forms of multiple sclerosis to reduce the frequency of clinical exacerbations	Biogen Idec; 2004
Palifermin (Kepivance)	Decreases the incidence and duration of severe oral mucositis in patients with hematologic malignancies receiving myelotoxic therapy requiring hematopoietic stem cell support	Amgen; 2004
Galsufase (Naglazyme)	Treatment of patients with MPS-VI	Biomarin Pharmaceuticals; 2005
Alglucosidase alpha (Myozyme)	Infantile-onset Pompe disease (GAA deficiency)	Genzyme; 2006
Ranibizumab injection (Lucentis)	For the treatment of neovascular (wet) age-related macular degeneration (AMD)	Genentech; 2006
Panitumumab (Vectibix)	For the treatment of patients with EGFR-expressing colorectal carcinoma with disease progression on or following fluoropyrimidine-, oxaliplatin-, and irinotecan-containing chemotherapy regimens	Amgen; 2006
Eculizumab (Soliris)	For the treatment of patients with paroxysmal nocturnal hemoglobinuria (PNH) to reduce hemolysis	Alexion Pharmaceuticals; 2007

ADA, adenosine deaminase; *AMI*, acute myocardial infarction; *CIS*, carcinoma-in-situ; *CMV*, cytomegalovirus; *DMARD*, disease-modifying antirheumatic drug; *DTaP*, diphtheria and tetanus toxoids and acellular pertussis; *EGFR*, epidermal growth factor receptor; *G-CSF*, granulocyte colony-stimulating factor; *GL*, globotriaosylceramide; *GM-CSF*, granulocyte-macrophage colony-stimulating factor; *HBsAg*, hepatitis B surface antigen; *HCV*, hepatitis C virus; *HER-2*, human epidural growth receptor 2; *HTLV*, human T lymphotropic virus; *MPS*, mucopolysaccharidosis; *PEG*, polyethylene glycol; *RSV*, respiratory syncytial virus.

[a] Gaucher disease is an autosomal dominant or recessive disorder caused by an excess of glucocerebroside in the reticuloendothelial cells because of the lack of the metabolic enzyme cerebrosidase. Proliferation of abnormal cells leads to splenomegaly, hepatomegaly, skeletal lesions, and other symptoms. Data from Biotechnology in the U.S. Pharmaceutical Industry. Research Triangle Park, NC, Institute for Biotechnology Information, 1995; and www.fda.gov.

G. DNA ligase is an enzyme that seals single-stranded nicks between nucleotides in double-stranded DNA. DNA ligase enables DNA fragments from different sources to be joined.
H. DNA polymerase is an enzyme that catalyzes the synthesis of DNA. It uses a single strand of DNA as the template and nucleotides as the substrates.
I. An enzyme is a protein that catalyzes a substrate during its conversion to a product.
J. A gene is a segment of DNA that codes for a specific polypeptide.
K. A genome is the genetic information content of a cell.
L. A hormone is an endogenous substance that is secreted by one type of cell and acts on another type of cell.
M. A hybridoma is a hybrid cell produced by the fusion of a myeloma cell and a specific antibodyproducing B lymphocyte. A single hybridoma produces a single type of antibody.
N. Interferon (INF) is any of a class of glycoproteins produced by animal cells in response to viral infection.
O. Interleukin is a group of proteins synthesized by macrophages and T lymphocytes in response to antigen and other stimulation.
P. A lymphokine is any of a class of soluble proteins produced by some white blood cells. These proteins stimulate other white blood cells as part of the immune response.
Q. A plasmid is a circular piece of duplex DNA that is not part of a chromosome and can replicate independently. Plasmids are used as vectors for the transfer of DNA in recombinant DNA technology.
R. RNA is a macromolecule that contains information for protein synthesis. The three types of RNA are ribosomal (rRNA), transfer (tRNA), and messenger (mRNA). RNA is also the genetic material of some viruses.
S. Recombinant DNA (rDNA) is a hybrid DNA that is formed when pieces of DNA from different sources are joined. The process is also known as gene splicing.
T. A restriction endonuclease is an enzyme that cleaves DNA at sequence-specific sites.
U. Tumor necrosis factor (TNF) is a lymphokine produced by macrophages. It can be activated to kill tumor cells.
V. Reverse transcriptase is an enzyme present in RNA viruses that catalyzes the formation of DNA from the viral RNA.

III. PROTEINS AND PEPTIDES.

Proteins and peptides play essential roles in all aspects of cellular function. Many endogenous substances synthesized in the body are essential proteins. Many enzymes that catalyze vital reactions in the body are proteins.
A. Hemoglobin (Hb) is a large protein involved in oxygen transport.
B. Globulins are special proteins in the plasma that are involved in immunogenic response and antibody formation.
C. Albumin is a plasma protein that binds to many drugs and is used as a carrier for new drugs.
D. Other well-known proteins include insulin and the enzymes involved in digestion.

Table 11-2. Immunoglobulin Applications

Gammaglobulinemia

Hepatitis A prophylaxis
Measles and rubella prophylaxis
Multiple myeloma with specific antibody deficiency
Prophylaxis in infants and children with HIV exposure
Chronic inflammatory demyelinating neuropathy
Acquired hemophilia
Orphan drug for the treatment of juvenile rheumatoid arthritis
Respiratory tract infections
Immune thrombocytopenic purpura
Orphan drug for the treatment of polymyositis and acute myocarditis
Acute exposure to hepatitis B surface antigen
Kawasaki disease in conjunction with high-dose aspirin

E. Protein is an important component of keratin in hair and myosin in muscles.
F. Albumin (human) 5% USP is used to reverse hypovolemia in shock patients, burn patients, and those with chronic hypoalbuminemia.

IV. Immunoglobulin (Ig)

is an important class of globulin proteins involved in immunity and the allergic response. IgG is used therapeutically to modulate or replace antibody in various immunodeficiency and disease states. Intramuscular and intravenous preparations are available from a variety of manufacturers (Tables 11-2 and 11-3). Most of these products must be stored under refrigeration (2-8°C) and have a limited shelf life.

V. RECOMBINANT HUMAN GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF)

A. CSFs are glycoproteins that regulate the production of many types of blood cells and components in the body. These include macrophages, eosinophils, neutrophils, basophils, and platelets. Natural and modified CSFs are used to treat a number of congenital disorders and several forms of cancer.
B. Lenograstim is a recombinant human granulocyte CSF (rhG-CSF) derived from Chinese hamster ovary cells. It is glycosylated at the same site as natural hG-CSF (threonine-133) and consists of 174 amino acids.
C. Filgrastim is an Escherichia coli-derived glycoprotein. It is not glycosylated, and it differs in structure from natural hG-CSF. Like natural hG-CSF and filgrastim, lenograstim selectively promotes the proliferation, differentiation, and maturation of blood cell precursors. Dose-related

increases in blood neutrophil counts are observed after lenograstim administration. Lenograstim reduces the duration of neutropenia and the severity of infection in patients who are receiving cytotoxic chemotherapy for nonmyeloid malignancy. Colony-forming assays show that lenograstim is approximately three times as potent as filgrastim. These agents were similarly potent in cell-proliferation assays. Both natural and recombinant G-CSF products stimulate the release of mature neutrophils from hematopoietic tissue, prolong their survival, and enhance their phagocytic and cytotoxic activity.

Table 11-3. Immunoglobulin Products

Gamimune-N	Nabi-HB
Gammagard	RespiGam
Polygram	Sandoglobulin
Gammar	Polygam
Iveegam	Venoglobulin

D. Other actions of rhG-CSF include synergism with interleukin 3 (IL-3) to induce megakaryocyte formation and with granulocyte-macrophage CSF (GM-CSF) to stimulate granulocyte- macrophage colonies.

VI. GLYCOPROTEINS

A. Many special proteins acquire biologic activity as a result of their covalent linking with a polymer of sugar or carbohydrate. The covalently linked protein-carbohydrate molecule is a glycoprotein. Glycoproteins form natural structural membranes in the cells of unicellular (e.g., bacteria) and multicellular (e.g., humans, animals) organisms.

B. N-acetylglucosamine (NAG) forms the cell membrane in bacteria. It is an example of a carbohydrate chain linked to a protein through a chain of amino acids. Bacterial resistance to penicillin is linked to the integrity of NAG in the cell membrane.

C. The extent and site of glycosylation of a protein molecule may affect the physicochemical properties, stability, and specificity of a surface receptor in a cell. Glycoproteins on the surface of red blood cells are involved in recognizing the specific blood type.

D. The charge at the site of a glycoprotein molecule may play a role in the orientation and interaction of the receptor. The charge may be modified by sialic acid, sulfate, and phosphate groups. The protein molecule presents potential sites for N-glycosylation and O-glycosylation. Change in glycosylation is a powerful tool for use in engineering the preferred configuration and stability when designing recombinant glycoprotein for therapeutic use.

E. Carbohydrates contribute to activities in a number of ways, including recognition of the terminal sialic acids of glycoproteins by various viruses and bacteria, recognition of polylactosamines on erythrocytes by autoimmune antibodies, and recognition of sialylated, fucosylated lactosaminoglycans on leukocytes by E-selectin of endothelial cells.

VII. DNA

A. DNA is the genetic material of all organisms except some viruses, whose genetic material is in the form of RNA. Most organisms have double-stranded DNA. Some viruses contain single-stranded DNA. This type of virus replicates itself by entering a host cell, where it makes a complementary copy of itself and temporarily forms a double strand.

B. All DNA molecules consist of many covalently linked subunits called nucleotides. The nucleotides consist of deoxyribose, phosphate, and one of the nitrogen-containing bases (adenine, guanine, thymine, or cytosine). DNA encodes information to produce all of the proteins needed by the organism. The DNA sequence may be modified or recombined with new strands. This recombinant technology may be used to correct genetic defects in living organisms.

VIII. ANTISENSE DRUGS

A. Many diseases occur because of genetic defects or errors in the gene involved in producing essential enzymes or proteins. Genetic information resides in chromosomes that house helical strands of DNA within the nucleus. The Human Genome Initiative was created several years ago to study all human genes. This national effort is now yielding information on many serious

diseases that involve congenital defects, cancer, infection, AIDS, and other disorders of the immune system.

B. Strategies are now available to moderate many disease processes by altering or blocking the transcription of DNA. If the DNA sequence is altered so that the complementary strand is transcribed instead of the normal "sense" gene, then the DNA cannot make a copy of the normal RNA that participates in protein synthesis. The aberrant copies of RNA may pair up (hybridize) with other RNA strands that complement it and thereby block protein synthesis. This technique involves targeting DNA or RNA with antisense drugs.

C. Many oligonucleotides are designed to target viral disease and cancer cells. To further stabilize the drug, phosphodiesters are chemically converted to phosphothioates.

D. Antisense drugs against cytomegalovirus (CMV), HIV, and other viruses are in various phases of clinical trials. The first antisense drug, Vitravene, was approved by the U.S. Food and Drug Administration (FDA) in 1998. Vitravene is a potent biotechnology drug that is indicated for the local treatment of CMV retinitis in patients with AIDS who are intolerant of other treatments, who have a contraindication to other treatments, or who were insufficiently responsive to previous treatments. The recommended labeled dosage is an induction dose on days 1 and 15, followed by a monthly intravitreal injection of 330 μg.

E. When the nucleotide base sequence of a gene that controls a specific body function is known, the antisense DNA strand can be synthesized. If necessary, the DNA strand can be modified to provide increased stability and potency. These strands can then be introduced into cells, where they attach themselves to the complementary sense DNA strands and depress transcription of these genes. This technique was performed successfully in cell culture for the gene that produces human squamous cell carcinoma of the larynx.

F. If a duplicate copy of a gene is inserted into a chromosome in reverse orientation to the normal gene, then the antisense DNA strand of this gene is transcribed. This process yields an antisense mRNA strand that is complementary to the mRNA strand transcribed for the normal gene. The two complementary RNA strands bind to each other, thereby preventing the translation of the normal RNA strand that may control protein synthesis.

IX. GENE THERAPY.

The first example of human gene therapy is from 1990, when the FDA approved PEG-ADA (Enzon) for adenosine deaminase deficiency. This rare, but serious, genetic disorder weakens the immune system and causes increased susceptibility to infection. Two girls were reinfused with their own genetically altered white blood cells. The altered cells live and function normally, and the two girls were living a relatively normal life after 5 years.

X. MISCELLANEOUS BIOTECHNOLOGIC PRODUCTS

A. Alteplase (Activase, Genentech) is a thrombolytic agent formerly known as tissue-plasminogen activator. Intravenous alteplase effectively produces recanalization of occluded coronary arteries after acute myocardial infarction. Intravenous alteplase is also effective in the treatment of acute massive pulmonary embolism. Adverse effects, including bleeding complications, reperfusion arrhythmias, and reinfarction, are the primary concerns with this therapy. Systemic fibrinolysis is less than that seen with streptokinase. The recommended dose to produce recanalization after myocardial infarction is 100 mg in divided doses. The recommended dose to treat pulmonary embolism is 100 mg infused intravenously over 2 hr.

B. Antithrombin III (heparin cofactor, human antithrombin III, ATnativ, Pharmacia) is designated an orphan product. It is used as replacement therapy to prevent or treat

thromboembolic episodes in congenital deficiency states. The amount of intravenous antithrombin III concentrate to be administered is based on antithrombin III levels. In patients who have congenital or acquired antithrombin III deficiency, the goal is to maintain levels between 80% and
P.245

120% of normal. Once-daily doses of antithrombin III should maintain serum levels above 80% of normal. Levels should be monitored twice daily until they stabilize, then daily thereafter immediately before the next dose is administered.
C. IL-3 is a hematopoietic growth factor used to treat patients with bone marrow failure. Recombinant human IL-3 (rhIL-3) alone improves neutrophil and platelet counts in patients who have chemotherapy-related bone marrow failure and myelodysplastic syndromes. However, only minimal improvements in hematopoiesis are seen in patients who have aplastic anemia. Enhanced responses are seen with the sequential combined use of rhIL-3 and other hematopoietic growth factors (e.g., GM-CSF). Recombinant human IL-3 is given subcutaneously or intravenously. Intravenous doses range from 30 to 1000 μg/m2/day infused over 4 hr.
D. Aldesleukin, a lymphokine, is a hrIL-2 product that is used to treat metastatic renal cell carcinoma. The starting dose is 0.037 mg/kg every 8 hr by a 15-min intravenous infusion. Aldesleukin is absorbed erratically after intramuscular or subcutaneous injection. It follows two-compartment pharmacokinetics, with an α-half-life of 13 min and a β-half-life of 85 min. It is eliminated renally. The principal side effects are hypotension and flulike symptoms. Most adverse effects are dose related.
E. Abciximab (c7E3 Fab, ReoPro) is a chimeric monoclonal antibody Fab fragment that is specific for platelet glycoprotein IIb-IIIa receptors. Abciximab is extremely effective in reducing fatalities (> 50%) in subjects who have unstable angina after they undergo angioplasty. The recommended dosage is an intravenous bolus of 0.25 mg/kg administered 10-60 min before the start of angioplasty, followed by a continuous infusion of 10 μg/min for 12 hr. Platelet aggregation is almost completely inhibited 2 hr after the initiation of abciximab therapy. The major complication of abciximab infusion is dose-related bleeding.
F. Campath-1 is a MAb that targets human lymphocytes and monocytes. It is used for immunosuppression in patients who undergo organ transplant. The intravenous dose is 25 mg once or twice daily. Campath-1 is also used to treat refractory autoimmune disorders, including rheumatoid arthritis. It is used experimentally to treat vasculitis. Campath-1 antibodies are used to prevent graft-versus-host disease and to treat lymphoid malignancy caused by immunosuppression in patients who undergo organ transplant.
G. Edobacomab is an immunoglobulin directed against gram-negative bacterial endotoxins. For septic shock, single doses of 2-15 mg/kg intravenously every 24 hr are used. The volume of distribution ranges from 4 to 8 L. The elimination half-life is 10-18 hr. The main side effects are hypersensitivity reactions and antibody production. The drug is also being investigated for the treatment of gram-negative sepsis and septic shock.
H. Muromonab-CD3 is an immunosuppressive agent with specific targeting. It is effective in reversing acute renal allograft rejection. The usual dose is 5 mg/day intravenously for 10-14 days after the initial signs and symptoms of rejection. The volume of distribution is approximately 6.5 L, and the half-life is 18 hr. Side effects include flulike symptoms, which appear to be associated with the release of cytokines. Symptoms may be self-limiting or severe and life threatening.

I. Nebacumab is an immunoglobulin directed against gram-negative bacterial endotoxins. The drug is being investigated for the treatment of gram-negative sepsis and septic shock. Signs and symptoms of septic shock usually resolve during the first 7 days after treatment. Its half-life is 15.9 hr, and the volume of distribution is 48.5 mL/kg.
J. Satumomab pendetide is an MAb conjugate produced from the murine MAb B72.3. It requires radiolabeling to form ^{111}indium chloride satumomab pendetide. It is used as a diagnostic imaging agent in the staging of patients with known colorectal and ovarian carcinoma. The metabolic fate of this agent is unclear. The antibody conjugate is cleared slowly. It has a terminal half-life of approximately 56 hr. Approximately 10% of an administered dose appears in the urine.
K. Zolimomab aritox (Orthozyme-CD5, Xoma/Ortho Biotech) is an immunoconjugate of monoclonal anti-CD5 murine IgG and the ricin A-chain toxin. Its primary use is in the treatment
P.246

of steroid-resistant graft-versus-host disease after allogeneic bone marrow transplant for hematopoietic neoplasms (e.g., acute myelogenous leukemia). Other potential uses include the treatment of rheumatoid arthritis and insulin-dependent diabetes mellitus. After therapeutic doses, peak serum levels range from 1 to 5 μg/mL. The serum half-life is 1.5-4 hr. The dose varies, depending on the indications.
L. Betaseron (INF-β, Berlex Laboratories) is a glycoprotein with antiviral, antiproliferative, and immunomodulatory activity. Many of its effects are similar to those of INF-α. Its uses include the treatment of multiple sclerosis, AIDS, malignant melanoma, herpesvirus, and papillomavirus infections. It is also recommended at a dose of 8 million units subcutaneously every other day to reduce exacerbations in patients who have relapsing-remitting multiple sclerosis. It is administered intravenously, intramuscularly, subcutaneously, intrathecally, topically, or intralesionally for a variety of indications. Its biologic activity is evident in the absence of detectable serum levels. Serum concentrations are not consistently detectable after subcutaneous or intramuscular administration. Interferon β may cross the disrupted blood-brain barrier. The compound does not appear in urine after systemic administration. Adverse effects include flulike symptoms, bone marrow suppression, neurotoxic effects with high doses, anorexia and other gastrointestinal symptoms, and elevations of liver enzymes and serum creatinine.
P.247

STUDY QUESTIONS
Directions: Each of the questions, statements, or items or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.
1. Which type of cell contains double-stranded DNA?
(A) Human cells
(B) Bacteria cells
(C) HIV cells
(D) Viruses
View Answer
1. The answer is A [see VII.A].

Human cells contain double-stranded DNA, whereas lower organisms (e.g., bacteria, viruses) do not.
2. Which enzyme is used by the human immunodeficiency virus (HIV) to form DNA in the host cell?
(A) Restrictive endonuclease
(B) DNA-directed polymerase
(C) Reverse transcriptase
(D) Both A and B
(E) None of the above
View Answer
2. The answer is C [see II.V].
Reverse transcriptase is the enzyme that a virus uses to assemble its DNA from RNA. Unlike higher organisms, viral particles have genetic material in the RNA and need a host cell for reproduction.
3. Gammaglobulin is considered to be
(A) DNA.
(B) RNA.
(C) a protein.
(D) None of the above
View Answer
3. The answer is C [see III.C; Table 11-2].
Gammaglobulin is a subclass of immunoglobulin protein involved in immunity and allergic response.
4. Glycoprotein is considered to be a protein linked to
(A) a carbohydrate.
(B) a hormone.
(C) a lipid.
(D) DNA.
(E) None of the above
View Answer
4. The answer is A [see III.B; VI].
Glycoprotein consists of a carbohydrate linked to a protein.
5. An enzyme that cleaves DNA at a specific site is called a
(A) restriction endonuclease.
(B) restrictive ribonuclease.
(C) trypsin.
(D) None of the above
View Answer
5. The answer is A [see II.T].
A restriction endonuclease is an enzyme that specifically cleaves DNA molecules. Ribonuclease will cleave RNA only, and trypsin is a digestive enzyme found in the gastrointestinal tract.
6. An example of a cytokine is
(A) interleukin.
(B) insulin.
(C) gonadotropin.
(D) thyroxine.
(E) None of the above
View Answer
6. The answer is A [see II.O;, X.C].

Interleukin is a “messenger” substance synthesized by the cell (cytokine) to communicate and trigger cellular response.
7. A common storage condition for most biotechnology products after reconstitution is
(A) at room temperature.
(B) in a cool place.
(C) in a warm place.
(D) no excessive heat.
(E) in a freezer.
View Answer
7. The answer is B [see I].
Most biologic compounds are heat labile and must be stored at low temperature.
8. What drug is used to prevent embolism in the lung and during myocardial infarction?
(A) Alteplase
(B) Human growth hormone
(C) Granulocyte-macrophage colony-stimulating factor (GM-CSF)
(D) Epogen (EPO)
(E) None of the above
View Answer
8. The answer is A [see X.A; Table 11-1].
Alteplase is a thrombolytic agent formerly known as tissue-plasminogen activator.
9. What base is found in DNA?
(A) Cytosine
(B) Adenine
(C) Guanine
(D) Thymine
(E) All of the above
View Answer
9. The answer is E [see VII.B].
All DNA molecules consist of nucleotides, which consist of deoxyribose, phosphate, and one of the following nitrogen-containing bases: adenine, guanine, thymine, and cytosine.

ANSWERS AND EXPLANATIONS
1. The answer is A [see VII.A].
Human cells contain double-stranded DNA, whereas lower organisms (e.g., bacteria, viruses) do not.
2. The answer is C [see II.V].
Reverse transcriptase is the enzyme that a virus uses to assemble its DNA from RNA. Unlike higher organisms, viral particles have genetic material in the RNA and need a host cell for reproduction.
3. The answer is C [see III.C; Table 11-2].
Gammaglobulin is a subclass of immunoglobulin protein involved in immunity and allergic response.
4. The answer is A [see III.B; VI].
Glycoprotein consists of a carbohydrate linked to a protein.
5. The answer is A [see II.T].

A restriction endonuclease is an enzyme that specifically cleaves DNA molecules. Ribonuclease will cleave RNA only, and trypsin is a digestive enzyme found in the gastrointestinal tract.

6. The answer is A [see II.O;, X.C].

Interleukin is a “messenger” substance synthesized by the cell (cytokine) to communicate and trigger cellular response.

7. The answer is B [see I].

Most biologic compounds are heat labile and must be stored at low temperature.

8. The answer is A [see X.A; Table 11-1].

Alteplase is a thrombolytic agent formerly known as tissue-plasminogen activator.

9. The answer is E [see VII.B].

All DNA molecules consist of nucleotides, which consist of deoxyribose, phosphate, and one of the following nitrogen-containing bases: adenine, guanine, thymine, and cytosine.

Principles of Pharmacodynamics and Medicinal Chemistry

Marc W. Harrold

Nelson S. Yee

I. INTRODUCTION.

Pharmacodynamics is a branch of pharmacology that focuses on the study of the biochemical and physiological effects of drugs and the mechanisms by which they produce such effects. Analysis of drug action provides the basis for rational design of therapeutic agents and provides insight into the regulation of cellular functions.

II. EFFECTS OF DRUGS

A. Perturbation of normal physiological processes. The actions of drugs are the consequences of the dynamic interactions between drug molecules and cellular components. Such interactions lead to alteration in the functions of these components, called **receptors.** The resulting biochemical and physiologic changes form the basis of the cellular response to the drug. Drugs act by modulating the ongoing processes inside the cells.

B. Agonists and antagonists

1. Potentially, any macromolecular component may act as a **drug receptor.** For example, c-Kit tyrosine kinase can be inhibited by imatinib mesylate (Gleevec), cyclooxygenase-2 is blocked by celecoxib (Celebrex), and chromosomal DNA is cross-linked by cisplatin (Platinol).

2. Certain drug receptors normally serve as receptors for endogenous ligands and thus are **physiological receptors.** For example, adrenergic receptors are physiological receptors for catecholamines; estrogen receptors for estradiol.

3. Drugs whose responses resemble the effects of the endogenous molecules are receptor **agonists.** For example, bethanechol directly stimulates cholinergic receptors and is thus an agonist.

4. Pharmacological antagonists are drugs that lack **intrinsic activity** and produce effects by **competitively** or **noncompetitively** inhibiting the action of the endogenous molecules at the receptor.

a. A **competitive antagonist** acts by interfering with binding of the endogenous ligand to the receptor in a reversible manner. For example, propanolol competes with catecholamines for binding with adrenergic β-receptors; tamoxifen competes with estrogen receptors for binding with estradiol.

b. A **noncompetitive antagonist** acts by interacting with the nonligand binding site of the receptor (e.g., through covalent modification), such that normal binding of the endogenous ligand to the receptor is irreversibly inhibited. For instance, monoamine oxidase (MAO) inhibitors such as tranylcypromine (Parnate) initially interact with MAO in a reversible manner but then form covalent adducts that irreversibly inhibit MAO.

5. Partial antagonists inhibit the endogenous ligand from binding the receptor but possess some intrinsic activity. Nalorphine is a partial antagonist for the opiate receptor.

6. Physiological antagonism occurs when the drugs act independently at different receptor sites, often yielding opposing actions. For example, epinephrine and acetylcholine act on the sympathetic and parasympathetic autonomic nervous system, respectively, and their effects are antagonistic to each other.

7. Neutralizing antagonism occurs when two drugs bind with each other to form an inactive compound. For example, digoxin-binding antibody used in digoxin overdose acts by sequestering the drug, resulting in the formation of an inactive complex.

III. MECHANISMS OF DRUG ACTION

A. Cell surface receptors

1. Receptors can be **proteins or glycoproteins.** For example, cellular determinants such as CD20 antigen on B lymphocytes can bind with rituximab (Rituxan), a chimeric monoclonal antibody targeted against the CD20 antigen.

2. The binding of drugs to receptors is highly specific and can involve a variety of interactions, including hydrophobic interactions and van der Waals forces with ionic, hydrogen, and covalent bonds. The type of interaction and the binding affinity can influence the duration and reversibility of the drug action.

3. The interaction and binding affinity are related to the chemical structure of both the drug and the ligand. Chemical modification of the structure of the drug molecule can change the pharmacological and pharmacokinetic properties of drugs.

4. Through structure-activity relationship studies, synthetic drug analogs can be developed to achieve a high selectivity of drug action—a desirable ratio of therapeutic to toxic effect with a better-tolerated side effect profile.

B. Signal transduction by cell-surface receptors

1. Cell-surface receptors are composed of extracellular domains that bind the ligands (drugs or physiological molecules). For example, epidermal growth factor (EGF) receptor normally binds EGF and transforming growth factor α, and it is the target of the monoclonal antibody cetuximab (Erbitux), which competitively binds to the EGF receptor.

2. The ligand binding serves as a triggering signal that can be propagated in the target cell through intracellular regulatory molecules, known as **second messengers** or **effectors.** For example, isoproterenol binds with the β-adrenergic receptor, which is functionally coupled to adenylate cyclase via the stimulatory G protein (G_s). As a result, adenylate cyclase is activated, and the cyclic adenosine monophosphate (cAMP) level increases.

3. Ligand binding of receptors often leads to interaction of the receptors with the cytoplasmic effectors, which in turn become activated. Integration of the multiple signal transducing events along the receptor-effector system might change the cellular phenotype or gene expression, leading to new protein synthesis. For

example, binding of the ligands to the EGF receptor leads to activation of the tyrosine kinase of the intracellular domain of the receptor, which then activates downstream signaling pathways that results in cellular proliferation. The monoclonal antibody erlotinib (Tarceva) binds to the adenosine triphosphate (ATP) pocket of the tyrosine kinase of the EGF receptor and inhibits normal ATP binding, thus inhibiting the activity of the tyrosine kinase.

C. Signaling mediated by intracellular receptors. Thyroid hormone, steroid hormones, vitamin D, and the retinoids act through binding cytoplasmic receptors, which translocate into the nucleus. These receptors are soluble, DNA-binding proteins that regulate the transcription of specific genes. For example, all-trans-retinoic acid (ATRA; Vesanoid) binds to retinoic acid receptor in the cytosol, resulting in up-regulation of target gene expression and differentiation of leukemic promyelocytes.

D. Target cell desensitization and hypersensitization

1. Cells have the ability to **respond** to endogenous regulatory molecules or exogenously added drugs over a wide range of concentrations. However, protective mechanisms are available for maintaining homeostatic control to prevent overstimulation or understimulation of the target cells.

2. Cell **regulation** can occur at different levels along the signal transduction pathway. Regulation can involve changes in the level of the receptors or alterations in the downstream effector molecules.

3. The expression of receptors is normally under homeostatic control through receptor internalization, recycling, and de novo synthesis.

4. Down-regulation and desensitization

a. Down-regulation of receptors is caused by continuous prolonged exposure of receptors to drugs that disrupt the homeostatic equilibrium and result in altered levels of the receptors. This disruption involves endocytosis of ligand-bound receptors, resulting in sequestration of receptors from the cell surface and possibly accelerated degradation of the receptors or inactivation of the receptors.

b. Desensitization is the result of down-regulation. The target cells become desensitized, and the effect of subsequent exposure to the same concentration of the drug is reduced. Therefore, an increased concentration of the drug is required to produce an effect of the same magnitude as the initial exposure with a smaller drug concentration.

c. Repeated doses of bronchodilator such as albuterol inhaler for the treatment of asthma can lead to down-regulation of β-adrenergic receptors in the bronchial cells. The patient develops tolerance and requires increased dosage of the drug to achieve relief of the initial extent. In this case, the target cells become desensitized only to ligands that bind to those receptors; this is called **homologous desensitization.**

5. Heterologous desensitization. Some forms of desensitization involve alteration of components in the signaling pathway, such as a G protein. When cultured

fibroblasts are exposed to prostaglandin E_1 (PGE_1), which normally activates adenylate cyclase through a G_s, the cells lose responsiveness not only to PGE_1 but also to other ligands binding to other receptors that act through the G_s-adenylate cyclase pathway.

6. Hyperreactivity or **supersensitivity** to receptor agonists is expected when target cells are subject to long-term exposure to receptor antagonists followed by abrupt cessation of administration of the drug. This can involve receptor **up-regulation** through synthesis of new receptors.

E. Pharmacological effects not mediated by receptors. The effects of some drugs do not involve binding with specific receptors because of interaction with molecules or ions, which are not typically defined as receptors.

1. Colligative drug effects are characterized by a lack of requirement for highly specific chemical structure.

a. Volatile general **anesthetic** agents with diverse structures are lipophilic and interact with the lipid bilayer of cell membranes, resulting in depressed excitability. Examples include nitrous oxide and desflurane.

b. Cathartics, such as magnesium sulfate and sorbitol, act by increasing the osmolarity of intestinal fluids and thus changing the distribution of water.

2. Methotrexate, cytarabine, and 5-fluorouracil are examples of **antimetabolites.** Antimetabolites are structural analogs of endogenous molecules and are incorporated into cellular components that interfere with the normal cellular functions.

3. Certain drugs interact with specific ions normally found in body fluids. For example, **antacids** such as aluminum hydroxide, calcium carbonate, and magnesium hydroxide act by neutralizing gastric acid.

IV. RELATIONSHIP BETWEEN DRUG CONCENTRATION AND EFFECT

A. Dose-response relationship. In general, the larger the drug dose, the higher the drug concentration at its site of action and the greater the effect of the drug, up to a maximum effect. Higher drug concentrations (or doses) will not produce an effect greater than the maximum effect.

B. A quantal dose-response curve describes the relationship between the number of patients exhibiting a defined response (e.g., a 50% increase in peak flow) and the specified dose of the drug (e.g., minimum dose of albuterol for 50% increase in peak flow). This relationship often follows a gaussian (bell-shaped) distribution (Figures 12-1 and 12-2).

C. A graded dose-response curve describes the relationship between the magnitude of the effect of a drug (e.g., reduction of blood pressure by nifedipine) in an individual and the dose of the drug (Figure 12-3).

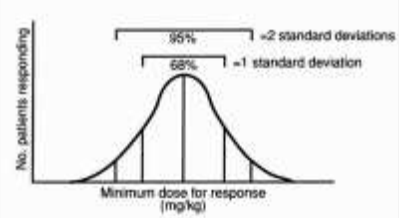

Figure 12-1. Frequency distribution curve, plotting the number of patients showing a quantal response to a drug against the minimum dose needed to produce the response.

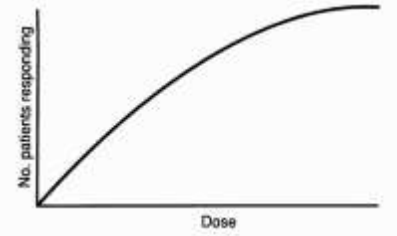

Figure 12-2. Quantal dose-response curve, cumulating the data used to plot Figure 12-1.

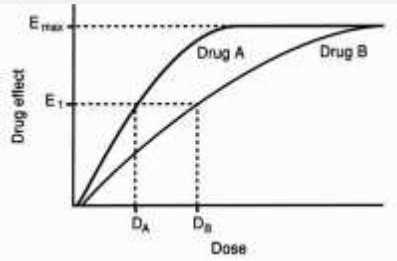

Figure 12-3. Graded dose-response curves for two drugs, A and B. D_A*and* D_B, amount (dose) of drug A and drug B, respectively, needed to produce the drug effect, E_1; E_{max}, maximum effect.

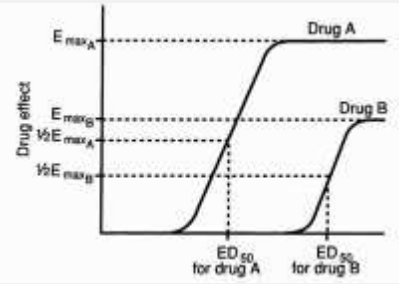

Figure 12-4. Log dose-response curves for two drugs, A and B. *ED_{50},* smallest dose showing an effect that is 50% of the maximum effect (*E_{max}*).

1. Generally, as the dose of a drug increases, the effect produced will reach a maximum level.

2. Graded dose-response curves for different drugs allow comparison of their efficacies and potencies.

a. Efficacy of a drug is measured by its maximum effect (E_{max}).

b. Potency of a drug is a relative measure that compares the different doses (molar doses) of different drugs needed to produce the same effect. From a clinical viewpoint, potency is considered in drug selection (e.g., triazolam is preferred for the treatment of insomnia instead of diazepam).

c. In clinical situations, a drug with greater efficacy might be needed to achieve the therapeutic outcome (e.g., hydromorphone is preferred to acetaminophen for controlling bone pain in a patient with metastatic breast cancer).

D. A **log dose-response curve** describes the relationship between the drug effect and the log of the dose. This curve facilitates comparison of potency and efficacy among different drugs with the same mechanism of action (which thus have the same slopes) (Figure 12-4).

1. The **efficacy** of a drug is determined by the **height** of its log dose-response curve (**E_{max}**); the higher the curve, the greater the E_{max} and efficacy.

2. The **potency** of two drugs can be compared by determining their **ED_{50}.** The ED_{50} is the **dose** of each drug producing 50% of the corresponding maximum effect (50% of E_{max}). The smaller the ED_{50}, the greater the potency.

3. A **competitive antagonist** shifts the log dose-response curve to the **right,** and the shift is **parallel.** A greater concentration of the agonist is required to produce the same response than when the competitive antagonist is absent. Even in the presence of the antagonist, the **same E_{max}** can be achieved if enough agonist is added (Figure 12-5).

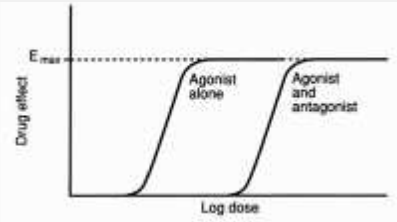

Figure 12-5. Shift in the log dose-response curve that occurs when an agonist is administered in the presence of a competitive antagonist. E_{max}, maximum effect.

P.254

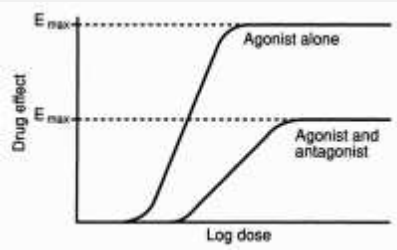

Figure 12-6. Shift in the log dose-response curve and lowering of the maximum effect (E_{max}) that occur when an agonist is given in the presence of a noncompetitive antagonist.

4. A **noncompetitive antagonist** binds to the same receptor or binds to another site that prevents the agonist from producing a response. The shift of the log dose-response curve is to the **right** and **nonparallel,** resulting in a **lower E_{max}.** The action of the antagonist cannot be overcome even if more agonist is present (Figure 12-6).

V. ENHANCEMENT OF DRUG EFFECTS

A. Addition occurs when two different drugs with the same effect are given together, resulting in a drug effect that is equal in magnitude to the sum of the individual effects of the two drugs. For example, trimethoprim and sulfamethoxazole inhibit different steps in the synthesis of folic acid, resulting in the suppression of bacterial growth.

B. Synergism occurs when two drugs with the same effect are given together, producing a drug effect that is greater in magnitude than the sum of the individual

effects of the two drugs. For example, penicillin and gentamicin are synergistic in their antipseudomonal activities.

C. Potentiation occurs when one drug, lacking an effect of its own, increases the effect of another drug that is active. For example, carbidopa is an inactive analog of dopa. When carbidopa blocks the degradation of dopa and is given with dopa, it prolongs the half-life of dopa and the duration of the anti-Parkinsonian effect.

VI. SELECTIVITY OF DRUG ACTION

A. The **therapeutic index** and the **margin of safety** are the relationship (ratio) between the dose of a drug required to produce undesired effects (toxic or lethal) and the dose required to produce the desired effects (therapeutic).

1. The **therapeutic index** of a drug is a relative measure of the safety and effectiveness in laboratory studies.

2. The **therapeutic index** is the ratio of the minimum dose that is toxic for 50% of the population (**median toxic dose; TD_{50}**) to the minimum dose that is effective for 50% of the population (**median effective dose; ED_{50}**).

B. In general, the greater the TD_{50} or the smaller the ED_{50}, the greater the therapeutic index and thus the safer the drug when used at the effective dosage.

C. The **margin of safety** is a more practical term to describe the relative safety and effectiveness of a drug. The margin of safety is the ratio of the minimum toxic dose for 0.1% of the population (**minimal toxic dose; $TD_{0.1}$**) to the minimum effective dose for 99.9% of the population (**minimal effective dose; $ED_{99.9}$**).

VII. DRUG SOURCES AND MAJOR CLASSES

A. Natural products are drugs obtained from plant and animal sources.

1. Alkaloids are nitrogen-containing compounds obtained primarily from plants through extraction and purification, which possess pharmacological activity. The majority of alkaloids are basic compounds (e.g., **morphine,** from the opium poppy; **atropine,** from the belladonna plant); although some are neutral amides (e.g., **colchicine,** from the autumn crocus). All alkaloids end in the suffix *-ine;* however, it is important to note that not all drugs that end in *-ine* are alkaloids (e.g., meperidine).

2. Peptides and polypeptides are polymers of amino acids, are obtained from either human or animal sources and are smaller than **proteins.** The amino acid length distinctions between these three classifications are vague and often vary from one source to another. Naturally occurring peptides have little to no oral activity and short half-lives (e.g., **somatostatin,** a 14-amino acid peptide; **glucagon,** a 29-amino acid polypeptide).

3. Steroids are chemical derivatives of cyclopentanoperhydrophenanthrene and can be obtained from either human or animal sources (e.g., **estradiol, testosterone, hydrocortisone**).

4. Hormones are chemical substances that are formed in one organ or part of the body and carried in the blood to another organ or part. They are principally proteins

or steroids and can be obtained either synthetically, through recombinant DNA technology (e.g., **insulin**), or from animal sources (e.g., **thyroid hormones** and **conjugated estrogens**).

5. Glycosides are organic substances consisting of a sugar moiety bound to a nonsugar (aglycone) moiety by means of a glycosidic bond (i.e., a bond between the anomeric carbon of the sugar and a hydroxy group on the aglycone). They can be of either plant (e.g., **digitoxin**) or microbial (e.g., **streptomycin, doxorubicin**) origin.

6. Vitamins are organic substances that are present in foods and are essential to normal metabolism.

a. Water-soluble vitamins are thiamine (B_1), riboflavin (B_2), niacin (B_3), pyridoxine (B_6), cyanocobalamin (B_{12}), ascorbic acid (C), folic acid, pantothenic acid, and biotin (H).

b. Lipid-soluble vitamins are retinol (A), ergocalciferol (D), α-tocopherol (E), and phytonadione (K).

7. Polysaccharides are polymers of sugars that can be obtained from either human or animal sources. These compounds can be used either directly (e.g., **heparin**), after partial depolymerization (e.g., **tinzaparin, enoxaparin**), or after structural modification (e.g., **sucralfate**).

8. Antibiotics are chemical substances produced by microorganisms that either suppress or kill other microorganisms (e.g., **penicillin, tetracycline, doxorubicin**).

B. Synthetic products are drugs synthesized from organic compounds.

1. Synthetic products can have **chemical structures closely resembling those of active natural products** (e.g., **hydroxymorphone,** which resembles morphine; **ampicillin,** which resembles penicillin).

2. Synthetic products can contain similar spacing of functional groups but lack the general structure of a naturally occurring compound. **Peptidomimetics** are molecules with no peptide bonds, a molecular weight < 700, and activity similar to the original peptide (e.g., **losartan** is a peptidomimetic and an angiotensin II receptor antagonist).

3. Synthetic products also can be **completely new products,** obtained by screening synthesized materials for drug activity (e.g., **barbiturates, antibacterial sulfonamides, thiazide diuretics, phenothiazine antipsychotics, benzodiazepine anxiolytics**).

C. Major chemical and pharmacologic classes of drugs (Table 12-1; Figures 12-7, 12-8, 12-9, 12-10, and 12-11)

Table 12-1. Major Chemical and Pharmacological Classes of Drugs

Classification[a]		Acid/Base Character[b]	Example[c] (Structure)
1.	Polyhalogenated ethers and hydrocarbons	Nonelectrolyte	Isoflurane (**1**)
	General anesthetics		
2.	Barbiturates	Acidic	Phenobarbital (**2**)
	Sedative/hypotonics; anticonvulsants		
3.	Benzodiazepines	Basic	Diazepam (**3**)
	Anxiolytic agents; sedative/hypnotics		
4.	Hydantoins	Acidic	Phenytoin (**4**)
	Anticonvulsants		
5.	Succinimides	Acidic or nonelectrolyte	Methsuximide (**5**)
	Anticonvulsants		
6.	Phenothiazines	Basic	Chlorpromazine (**6**)
	Antipsychotics; antihistamines; antiemetics		
7.	Thioxanthenes	Basic	Thiothixene (**7**)

	Antipsychotics		
8.	Butyrophenones	Basic	Haloperidol (**8**)
	Antipsychotics		
9.	Tricyclic antidepressants	Basic	Imipramine (**9**)
	Antidepressant agents		
10.	Selective serotonin reuptake inhibitors	Basic	Fluoxetine (**10**)
	Anxiolytic agents		
11.	Benzazepines	Basic	Olanzapine (**11**)
	Atypical antipsychotics		
12.	Methylxanthines	Basic (weak)	Theophylline (**12**)
	CNS stimulants; bronchodilators		
13.	Opioids	Basic	Codeine (**13**)
	Narcotic analgesics; antitussives		
14.	4-Phenylpiperidines	Basic	Meperidine (**14**)
	Narcotic analgesics		
15.	Phenylpropylamines	Basic	Methadone (**15**)

	Narcotic analgesics		
16.	Direct-acting cholinergics	Quaternary ammonium salt	Bethanechol (**16**)
	GI smooth-muscle stimulant; cataract therapy		
17.	Aminoalkyl esters	Basic or quaternary ammonium salt	Dicyclomine (**17**)
	Anticholinergic agents		
18.	Aminoalkyl ethers	Basic	Benztropine (**18**)
	Anticholinergic agents; antihistamines (H_1-antagonists)		
19.	Aminoalcohols	Basic or quaternary ammonium salt	Biperiden (**19**)
	Anticholinergic agents		
20.	Ethylenediamines	Basic	Tripelennamine (**20**)
	Antihistamines (H_1-antagonists)		
21.	Alkylamines (propylamines)	Basic	Chlorpheniramine (**21**)

	Antihistamines (H_1-antagonists)		
22.	Piperazines	Basic	Cyclizine (**22**)
	Antihistamines (H_1-antagonists); antivertigo; antiemetics		
23.	Mast cell degranulation inhibitors	Acidic	Cromolyn sodium (**23**)
	Antiallergenics		
24.	Phenylethylamines	Basic	Albuterol (**24**)
	Sympathomimetics (α- and β-adrenergic agonists)		
25.	Adrenergic α_2-agonists	Basic	Guanabenz (**25**)
	Antihypertensive agents		
26.	Adrenergic α_1-agonists	Basic	Terazosin (**26**)
	Antihypertensive agents		
27.	Aryloxypropanolamines	Basic	Propranolol (**27**)
	β-adrenergic blockers		
28.	Prostaglandins	Acidic	Misoprostol (**28**)
	Eicosanoids		

29.	Salicylates	Acidic	Aspirin (**29**)
	NSAIDs		
30.	Fenamates	Acidic	Mefenamic acid (**3**)
	NSAIDs		
31.	Pyrazolidinediones	Acidic	Phenylbutazone (**31**)
	NSAIDs		
32.	Arylacetic acids (includes indoleacetic acids, pyrrolacetic acids, and propionic acids)	Acidic	Tolmetin (**32**)
	NSAIDs		
33.	Selective COX-2 inhibitors	Acidic (weak) or nonelectrolyte	Celecoxib (**33**)
	NSAIDs		
34.	Triptans	Basic	Sumatriptan (**34**)
	5-$HT_{1B/1D}$ agonists		
35.	Serotonin 5-HT_3 antagonists	Basic	Ondansetron (**35**)
	Antiemetic agents		

36.	Coumarins	Acidic	Warfarin (**36**)
	Oral anticoagulants		
37.	Sulfated polysaccharides	Acidic	Heparin (**37**)
	Anticoagulants		
38.	Benzothiadiazides (thiazides)	Acidic	Chlorothiazide (**38**)
	Diuretics; saluretics		
39.	High-ceiling (loop) diuretics	Acidic	Furosemide (**39**)
	Diuretics; saluretics		
40.	Organic nitrates	Nonelectrolyte	Isosorbide dinitrate (**40**)
	Antianginal agents		
41.	Dihydropyridines	Basic (weak)	Nifedipine (**41**)
	Antihypertensives; antianginal agents; antiarrhythmics		
42.	Angiotensin II receptor antagonists	Acidic	Losartan (**42**)
	Antihypertensive agents		
43.	ACE inhibitors	Amphoteric	Enalapril (**43**)

	Antihypertensive agents		
44.	HMG-CoA reductase inhibitors	Acidic	Pravastatin (**44**)
	Cholesterol-lowering agents		
45.	Bile acid sequestrants	Basic or quaternary ammonium salt	Cholestyramine (**45**)
	Cholesterol-lowering agents		
46.	Fibrates	Acidic	Gemfibrozil (**46**)
	Cholesterol- and triglyceride-lowering agents		
47.	Steroids	Nonelectrolyte	Dexamethasone (**47**)
	Estrogens; progestins; androgens; adrenocorticoids		
48.	Selective estrogen receptor modulators	Basic	Raloxifene (**48**)
	Estrogen receptor agonists and antagonists		
49.	5α-Reductase inhibitors	Nonelectrolyte	Finasteride (**49**)

	Antiandrogen		
50.	Androgen receptor antagonists	Nonelectrolyte	Nilutamide (**50**)
	Antiandrogen		
51.	Sulfonylureas	Acidic	Tolbutamide (**51**)
	Oral hypoglycemics		
52.	Meglitinides	Acidic	Repaglinide (**52**)
	Oral hypoglycemics		
53.	Thiazolidinediones (glitazones)	Amphoteric (acid stronger than base)	Pioglitazone (**53**)
	Insulin sensitizers; antidiabetic agents		
54.	α-Glucosidase inhibitors	Basic	Miglitol (**54**)
	Antidiabetic agents		
55.	H_2-receptor antagonists	Basic	Cimetidine (**55**)
	Antiulcer agents		
56.	Proton pump inhibitors	Basic	Omeprazole (**56**)
	Antiulcer agents		
57.	Nitrosoureas	Nonelectrolyte	Carmustine (**57**)

	Antineoplastic agents		
58.	β-Chloroethylamines (nitrogen mustards)	Basic	Mechlorethamine (**58**)
	Antineoplastic agents		
59.	Folate antimetabolites	Amphoteric	Methotrexate (**59**)
	Antineoplastic agents; antibacterial agents; antifungals		
60.	Purine antimetabolites	Basic	6-Mercaptopurine (**60**)
	Antineoplastic agents; Antiviral agents		
61.	Pyrimidine antimetabolites	Basic	Cytarabine (**61**)
	Antineoplastic agents; antiviral agents		
62.	Anthracyclines	Basic	Doxorubicin (**62**)
	Antineoplastic agents		
63.	Topoisomerase inhibitors	Basic	Topotecan (**63**)
	Antineoplastic agents		
64.	HIV protease inhibitors	Basic	Saquinavir (**64**)

	Antiretroviral agents		
65.	Sulfanilamides	Acidic	Sulfamethoxazole (**65**)
	Antibacterial agents		
66.	Penicillins	Acidic	Ampicillin (**66**)
	Antibacterial agents		
67.	Cephalosporins	Acidic	Cefoxitin (**67**)
	Antibacterial agents		
68.	Tetracyclines	Amphoteric	Tetracycline (**68**)
	Antibacterial agents		
69.	Aminoglycosides	Basic	Gentamicin (**69**)
	Antibacterial agents		
70.	Macrolides	Basic	Erythromycin (**70**)
	Antibacterial agents		
71.	4-Quinolones	Amphoteric	Ofloxacin (**71**)
	Antibacterial agents		
72.	Allylamines	Basic	Terbinafine (**72**)

	Antifungal agents		
73.	Polyenes	Amphoteric	Amphotericin B (**73**)
	Antifungal agents		
74.	Imidazoles	Basic	Oxiconazole (**74**)
	Antifungal agents		

ACE, angiotensin-converting enzyme; *COX,* cyclooxygenase; *5-HT,* 5-hydroxytryptamine (serotonin), *Gl,* gastrointestinal; *HMG-CoA,* β-hydroxy-β-methylglutaryl coenzyme A; *NSAID,* nonsteroidal anti-inflammatory drug.

[a] Organized according to chemical structure. Not an inclusive list; includes only classifications that contain multiple compounds with a similar structure. In some instances (e.g., direct-acting cholinergic agonists and H_2-receptor antagonists), drugs are chemically similar but are usually denoted only by pharmacological classifications.

[b] A general notation; some specific singular agents fall outside these general notations (e.g., ampicillin is amphoteric, whereas the penicillins are generally acidic).

[c] Structures are given in Figures 12-7, 12-8, 12-9, 12-10 and 12-11.

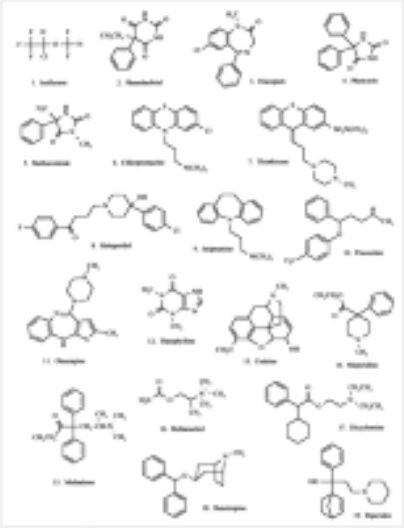

Figure 12-7. Chemical structures (**1-19**) representing the major chemical classes of drugs listed in Table 12-1.

P.260

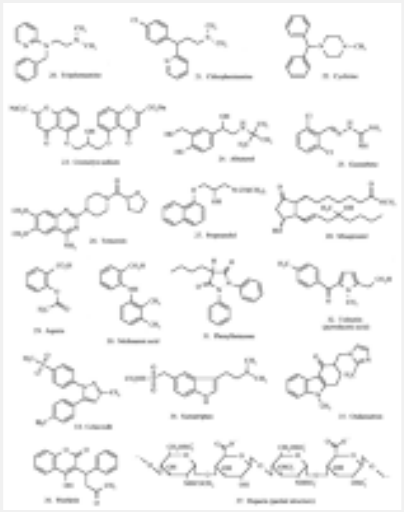

Figure 12-8. Chemical structures (**20-37**) representing the major chemical classes of drugs listed in Table 12-1.

VIII. DRUG ACTION AND PHYSICOCHEMICAL PROPERTIES

A. Drug action results from the interaction of drug molecules with either normal or abnormal physiological processes. Drugs normally interact with receptors, which can be either proteins, enzymes, cell lipids, or pieces of DNA or RNA.

P.261

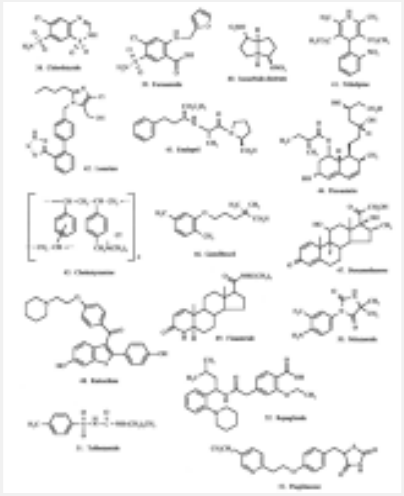

Figure 12-9. Chemical structures (**38-53**) representing the major chemical classes of drugs listed in Table 12-1.

1. Systemically active drugs must **enter** and **be transported by body fluids.**

a. The drug must **pass various membrane barriers, escape excessive distribution** into sites of loss, and **penetrate to the active site.**

b. At the active site, the drug molecules must orient themselves and interact with the receptors to **alter function.**

P.262

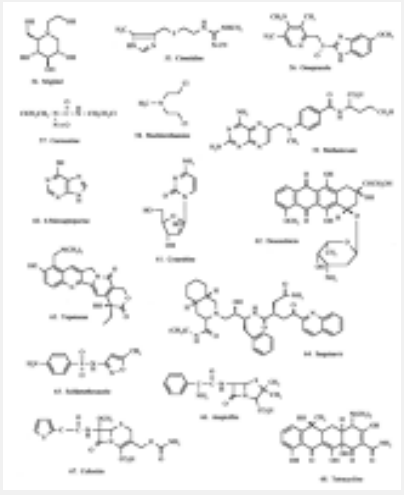

Figure 12-10. Chemical structures (**54-68**) representing the major chemical classes of drugs listed in Table 12-1.

c. The drug must be removed from the active site and **metabolized** to a form that is easily **excreted** by the body.

2. Drug absorption, metabolism, utilization, and excretion all depend on the **drug's physicochemical properties** and the **host's physiological** and **biochemical properties.** A drug's physicochemical properties can be altered via the synthesis of chemical analogs, whereas the host's properties usually cannot be altered.

P.263

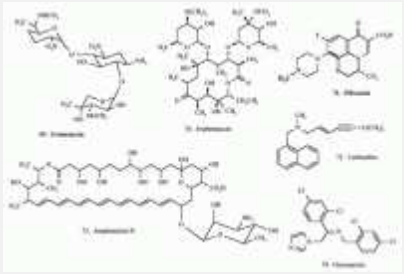

Figure 12-11. Chemical structures (**69-74**) representing the major chemical classes of drugs listed in Table 12-1.

B. Two of the most important **physicochemical properties** of a drug molecule are its polarity and its acid-base nature.

1. Drug polarity is a relative measure of a drug's lipid and water solubility and is usually expressed in terms of a **partition coefficient.**

a. The partition coefficient (*P*) of a drug is defined as the ratio of the solubility of the compound in an organic solvent to the solubility of the same compound in an aqueous environment:

$$P = \frac{[\text{Drug}]_{\text{lipid}}}{[\text{Drug}]_{\text{aqueous}}}$$

The partition coefficient is often expressed as a log value.

b. Water solubility (or **hydrophilicity**) depends primarily on two factors: ionic character and hydrogen-bonding capabilities. The presence of oxygen- and nitrogen-containing functional groups usually enhances water solubility. Water solubility is required for:

(1) Dissolution in the gastrointestinal (GI) tract

(2) Preparation of parenteral solutions (as opposed to suspensions)

(3) Preparation of ophthalmic solutions

(4) Adequate urine concentrations (pertains primarily to antibiotics)

c. **Lipid solubility** (or **lipophilicity**) is enhanced by nonionizable hydrocarbon chains and ring systems. Lipid solubility is required for:

(1) Penetration through the lipid bilayer in the GI tract

(2) Penetration through the blood-brain barrier

(3) Preparation of intramuscular (IM) depot injectable formulations

(4) Enhanced pulmonary absorption within the respiratory tract

(5) Enhanced topical potency (seen with many topical glucocorticoids)

(6) Enhanced plasma protein binding

2. Ionization of **acids** and **bases** plays a role with substances that dissociate into ions.

a. The **ionization constant (K_a)** indicates the relative strength of the acid or base. An acid

with a K_a of 1×10^{-3} is stronger (more ionized) than one with a K_a of 1×10^{-5}, whereas a base with a K_a of 1×10^{-7} is weaker (less ionized) than one with a K_a of 1×10^{-9}.

b. The **negative log** of the **ionization constant (pK_a)** also indicates the relative strength of the acid or base. An acid with a pK_a of 5 ($K_a = 1 \times 10^{-5}$) is weaker (less ionized) than one with a pK_a of 3 ($K_a = 1 \times 10^{-3}$), whereas a base with a pK_a of 9 ($K_a = 1 \times 10^{-9}$) is stronger (more ionized) than one with a pK_a of 7 ($K_a = 1 \times 10^{-7}$).

c. Strong acids—for example, **hydrochloric acid** (HCl), sulfuric acid (H_2SO_4), nitric acid (HNO_3), hydrobromic acid (HBr), iodic acid (HIO_3), and perchloric acid ($HClO_4$)—are completely ionized. Almost all other acids, including organic acids, are weak. **Organic acids** contain one or more of these functional groups:

(1) Carboxylic acid group (—COOH)

(2) Phenolic group (Ar—OH)

(3) Sulfonic acid group ($—SO_3H$)

(4) Sulfonamide group ($—SO_2NH—R$)

(5) Imide group (—CO—NH—CO—)

(6) β-Carbonyl group (—CO—CHR—CO—)

(7) Tetrazole ring (five-member CHN_4 ring; see Figure 12-9, **42,** for example)

d. Strong bases—for example, sodium hydroxide (NaOH), potassium hydroxide (KOH), magnesium hydroxide ($Mg(OH)_2$), calcium hydroxide ($Ca(OH)_2$), barium hydroxide ($Ba(OH)_2$), and quaternary ammonium hydroxides—are also completely ionized. Almost all other bases, including organic bases, are weak.

(1) Organic bases contain a primary, secondary, or tertiary aliphatic or alicyclic amino group ($—NH_2$, —NHR, or $—NR_2$).

(2) Most aromatic or unsaturated heterocyclic nitrogens are so weakly basic that they do not readily form salts with acids. Saturated heterocyclic nitrogens, in contrast, are similar to aliphatic amines.

(3) Additional basic functional groups include imine nitrogens (—N=C—), hydrazine nitrogens ($—NH—NH_2$), amidine nitrogens (—NH—C=N—), and guanidine nitrogens (four atom functional group, CH_4N_3; see Figure 12-8, **25,** for example).

e. Weak acids. Ionization of a weak acid (e.g., acetic acid, which has a pK_a of 4.76) takes place as follows:

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$

(1) When a weak acid (such as acetic acid) is placed in an **acid medium,** the equilibrium shifts to the left, suppressing ionization. This decrease in ionization conforms to **Le Chatelier's principle,** which states that when a stress is placed on an equilibrium reaction, the reaction will move in the direction that tends to relieve the stress.

(2) When a weak acid is placed in an **alkaline medium,** ionization increases. The H^+ ions from the acid and the OH^- ions from the alkaline medium combine to form water, shifting the equilibrium to the right.
(3) Weakly acidic drugs are less ionized in acid media than in alkaline media. When the pK_a of an acidic drug is greater than the pH of the medium in which it exists, it will be > 50% in its nonionized (molecular) form and thus more likely to cross lipid cellular membranes.
f. Weak bases. Ionization of a weak base is the opposite of that for a weak acid.
(1) Weak bases are less ionized in a **basic (alkaline) medium** and more ionized in an **acid medium.**
(2) Weakly basic drugs are less ionized in alkaline media than in acid media. When the pK_a of a basic drug is less than the pH of the medium in which it exists, it will be > 50% in its nonionized (molecular) form and thus more likely to cross lipid cellular membranes.
g. Percent ionization can be approximated by using the **rule of nines.** If the $|pH - pK_a| = 1$, then a 90:10 ratio (note that there is one nine in the ratio) exists. If the $|pH - pK_a| = 2$, the ratio becomes 99:1 (two nines in the ratio), and if the $|pH - pK_a| = 3$, the ratio is 99.9:0.1 (three nines in the ratio). The predominant form, ionized or unionized, in these ratios can easily be determined (see VIII.B.2.e.(3); VIII.B.2.f.(2)).
3. A **salt** is the combination of an acid and a base.
a. With a few minor exceptions (mercuric and cadmium halides and lead acetate), **all salts are strong electrolytes.**

b. Because the vast majority of drugs are organic molecules, drug salts can be divided into two classes based on the chemical nature of the substance forming the salt.
(1) Inorganic salts are made by combining drug molecules with inorganic acids and bases, such as hydrochloric acid, sulfuric acid, potassium hydroxide, and sodium hydroxide. The salt form of the drug has increased water solubility in comparison with the parent molecule. Inorganic salts are generally used to increase the aqueous dissolution of a compound.
(2) Organic salts are made by combining drug molecules with either **small, hydrophilic** organic compounds (e.g., succinic acid, citric acid) or **lipophilic** organic compounds (e.g., procaine). Water-soluble organic salts are used to increase dissolution and bioavailability as well as to aid in the preparation of parenteral and ophthalmic formulations (e.g., timolol maleate). Lipid-soluble organic salts are primarily used to make depot injections (e.g., procaine penicillin).
c. **Amphoteric compounds** contain both acidic and basic functional groups and are capable of forming **internal salts,** or zwitterions, which often have dissolution problems.
d. Dissolution of salts can alter the pH of an aqueous medium.

(1) Salts of **strong acids** (e.g., HCl, H_2SO_4) and **basic drugs** (e.g., cimetidine) dissociate in an aqueous medium to yield an **acidic solution.**
(2) Salts of **strong bases** (e.g., NaOH, KOH) and **acidic drugs** (e.g., phenobarbital) dissociate in an aqueous medium to yield a **basic solution.**
(3) Salts of **weak acids** and **weak bases** dissociate in an aqueous medium to yield an **acidic, basic,** or **neutral solution,** depending on the respective ionization constants involved.
(4) Salts of **strong acids** and **strong bases** (e.g., NaCl) do not significantly alter the pH of an aqueous medium.
4. A **neutralization reaction** might occur when an acidic solution of an organic salt (a solution of a salt of a strong acid and a weak base) is mixed with a basic solution (a solution of a salt of a weak acid and a strong base). The nonionized organic acid or the nonionized organic base is likely to **precipitate** in this case. This reaction is the basis for many **drug incompatibilities,** particularly when intravenous solutions are mixed. Neutralization reactions can be avoided by knowing how to predict the approximate pH of the aqueous solutions of common drug salts.
a. Generally, a drug's **salt form** can be recognized when the generic or trade name consists of two separate words, indicating a **cation** and an **anion.**
b. Drugs with **nitrate, sulfate,** or **hydrochloride notations** (e.g., pilocarpine nitrate, morphine sulfate, meperidine hydrochloride) are salts of **strong acids.** Thus these drugs (e.g., pilocarpine, morphine, meperidine) must be **bases.**
c. Drugs with **sodium** or **potassium cations** (e.g., warfarin sodium, potassium penicillin G) are salts of **strong bases.** Thus these drugs (e.g., warfarin, penicillin G) must be **acids.**
d. Drugs whose cation name ends with the suffix **"-onium"** or **"-inium"** and whose anion is a chloride, bromide, iodide, nitrate, or sulfate (e.g., benzalkonium chloride, cetylpyridinium chloride), are known as quaternary ammonium salts and form **neutral aqueous solutions.**

IX. STRUCTURAL FEATURES AND PHARMACOLOGIC ACTIVITY.

Drugs can be classified as structurally nonspecific or structurally specific.
A. Structurally nonspecific drugs are those for which the drug's interaction with the cell membrane depends more on the drug molecule's physical characteristics than on its chemical structure. Usually, the interaction is based on the **cell membrane's lipid nature** and the **drug's lipid attraction.** Most **general anesthetics,** as well as some **hypnotics** and some **bactericidal agents,** act through this mechanism.
B. Structurally specific drugs are those for which pharmacological activity is determined by the drug's ability to bind to a **specific endogenous receptor.**
1. Receptor-site theory describes the pharmacological activity of such drugs.
a. The **lock-and-key theory** postulates a completely complementary relationship between the drug molecule and a specific area on the surface of the receptor molecule (i.e., the

active, or **catalytic, site**). This theory does not account for conformational changes in either drug or receptor molecules and is an oversimplification of a complex process.

b. The **induced-fit theory** also postulates a complementary relationship between the drug molecule and its active site; however, it provides for **mutual conformational changes** between the drug and its receptor. Conformational changes in the receptor molecule are then translated into biological responses. This theory explains many more phenomena (e.g., **allosteric inhibitors**) than the lock-and-key model.

c. The **occupational theory of response** further postulates that, for a structurally specific drug, the intensity of the pharmacological effect is directly proportional to the number of receptors occupied by the drug.

2. Receptor-site binding. The **ability to bind to a specific receptor,** although not independent of the drug's physical characteristics, is primarily determined by the drug's **chemical structure.**

a. In such an interaction, the drug's **chemical reactivity** plays an important role, reflected in its **bonding ability** and in the **exactness of its fit** to the receptor.

b. Drug interaction with a specific receptor is analogous to the fitting together of jigsawpuzzle pieces. Only drugs of similar shape (i.e., similar chemical structure) can bind to a specific receptor and initiate a biological response.

c. Often, only a **critical portion of the drug molecule** (rather than the whole molecule) is involved in receptor-site binding.

(1) The functional group making up this critical portion is known as a **pharmacophore.**

(2) Drugs with **similar critical regions** but differences in other parts may have similar qualitative (although not necessarily quantitative) pharmacological activity.

d. In general, the **better a drug fits** the receptor site, the **higher the affinity** between the drug and the receptor and the **greater** the observed biological response. A drug that binds to a receptor and elicits a biological response is called an **agonist.**

e. Some drugs, lacking the specific pharmacophore for a particular receptor, can nonetheless bind to that receptor. Such a drug will have little or no pharmacological effect and might also prevent a molecule having the specific pharmacophore from binding, blocking the expected biological response. A drug that blocks a natural agonist and prevents it from binding to its receptor is called an **antagonist.**

3. The **stereochemistry** of both the receptor-site surface and the drug molecule helps determine the nature and efficiency of the drug-receptor interaction. Stereoisomers can be divided into three main groups: **optical isomers, geometric isomers,** and **conformational isomers.**

a. Optical isomers contain at least one asymmetric, or chiral, carbon atom (i.e., a carbon atom that is covalently bonded to four different substituents). Each asymmetric carbon atom can exist in one of two nonsuperimposable isomeric forms (Figure 12-12).

(1) Enantiomers are optical isomers that are mirror images of one another. Enantiomers have identical physical and chemical properties except that one rotates the plane of polarized light in a clockwise direction (**dextrorotatory;** designated D or +) and the other in a counterclockwise direction (**levorotatory;** designated L or -).

(2) An equal mixture of D and L enantiomers is called a **racemic mixture** and is optically inactive.

(3) Enantiomers can have large differences in potency, receptor fit, biological activity, transport, and metabolism. These differences result when the drug molecule has an asymmetric interaction with a receptor, a transport protein, or a metabolizing enzyme. For example, **levorphanol** has narcotic, analgesic, and antitussive properties, whereas its mirror image, **dextrorphanol,** has only antitussive activity.

(4) Diastereomers are stereoisomers, which are neither mirror images nor superimposable. A drug must have at least two chiral centers to exist in diastereomers. Unlike enantiomers, in which all stereochemical centers are opposite, diastereomers have

some stereochemical centers that are identical and some that are opposite. Diastereomers possess different physicochemical properties and thus differ in properties such as solubility, volatility, and melting point.

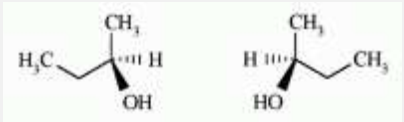

Figure 12-12. The two enantiomers of 2-hydroxybutane. The chiral, or asymmetric, carbon is bonded to four different groups: a methyl group, an ethyl group, a hydroxy group, and a hydrogen. The structures shown are mirror images, which cannot be superimposed.

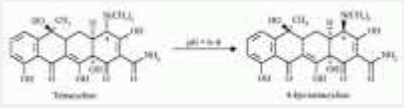

Figure 12-13. Epimerization of tetracycline to 4-epi-tetracycline. The stereochemistry of the 4-dimethylamino group is inverted; however, the stereochemistry of all other chiral centers remains unchanged.

(5) Epimers are a special type of diastereomers because all epimers are also diastereomers; however, the opposite is not true. Epimers are compounds that are structurally identical in all respects except for the stereochemistry of one chiral center. The process of **epimerization** (in which the stereochemistry of one chiral center is inverted) is important in drug degradation and inactivation (Figure 12-13).

b. Geometric isomers (*cis-trans* isomers) occur as a result of restricted rotation around a chemical bond, owing to double bonds or rigid ring systems in the molecule.

(1) *Cis-trans* isomers are not mirror images and have different physicochemical properties and pharmacologic activity.

(2) Because the functional groups of these isomers are separated by different distances, they generally do not fit the same receptor equally well. If these functional groups are pharmacophores, the isomers will **differ in biological activity.** For example, *cis*-diethylstil-bestrol has only 7% of the estrogenic activity of *trans*-diethylstilbestrol (Figure 12-14).

c. **Conformational isomers,** also known as **rotamers** or **conformers,** are nonsuperimposable orientations of a molecule that result from the rotation of atoms around single bonds. Almost every drug can exist in more than one conformation, and this ability allows many drugs to bind to multiple receptors and receptor subtypes. For example, the *trans* conformation of acetylcholine binds to the muscarinic receptor, whereas the *gauche* conformation binds to the nicotinic receptor (Figure 12-15).

d. Bioisosteres are molecules containing groups that are spatially and electronically equivalent and thus are interchangeable without significantly altering the molecules' physicochemical properties. **Isosteric replacement** of functional groups can increase potency,

decrease side effects, separate biological activities, and increase the duration of action by altering metabolism. In addition, **isosteric analogs** may act antagonistically to the parent molecule.

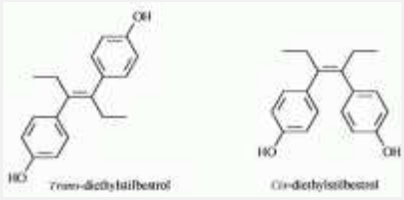

Figure 12-14. The presence of the double bond in diethylstilbestrol allows for the formation of *cis* and *trans* geometric isomers. Only the *trans* isomer has estrogenic activity.

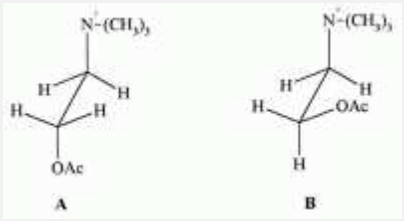

Figure 12-15. The *trans* (**A**) and *gauche* (**B**) conformations of acetylcholine occur as the result of rotation around the carbon-carbon single bond.

(1) Procainamide, an amide, has a longer duration of action than **procaine,** an ester, because of the isosteric replacement of the ester oxygen with a nitrogen atom (Figure 12-16).

(2) Alloxanthine is an inhibitor of xanthine oxidase. It is also an isostere of **xanthine,** the normal substrate for the enzyme (Figure 12-16).

X. MECHANISMS OF DRUG ACTION

A. Interaction with receptors (see IX.B.1 and 2)

1. Agonists interact with specific cellular constituents, known as receptors, and elicit an observable biological response. Agonists have both **affinity** for the receptor and **intrinsic activity.**

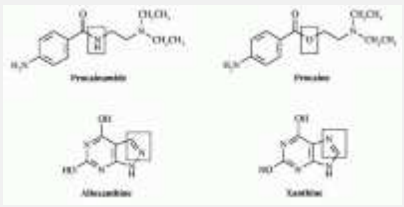

Figure 12-16. Bioisosteric pairs procainamide/procaine and alloxanthine/xanthine. The isosteric replacements are boxed.

2. Partial agonists interact with the same receptors as full agonists but are unable to elicit the same maximum response. Partial agonists have lower intrinsic activity than full agonists; however, their affinity for the receptor can be greater than, less than, or equal to that of full agonists.

3. Antagonists inhibit the actions of agonists.

a. Pharmacological antagonists bind to the same receptor as the agonist, either at the same site or at an allosteric site. They have affinity for the receptor but lack intrinsic activity. Pharmacological antagonists can be subdivided into reversible, irreversible, competitive, and noncompetitive categories similar to enzyme inhibitors (see X.B.2).

b. Chemical antagonists react with one another, resulting in the inactivation of both compounds.

(1) The anticoagulant **heparin,** an acidic polysaccharide, is chemically antagonized by **protamine,** a basic protein, via an acid-base interaction.

(2) Chelating agents can be used as **antidotes for metal poisoning. Ethylenediaminetetraacetic acid** (EDTA) chelates calcium and lead; **penicillamine** chelates copper; and **dimercaprol** chelates mercury, gold, antimony, and arsenic.

c. **Functional (or physical) antagonists** produce antagonistic physiological actions through binding at separate receptors. The adrenergic and cholinergic nervous systems frequently produce this type of antagonism. **Acetylcholine** constricts the pupil by acting on receptors that control the circular muscles of the eye, whereas **norepinephrine** dilates the pupil by acting on receptors that control ocular dilator muscles.

B. Interaction with enzymes

1. Activation, or **increased enzyme activity,** can result from induction of enzyme protein synthesis by such drugs as barbiturates, phenytoin and other antiepileptics, rifampin, antihistamines, griseofulvin, and oral contraceptives.

a. Allosteric binding. A drug can enhance enzyme activity by allosteric binding, which triggers a conformational change in the enzyme system and thus alters its affinity for substrate binding.

b. Coenzymes play a role in optimizing enzyme activity. Coenzymes include **vitamins** (particularly the **vitamin B complex**) and **cofactors**—mainly metallic ions such as sodium (Na^{+}), potassium (K^{+}), magnesium (Mg^{++}), calcium (Ca^{++}), zinc (Zn^{++}), and iron (Fe^{++}). Coenzymes activate enzymes by complexation and stereochemical interaction.

2. Inhibition, or **decreased enzyme activity,** can result from drugs that interact with the apoenzyme, the coenzyme, or even the whole enzyme complex. The drug might modify or destroy the apoenzyme's protein conformation, react with the coenzyme (thus reducing the enzyme system's capacity to function), or bind with the enzyme complex (rendering it unable to bind with its substrate).

a. Reversible inhibition results from a **noncovalent interaction** between the enzyme and the drug. The drug is free to associate and dissociate with the enzyme, and an equilibrium exists between bound and free drug.

b. Irreversible inhibition results from a stable, **covalent interaction** between the enzyme and the drug. Once bound to the enzyme, the drug is not able to dissociate.

c. **Competitive inhibition** occurs when there is **mutually exclusive binding** of the substrate and the inhibitor. While it is possible for competitive inhibitors to bind to allosteric sites, these inhibitors are usually structurally similar to the natural substrates and compete with the substrates for common binding sites. Competitive inhibition can be overcome by increasing the concentration of the substrate.

d. Noncompetitive inhibition occurs when a drug binds to an **allosteric site** on the enzyme. This binding induces a conformational change in the enzyme that inhibits enzyme action, even if a substrate is bound to the enzyme. Increasing substrate concentration does not overcome this type of inhibition.

C. Interaction with DNA/RNA formation and function

1. Inhibition of nucleotide biosynthesis occurs when folate, purine, and pyrimidine **antimetabolites** interfere with the biosynthesis of purine and pyrimidine building blocks.

a. Folic acid analogs (e.g., methotrexate, trimetrexate) inhibit purine and thymidylate synthesis by inhibiting dihydrofolate reductase.

b. Purine analogs (e.g., 6-mercaptopurine, thioguanine) act as antagonists in the synthesis of purine bases. These analogs do not act as active inhibitors until they are converted to their respective nucleotides.

c. **Pyrimidine analogs** (e.g., 5-fluorouracil) inhibit the synthesis of thymidylic acid by inhibiting thymidine synthetase. As with purine analogs, pyrimidine analogs are not active until they are converted to their respective nucleotides.

2. Inhibition of DNA or RNA biosynthesis occurs when drugs interfere with nucleic acid synthesis. These drugs are used primarily as antineoplastic agents for cancer chemotherapy.

a. Drugs that interfere with DNA replication and function include intercalating agents (e.g., the **anthracyclines, dactinomycin**), alkylating agents (e.g., **nitrogen mustards, nitrosoureas**), and antimetabolites.
b. Drugs that can damage and destroy DNA include compounds that produce free radicals (e.g., **bleomycin,** the **anthracyclines**) and compounds that inhibit topoisomerases (e.g., **epipodophyllotoxins, mitoxantrone, irinotecan, topotecan**).
c. Drugs that interfere with microtubule assembly in the metaphase of **cell mitosis** include the **vinca alkaloids** and **paclitaxel.**

D. Inhibition of protein synthesis

1. Tetracyclines interfere with protein synthesis by inhibiting transfer RNA (tRNA) binding to the ribosome and blocking the release of completed peptides from the ribosome.
2. Chloramphenicol and **erythromycin** (which compete for the same binding site) bind to the ribosome and inhibit peptidyl transferase, blocking formation of the peptide bond and interrupting formation of the peptide chain.
3. Aminoglycosides decrease the fidelity of transcription by binding to the ribosome, which permits formation of an abnormal initiation complex and prohibits addition of amino acids to the peptide chain. In addition, aminoglycosides cause misreading of the messenger RNA (mRNA) template, so that incorrect amino acids are incorporated into the growing polypeptide chain.
4. Quinupristin and dalfopristin, in combination, constrict the exit channel on ribosomal RNA (rRNA). This action prevents newly synthesized polypeptides from being released and in turn inhibits further protein synthesis.

E. Interaction with cell membranes

1. Digitalis glycosides inhibit the cell membrane's sodium-potassium pump, inhibiting the influx of K^+ and the outflow of Na^+.
2. Quinidine affects the membrane potential of myocardial membranes by prolonging both the polarized and depolarized states.
3. Local anesthetics block impulse conduction in nerve cell membranes by interfering with membrane permeability to Na^+ and K^+.
4. Polyene antifungal drugs (e.g., amphotericin B, nystatin) affect cell membrane permeability, causing leakage of cellular constituents.
5. Certain antibiotics (e.g., polymyxin B, colistin) affect cell membrane permeability through an unknown mechanism.
6. Acetylcholine increases membrane permeability to cations.
7. Omeprazole and **lansoprazole** inhibit the H^+/K^+ pump (located in parietal cell membranes), thus decreasing the efflux of protons into the stomach.
8. Several **antineoplastic** agents exert their actions by initially binding to **cellular determinants (CDs)** expressed by tumor cells.
a. Gemtuzumab ozogamicin binds with CD33 expressed by leukemic cells and immature myelomonocytic cells.
b. Alemtuzumab, a monoclonal antibody, binds to the CD52 antigen expressed on B lymphocytes, T lymphocytes, and various other cells.

F. Nonspecific action

1. Structurally nonspecific drugs form a monomolecular layer over entire areas of certain cells. Because they involve such large surfaces, these drugs are usually given in relatively large doses.

2. Drugs that act by nonspecific action include the **volatile general anesthetic gases** (e.g., ether, nitrous oxide), some **depressants** (e.g., ethanol, chloral hydrate), and many antiseptic compounds (e.g., phenol, rubbing alcohol).

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 40-year-old man complains of dysuria and urinary urgency and is diagnosed to have uncomplicated gonococcal urethritis. He is given procaine penicillin G intramuscularly. In addition, probenecid is given to prolong the duration of action of penicillin. This type of combined drug effect is known as

(A) synergism.

(B) competitive antagonism.

(C) addition.

(D) potentiation.

(E) noncompetitive antagonism.

View Answer***1. The answer is D[see].*****2. A 40-year-old teacher was prescribed lovastatin for the treatment of hypercholesterolemia. She wanted to know the mechanism of the drug before taking it. Her pharmacist explained to her that lovastatin acts by blocking the substrate-binding site of the enzyme β-hydroxy-β-methylglutaryl-coenzyme A (HMG-CoA) reductase, which catalyzes the rate-limiting step in cholesterol biosynthesis. Such drug effect is known as**

(A) addition.

(B) synergism.

(C) noncompetitive antagonism.

(D) potentiation.

(E) competitive antagonism.

View Answer***2. The answer is E[see].*****3. A 70-year-old man had prolonged bleeding during an elective knee surgery. Subsequently, the patient admitted to the surgeon that he had been self-administering 81** mg **aspirin daily. The consultant pharmacist explained to the patient that, although aspirin has a short plasma half-life, it can irreversibly inhibit platelet function by acetylating the nonsubstrate-binding site of the platelet cyclooxygenase, resulting in prolonged effect on platelet aggregation. This drug effect is known as**

(A) potentiation.

(B) competitive antagonism.
(C) synergism.
(D) addition.
(E) noncompetitive antagonism.

View Answer***3. The answer is E[see].*****4. A 65-year-old woman with intractable pain secondary to bony metastasis of breast cancer had been receiving escalating doses of morphine sulfate intravenously. At 10 A.M., she was found to be unresponsive, her respiratory rate was 4 breaths per minute, and her pupils were pin-pointed. Naloxone, a competitive antagonist of the opiate receptor, was given intravenously and repeated once. She gradually became conscious and began to complain of pain unrelieved by morphine given at the previous dose. This is most likely because**

(A) naloxone directly aggravates the pain caused by the bony metastasis.
(B) naloxone reduces the Emax for morphine.
(C) naloxone reduces the ED50 for morphine.
(D) naloxone increases the Emax for morphine.
(E) naloxone increases the ED50 for morphine.

View Answer***4. The answer is E[see].*****5. Which of the following statements regarding signal transduction is *incorrect*?**

(A) Thyroxine-bound receptors act on DNA and regulate specific transcription of genes.
(B) Cyclic adenosine monophosphate can act as a second messenger.
(C) The level of drug receptors at the cell surface increases with chronic stimulation by receptor agonists.
(D) Binding of ligand to cell-surface receptors can lead to synthesis of proteins.
(E) Antacids act by interacting with small ions normally found in the gastrointestinal tract.

View Answer***5. The answer is C[see].*****6. A pharmacist is consulted about selecting a drug that is relatively safe and effective for treating the patient. He searches the literature and obtains the following data that may help guide his decision. The $TD_{0.1}$ and $ED_{99.9}$ for drug A are 20 mg and 0.4 mg, respectively; whereas the $TD_{0.1}$ and $ED_{99.9}$ for drug B are 15 mg and 0.2 mg, respectively. Which of the following statements is true?**

(A) Drug A has a higher $TD_{0.1}$ and thus should be the drug of choice.
(B) Both drugs have the same margin of safety, so more information is needed.
(C) Drug B has a higher margin of safety and thus is preferred to drug A.
(D) Drug A is preferred because it has a greater margin of safety than drug B.
(E) The information obtained is irrelevant.

View Answer***6. The answer is C[see].***P.273

7. Which of the following statements concerning a drug receptor is true?

(A) It mediates the nonspecific action of volatile anesthetics.
(B) Its expression is induced only by exogenously added drugs.
(C) It can bind endogenous ligand to produce physiological activity.

(D) It mediates the cathartic activity of magnesium citrate.
(E) Down-regulation of receptor level can lead to sensitization of the target cell to the receptor agonist.

View Answer***7. The answer is C[seeand].*****8. Which of the following statements concerning morphine and hydromorphone is true?**
(A) Hydromorphone is a more effective analgesic because it has a smaller ED_{50} than morphine.
(B) Morphine and hydromorphone are equally potent because they have the same E_{max}.
(C) Morphine has a greater ED50 and is thus a less effective analgesic than hydromorphone.
(D) Hydromorphone is a more potent analgesic because it has a greater E_{max} than morphine.
(E) Hydromorphone has a smaller ED_{50} and thus is a more potent analgesic than morphine.

View Answer***8. The answer is E[seeand].*****9. A 72-year-old man with hypertension has been taking high-dose propranolol for 20 years. He left home for a week and forgot to bring his medication with him. One day, he was found collapsed on the floor and was brought to the emergency room. His blood pressure was 300/180, heart rate was 180 beats per minute, and retinal hemorrhage was observed. Which of the following best explains this situation?**
(A) The β-adrenergic receptors in the cardiac muscles underwent spontaneous mutation and became hyperactive.
(B) Reduction in the chronic antagonism of the β-adrenergic receptor led to down-regulation of the β-adrenergic receptor.
(C) The propranolol that he had previously ingested remained in his body and acted as a receptor agonist.
(D) Long-term administration of propranolol results in desensitization of cardiac muscles to endogenous β-adrenergic stimulation.
(E) Reduction in the chronic level of receptor blockade results in supersensitivity to stimulation with endogenous catecholamines.

View Answer***9. The answer is E[see].*****10. A 42-year-old man with chronic lymphocytic leukemia undergoing therapy mentioned to his pharmacist that his doctor had prescribed rituximab for treating his cancer. The patient asked what rituximab is and how it works. His pharmacist explained to him that rituximab is a monoclonal antibody that**
(A) inhibits DNA synthesis.
(B) blocks cell cycle progression.
(C) binds to cell surface molecules.
(D) boosts the immune response.

View Answer***10. The answer is C[see].*****11. A 65-year-old woman experienced anginal pain with ST segment elevation on EKG. She was treated with IV heparin, nitroglycerin, and atenolol for acute myocardial infarction. Then 2 hr later, when her nurse replaced her Foley bag, she noticed frank blood draining out of the Foley catheter. The physician checked the patient's**

partial thrombin time which was > 150 s. **The patient was then administered protamine, which acts by**

(A) promoting thrombosis.

(B) reacting with heparin and thus neutralizing the effect of heparin.

(C) directly inhibiting bleeding.

(D) enhancing secretion of procoagulants.

View Answer***11. The answer is B[see].*****12. A 45-year-old man with acute promyelocytic leukemia is being treated with all-*trans*-retinoic acid (ATRA). He asks the pharmacist if ATRA works like vitamin A as a health supplement. The pharmacist explained that ATRA is a form of vitamin A that acts by**

(A) improving immune functions.

(B) inhibiting leukemic cell secretion.

(C) limiting leukemic cell growth.

(D) inducing differentiation of leukemic cells.

View Answer***12. The answer is D[see].*****13. A 55-year-old man with a history of heavy smoking had been diagnosed with non-smallcell lung cancer, which was treated with chemotherapy; his disease progressed. He is now receiving erlotinib, and he asks his pharmacist how erlotinib works. The pharmacist explains that erlotinib acts by**

(A) inhibiting protein tyrosine kinase activity of tumor cells.

(B) decreasing level of protein tyrosine kinase of tumor cells.

(C) increasing ligand binding of protein tyrosine kinase of tumor cells.

(D) inducing tumor cell differentiation.

View Answer***13. The answer is A[see].***P.274

14. Which of the following drug-action pairs involves specific receptors?

(A) Magnesium sulfate for treatment of constipation.

(B) Calcium carbonate for relief of heartburn.

(C) Desflurane for inducing sedation.

(D) Tamoxifen for therapy of breast cancer.

(E) Sorbitol for reducing intracranial hypertension.

View Answer***14. The answer is D[see].*****15. Which of the following salts will most likely yield an aqueous solution with a pH < 7?**

(A) Sodium salicylate

(B) Potassium chloride

(C) Magnesium sulfate

(D) Potassium penicillin

(E) Atropine sulfate

View Answer***15. The answer is E[see].*****16. Which of the following chemical/pharmacological classes of agents is *incorrectly* matched with its acid-base nature?**

(A) Adrenergic β_2-agonists: basic

(B) Prostaglandins: acidic

(C) Organic nitrates: nonelectrolytes

(D) Meglitinides: acidic

(E) 4-Quinolones: basic

View Answer***16. The answer is E[seeand].*****17. All of the following medicinal agents are classified as natural products *except***

(A) atropine.

(B) diazepam.

(C) digitoxin.

(D) penicillin.

(E) morphine.

View Answer***17. The answer is B[seeand].*****18. All of the following statements about a structurally specific agonist are true *except* which one?**

(A) Activity is determined more by its chemical structure than by its physical properties.

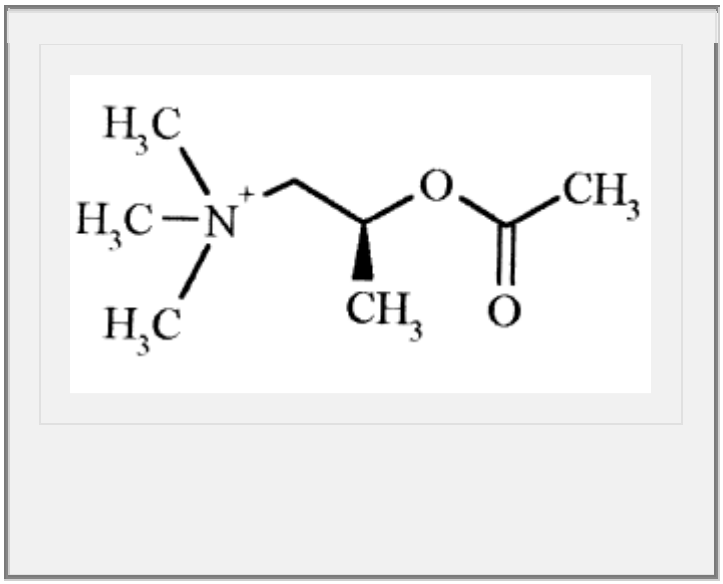
(B) The entire molecule is involved in binding to a specific endogenous receptor.

(C) The drug cannot act unless it is first bound to a receptor.

(D) A minor structural change in a pharmacophore can produce a loss in activity.

(E) The higher the affinity between the drug and its receptor, the greater the biological response.

View Answer***18. The answer is B[see].*****19. The dextro (D) form of β-methacholine (structure shown) is approximately 500 times more active than the levo (L) enantiomer. The observed difference in pharmacological activity between the two isomers is most likely the result of differences in**



(A) receptor selectivity.

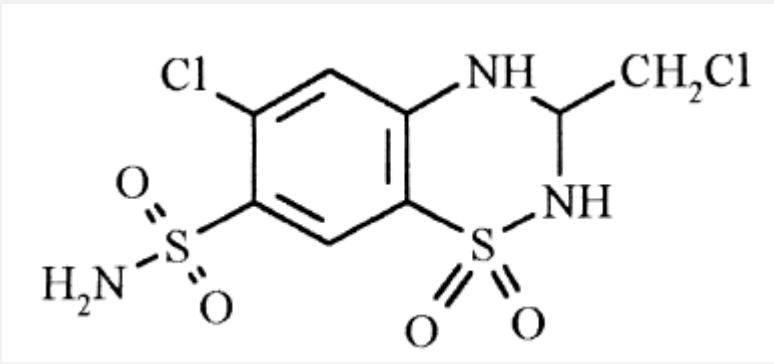
(B) dissolution.

(C) distribution.

(D) interatomic distance between pharmacophore groups.

(E) solubility.

View Answer***19. The answer is A[see].enantiomer*****20. The compound shown below can be classified as a**



(A) penicillin.

(B) thiazide.

(C) coumarin.

(D) phenothiazine.

(E) hydantoin.

View Answer***20. The answer is B[seeand].*****21. Which of the following acids has the highest degree of ionization in an aqueous solution?**

(A) Aspirin; pK_a = 3.5

(B) Indomethacin; pK_a = 4.5

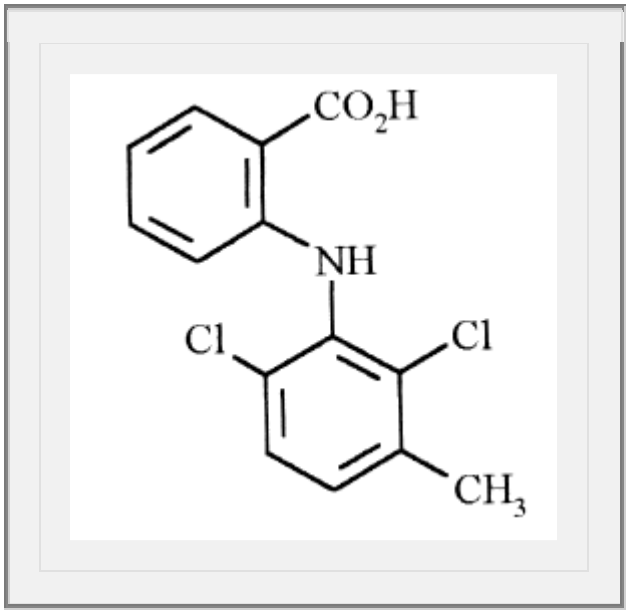
(C) Warfarin; pK_a = 5.1

(D) Ibuprofen; pK_a = 5.2

(E) Phenobarbital; pK_a = 7.4

View Answer***21. The answer is A[see].***P.275

22. Which of the following statements concerning the structure shown below is *not* correct?



(A) The compound is an acid.

(B) The compound can be used to treat arthritis.

(C) The compound is a fenamate.

(D) The compound increases prostaglandin production.

(E) The compound is a nonsteroidal anti-inflammatory drug (NSAID).

View Answer***22. The answer is D[see].*****23. All of the following classes of drugs are used to treat hypertension *except***

(A) aryloxypropanolamines.

(B) thiazides.

(C) fibrates.

(D) dihydropyridines.

(E) angiotensin-converting enzyme (ACE) inhibitors.

View Answer***23. The answer is C[see].*****24. Flurazepam has pK_a of 8.2. What percentage of flurazepam will be ionized at a urine pH of 5.2?**

(A) 0.1%

(B) 1%

(C) 50%

(D) 99%

(E) 99.9%

View Answer***24. The answer is E[seeand].*****Directions for questions 25-29:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, A-E.

25. Drugs that act systemically must

I. undergo biotransformation into an active form after reaching their active site.

II. be in a form capable of passage through various membrane barriers.

III. be in or be converted to a form that is readily excreted from the body.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* V.C*].*

Probenecid alone is inactive against gonococci. However, it can compete with penicillin for urinary excretion. Thus probenecid can reduce the elimination rate of penicillin, whose duration of action becomes prolonged. Therefore, probenecid potentiates the activity of penicillin when the two are given together.

2. The answer is E *[see* II.B.4.a; IV.D.3*].*

Lovastatin reversibly binds to the substrate-binding site of the enzyme HMG-CoA reductase, which catalyzes the rate-limiting step in the synthesis of cholesterol, thus lowering the cholesterol level. Therefore, lovastatin inhibits the enzyme by competitive antagonism.

3. The answer is E *[see* II.B.4.b; IV.D.4*].*

Aspirin can covalently modify the platelet cyclooxygenase through acetylation of the enzyme other than the substrate-binding site, causing irreversible inhibition of platelet aggregation. Therefore, aspirin inhibits platelet function by noncompetitive antagonism of cyclooxygenase.

4. The answer is E *[see* IV.D.3*].*

Naloxone is a competitive antagonist of opiate receptor. If one compares the log dose-response curve of both morphine and naloxone to that of morphine alone, the morphine-naloxone curve is shifted to the right. As a result, the ED_{50} for morphine is increased. This means that a larger than previous dose of morphine is required for achieving the same analgesic effect.

5. The answer is C *[see* III.D.4*].*

The level of drug receptors at the cell surface usually decreases when the target cells are chronically stimulated by receptor agonists. Down-regulation of receptors is a protective mechanism that can prevent the target cells from being overstimulated.

6. The answer is C *[see* VI.C*].*

The margin of safety of the two drugs can be helpful in guiding selection of a drug. Margin of safety is the ratio of $TD_{0.1}$ to $ED_{99.9}$. Thus the margin of safety for drug A is 20 mg ÷ 0.4 mg, or 50, whereas the margin of safety for drug B is 15 mg ÷ 0.2 mg, or 75. Because drug B has a greater margin of safety than drug A, drug B is relatively safe at the dosage given to produce the desired effect.

7. The answer is C *[see* II.B.2; III.D.4; III.E.1.a *and* b*].*

A drug receptor, such as muscarinic cholinergic receptor, which can bind atropine, normally binds endogenous acetylcholine to produce the physiological responses controlled by the parasympathetic autonomic nervous system. Volatile anesthetics act colligatively as solutes in the lipid bilayer of the cell membrane. Drug receptors are endogenously expressed, but their level can be modulated by exogenously added drugs. The cathartic activity of magnesium citrate is a consequence of increase in the osmolarity of the gastrointestinal fluids. Down-regulation of receptor level can lead to desensitization, not sensitization, of the target cell to the receptor agonist.

8. The answer is E *[see* IV.D.1 *and* 2*].*

The efficacy of a drug is determined by its E_{max}, whereas its potency is measured by the ED_{50}. Hydromorphone has a smaller ED_{50} and thus is a more potent analgesic than morphine. Hydromorphone and morphine are both agonists for opiate

receptors, and they have the same analgesic efficacy (i.e., they have the same E_{max}) if sufficient amounts of both drugs are used.

9. The answer is E *[see* III.D.6*].*

A chronic level of blocking the β-adrenergic receptors by propranolol results in up-regulation of the receptor level. When the patient ceased taking the drug, the cardiac muscles became supersensitive to stimulation with endogenous catecholamines. This resulted in the hypertensive crisis that caused cerebral hemorrhage and loss of consciousness.

10. The answer is C *[see* III.A.1*].*

Rituximab is a monoclonal antibody that specifically binds to CD20 antigen on malignant and normal B lymphocytes, leading to their destruction.

11. The answer is B *[see* X.A.3.b.(1)*].*

Protamine is a chemical antagonist of heparin that acts via an acid-base interaction.

12. The answer is D *[see* III.C*].*

ATRA binds to retinoic acid receptor on the cell membrane, leading to expression of target genes and resulting in differentiation of leukemic promyelocytes.

13. The answer is A *[see* III.B.3*].*

Erlotinib binds to the ATP pocket of the tyrosine kinase of the EGF receptor and thus inhibits tyrosine kinase activity.

14. The answer is D *[see* II.B.4.a, III.E.*].*

Tamoxifen and its metabolites bind to estrogen receptors, and prevent them from binding estradiol. This results in suppression of estrogen-dependent growth in breast cancer cells. The pharmacological effects of the other drugs are not mediated by receptors.

15. The answer is E *[see* VIII.B.3.d*].*

The solution must contain an acidic substance to have a pH < 7. Atropine sulfate is a salt of a weak base and a strong acid; therefore, its aqueous solution is acidic. Sodium salicylate and potassium penicillin are both salts of strong bases and weak acids; therefore, their aqueous solutions are alkaline. Magnesium sulfate and potassium chloride are salts of strong bases and strong acids; therefore, their aqueous solutions are neutral.

16. The answer is E *[see* Table 12-1; Figures 12-8, 12-9, *and* 12-11*].*

4-Quinolones are amphoteric compounds. All compounds in this chemical class contain a carboxylic acid as well as a basic nitrogen. Most 4-quinolones contain a basic piperazine ring and basic heterocyclic rings; however, some of the older compounds in this class only have the basic heterocyclic rings. All other compounds are correctly matched with their acid-base nature.

17. The answer is B *[see* VII.A *and* B*].*

Diazepam is a benzodiazepine anxiolytic, which—although it is a heterocyclic nitrogen-containing molecule—is not an alkaloid and is prepared synthetically. Natural products refer to substances biosynthesized in plants or animals. Natural products include alkaloids, such as atropine and morphine; peptides, such as

glucagon; steroids, such as estradiol; hormones, such as insulin; glycosides, such as digitoxin; vitamins, such as riboflavin; polysaccharides, such as heparin; and antibiotics, such as penicillin.

18. The answer is B *[see* IX.B*].*

The binding of a drug to its receptor usually involves only specific functional groups. These groups make up what is known as the pharmacophore of the drug molecule. Although the entire drug molecule is present at the receptor site, only a portion of it, the pharmacophore, is required for a biological response.

19. The answer is A *[see* IX.B.3.a; Figure 12-12*].*

The term *enantiomer* and the D and L indicate that the β-methacholine has a chiral center and exhibits optical isomerism. Because the optical isomers have different orientations in space, one orientation will give a better fit than the other and will most likely have greater biological activity than the other. Dissolution, distribution, interatomic distances, and solubility are all related to the physical and chemical properties of the two compounds, which are identical because the compounds are enantiomers.

20. The answer is B *[see* Table 12-1; Figures 12-7, 12-8, 12-9 *and* 12-10*].*

Key structural features of a thiazide—a benzothiadiazine ring with an electron-withdrawing chloride atom and a sulfonyl group on the benzene ring—identify this compound as a thiazide.

21. The answer is A *[see* VIII.B.2.b*].*

The pK_a (the negative log of the acid ionization constant) indicates the relative strength of an acidic drug. The lower the pK_a of an acidic drug, the stronger it is as an acid. A strong acid is defined as one that is completely ionized or dissociated in an aqueous solution; therefore, the stronger the acid, the greater the ionization.

22. The answer is D *[see* Table 12-1; Figure 12-8*].*

The carboxylic acid identifies this compound as an acid. Other structural features identify it as a fenamate. Fenamates are NSAIDs that can be used for inflammatory disorders (e.g., arthritis, bursitis). The mechanism of action of NSAIDs is inhibition of cyclooxygenase, which results in a decrease in the production of prostaglandins.

23. The answer is C *[see* Table 12-1*].*

Fibrates decrease cholesterol and triglyceride levels. All of the other chemical classes can be used to treat hypertension. Aryloxypropanolamines are β-blockers, thiazides are diuretics, dihydropyridines are calcium channel blockers, and ACE inhibitors decrease the synthesis of angiotensin II, a potent vasoconstrictor.

24. The answer is E *[see* VIII.B.2.f *and* g; Table 12-1*].*

Flurazepam (take note of the suffix, which helps classify the compound) is a benzodiazepine and thus a basic compound. Because the pH is less than the pK_a, flurazepam is in an acidic environment and, therefore, exists primarily in the ionized form. The percent ionized can be easily calculated by using the rule of nines. The $|pH - pK_a|$ is 3, so the ratio is 99.9%:0.01% in favor of the ionized form.

25. The answer is D (II, III) *[see* VIII.A.1 *and* 2*].*

Generally, drugs must be lipophilic to pass through lipoprotein membranes and hydrophilic to be excreted by the kidney. Drugs do not have to be converted into an active form at their active site, although most drugs must be in their active form when they reach their active site. Many drugs are active in the form in which they are administered. Some drugs, usually referred to as prodrugs, are biotransformed into their active form after administration. Theoretically, drugs that reach their active site and then are metabolically activated should be more specific in their action and have fewer side effects. Currently, research efforts are under way to develop site-specific delivery systems and processes.

26. The answer is D (II, III) *[see* VIII.B.2.c; VIII.B.3.a; VIII.B.4.a*].*

Almost all salts (with very few exceptions) are strong electrolytes, and the terminology *pentobarbital sodium* and *diphenhydramine hydrochloride* indicate that each compound is salt. Acetic acid is a weak acid; therefore, it is a weak electrolyte.

27. The answer is A (I) *[see* VIII.B.3 *and* 4*].*

When meperidine hydrochloride solution is mixed with the alkaline solution of sodium bicarbonate, a neutralization reaction occurs with the possible precipitation of the water-insoluble free base meperidine. A neutralization reaction occurs when acidic solutions are mixed with basic solutions, or conversely. No reaction, in terms of acid-base, occurs when solutions are mixed with other acidic or neutral solutions or when basic solutions are mixed with other basic or neutral solutions. There should be no reaction, then, when the meperidine hydrochloride solution, which is acidic, is mixed with the acidic solution of atropine sulfate or the neutral solution of sodium chloride.

28. The answer is C (I, II) *[see* IX.B.3.d; X.C.1; X.E.1*].*

Both sulfisoxazole and 5-fluorouracil compete with and antagonize isosteric normal biological molecules and thus are antimetabolites. Digoxin is a drug that is thought to inhibit Na^+/K^+-ATPase or to affect intracellular influx or use of calcium ion (Ca^{++}). Because digoxin is steroidal, it is not isosteric with either an enzyme, which is a protein, or an ion; therefore, it is not classified as an antimetabolite.

29. The answer is A (I) *[see* VIII.B.1; VIII.B.2.e*].*

A weakly acidic drug will be more ionized in an alkaline urine; therefore, it will be more polar and thus more soluble in the aqueous urine. It would also be less liposoluble, less likely to undergo tubular reabsorption, and thus be more likely to be excreted.

30. The answer is C (I, II) *[see* VIII.B.2 *and* 3; Figure 12-7*].*

31. The answer is B (III) *[see* VIII.B.2 *and* 3; Figure 12-7*].*

32. The answer is A (I) *[see* VIII.B.2 *and* 3; Figure 12-7*].*

33. The answer is B (III) *[see* VIII.B.2 *and* 3; Figure 12-7*].*

The molecule contains a basic nitrogen, which is bonded to three carbon atoms (i.e., a tertiary amine), and an ethyl carboxylate, which is an ester group. An ester is the product of the reaction of an alcohol with a carboxylic acid that forms an alkyl

carboxylate. There is no free carboxylic acid present. However, if this molecule is subjected to hydrolysis, it forms a carboxylic acid and ethyl alcohol.
Because meperidine contains a tertiary amine, it is classified as a base; because it is an organic base, it is considered weak. The nitrogen is not protonated. It is not ionic and, therefore, is not a salt.
Alkalinization of the urine decreases the ionization of meperidine, making it more liposoluble and thus more likely to undergo reabsorption in the kidney tubule. This results in a decreased rate of excretion and an increased duration of action. The six-member, nonaromatic ring is a piperidine ring that is substituted at the 4-position (nitrogen is position 1) with a phenyl ring. The compound does not contain a piperazine ring or a propyl group.

34. The answer is C *[see* IX.B.3.a.4; Figure 12-13*].*
These molecules are isomers that have two asymmetric carbon atoms. They are not superimposable and are not mirror images; therefore, they are known as diastereomers.

35. The answer is B *[see* IX.B.3.a.1; Figure 12-12*].*
These molecules are isomers that have one asymmetric carbon atom. They are nonsuperimposable mirror images; therefore, they are enantiomers.

36. The answer is A *[see* IX.B.3.b; Figure 12-14*].*
These molecules have different spatial arrangements; however, these molecules do not have an asymmetric center. The presence of the double bond, which restricts the rotation of the groups on each carbon atom involved in the double bond, characterizes this type of isomerism as geometric.

37. The answer is D *[see* IX.B.3.d; Figure 12-16*].*
These molecules are neither isomers nor the same compound because one contains three oxygens, whereas the other contains two oxygens and a sulfur. Because oxygen and sulfur are in the same periodic family, they are isosteric and are known as bioisosteres.

38. The answer is E *[see* IX.B.3.c; Figure 12-15*].*
These structures are actually two views of the same compound. Rotation around the side chain single bonds connecting the ring nitrogen to the tertiary nitrogen produces these two different conformations. Thus these are conformational isomers.

13

Medicinal Chemistry and Pharmacology: Drugs Affecting the Nervous System

Habiba O. U. Vongtau

Ashiwel S. Undieh

INTRODUCTION.

Drugs affecting the nervous system modulate neurotransmission in the **central nervous system (CNS),** which consists of the brain and the spinal cord, or in the **peripheral nervous system (PNS),** which includes the **autonomic nervous system (ANS)** and the somatic system that innervates the skeletal muscles. The ANS, in turn, consists of sympathetic (or adrenergic) and parasympathetic (or cholinergic) branches. Agents acting in the ANS include adrenergic agonists and antagonists, cholinergic agonists and antagonists, and indirectly acting agents that could affect one or both ANS systems. Drugs affecting the PNS are useful for treating a variety of ailments including blood pressure disturbances, bronchial asthma, cardiac dysfunctions, anaphylactic reactions, nasal congestion, and skeletal muscle spasticity. Drugs affecting the CNS provide anesthesia and sedation, relieve pain and anxiety, suppress movement disorders and epileptic seizures, and treat psychotic and affective disorders. These drugs include general and local anesthetics, anxiolytics and sedative-hypnotics, opioid analgesics, antiparkinsonian agents, antiepileptics, antipsychotics, and antidepressants.

I. GENERAL MECHANISMS OF DRUG ACTION IN THE NERVOUS SYSTEM.

Drugs acting in the nervous system achieve their pharmacologic effects by modifying the synaptic concentrations or receptor actions of neurotransmitters. Other drugs modulate the intracellular response pathways by which the receptor actions of the transmitters are conveyed to yield the ultimate physiological response. The major neurotransmitters in the nervous system, their primary receptor subtypes, and the predominant effects of receptor stimulation on neurotransmission are shown in Table 13-1. Some general mechanisms by which diverse drugs modulate the activity of the nervous system are summarized in Table 13-2, with examples drawn from the adrenergic and cholinergic components of the PNS. In addition, there are various classes of drugs that modulate neural function by interacting with the pores of ion channels or by binding to allosteric sites on the protein subunits that constitute the channel.

II. ADRENERGIC AGONISTS

A. Chemistry

1. Direct-acting adrenergic agonists interact directly with adrenergic receptors to elicit a response. These agonists include norepinephrine and epinephrine, which are endogenous or naturally occurring catecholamines. The catecholamines are biosynthesized from tyrosine, an amino acid (Figure 13-1). Examples of other direct-acting adrenergic agonists include naphazoline, terbutaline, and dobutamine (Figure

13-2). The classification of adrenergic agonists and antagonists shown in Table 13-3 should provide a broad perspective on the variety of agents that act on this system to produce their pharmacologic and therapeutic effects.

a. The ethylamine chain common to these agonists is essential to their adrenergic activity.

b. N-substitution alters drug activity. Small substituents (e.g., hydrogen, α-methyl group) produce α-receptor activity, as with norepinephrine; larger substituents (e.g., isopropyl group) produce β-receptor activity, as with isoproterenol.

c. Removal of the *para* (4) hydroxyl group leaves only α-receptor activity, as with phenylephrine.

P.283

Table 13-1. Major Neurotransmitters in the Nervous System, Their Major Postsynaptic Receptors, and Receptor Effects on Ionic Conductance and Second Messenger (Signaling) Pathways

Neurotransmitter	Primary Receptor Subtypes	Effects of Receptor Stimulation
Acetylcholine	Muscarinic M_1 (and M_3, M_5)	Excitatory (↑IP3/DAG)
	Muscarinic M_2 (and M_4)	Inhibitory (↓cAMP)
	Nicotinic (N_1 and N_2)	Excitatory (↑cation conductance)
Dopamine	D_1 (and D_5)	Excitatory (↑cAMP; ↑IP3/DAG)
	D_2 (and D_3, D_4)	Inhibitory (↓cAMP; ↑K^+ conductance)
GABA	$GABA_A$	Inhibitory (↑Cl^- ion conductance)
	$GABA_B$	Mixed (cAMP modulation; ↓Ca^{2+}; ↑K^+ fluxes)

Glutamate	Ionotropic-NMDA	Excitatory (↑Ca^{2+} ion conductance)
	Ionotropic-AMPA/Kainate	Excitatory (↑cation conductance)
	Metabotropic	Excitatory (↑IP3/DAG; modulate cAMP)
Histamine	H_1	Excitatory (↑IP3/DAG)
	H_2	Excitatory (↑cAMP)
Norepinephrine	α_1	Excitatory (↑IP3/DAG)
	α_2	Inhibitory (↓cAMP)
	β_1	Excitatory (↑cAMP)
	β_2	Inhibitory in ANS (↑cAMP)
	β_3	Excitatory (↑cAMP)
Serotonin (5HT)	$5HT_1$	Inhibitory (↓cAMP)
	$5HT_2$	Excitatory (↑IP3/DAG)
	$5HT_{(3/4/5/6/7)}$	Mixed (type 4,6,7 ↑cAMP)
Opioid peptides	*Mu* (μ)	Mixed (↓cAMP; Ca^{2+} & K^+ channel effects)
	Delta (δ)	Mixed (↓cAMP; Ca^{2+} & K^+ channel effects)

	Kappa (κ)	Mixed (↓cAMP; Ca^{2+} & K^+ channel effects)

Table 13-2. Some General Mechanisms of Drug Action in the Nervous System Exemplified by the Adrenergic and Cholinergic Neurotransmitter Systems

Mechanism		Adrenergic System	Cholinergic System
1.	Ganglionic stimulation	Nicotine	
2.	Ganglionic blockade	Hexamethonium, trimethaphan	
3.	Inhibition of neurotransmitter synthesis	Metyrosine, carbidopa	Hemicholinium
4.	Inhibition of neurotransmitter release	Bretylium, guanethidine	Botulinum toxin
5.	Facilitation of neurotransmitter release	Amphetamine, tyramine	α-Iatrotoxin
6.	Depletion of vesicular transmitter storage	Reserpine	Vesamicol
7.	Blockade of	Cocaine,	See note[a]

	neurotransmitter reuptake	desipramine	
8.	Inhibition of neurotransmitter metabolism	Clorgyline (inhibits MAO-A)[b]	Neostigmine and other AChE inhibitors
		Selegiline (inhibits MAO-B)	
		Tolcapone (inhibits COMT)	
9.	Direct interaction with postsynaptic receptors	Adrenoceptor agonists	Cholinergic agonists
		Adrenoceptor antagonists	Cholinergic antagonists

[a] Reuptake is not a major mechanism for termination of acetylcholine's action; most of the released transmitter is metabolized by acetylcholinesterase (AChE).

[b] COMT (catechol-O-methyl transferase); MAO-A, MAO-B (monoamine oxidase-A, -B).

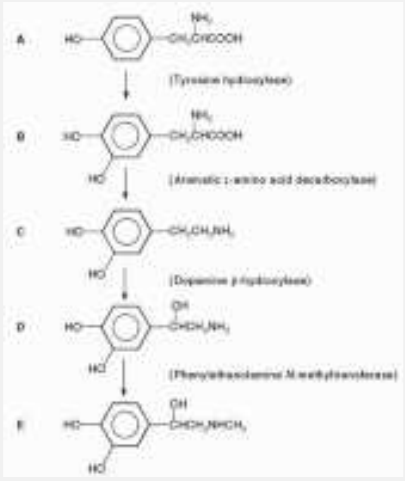

Figure 13-1. Synthesis of catecholamines from the amino acid tyrosine. In the presence of tyrosine hydroxylase, **(A)** tyrosine is converted to **(B)** dihydroxyphenylalanine (dopa). Further substitutions permit the synthesis of **(C)** dopamine, **(D)** norepinephrine, and **(E)** epinephrine.

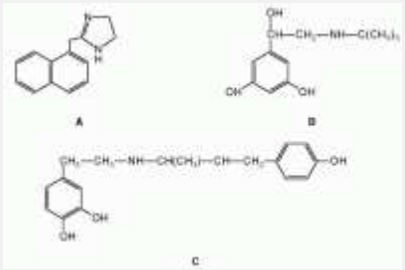

Figure 13-2. Structural formulas of representative direct-acting sympathomimetic amines. **(A)** Naphazoline, **(B)** terbutaline, **(C)** dobutamine.

Table 13-3. Classification of Adrenoceptor Agonists and Antagonists*

Class		Adrenoceptor Agonist	Adrenoceptor Antagonist
A.	**Nonselective**		
A.1	Indirect-acting	Tyramine	
		Ephedrine	
		Amphetamine	
		Cocaine	
A.2	Direct-acting	Norepinephrine	Labetalol
		Epinephrine	Carvedilol
B.	**α-Receptor-Selective**		
B.1	Nonselective α	Oxymetazoline	Phenoxybenzamine
		Xylometazoline	
		Tetrahydrozoline	Phentolamine
B.2	Selective α_1	Phenylephrine	Prazosin
		Methoxamine	Terazosin
		Metaraminol	Doxazosin
			Indoramin
B.3	Selective α_2	Clonidine	Rauwolscine
		Guanabenz	Yohimbine

		Guanfacine	Tolazoline
		Rilmenidine	
		Moxonidine	
		α-Methyldopa	
C.	**β-Receptor-Selective**		
C.1	Nonselective β	Isoproterenol	Propranolol
			Nadolol
			Pindolol
			Carteolol
			Timolol
			Sotalol
			Penbutolol
C.2	Selective β_1	Xamoterol	Acebutolol
			Atenolol
			Betaxolol
			Celiprolol
			Esmolol

			Metoprolol
C.3	Selective β_2	Metaproterenol	Butoxamine
		Fenoterol	
		Terbutaline	
		Albuterol (Salbutamol)	
		Ritodrine	
		Salmeterol	
		Formoterol	
		Pirbuterol	
		Bitolterol	
C.4	Selective β_3	BRL37344; CL316243	

* To describe the classification of a particular drug, the receptor selectivity class on the left is combined with the receptor activity descriptor on the top of the column; for example, tyramine is an indirect-acting adrenoceptor agonist, and tolazoline is a selective α_2-adrenoceptor antagonist.

d. The *meta* (3) hydroxyl group is essential for direct α- and β-activity. However, drugs in which the *meta* hydroxyl is replaced by a methoxy group (e.g., methoxamine) retain α-activity.

e. Catecholamines are inactivated by methylation of the *meta* hydroxyl group (catalyzed by catechol O-methyltransferase [COMT]) and by oxidative deamination (catalyzed by monoamine oxidase [MAO]).

2. Indirect-acting adrenergic agonists are chemically related to the catecholamines, but they do not significantly interact directly with adrenergic receptors. These mostly synthetic compounds induce their pharmacological effects by enhancing the release of the endogenous neurotransmitters. Physiologically, therefore, they have effects similar to the catecholamine neurotransmitters, hence their nickname of sympathomimetic amines. Examples include amphetamine, ephedrine, phenylephrine, and tyramine (Figure 13-3).

a. Indirect-acting sympathomimetic amines may have two, one, or no hydroxyl groups. The fewer the hydroxyl groups, the higher the lipophilicity, and the greater the absorption and the duration of activity after oral administration. Faster and greater absorption also implies less intestinal destruction of the drug.

b. Alkyl substitution at the α-carbon (adjacent to the amino group) retards destruction of phenol and phenyl compounds and increases lipophilic character, contributing to prolonged activity.

c. N-substitution with bulky groups increases direct β-receptor activity, as with the directacting agents.

B. Pharmacology

1. Adrenergic peripheral responses are mediated by both α- and β-adrenoceptors (Table 13-4). Adrenergic (and other ANS) receptors may be located at the cell membranes of nerve terminals (prejunctional receptors) or at the membranes of postjunctional cells which receive the neural input from the nerve terminals. Prejunctional and postjunctional receptors are also called presynaptic and postsynaptic receptors, respectively, where both the prejunctional cell and the postjunctional cell are nerve cells separated by a synaptic space.

a. α-Receptors fall into two main groups.

(1) Postjunctional α_1-adrenergic receptors are found in the radial smooth muscle of the iris; in the arteries, arterioles, and veins; in the pilomotor smooth muscle of hair follicles; in the heart; and in the sphincters of the gastrointestinal (GI) tract. Drugs that are **α_1-selective agonists** cause excitatory responses such as vasoconstriction and smooth muscle contraction, and include phenylephrine and methoxamine.

(2) Prejunctional α_2-adrenergic receptors mediate the inhibition of adrenergic neurotransmitter release. Drugs that are **α_2-selective agonists** also inhibit lipolysis in fat cells and promote platelet aggregation. Examples of such drugs include clonidine and guanabenz.

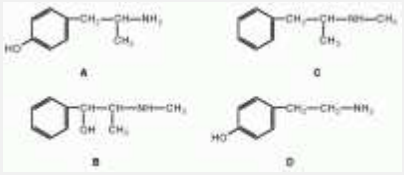

Figure 13-3. Chemical structures of some indirect-acting sympathomimetic amines. **(A)** Hydroxyamphetamine (Paredrine), **(B)** ephedrine or pseudoephedrine (Sudafed), **(C)** methamphetamine (Methedrine), **(D)** tyramine.

Table 13-4. Adrenoceptor-Mediated Responses to Adrenergic Agonists

Organ/Tissue	Receptor Type	Response
Heart	β_1	Increases conduction velocity (dromotropic)
	β_1	Increases contraction force (inotropic)
	β_1	Increases contraction rate (chronotropic)
Arterioles	α_1	Constricts cerebral arterioles
	α_1	Constricts cutaneous arterioles
	α_1	Constricts visceral arterioles
	β_2	Dilates skeletal muscle arterioles
Eye	α_1	Contracts iris sphincter muscle, producing mydriasis
Lung	β_2	Relaxes tracheal and bronchial muscles

Intestine	α, β	Decreases peristalsis
	α_1	Contracts sphincters
Urinary bladder	α_1	Contracts trigone and sphincter muscles, inhibiting micturition
Uterus	β_1	Relaxes detrusor muscle
	α_1	Excites uterine contractions
	β_2	Inhibits uterine contractions
Adipose tissue	β_3	Causes adipolysis; mobilizes fatty acids

b. β-Receptors fall into three main groups.

(1) Postjunctional β_1-adrenergic receptors are found mainly in the myocardium, where their stimulation increases myocaridal conduction speed (dromotropic effect) and the force (inotropic effect) and rate (chronotropic effect) of myocardial contraction. Drugs that are **β_1-selective agonists** include xamoterol and to some extent dobutamine.

(2) Postjunctional β_2-adrenergic receptors are found in the smooth muscle of the vasculature, bronchioles, and uterus; stimulation of these receptors causes smooth-muscle relaxation. Drugs that are **β_2-selective agonists** include albuterol and terbutaline.

(3) Postjunctional β_3-adrenergic receptors are expressed on fat cells, and their stimulation causes lipolysis. A number of β_3-agonists are under development as potential treatments for obesity, non-insulin-dependent diabetes mellitus, and frequent urination.

2. Direct-acting adrenergic agonists (e.g., norepinephrine, phenylephrine, clonidine, terbutaline) produce their effects primarily by direct stimulation of adrenergic receptors. They may be receptor-selective, as with the drugs listed previously, or they may be nonselective. For example, the adrenergic neurotransmitter norepinephrine affects all adrenergic receptors, especially α_1-, α_2-, and β_1-receptors, whereas the adrenal medullary hormone epinephrine affects α_1-, α_2-, β_1-, and β_2-receptors. Isoproterenol affects both β_1- and β_2-receptors but not α-receptors.

3. Indirect-acting adrenergic agonists work through other primary mechanisms, which ultimately lead to receptor effects. For example, tyramine acts by releasing

norepinephrine from storage sites in adrenergic neurons, while cocaine blocks the reuptake of norepinephrine, thereby increasing the duration and activity of the transmitter at the synapse.

4. Certain agonists (e.g., ephedrine, metaraminol, mephentermine) produce their effects through both direct and indirect mechanisms.

C. Therapeutic indications

1. Epinephrine, an α- and β-adrenergic agonist, is indicated to treat bronchospasm and hypersensitivity reactions and is the agent of choice for anaphylactic reactions. It is used to

prolong the activity of local anesthetic solutions and to restore cardiac activity in cardiac arrest. Epinephrine is also used topically in the treatment of glaucoma, presumably decreasing intraocular pressure by enhancing the outflow of aqueous humor and through vasoconstriction-induced decrease in production of aqueous humor. Local application of epinephrine is used to arrest blood flow in epistaxis and gingival surgery.

2. Phenylephrine, an α_1-selective agonist, is used to provide pressor activity in hypotensive emergencies, to prolong the activity of local anesthetic solutions, and to relieve paroxysmal atrial tachycardia. Phenylephrine or phenylpropanolamine is given systemically for nasal decongestion. Oxymetazoline and xylometazoline, also α-receptor agonists, are applied locally to relieve nasal congestion.

3. Clonidine and related α_2-selective agonists (e.g., methyldopa, guanfacine, guanabenz) are used as antihypertensives based on their inhibition of central sympathetic outflow. Apraclonidine is used topically in the eye to decrease intraocular pressure during surgery.

4. Isoproterenol, a β-adrenergic agonist, is used as a bronchodilator and as a cardiac stimulant in shock and cardiac arrest.

5. Dobutamine, a relatively **β_1**-selective agonist, is used to improve myocardial function in congestive heart failure, especially in emergency situations.

6. Terbutaline and other **β_2**-selective agonists (e.g., metaproterenol, albuterol, bitolterol, salmeterol) are used as systemic or local bronchodilators in the treatment of bronchospastic conditions such as asthma.

7. The **β_2**-selective agonists, especially ritodrine, may be used to relax uterine smooth muscle in the treatment of premature labor.

D. Adverse effects. Adrenergic agonists may cause cardiac dysrhythmias, cerebral hemorrhage, pulmonary hypertension and edema, anxiety, headache, and rebound nasal congestion.

III. ADRENERGIC ANTAGONISTS

A. Chemistry

1. α-Adrenergic antagonists (α-blockers) have varied structures and bear little resemblance to the adrenergic agonists. Antagonists include the ergot alkaloids (e.g., ergotamine), the dibenzamines (e.g., phenoxybenzamine), the benzolines (e.g., tolazoline), and the quinazolines (e.g., prazosin) (Figure 13-4).

2. β-Adrenergic antagonists (β-blockers) are structurally similar to β-agonists (Figure 13-5). The **catechol ring** can be replaced by a variety of other ring systems without loss of antagonistic activity. The length of the side chain is important and the side chain hydroxyl, as well as a propyl or other bulky substitution on the chain nitrogen, are essential for interaction with β-receptors.

B. Pharmacology

1. Adrenergic antagonists inhibit or block adrenergic receptor-mediated responses.

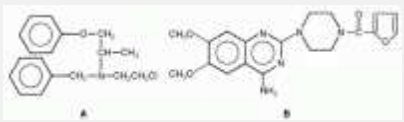

Figure 13-4. The structural formulas of **(A)** phenoxybenzamine (Dibenzyline) and **(B)** prazosin (Minipress), representative α-blockers.

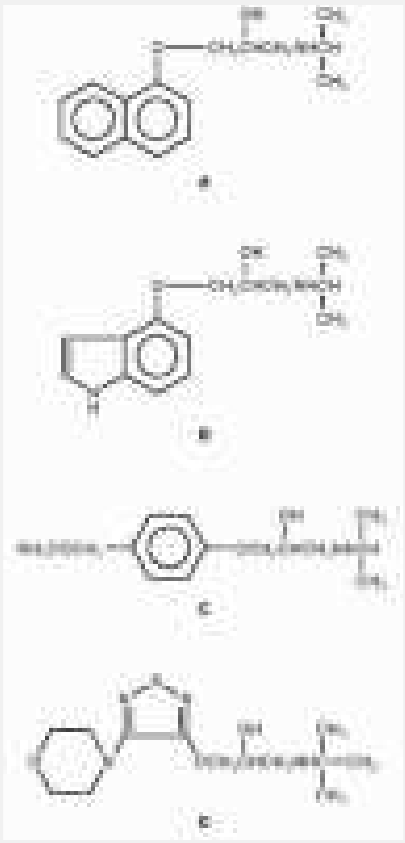

Figure 13-5. The structural formulas of **(A)** propranolol (Inderal); **(B)** pindolol (Visken); **(C)** atenolol (Tenormin), and **(D)** timolol (Blocadren), representative β-blockers.

2. α-Adrenergic antagonists may be α_1-selective (e.g., prazosin) or nonselective (e.g., phenoxybenzamine). Phenoxybenzamine is an irreversible antagonist because it forms covalent bonds with α-receptors, thereby inactivating the receptors.

3. β-Adrenergic antagonists may be β_1-selective (e.g., metoprolol) or nonselective (e.g., propranolol). Generally, however, β_1-selective agents may lose their selectivity at higher doses and thus block β_2-receptors as well (a potential problem in asthmatics).

C. Therapeutic indications

1. Prazosin and related α_1-selective antagonists (e.g., doxazosin, terazosin, trimazosin, alfuzosin) produce vasodilation (by blocking basal vascular tone maintained by circulating catecholamine activation of vascular α_1-receptors). They are thus important antihypertensive agents. They are also useful in the symptomatic treatment of benign prostatic hyperplasia.

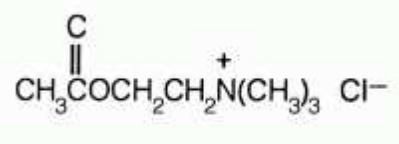

Figure 13-6. The structural formula of acetylcholine.

2. Phenoxybenzamine and **phentolamine** (nonselective α-blockers) can be used to relieve vasospasm in Raynaud's syndrome and for acute hypertensive emergencies resulting from pheochromocytoma or from intake of MAO inhibitors or sympathomimetics. Tolazoline, a similar agent, is used to treat persistent neonatal pulmonary hypertension.

3. Labetalol, an agent that possesses both selective α_1-blocking activity and nonselective β-blocking activity, is used in the treatment of hypertension.

4. Propranolol, a nonselective β-antagonist, is used for the prophylaxis of angina pectoris, supraventricular and ventricular dysrhythmias, and migraine headache. It is also used as an antihypertensive, a negative inotropic agent in hypertrophic obstructive cardiomyopathy, and a negative chronotropic agent in anxiety and hyperthyroidism.

5. β_1-Selective antagonists (e.g., metoprolol, betaxolol, atenolol, acebutolol) are used in the treatment of hypertension, tachyarrhythmias, and angina.

6. Both β_1-selective (betaxolol) and nonselective (timolol) blockers decrease ciliary body production of aqueous humor and may be used in the topical treatment of glaucoma.

D. Adverse effects

1. Prazosin can cause sudden syncope with the first dose, orthostatic hypotension, dizziness, headache, drowsiness, palpitations, fluid retention, and priapism.

2. Phenoxybenzamine can cause orthostatic hypotension, tachycardia, inhibition of ejaculation, miosis, and nasal congestion.

3. Propranolol can cause bradycardia and congestive heart failure, increased airway resistance, increased serum triglycerides, decreased high-density lipoprotein cholesterol, blood dyscrasias, psoriasis, depression, hallucinations, and transient hearing loss. Sudden withdrawal can be cardiotoxic due to rebound sympathomimetic activity.

4. Metoprolol has adverse effects similar to those of propranolol, except that it is less likely to increase airway resistance given its β_1-selectivity.

IV. CHOLINERGIC AGONISTS

A. Chemistry

1. Acetylcholine, the natural endogenous mediator and the most potent cholinergic agonist, is an ester of acetic acid and choline—a quaternary amino alcohol (Figure 13-6). Acetylcholine in the blood is unstable as it is quickly inactivated through hydrolysis by acetylcholinesterase. Thus, it is extremely short acting and usually is not a satisfactory therapeutic agent.

2. Therapeutically useful cholinergic agonists may be direct acting or indirect acting.

a. Direct-acting agonists may be produced by replacing the acetyl group of acetylcholine with a carbamoyl group or by substituting a methyl group of the β-carbon. These substitutions produce compounds that are more **resistant to acetylcholinesterase** and thus have longer durations of action. Such stable agonists include methacholine (Provocholine) and bethanechol (Urecholine) (Figure 13-7).

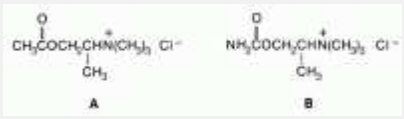

Figure 13-7. Clinically useful direct-acting cholinergic agonists include **(A)** methacholine chloride (Provocholine) and **(B)** bethanechol chloride (Urecholine).

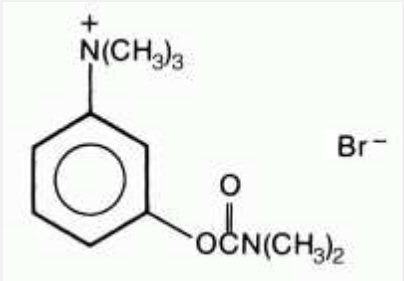

Figure 13-8. The structural formula of neostigmine bromide (Prostigmin), a reversible acetylcholinesterase inhibitor.

b. Indirect-acting agonists are generally acetylcholinesterase inhibitors and are divided into two major classes.

(1) Reversible (short-acting) agents are principally carbamates (carbamic acid esters), such as physostigmine (Eserine), neostigmine, and ambenonium (Metylase) (Figure 13-8).

(2) Irreversible (long-acting) agents are principally organophosphate esters, such as echothiophate (Phospholine) (Figure 13-9).

B. Pharmacology

1. Cholinergic responses are mediated by both muscarinic and nicotinic receptors (Table 13-5).

a. PNS muscarinic receptors are present at parasympathetic postjunctional neuroeffector sites.

b. PNS nicotinic receptors are present at the ganglia of both the parasympathetic and sympathetic branches of the ANS and also at the neuromuscular junctions of the somatic nervous system.

2. Cholinergic agonists act by mimicking the activity of endogenous acetylcholine at muscarinic and nicotinic receptor sites.

a. Direct-acting agonists interact directly with these receptors.

b. Indirect-acting agonists inhibit or block the activity of cholinesterase enzymes (e.g., acetylcholinesterase, butyrylcholinesterase), which break down endogenous acetylcholine to inactive metabolites. Thus, following physiological release of acetylcholine from nerve terminals, these agents allow the neurotransmitter to accumulate at cholinergic synapses, thereby enhancing cholinergic receptor stimulation. Organophosphate cholinesterase inhibitors, such as certain agricultural insecticides and the so-called nerve gases, can be extremely toxic as they bind to the enzyme to form an irreversible or long-lasting enzyme inhibitor complex.

C. Therapeutic indications

1. Direct-acting agonists are indicated to:

a. Initiate micturition in acute nonobstructive urinary retention (e.g., bethanechol)

b. Produce miosis in the treatment of glaucoma (e.g., pilocarpine)

2. Indirect-acting agonists are indicated to:

a. Produce miosis in the treatment of glaucoma (e.g., physostigmine, echothiophate)

b. Aid in the differential diagnosis of myasthenia gravis (a disease caused by nicotinic receptor hypofunction at the neuromuscular junction) and hypercholinergic crisis (which produces depolarization blockade of the neuromuscular junction). Edrophonium is used for this purpose.

c. Treat myasthenia gravis (e.g., ambenonium, neostigmine, pyridostigmine)

d. Counteract intoxication or adverse effects from compounds with anticholinergic activity (e.g., physostigmine)

e. Improve cognitive function in Alzheimer's disease patients (e.g., tacrine, donepezil, galantamine, and rivastigmine)

f. Treat paralytic ileus or cardiac tarchyarrythmias (e.g., edrophonium).

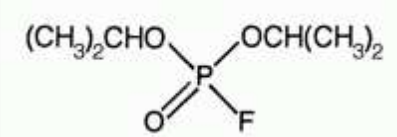

Figure 13-9. The structural formula of isoflurophate (Floropryl), an irreversible acetylcholinesterase inhibitor.

Table 13-5. Cholinoceptor-Mediated Responses to Cholinergic Agonists

Organ		Response
Heart		
	Atrioventricular node	Decreased conduction velocity (negative dromotropy)
	Atria, ventricles	Decreased contraction force (negative inotropy)
	Sinoatrial node	Decreased contraction rate (negative chronotropy)
Eye		
	Sphincter muscle	Contraction, producing miosis
	Ciliary muscle	Contraction, accommodates for near vision
Lung		

	Bronchial muscle	Contraction (bronchoconstriction)
	Bronchial glands	Increased secretion
Gastrointestinal tract		
	Intestine	Increased motility (peristalsis)
	Sphincters	Relaxation of sphincters
	Glands	Increased secretions
Urinary bladder		
	Detrusor muscle	Contraction
	Trigone and sphincter	Relaxation
Glands (sweat, salivary, nasopharyngeal, lacrimal)		Increased glandular secretion

D. Adverse effects

1. Topical adverse effects include congested conjunctivae, myopic accommodation, and transient lenticular opacity.

2. Systemic adverse effects include headache, syncope, nausea, vomiting, bradycardia, hypotension, bronchospasm, abdominal cramps, diarrhea, epigastric distress, salivation, sweating, lacrimation, flushing, and tremors.

V. CHOLINERGIC ANTAGONISTS

block the actions of acetylcholine at muscarinic or nicotinic cholinoceptors.

A. Chemistry

1. Atropine, an alkaloid extracted from the belladonna plant, is the prototypical cholinergic antagonist (anticholinergic agent). A portion of the atropine molecule is structurally similar to acetylcholine (Figure 13-10), permitting the molecule to bind to postjunctional receptors.

However, the molecule has no intrinsic activity,and its bulky shape prevents acetylcholine from binding to the receptor.

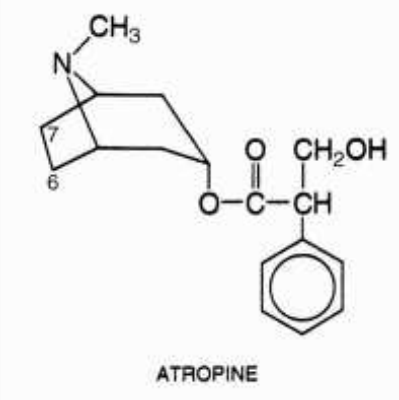

Figure 13-10. Structural formula of atropine, a cholinergic antagonist.

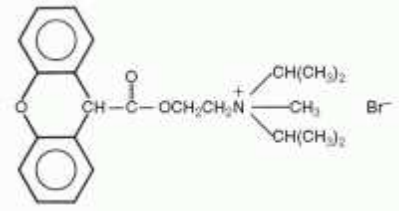

Figure 13-11. Structural formula of propantheline bromide (Pro-Banthine), a synthetic cholinergic antagonist.

2. Synthetic anticholinergic agents (e.g., dicyclomine [Bentyl], glycopyrrolate [Robinul], propantheline [Pro-Banthine], pirenzepine and tropicamide) are also available. These agents, like atropine, are bulky analogues of acetylcholine (Figure 13-11).

3. An important factor that determines the pharmacologic spectrum of anticholinergic agents is the presence of a **quaternary nitrogen** (as in propantheline, glycopyrrolate, and ipratropium), which reduces passage across the blood-brain barrier, or a **tertiary nitrogen** (as in dicyclomine, pirenzepine, tropicamide, and benztropine), which permits a broader volume of distribution (or accessibility to a wider range of tissues).

B. Pharmacology

1. Cholinergic antagonists **competitively inhibit** the activity of endogenous acetylcholine.

2. Antagonists that inhibit muscarinic receptor-mediated responses are called **antimuscarinic agents;** those that inhibit nicotinic receptor-mediated responses at the ganglia are called **ganglionic-blocking agents,** whereas those that inhibit

nicotinic receptor-mediated responses at the neuromuscular junction are called **neuromuscular-blocking agents.**

C. Therapeutic indications

1. Antimuscarinic agents are indicated to:

a. Reduce glandular and bronchiolar secretions before anesthesia (e.g., atropine, glycopyrrolate)

b. Induce sedation (e.g., scopolamine)

c. Alleviate motion sickness (e.g., scopolamine)

d. Reduce vagal stimulation of the myocardium (e.g., atropine)

e. Produce ophthalmic mydriasis and cycloplegia (e.g., homatropine)

f. Reduce GI smooth-muscle spasms (e.g., propantheline)

g. Treat bronchospasm associated with chronic obstructive pulmonary disease (e.g., ipratropium)

h. Control Parkinson's disease symptoms and some neuroleptic-induced extrapyramidal reactions (e.g., benztropine, trihexyphenidyl)

i. Treat intoxication by cholinergic agonists or by acute mushroom poisoning (e.g., atropine)

2. Ganglionic-blocking agents are indicated to treat hypertensive crisis (e.g., trimethaphan, mecamylamine, hexamethonium). By blocking ganglionic transmission, these agents reduce sympathetic activity, resulting in a hypotensive effect.

D. Adverse effects

1. Topical adverse effects include hyperopic accommodation and increased intraocular pressure.

2. Systemic adverse effects include headache, nervousness, drowsiness, dizziness, palpitations, tachycardia, dry mouth, mydriasis, blurred vision, nausea, vomiting, constipation, urinary retention, and fever.

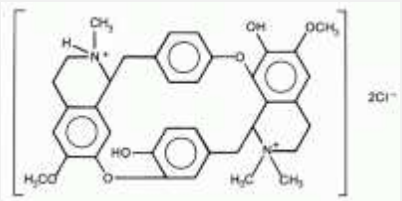

Figure 13-12. Structural formula of tubocurarine chloride (Tubarine), a competitive nondepolarizing agent.

VI. NEUROMUSCULAR BLOCKING AGENTS

act by blocking the effects of acetylcholine at the nerve-muscle junction of skeletal muscles.

A. Chemistry

1. Neuromuscular blocking agents can be competitive (as with the prototypical curare alkaloids) or depolarizing (as with succinylcholine). Members of either category ultimately prevent the action of acetylcholine at nicotinic receptors located in the nerve-muscle junction.

2. The **competitive nondepolarizing agents** include the naturally occurring alkaloids of **curare,** which are bulky and rigid molecules, as well as several synthetic analogues.

a. The **principal active alkaloid** in curare is tubocurarine (Figure 13-12). A closely related trimethylate derivative is metocurine (Metubine). Their most important structural feature is the presence of a tertiary-quaternary amine in which the distance between the two cations is rigidly fixed at about twice the length of the critical receptor-binding moiety of acetylcholine.

b. A number of **potent synthetic analogues** have been developed. These include the structurally similar **isoquinolines** atracurium (Tracrium), doxacurium (Nuromax), and mivacurium (Mivacron), as well as the **steroid derivatives** pancuronium (Pavulon), vecuronium (Norcuron), and pipecuronium (Arduan).

3. The **noncompetitive depolarizing agents** include succinylcholine (Anectine) and gallamine (Flaxedil) (Figure 13-13).

a. Unlike the large, bulky competitive agents, noncompetitive agents are slender aliphatic molecules.

b. Succinylcholine has a short duration of action compared with the other neuromuscular blocking agents. This results from its simple ester functional group, which is rapidly hydrolyzed by plasma and liver pseudocholinesterase (butyrylcholinesterase). Its action may be prolonged, however, in patients with an abnormal genetic variant of pseudocholinesterase, which has only about 20% the activity of normal pseudocholinesterase.

B. Pharmacology

1. The **competitive nondepolarizing agents** compete with acetylcholine for nicotinic receptors at the neuromuscular junction. These agents decrease the end-plate potential so that the depolarization threshold is not reached. Competitive nondepolarizing agents produce

a surmountable blockade of neuromuscular transmission in that administration of cholinesterase inhibitors or prejunctional release of a large quantity of acetylcholine can relieve the blockade.

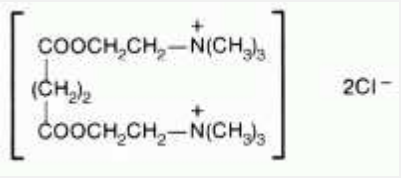

Figure 13-13. Structural formula of succinylcholine chloride, a noncompetitive depolarizing agent.

2. The **noncompetitive depolarizing agents** desensitize the nicotinic receptors at the neuromuscular junction. These agents react with the nicotinic receptors, decreasing receptor sensitivity in a manner similar to that of excess released acetylcholine. They depolarize the excitable membrane for a prolonged period (2-3 minutes); the membrane then becomes unresponsive (desensitized).

C. Therapeutic indications. Neuromuscular blocking agents, which cause only skeletal muscle paralysis (the patient remains conscious and capable of sensation), are used to:

1. Promote skeletal muscle relaxation and facilitate endotracheal intubation, as an adjunct to surgical anesthesia

2. Limit the trauma that could result from excessive skeletal muscle contraction during electroconvulsive shock therapy

3. Relax the skeletal muscles and facilitate bone placement and manipulations during orthopedic procedures

D. Adverse effects

1. Competitive nondepolarizing agents can cause respiratory paralysis, histamine release, bronchospasm, and hypotension (e.g., tubocurarine) or respiratory paralysis, tachycardia, and hypertension (e.g., pancuronium).

2. Noncompetitive depolarizing agents (e.g., succinylcholine, gallamine) can cause respiratory paralysis, muscle fasciculation with pain, extraocular muscle contraction with increased intraocular pressure, and increased intragastric pressure. In addition, succinylcholine may cause muscarinic responses such as bradycardia, increased glandular secretions, and cardiac arrest. In combination with the anesthetic halothane, succinylcholine may cause malignant hyperthermia in genetically predisposed individuals.

VII. GENERAL ANESTHETICS

induce a combined state of analgesia, amnesia, loss of consciousness, inhibition of sensory and autonomic reflexes, and skeletal muscle relaxation. Ideal general anesthetics induce anesthesia rapidly and smoothly and permit rapid recovery of the patient once administration of the agent ceases.

A. Chemistry

1. Volatile or inhalation anesthetics are drugs inhaled as gases or vapors. These diverse drugs are relatively simple lipophilic molecules. They include the inorganic agent nitrous oxide (N_2O) and the **nonflammable** halogenated hydrocarbons (e.g., halothane) and ethers (e.g., methoxyflurane, isoflurane, desflurane, sevoflurane).

2. Nonvolatile or intravenous anesthetics are administered intravenously or occasionally intramuscularly and come as aqueous solutions, aqueous propylene glycol solutions, or emulsions.

a. The **water-soluble** and relatively short-acting agents include ultra-short-acting barbiturates (e.g., thiopental, methohexital, thiamylal), cyclohexylamines (e.g., ketamine), benzo-diazepines (e.g., diazepam, midazolam), butyrophenones (e.g., droperidol), and opioid analgesics (e.g., morphine, fentanyl).

b. The imidazole, etomidate, is prepared as an **aqueous propylene glycol solution,** which is compatible with many preanesthetics.

c. The dialkylphenol, propofol, is administered as an **emulsion,** which should not be mixed with other therapeutic agents before administration (Figure 13-14).

B. Pharmacology

1. General anesthetics depress the CNS, producing a reversible loss of consciousness and loss of all forms of sensation.

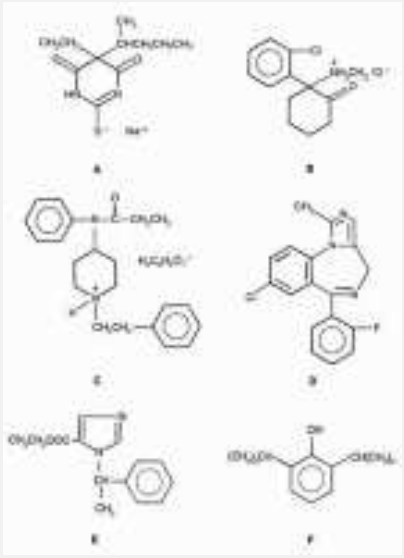

Figure 13-14. Structural formulas of nonvolatile general anesthetics: **(A)** thiopental sodium (Pentothal), **(B)** ketamine hydrochloride (Ketaject), **(C)** fentanyl citrate (Sublimaze), **(D)** midazolam (Versed), **(E)** etomidate (Amidate), and **(F)** propofol (Diprivan).

2. Inhalational anesthetics are absorbed and primarily excreted through the lungs. Frequently, these drugs are supplemented with analgesics, a skeletal muscle relaxant, and an antimuscarinic agent.

a. Analgesics permit a reduction in the required concentration of inhalational anesthetic.

b. Skeletal muscle relaxants cause adequate muscle relaxation during surgery.

c. **Antimuscarinic agents** decrease buccal and bronchiolar secretions.

3. Nonvolatile anesthetics are usually administered intravenously (e.g., thiobarbiturates, benzodiazepines), but some agents may also be given intramuscularly (e.g., ketamine).

C. Therapeutic indications

1. Inhalational anesthetics are indicated to provide general surgical anesthesia.

2. Nonvolatile anesthetics (e.g., thiopental, diazepam, midazolam) are indicated to induce drowsiness and provide relaxation before the induction of inhalational general anesthesia.

3. Use of some previously popular volatile anesthetics has been discontinued because of serious toxicity (e.g., chloroform) or because of the flammable and explosive properties of the compounds (e.g., cyclopropane, diethylether).

D. Adverse effects. General anesthetics depress respiration, circulation, and the CNS. They can also decrease hepatic and kidney function (e.g., methoxyflurane) and cause cardiac dysrhythmias as a result of increased myocardial sensitivity to catecholamines (e.g., halothane).

VIII. LOCAL ANESTHETICS

A. Chemistry. Most local anesthetics are structurally similar to the alkaloid cocaine (Figure 13-15). These drugs consist of a hydrophilic amino group linked through an ester or amide connecting group to a lipophilic aromatic moiety. A few phenols and aromatic alcohols also have local anesthetic activity.

1. Ester-type agents are generally short acting due to rapid hydrolysis by plasma esterases. These agents include cocaine, procaine, chloroprocaine, benzocaine, butamben, and tetracaine.

2. Amide-type agents are generally longer acting and are metabolized in the liver. Examples of the amide-type local anesthetics include lidocaine, dibucaine, prilocaine, mepivacaine, bupivacaine, and etidocaine.

3. The drug's pK_a (or dissociation constant) influences its chemical state, which in turn determines the anesthetic effectiveness of the compound. The site of anesthetic action is at the inner surface of the cell membrane. At tissue pH, the drug is in the form of a lipophilic, uncharged, secondary or tertiary amine, and thus diffuses across connective tissue and cell membranes and enters nerve cells where it is ionized to a charged ammonium cation. The cationic form of the drug is the active form of the drug that blocks the generation of action potentials at the membrane receptor complex. Also, because of its charged ammonium cation, the intracellular ionized molecule poorly penetrates the cell membrane and thus remains trapped within the cell, thereby enhancing its duration of action.

B. Pharmacology

1. Local anesthetics **reversibly block nerve impulse conduction** and **produce reversible loss of sensation** at their administration site. They do not produce a loss of consciousness.

a. Small, nonmyelinated nerve fibers, which conduct pain and temperature sensations, are affected first.

b. Local anesthetics appear to become entrapped within the nerve membrane or to bind to specific membrane sodium ion (Na^+) channels, restricting Na^+ permeability in response to partial depolarization.

2. Local anesthetic solutions frequently contain the vasoconstrictor **epinephrine,** which reduces vascular blood flow at the administration site. This prolongs the duration of action, and reduces systemic absorption, and hence systemic toxicity.

Figure 13-15. Structural formulas of local anesthetics structurally similar to cocaine: **(A)** procaine (Novocaine) and **(B)** lidocaine (Xylocaine).

C. Therapeutic indications. Local anesthetics are indicated to:

1. Produce regional nerve block for the relief of pain when injected close to the innervating nerve

2. Provide anesthesia for minor operations when infiltrated around the tissue site

3. Provide anesthesia for surgery of the lower limbs and pelvis and for obstetric surgery when injected into the epidural space or the subarachnoid space of the spinal cord

4. Provide anesthesia of the skin and mucous membranes when applied locally. This includes two miscellaneous local anesthetics: **dyclonine,** used primarily in throat lozenges and sprays, and **pramoxine,** used primarily in antihemorrhoidal preparations.

D. Adverse effects

1. Ester-type local anesthetics can cause hypersensitivity reactions in susceptible individuals.

2. Systemic absorption of toxic concentrations of local anesthetics can cause seizures; CNS, respiratory, and myocardial depression; and circulatory collapse.

IX. ANTIPSYCHOTICS.

The classic antipsychotic agents are the phenothiazines, thioxanthenes, and butyrophenones. Chemical classes of newer compounds having antipsychotic

activity include the dihydroindolones (e.g., molindone), dibenzoxazepines (e.g., loxapine), dibenzodiazepines (e.g., clozapine), diphenylbutylpiperidines (e.g., pimozide), and benzisoxazoles (e.g., risperidone).

A. Chemistry

1. Phenothiazines (e.g., chlorpromazine, triflupromazine, thioridazine, prochlorperazine, trifluoperazine, fluphenazine) must have a **nitrogen-containing side-chain substituent** on the ring nitrogen for antipsychotic activity (Table 13-6). The ring and side-chain nitrogens must be separated by a three-carbon chain; phenothiazines in which the ring and side-chain nitrogens are separated by a two-carbon chain have only antihistaminic or sedative activity.

a. The side chains are either aliphatic, piperazine, or piperidine derivatives. Piperazine side chains confer the greatest potency and the highest pharmacological selectivity.

b. Fluphenazine and long-chain alcohols form stable, **highly lipophilic esters** (e.g., enanthate, decanoate), which possess markedly prolonged activity.

2. Thioxanthenes (e.g., chlorprothixene, thiothixene) lack the ring nitrogen of phenothiazines and have a side chain attached by a double bond (Figure 13-16).

3. Butyrophenones (e.g., haloperidol) are chemically unrelated to phenothiazines but have similar activity (Figure 13-17).

4. Newer agents derive from diverse chemical classes and include clozapine, olanzapine, loxapine, pimozide, molindone, quetiapine, risperidone, remoxipride, ziprasidone and **aripiprazole.**

B. Pharmacology

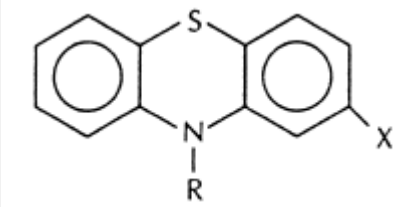
1. These agents have generally **similar** pharmacodynamic effects in the treatment of psychotic illness. Their antipsychotic action (i.e., improvement of cognitive and behavioral abnormalities) results primarily from their blockade of dopamine receptors in cortical and limbic areas of the brain, whereas their adverse extrapyramidal effects such as parkinsonian reactions result from antagonism of dopamine receptors in the basal ganglia.

2. Other effects vary among the classes of antipsychotics. These include antiemetic activity and blockade of muscarinic, serotonergic, α_1-adrenergic, and H_1-histaminergic receptors.

3. The atypical antipsychotics (e.g., clozapine, aripiprazole) are newer agents that show strong antagonistic properties at serotonin receptors in addition to their blockade of dopamine receptors. Compared to the phenothiazines, butyrophenones, and other classic antipsychotic drugs, the atypical agents are effective in ameliorating a wider range of symptoms, including negative symptoms, and they also are less likely to induce extrapyramidal side effects.

Table 13-6. Antipsychotic Phenothiazines

General Phenothiazine Structure*



Drug	X-Substituent	R-Substituent*
Chlorpromazine (Thorazine)	**-Cl**	**$-(CH_2)_3-N(CH_3)_2$**
Trifluprom azine (Vesprin)	**$-CF_3$**	**$-(CH_2)_3-N(CH_3)_2$**
Thioridazine (Mellaril)	**$-SCH_3$**	Prochlorperazine (Compazine)	**-Cl**	Trifluoperazine (Stelazine)	**$-CF_3$**	Fluphenazine (Prolixin)	**$-CF_3$**	
* Antipsychotic phenothiazines have the general structure illustrated in the table. Substituents at positions marked X and R result in different drugs.

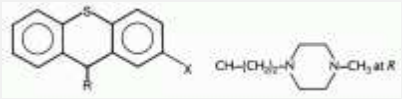

Figure 13-16. Thioxanthenes, similar to phenothiazines, have substituents at X and R positions that alter drug activity. Chlorprothixene (Taractan) has a —Cl substituent at X and CH—$(CH_2)_2$—$N(CH_3)_2$ at R. Thiothixene (Navane) has a—SO_2 $N(CH_3)_2$ substituent at X and the group:

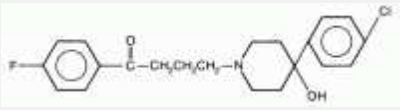

Figure 13-17. Structural formula of haloperidol (Haldol), a butyrophenone antipsychotic.

Figure 13-18. Structural formulas of **(A)** phenelzine (Nardil), a hydralazine derivative monoamine oxidase (MAO) inhibitor, and **(B)** tranylcypromine (Parnate), a cyclopropylamine derivative MAO inhibitor.

C. Therapeutic indications. Antipsychotics are indicated primarily for the treatment of psychosis associated with schizophrenia (e.g., haloperidol, aripiprazole), paranoia, and Tourette's syndrome (e.g., pimozide). Promethazine and other classic agents are used as antiemetics based on their blockade of dopamine receptors in the chemoreceptor trigger zone of the medulla and in the stomach.

D. Adverse effects

1. Centrally mediated adverse effects include drowsiness; extrapyramidal symptoms such as akathisia, acute dystonia, akinesia, and tardive dyskinesia; alteration of temperatureregulating mechanisms including poikilothermy; increased appetite and weight gain; and alterations in hypothalamic and endocrine function such as increased release of corticotropin, gonadotropins, prolactin, growth hormone, and melanocyte-stimulating hormone.

2. Peripheral adverse effects include postural hypotension and reflex tachycardia; hepatotoxicity and jaundice; failure of ejaculation; bone marrow depression; photosensitivity; xerostomia; and blurred vision.

X. ANTIDEPRESSIVE AND ANTIMANIC AGENTS

may be broadly classified into five structurally and mechanistically unrelated groups: the MAO inhibitors, classical or tricyclic antidepressants, selective serotonin reuptake inhibitors (SSRIs), third-generation or atypical antidepressants, and antimanic antidepressants or mood stabilizers.

A. Chemistry

1. MAO inhibitors may be weakly potent **hydralazines** (e.g., phenelzine) or extremely potent **phenylcyclopropylamines** such as tranylcypromine which is a ring-closed amphetamine derivatives (Figure 13-18).

2. Tricyclic antidepressants, which are used commonly, are secondary or tertiary amine derivatives of molecules that have a fused three-ring system.

a. The principal tricyclic antidepressants are derivatives of dibenzazepine (e.g., **imipramine,** desipramine, clomipramine, trimipramine) and dibenzocycloheptadiene (e.g., amitriptyline, nortriptyline, protriptyline) (Figures 13-19 and 13-20).

Figure 13-19. Structural formulas of tricyclic antidepressants derived from dibenzazepine: **(A)** imipramine (Tofranil) and **(B)** desipramine (Norpramin).

Figure 13-20. Structural formulas of tricyclic antidepressants derived from dibenzocycloheptadiene: **(A)** amitriptyline (Elavil) and **(B)** nortriptyline (Aventyl).

b. Other closely related tricyclic antidepressants include doxepin, a dibenzoxepine, and amoxapine, a dibenzoxazepine.

3. Atypical antidepressants have varied structures ranging from the simple phenethylamine venlafaxine and the phenylpiperazine nefazodone to the aminoketone bupropion and the complex heterocyclics maprotiline and mirtazepine.

4. SSRIs have varied chemical structures and are related only by their pharmacologically common ability to inhibit the reuptake of serotonin from the synaptic cleft. These compounds include fluoxetine, paroxetine, sertraline, and fluvoxamine (Figure 13-21).

5. Lithium is an alkali metal that is used in the form of the carbonate salt in the treatment of manic depression or bipolar disease. Other agents in this therapeutic category include the organic compounds **valproic acid** and **carbamazepine.**

B. Pharmacology

1. MAO inhibitors appear to produce their antidepressant effects by blocking the intraneuronal oxidative deamination of brain biogenic amines (e.g., dopamine, norepinephrine, serotonin). This action increases the availability of biogenic amines at central aminergic synapses, and hence the probability of interaction with postsynaptic receptors to elicit the desired therapeutic effects. Other biochemical events (e.g., the down-regulation of central β-adrenergic and serotonergic receptors) that result from chronic inhibition of MAO and reuptake blockade can also explain the therapeutic action of antidepressants. This explanation is suggested by the latency period of MAO inhibitors, which take 2-4 weeks to become effective.

2. Tricyclic antidepressants appear to act principally by reducing CNS neuronal reuptake of the biogenic amines norepinephrine and serotonin. This prolongs the synaptic availability of biogenic amines and hence their action at central aminergic receptors.

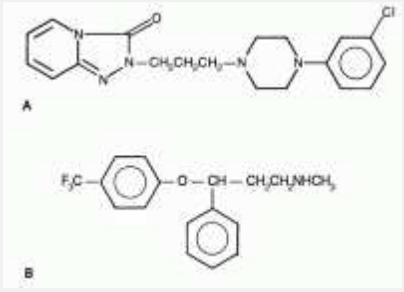

Figure 13-21. Structural formulas of **(A)** trazodone (Desyrel) and **(B)** fluoxetine (Prozac), atypical antidepressants.

3. SSRIs and atypical antidepressants have varying effects on reuptake of biogenic amines. The SSRIs selectively inhibit serotonin reuptake into the nerve terminal, thus prolonging the synaptic activity of the amine. Trazodone and other heterocyclics also inhibit amine transmitter reuptake. While bupropion appears to selectively inhibit dopamine reuptake, its mechanism may involve additional currently unknown actions since some other inhibitors of dopamine reuptake may not exhibit antidepressive effects.

4. Lithium appears to interfere with transmembrane Na^+ exchange, alters the release of aminergic neurotransmitters, and blocks inositol metabolism, ultimately leading to depletion of cellular inositol and inhibition of phospholipase C-mediated signal transduction. The relevance of these actions to the mood-stabilizing effects of lithium, however, has not been established. **Carbamazepine and valproic acid** are known to interfere with ionic conductances in nerve cells, and to modulate other intracellular signaling cascades, but the contributions of these actions to their clinical effectiveness in bipolar disorder remain unclear.

C. Therapeutic indications

1. MAO inhibitors are indicated to treat depression, phobic anxiety, and narcolepsy that has not responded to other treatments. However, their use is limited by their adverse effects (see X.D.1).

2. Tricyclic and atypical antidepressants and the SSRIs are the agents of choice for endogenous depression. Additionally, imipramine is used to treat enuresis; clomipramine, fluoxetine, and fluvoxamine are used in obsessive-compulsive disorder; and doxepin, for anxiety.

3. Lithium and valproic acid are indicated for the treatment of manic-depression (or bipolar disease). The antiepileptic drug, carbamazepine, has also been used as a mood-stabilizer in bipolar illness.

D. Adverse effects

1. MAO inhibitors interact with sympathomimetic drugs and with foods that have a high tyramine content such as cheese, wine, and sausage. Hypertensive crises can result. In addition, MAO inhibitors can cause a wide range of adverse effects, including:

a. CNS effects, such as CNS stimulation, tremors, agitation, overactivity, hyperreflexia, mania, and insomnia followed by weakness, fatigue, and drowsiness

b. Cardiovascular effects, such as postural hypotension

c. GI effects, such as nausea, abdominal pain, and constipation

d. Antimuscarinic effects, such as dry mouth, urinary retention, and constipation

2. Tricyclic antidepressants can cause adverse effects, including:

a. CNS effects, such as drowsiness, dizziness, weakness, fatigue, and confusion

b. Cardiovascular effects, such as orthostatic hypotension, tachycardia, and interference with atrioventricular conduction

c. Antimuscarinic effects, such as dry mouth, urinary retention, and constipation

d. GI effects, such as nausea, vomiting, diarrhea, and anorexia

e. Bone marrow depression

f. Mania precipitation (in patients with manic-depressive illness)

3. Atypical antidepressants can cause adverse effects, including:

a. CNS effects, such as dizziness, nightmares, confusion, drowsiness, fatigue, headache, insomnia, impaired memory, akathisia, numbness, and tonic-clonic seizures

b. Cardiovascular effects, such as hypertension, hypotension, tachycardia, chest pain, and syncope

c. GI effects, such as nausea, vomiting, diarrhea, and constipation

d. Blurred vision and tinnitus

e. Antimuscarinic effects, such as urinary retention, dry mouth, and constipation

f. Bone marrow depression

g. Sexual dysfunction and menstrual irregularities

4. Lithium therapy may be associated with development of fine hand tremors and increased urination; these side effects, however, usually diminish with continued therapy.

XI. ANXIOLYTICS AND SEDATIVE-HYPNOTICS.

Antianxiety and sedative-hypnotic agents in current use comprise the highly effective benzodiazepines (e.g., alprazolam, diazepam, flurazepam) and the atypical azaspirodecanediones (e.g., buspirone) and imidazopyridines (e.g., zolpidem). Diverse classes of agents previously used as anxiolytics and sedative-hypnotics (e.g., barbiturates, meprobamate, and hydroxyzine) are no longer favored because of their liability to produce tolerance, physical dependence, severe withdrawal reactions, and serious toxicity with overdosage.

A. Chemistry

1. Benzodiazepines (e.g., alprazolam, diazepam, chlordiazepoxide, clonazepam, clorazepate, lorazepam, and oxazepam) have varying durations of action, which can be correlated with their structures in some cases (Table 13-7).

a. Agents with a 3-hydroxyl group are easily metabolized by phase II glucuronidation and are short acting (see R3-substituent column in Table 13-7).

b. Agents lacking a 3-hydroxyl group must undergo considerable phase I metabolism, including 3-hydroxylation. These agents are long acting. Most long-acting agents form the intermediate metabolite desmethyldiazepam, which has a very long half-life. Thus, these agents can have a cumulative action.

c. Triazolobenzodiazepines (e.g., alprazolam) undergo a different pattern of metabolism and are intermediate in activity.

d. Agents lacking an amino side chain are not basic enough to form water-soluble salts with acids. For example, intravenous solutions of diazepam contain propylene glycol as a solvent. Precipitation can occur if these solutions are mixed with aqueous solutions.

2. Azaspirodecanediones or azapirones (e.g., buspirone, gepirone, ipsapirone, tiaspirone) are chemically unrelated to the benzodiazepines. Represented by buspirone, these agents have anxiolytic activity resembling that of the benzodiazepines. Unlike the benzodiazepines, buspirone lacks CNS depressant activity and is considered an atypical anxiolytic (Figure 13-22).

3. The **imidazopyridine** zolpidem is a nonbenzodiazepine sedative-hypnotic with actions generally resembling those of the benzodiazepines.

4. Barbiturates are 5,5-disubstituted derivatives of barbituric acid, a saturated triketopyrimidine (Table 13-8).

a. Two side chains in position 5 are essential for sedative-hypnotic activity.

b. Long-acting agents have a phenyl and an ethyl group in position 5.

c. Branched side chains, unsaturated side chains, or side chains longer than an ethyl group increase lipophilicity and metabolism rate. Increased lipophilicity leads to a shorter onset of action, a shorter duration of action, and increased potency.

d. Replacement of the position 2 oxygen with sulfur produces an extremely lipophilic molecule that distributes rapidly into lipid tissues outside the brain.

(1) These ultra-short-acting barbiturates are not useful as sedative-hypnotics but are effective in facilitating the induction of anesthesia (see XII.C.4). The action of these drugs is terminated very quickly.

(2) The prototype ultra-short-acting barbiturate is thiopental (Pentothal), the 2-thio isostere of pentobarbital.

e. The barbiturates and many of their metabolites are weak acids, and changes in urinary pH greatly influence their excretion. This is particularly true with overdoses, when a relatively large amount of unchanged drug appears in the glomerular filtrate.

f. Phenobarbital is one of the most powerful and versatile agents that can induce certain enzyme systems (e.g., the cytochrome P-450 metabolic system). This increases the potential for drug interactions and includes interaction with any drug metabolized by this system. Other barbiturates have less enzyme-inducing effect, except when they are used continuously in higher-than-normal doses.

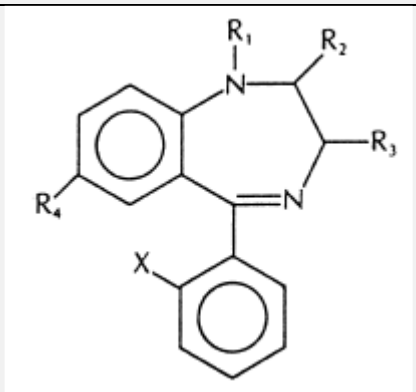
5. Piperidinediones (e.g., glutethimide, methyprylon) and **aldehydes** (e.g., paraldehyde, chloral hydrate) differ structurally (Figure 13-23) and are used less commonly than the benzodiazepines as sedative-hypnotics.

B. Pharmacology

1. Benzodiazepines appear to produce their calming and hypnotic effects by depressing the limbic system and reticular formation through potentiation of the inhibitory neurotransmitter γ-aminobutyric acid (GABA).

Table 13-7. Benzodiazepine Anxiolytics and Sedative-Hypnotics

General Benzodiazepine Structure*



Drug	R_1	R_2	R_3	X (R_2')	Comments
Diazepam (Valium)	—CH_3	=O	—H	—H	
Chlordiazepoxide (Librium)	= (Ring double bond)	—NH—CH_3	—H	—H	—O (N-oxide) at position 4
Halazepam (Paxipam)	—CH_2CF_3	=O	—H	—H	
Clorazepate (Tranxene)	—H	=OH (—OK)	—COOH (—COOK)	—H	

Oxazepam (Serax)	—H	=O	—OH	—H
Lorazepam (Ativan)	—H	=O	—OH	—Cl
Alprazolam (Xanax)	R1-C(CH_3)=N-N=R2 (Fused R1-R2 triazolo ring)	—H	—H	
Flurazepam (Dalmane)	$CH_2CH_2N(C_2H_5)_2$	=O	—H	—F
Quazepam (Doral)	—CH_2CF_3	=S	—H	—F
Triazolam (Halcion)	R1-C(CH_3)=N-N=R2 (Fused R1-R2 triazolo ring)	—H	—H	
Temazepam (Restoril)	—CH_3	=O	—OH	—H

* Benzodiazepine anxiolytics and sedative-hypnotics have the general structure illustrated in the table. Substituents at the positions marked R_1, R_2, R_3, R_7, and X (R_2') and the ring nitrogen at the position 2 result in different drugs and clinical properties. All compounds shown have Cl substitution at position R_7. Clonazepam, not shown, has an NO_2 substituent at R_7 and is used primarily as an anticonvulsant.

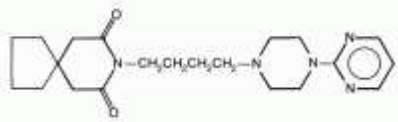


Figure 13-22. Structural formula of buspirone (Buspar), the prototypical azaspirodecanedione anxiolytic.

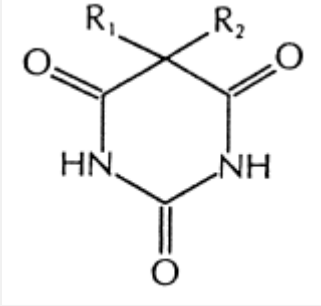
Table 13-8. Barbiturate Sedative-Hypnotics

General Barbiturate Structure*



Drug	R_1-Substituent	R_2-Substituent	Duration of Action
Phenobarbital (Luminal)	$-CH_2CH_3$		Long
Amobarbital (Am	$-CH_2CH_3$	$-CH_2CH_2CH(CH_3)_2$	Intermediate

ytal)			
Butabarbital (Butisol)	—CH_2 CH_3		Intermediate
Pentobarbital (Nembutal)	—CH_2 CH_3		Short

Secobarbital (Seconal)	—CH_2CH=CH_2		Short

* Barbiturate sedative-hypnotics have the general structure illustrated in the table. Substituents at R_1 and R_2 positions result in different drugs with different durations of action.

a. Anxiolytic activity correlates with the drug's binding affinity to a macromolecular complex consisting of GABAA receptors and chloride channels.

b. The interaction of benzodiazepines with GABA causes an increase in the frequency of chloride channel opening events, leading to a facilitation of chloride ion conductance, membrane hyperpolarization, and ultimately synaptic inhibition.

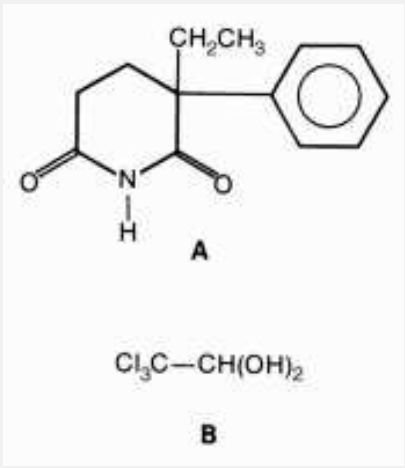


Figure 13-23. Structural formulas of **(A)** glutethimide (Doriden), a piperidinedione sedative-hypnotic and **(B)** chloral hydrate (Noctec), an aldehyde sedative-hypnotic.

c. In addition to their anxiolytic properties, most benzodiazepines have other significant CNS actions, including hypnotic, anesthetic, anticonvulsant, and muscle relaxant effects at appropriate doses.

d. Benzodiazepines increase the depressant effects of alcohol and other CNS depressant drugs.

2. Azaspirodecanediones have multiple biochemical actions, but their principal mechanism of anxiolytic effect is still unknown.

a. Buspirone binds to central dopamine and serotonin receptors rather than to GABA-chloride ionophore receptor complexes. Interactions of azapirones with serotonin receptors may be agonistic when acting at somatodendritic 5-$HT1_A$ autoreceptors or antagonistic when acting at postsynaptic 5-$HT1_A$ receptors.

b. Buspirone possesses no hypnotic or anticonvulsant properties and does not appear to enhance the depressant effects of alcohol or other CNS depressant drugs.

c. Buspirone has minimal abuse liability and does not produce rebound anxiety following abrupt discontinuation.

3. The imidazopyridines have strong sedative effects with minimal clinical anxiolytic actions.

a. Zolpidem is as effective as the benzodiazepines in shortening sleep latency and in prolonging total sleep time in patients with insomnia.

b. Zolpidem is rarely associated with physical dependence, rebound insomnia, or respiratory depression even in overdosage.

4. Barbiturates are less selective than benzodiazepines and produce generalized CNS depression.

a. Barbiturates bind to a site that is distinct from the benzodiazepine binding site on a macromolecular GABA-chloride ionophore receptor complex. Barbiturate binding induces an increase in the duration of channel opening events, and thus mimics or enhances the inhibitory actions of GABA.

b. Barbiturates have a wide range of dose-dependent pharmacological actions related to CNS depression, including sedation, hypnosis, and anesthesia. They also act as potent respiratory depressants and inducers of hepatic microsomal drug-metabolizing enzyme activity.

5. Piperidinediones, aldehydes, and other nonbarbiturate sedative-hypnotics have similar pharmacological actions related to CNS depression.

a. Chloral hydrate is commonly used to induce sleep in pediatric or geriatric patients. Its low cost is the major factor accounting for its preferred usage in institutional settings.

b. Chloral hydrate is biotransformed to trichloroethanol, which is responsible for the pharmacological activity of the drug. Chloral hydrate induces hepatic microsomal drug-metabolizing enzyme activity.

C. Therapeutic indications

1. Benzodiazepines and the azaspirodecanedione buspirone are indicated to treat anxiety. Buspirone is more effective in patients with generalized anxiety of mild to moderate severity. The antianxiety effects of buspirone may require up to a week to be established.

2. Benzodiazepines and the imidazopyridine are indicated to produce drowsiness and promote sleep.
3. Benzodiazepines are indicated for use as a preanesthetic medication, as anticonvulsants, and during acute alcohol withdrawal.
4. Barbiturates are no longer considered appropriate as anxiolytics or sedative-hypnotics in view of the availability of the safer benzodiazepines. Long-acting barbiturates continue to be widely used as antiepileptics, while the ultra-short-acting barbiturates are used for the induction of general anesthesia and as general anesthetics (in combination with an analgesic) for short surgical procedures.
5. Chloral hydrate is indicated for use as a pediatric or geriatric hypnotic, and also as a preanesthetic agent for minor surgical and dental procedures.

D. Adverse effects
1. Adverse effects associated with **benzodiazepines** include:
a. CNS effects, such as CNS depression, drowsiness, sedation, ataxia, confusion, and dysarthria
b. GI effects, such as nausea, vomiting, and diarrhea
c. Psychiatric effects are rare and include paradoxical excitement, insomnia, paranoia, and rage reactions
d. Potential for abuse and dependence
2. Adverse effects of **buspirone** are limited to restlessness, dizziness, headache, nausea, diarrhea, and paresthesias.
3. Barbiturates can cause a variety of adverse effects, including:
a. CNS effects, such as drowsiness, confusion, nystagmus, dysarthria, depressed sympathetic ganglionic transmission, hyperalgesia, impaired judgment, impaired fine motor skills, paradoxical excitement (in geriatric patients), and potentiation of other CNS depressant drugs.
b. Respiratory and cardiovascular effects, such as respiratory depression, bradycardia, and orthostatic hypotension.
c. GI effects, such as nausea, vomiting, constipation, diarrhea, and epigastric distress.
d. Exfoliative dermatitis and Stevens-Johnson syndrome.
e. Headache, fever, hepatotoxicity, and megaloblastic anemia (with the chronic use of phenobarbital).
4. Trichloroethanol, the active metabolite of **chloral hydrate,** is metabolized to trichloroacetic acid, which is highly toxic and tends to accumulate with repeated administration of chloral hydrate. Use of chloral hydrate is associated with the following adverse effects.
a. GI effects, such as GI irritation and upset, nausea, and vomiting.
b. CNS effects, such as CNS depression, disorientation, incoherence, drowsiness, ataxia, headache, and potentiation of other CNS depressants (particularly alcohol).
c. Leukopenia

XII. ANTIEPILEPTICS

A. Chemistry. Antiepileptics (anticonvulsants) vary widely in structure (Figure 13-24).

1. Older agents, which are still widely used, include derivatives of the long-acting barbiturates (e.g., phenobarbital, mephobarbital, metharbital, primidone), hydantoins (e.g., phenytoin, ethotoin), succinimides (e.g., ethosuximide, phensuximide), oxazolidinediones (e.g., trimethadione, dimethadione), and dialkylacetates (e.g., valproic acid).

2. Newer agents, which are more structurally diverse, include the iminostilbenes (e.g., carbamazepine), benzodiazepines (e.g., diazepam, clonazepam, clorazepate), GABA analogs (vigabatrin, gabapentin, pregabalin), and the miscellaneous agents lamotrigine, felbamate, levetiracetam, zonisamide, and topiramate which is actually a substituted monosaccharide.

B. Pharmacology

1. Antiepileptics prevent or reduce excessive discharge and reduce the spread of excitation from CNS seizure foci.

2. The mechanisms of action of antiepileptics appear to be alteration of Na^+ neuronal concentrations by promotion of Na^+ efflux (e.g., hydantoins) and restoration or enhancement of GABA-ergic inhibitory neuronal function (e.g., barbiturates, benzodiazepines, valproic acid).

C. Therapeutic indications. These agents are generally categorized by the type of seizure against which they are effective.

1. Drugs that are indicated for the treatment of **tonic-clonic (grand mal) seizures** include phenobarbital, phenytoin, primidone, and carbamazepine.

2. Drugs that are indicated for the treatment of **absence (petit mal) seizures** include phenobarbital, ethosuximide, trimethadione, clonazepam, and valproic acid.

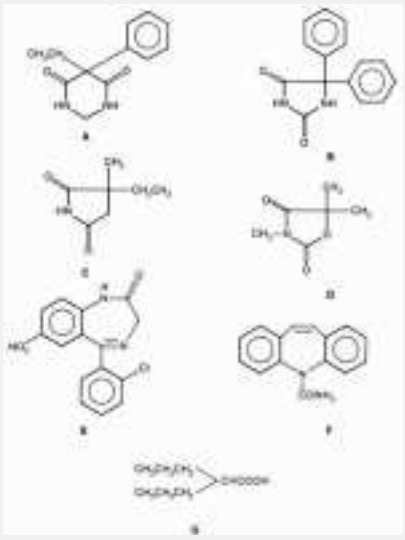

Figure 13-24. Structural formulas of the antiepileptic agents: **(A)** primidone (Mysoline), **(B)** phenytoin (Dilantin), **(C)** ethosuximide (Zarontin), **(D)** trimethadione (Tridione), **(E)** clonazepam (Klonopin), **(F)** carbamazepine (Tegretol), and **(G)** valproic acid (Depakene).

3. Clonazepam is indicated for the treatment of **myoclonic seizures.**

4. Agents that are effective against **partial seizures** include clorazepate, felbamate, gabapentin, and lamotrigine.
5. Phenytoin, phenobarbital, primidone, and carbamazepine are effective against **psychomotor seizures.**
6. Intravenous diazepam, phenytoin, and phenobarbital are indicated for the treatment of **status epilepticus.**
7. Topiramate has multiple mechanisms of action and exerts beneficial effects against a broad spectrum of seizures.
D. Adverse effects
1. Barbiturates (see XII.D.3) and **benzodiazepines** (see XII.D.1) used as antiepileptics have the same adverse effects as when used for anxiolytic or sedative-hypnotic purposes. Intravenous use of these agents could cause cardiovascular collapse and respiratory depression.

2. Antiepileptic agents generally have the propensity to cause the following side effects:
a. GI irritation, nausea, and vomiting
b. CNS sedation, diplopia, nystagmus, ataxia, dizziness, and confusion
c. Blood dyscrasias, including aplastic anemia and bleeding disorders
d. Allergic-type reactions, including Stevens-Johnson syndrome
e. Various organ-system toxicities, including renal and liverfailure, pancreatitis, and cardiotoxicity
3. The hydantoins (e.g., phenytoin) can also cause specific **arrhythmias** and **gingival hyperplasia.**
4. Antiepileptics as a class also have the potential to cause various **birth defects,** including cleft palate (e.g., carbamazepine, phenytoin) and neural tube defects (e.g., valproic acid). These effects present a unique problem in treating pregnant women with convulsive disorders. Discontinuation of anticonvulsant therapy can result in a seizure state that could harm the fetus. However, continued therapy can increase the risk of birth defects and place the mother at risk of bleeding disorders during delivery. Moreover, pregnancy by itself can either increase or decrease seizure incidence of the mother. Risk/benefit evaluation of therapy should be made on individual cases based on the patient's history.

XIII. ANTIPARKINSONIAN AGENTS

A. Chemistry. The principal antiparkinsonian agents are either **dopaminergic agonists** or **cholinergic antagonists.**
1. Some **anticholinergic antiparkinsonian** agents are structurally related to **atropine** (e.g., benztropine, trihexyphenidyl). Other antiparkinsonian anticholinergic agents include procyclidine (Kemadrin), orphenadrine (Norflex), and biperiden (Akineton).
2. The prototypical **dopaminergic** antiparkinsonian agent is the **catecholamine levodopa** (Figure 13-25), a prodrug that must be converted in vivo to dopamine by

dopa decarboxylase. Direct receptor-acting dopaminergics include **ergolines** such as bromocriptine (Parlodel)
P.310

and pergolide (Permax), the phenanthrene **apomorphine,** and the newer nonergoline dopamine agonists **pramipexole** (Mirapex) and **ropinirole** (Requip).

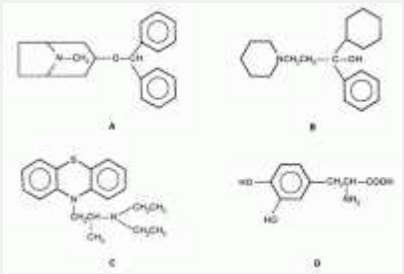

Figure 13-25. Structural formulas of antiparkinsonian agents: **(A)** benztropine (Cogentin), **(B)** trihexyphenidyl (Artane), **(C)** ethopropazine (Parsidol), and **(D)** levodopa (Larodopa).

3. Several agents are available to improve the therapeutic efficacy and safety of levodopa.
a. Carbidopa, a levodopa analogue that does not cross the blood-brain barrier, is a **decarboxylase inhibitor** that diminishes the decarboxylation and subsequent inactivation of levodopa in **peripheral tissues.** When coadministered, more levodopa is preserved to enter the CNS. A combination of levodopa and carbidopa (Sinemet) is available for clinical use.
b. Selegiline (deprenyl), is a **selective monoamine oxidase-B (MAO-B) inhibitor** that inhibits the intracerebral degradation of endogenous or levodopa-derived dopamine.
c. **Tolcapone** or **entacapone** are selective inhibitors of COMT, thus reducing the conversion of levodopa to 3-O-methyldopa, an inactive metabolite that also inhibits levodopa uptake into the brain. Additionally, inhibition of dopamine breakdown by COMT may prolong the availability and action of the transmitter in the CNS.
B. Pharmacology. Antiparkinsonian agents act by restoring the striatal balance of dopaminergic and cholinergic neurotransmission, which is deranged in parkinsonism as a result of degeneration of dopaminergic neurons that supply dopamine to the **basal ganglia (caudate-putamen).**
1. Levodopa, which can cross the blood-brain barrier, is the immediate precursor of the striatal neurotransmitter dopamine and is converted to dopamine in the body.
2. Amantadine, an antiviral agent, appears to stimulate the release of dopamine from intact striatal terminals of remaining dopaminergic neurons. As the disease progresses and fewer dopaminergic neurons remain, amantadine becomes progressively ineffective.

3. Apomorphine, bromocriptine, pergolide, pramipexole, and ropinirole, which are direct dopaminergic receptor agonists, mimic the activity of dopamine in the caudate-putamen. Nevertheless, the drugs cannot reproduce the pulsatile rhythm of endogenous dopamine release.
4. Selegiline, an inhibitor of the central MAO-B isoenzyme, blocks the central catabolism of dopamine, increasing its availability in the caudate-putamen.
5. Anticholinergics, such as trihexyphenidyl, benztropine, and orphenadrine, block the excitatory cholinergic system, thus reducing the functional imbalance between dopamine and acetylcholine in the striatum.
6. The enzyme inhibitors, **carbidopa and tolcapone,** increase the transport and bioavailability of levodopa in the brain and are thus given as adjunctive treatments with levodopa.

C. Therapeutic indications

1. Levodopa, currently the most effective treatment for parkinsonism, is indicated to treat idiopathic, postencephalitic, or arteriosclerotic forms of the disease.
2. Amantadine is indicated to treat idiopathic, postencephalitic, or arteriosclerotic parkinsonism, as well as extrapyramidal symptoms (except tardive dyskinesia) induced by antipsychotic drugs.
3. Apomorphine (Apokyn) has been approved for treating the rigidity and akinesia or immobility associated with Parkinson disease.
4. Bromocriptine is indicated to treat idiopathic or postencephalitic parkinsonism.
5. Selegiline, anticholinergics, and **antihistamines** are indicated for use as adjunctive therapy for all types of parkinsonism, including drug-induced extrapyramidal symptoms (with the exception of tardive dyskinesia).

D. Adverse effects

1. Levodopa is associated with these adverse effects:
a. GI effects, such as GI upset, nausea, vomiting, anorexia, and excessive salivation
b. Cardiovascular effects, such as orthostatic hypotension, tachycardia, and dysrhythmias
c. CNS effects, such as headache, dizziness, and insomnia

d. Abnormal involuntary movements, such as dyskinesia and choreiform or dystonic movements
e. Psychiatric effects, such as delusions, hallucinations, confusion, psychoses, and depression
2. Apomorphine can cause nausea and vomiting, somnolence, dizziness, and hallucinations, and may exacerbate existing dyskinesia. The drug has a reasonable potential for abuse due primarily to its perceived pro-libido effects.
3. Amantadine is associated with these adverse effects:
a. CNS effects, such as drowsiness, insomnia, dizziness, slurred speech, and nightmares
b. Urinary retention and ankle edema

c. Livedo reticularis (mottling of skin on the extremities)

d. Psychiatric effects, such as hallucinations and confusion

4. Bromocriptine and related ergolines are associated with nausea, hypotension, psychiatric effects such as confusion and hallucinations, livedo reticularis, and abnormal involunatry movements such as dyskinesia and choreiform or dystonic movements.

5. Selegiline is associated with adverse effects that are similar to those of bromocriptine, including dyskinesias and hallucinations.

6. Anticholinergic antiparkinsonian agents have the same adverse effects as other cholinergic antagonists (see VI.D).

XIV. OPIOID ANALGESICS and ANTAGONISTS.

Analgesic opioids are opioid receptor agonists that consist of natural opiate alkaloids and their synthetic derivatives.

A. Chemistry. The opiate alkaloids are derived from opium, which is considered the oldest drug on record. **Opium** (the dried exudate of the poppy seed capsule) contains about 25 different alkaloids. Of these, morphine is the most important, both quantitatively and pharmacologically (Figure 13-26).

1. Morphine's phenolic hydroxyl group is extremely important for activity; however, analgesic activity appears to depend on a *p*-phenyl-*N*-alkylpiperidine moiety, in which the piperidine ring is in the chair form and is perpendicular to the aromatic ring. The alkyl group is usually methyl. The **morphine molecule** can be altered in a variety of ways; related compounds also can be synthesized from other starting materials.

2. Natural or synthetic opioids may be classified into four chemical groups (Figure 13-27):

a. Phenanthrenes (e.g., morphine and hydromorphone, codeine and hydrocodone, nalbuphine and buprenorphine, and nalorphine, naltrexone, and naloxone). Methylation of the phenolic (3)-hydroxyl group with or without modification of the 6-hydroxyl group of morphine yields agents with reduced agonist potency but enhanced oral bioavailability (e.g., codeine, hydrocodone, oxycodone).

b. Phenylheptylamines (e.g., methadone and propoxyphene) are bisphenyl derivatives of heptylamine that have strong (methadone) or moderate (propoxyphene) agonist potency and excellent oral bioavailability.

c. **Phenylpiperidines** include meperidine, fentanyl, and sufentanil, which are strong agonists that are more effective when given parenterally, and the moderate agonists diphenoxylate and loperamide.

d. The **morphinan** levorphanol is a strong agonist with high oral bioavailability.

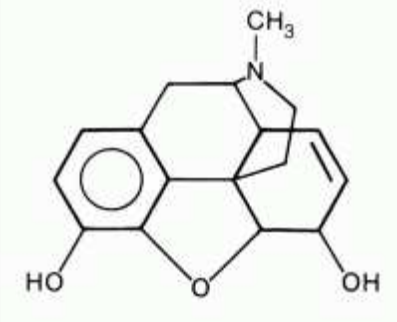

Figure 13-26. Structural formula of morphine.

P.312

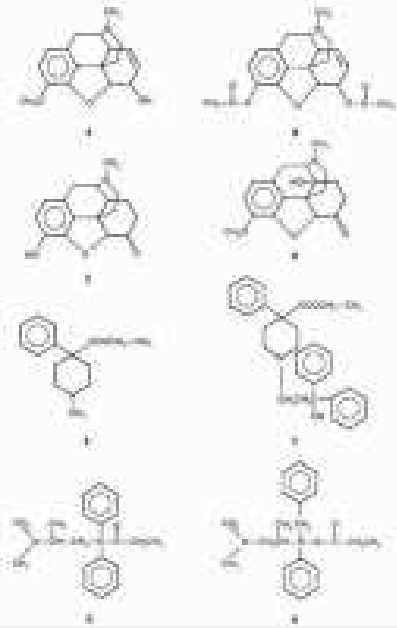

Figure 13-27. Structural formulas of selected opioid agonists, including **(A)** codeine, **(B)** heroin, **(C)** hydromorphone (Dilaudid), and **(D)** oxycodone (Percodan), morphine analogues; **(E)** meperidine (Demerol) and **(F)** diphenoxylate (Lomotil), piperidine analgesics; and **(G)** methadone (Dolophine) and **(H)** propoxyphene (Darvon), methadone analgesics.

P.313

3. Opioid antagonists are derived by replacing the methyl group on the nitrogen atom with more bulky substitutions. Thus, nalbuphine and buprenorphine are phenanthrene **mixed agonist-antagonists;** naltrexone and naloxone are phenanthrene **pure antagonists;** and butorphanol and levallorphan are morphinan-derived antagonists (Figure 13-28).

4. Agents having both a free phenolic hydroxyl group and a tertiary amine function (e.g., morphine and nalbuphine) are chemically amphoteric. Amphotericity probably accounts for the erratic absorption of morphine when administered orally.

5. Some newer opioid analgesic agents, such as **tramadol,** are chemically unrelated to the natural, semisynthetic, and synthetic opiate derivatives.
6. Numerous analogues of endogenous opioid peptides have been synthesized and are being used in research.

B. Pharmacology

1. Opioid analgesics mimic the actions of endogenous opioid peptides at CNS opioid receptors, raising the pain threshold and increasing pain tolerance. The analgesic actions are mediated primarily through the μ-subtype of opioid receptors.
2. Other actions attributable to stimulation of opioid receptors include induction of euphoria, sedation, cough suppression, and chemoreceptor trigger-zone stimulation leading to nausea and vomiting.
3. Tramadol appears to act via a metabolite, which is selective for the μ-opioid receptor and also inhibits reuptake of norepinephrine and serotonin. Its nonopiate character appears to confer no clear benefits over the opiates.
4. Pure opioid antagonists such as naloxone block the actions of opioid agonists. **Mixed agonist-antagonists** such as nalbuphine, buprenorphine, butorphanol, and pentazocine block the actions of agonists at some receptors while directly stimulating other receptors to produce agonistic effects.

C. Therapeutic indications

1. Opioid analgesics are indicated to relieve **moderate to severe pain,** such as the pain associated with myocardial infarction, cancer, and labor. In the latter use, meperidine is preferred to morphine because meperidine is less likely to induce **neonatal respiratory depression.**
2. Opioids are used also as **preanesthetic medications,** as **analgesic adjuncts during anesthesia,** and occasionally as a primary anesthetic agent.
3. Mild to moderate agonistic opioids are used as **antitussives** (e.g., codeine and dextromethorphan) and as **antidiarrheals** (e.g., diphenoxylate and loperamide).

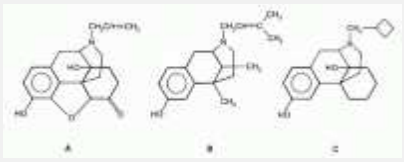

Figure 13-28. Structural formulas of opioid antagonists: **(A)** naloxone (Narcan), **(B)** pentazocine (Talwin), and **(C)** butorphanol (Stadol).

4. Pure opioid antagonists are used as antidotes to reverse the adverse effects (e.g., respiratory depression, cardiovascular depression, sedation) of opioid agonists or opioid agonist-antagonists. Naltrexone is an orally active compound that possesses pure antagonistic activity and is used in the treatment of opioid addiction.

D. Adverse effects

1. Opioid analgesics are associated with the following adverse effects:

a. CNS effects, including CNS depression, miosis, dizziness, sedation, confusion, disorientation, and coma

b. GI effects, including nausea, vomiting, constipation, biliary spasm, and increased biliary tract pressure

c. Cardiovascular effects, such as orthostatic hypotension, peripheral circulatory collapse, dysrhythmias, and cardiac arrest

d. Respiratory depression

e. Bronchoconstriction

f. Psychiatric effects, such as euphoria, dysphoria, and hallucinations

g. Abuse potential and dependence

h. Precipitation of withdrawal symptoms in opioid-dependent patients (when opioid agonist-antagonists, such as pentazocine or nalbuphine, are used as analgesics)

i. Classic opioid analgesics can also prompt the release of histamine, causing intense pruritus, vasodilation, and bronchoconstriction, which can be confused with a true allergic reaction.

j. Tramadol appears to have significantly fewer respiratory depressant effects than the classic opioids. It also does not appear to cause the release of histamine. It has fewer cardiovascular effects with the exception of orthostatic hypotension, which is produced. Tramadol does possess the typical μ-receptor-mediated side effects of constipation, nausea, vomiting, and sedation.

2. Opioid antagonists are associated with the following adverse effects:

a. Pure opioid antagonists can precipitate a withdrawal syndrome in opioid-dependent patients. Pure antagonists, given in the absence of opioid agonists or agonist-antagonists, produce no clinically significant effects.

b. In the absence of opioids, mixed agonist-antagonists produce opioid-like effects, such as respiratory depression.

STUDY QUESTIONS

Directions for questions 1-14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following drugs would most likely be used in the treatment of bronchospasm that is associated with chronic obstructive pulmonary disease?

(A) edrophonium

(B) ipratropium

(C) ambenonium
(D) propantheline
(E) homatropine

View Answer***1. The answer is B[V.C.2.b, c; VI.C.1.e-g].***2. **All of the following adverse effects are manifestations of cholinergic agonists *except***
(A) bradycardia.
(B) bronchoconstriction.
(C) xerostomia.
(D) lacrimation.
(E) myopic accommodation.

View Answer***2. The answer is C[].***3. **Which of the following drugs is considered to be the agent of choice for anaphylactic reactions?**
(A) clonidine
(B) isoproterenol
(C) epinephrine
(D) phenylephrine
(E) terbutaline

View Answer***3. The answer is C[].***4. **Which of the following neuromuscular blocking agents can cause muscarinic responses such as bradycardia and increased glandular secretions?**
(A) tubocurarine
(B) succinylcholine
(C) pancuronium
(D) decamethonium
(E) gallamine

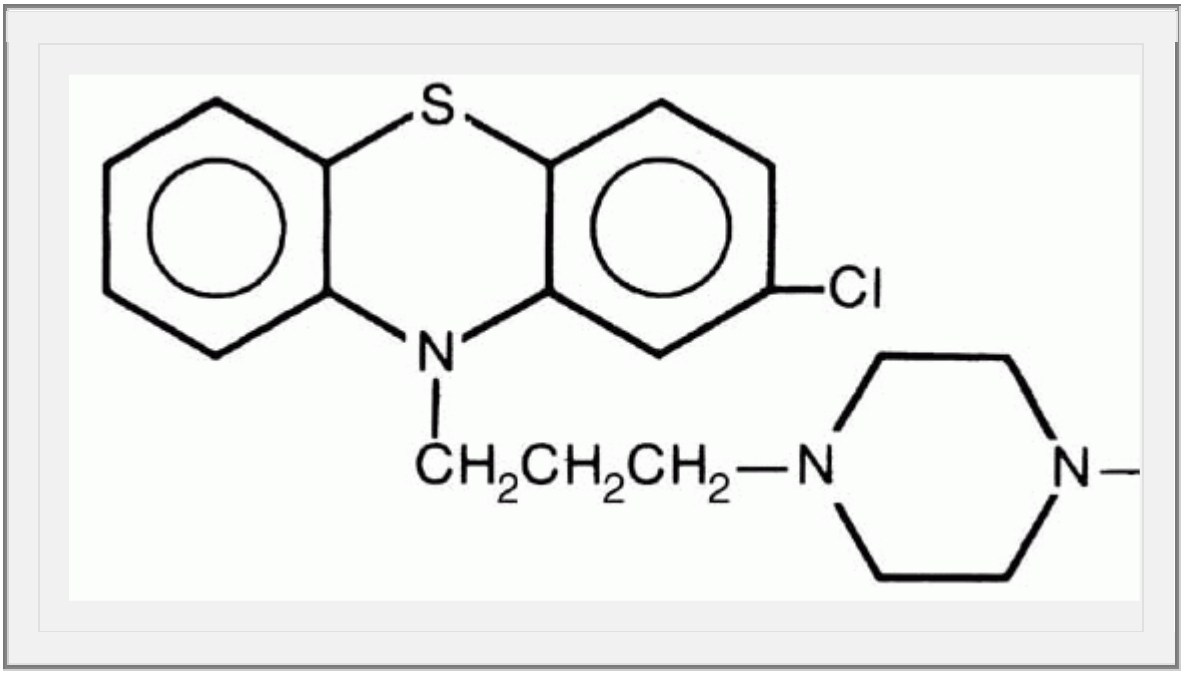
View Answer***4. The answer is B[VII.D.2].***5. **Which of the following agents would *not* be appropriate in the treatment of glaucoma?**
(A) atropine
(B) pilocarpine
(C) physostigmine
(D) timolol
(E) epinephrine

View Answer***5. The answer is A[and].***6. **Adverse reactions to atropine include all of the following *except***
(A) photophobia.
(B) dry mouth.
(C) sedation.
(D) diarrhea.
(E) tachycardia.

View Answer***6. The answer is D[].***7. **Which of the following drugs is a volatile substance that is administered by inhalation?**
(A) thiopental
(B) halothane
(C) alprazolam
(D) buspirone

(E) phenytoin

View Answer***7. The answer is B[].***8. **The structure of prochlorperazine is shown. Which of the following medications, because of its chemical relationship to prochlorperazine, would most likely cause similar side effects?**



(A) fluphenazine

(B) thioridazine

(C) alprazolam

(D) buspirone

(E) pentobarbital

View Answer***8. The answer is A[].***9. **The brief duration of action of an ultra-short-acting barbiturate is the result of a**

(A) slow rate of metabolism in the liver.

(B) low lipid solubility, resulting in a minimal concentration in the brain.

(C) high degree of binding to plasma proteins.

(D) rapid rate of redistribution from the brain owing to its high liposolubility.

(E) slow rate of excretion by the kidneys.

View Answer***9. The answer is D[XII.A.4.c, d;].***P.316

10. Which of the following mechanisms of action is true and most likely contributes to the treatment of parkinsonism?

(A) The direct-acting dopaminergic agonist amantadine mimics the activity of striatal dopamine.

(B) The antimuscarinic activity of diphenhydramine contributes to the restoration of striatal dopaminergic-cholinergic neurotransmitter balance.

(C) Striatal H_1-receptors are blocked by the antihistaminic trihexyphenidyl.

(D) The ergoline bromocriptine stimulates the release of striatal dopamine from intact terminals.

(E) The ability of dopamine to cross the blood-brain barrier allows it to restore striatal dopaminergic-cholinergic neurotransmitter balance.

View Answer***10. The answer is B[].*****11. All of the following adverse effects are associated with the use of levodopa *except***

(A) sialorrhea.

34. Tyramine exemplifies the pharmacologic mechanism of

(A) ganglionic blockade.
(B) inhibition of transmitter release.
(C) facilitation of transmitter release.
(D) interference with vesicular storage.
(E) blockade of transmitter reuptake.

View Answer***34. The answer is C[].***35. **Considering the general chemical structures of sympathomimetic amines, deletion of the 3-hydroxy group on the phenyl ring of norepinephrine would likely produce**
(A) increased α-receptor potency.
(B) increased β-receptor potency.
(C) indirect sympathomimetic activity.
(D) decreased transport through the blood-brain barrier.
(E) loss of any biological activity in the nervous system.

View Answer***35. The answer is C[].***36. **Sometimes combination treatment of Parkinson disease is warranted. Which of the following drug combinations could work cooperatively to enhance a clinical antiparkinsonian response?**
(A) amphetamine and reserpine
(B) levodopa and carbidopa
(C) carbidopa and tolcapone
(D) amantadine and haloperidol
(E) dopamine and tyramine

View Answer***36. The answer is B[].***37. **Terazosin is able to facilitate micturition when used in the treatment of benign prostatic hypertrophy (BPH) because the drug**
(A) relaxes the prostate gland.
(B) constricts the neck of the bladder.
(C) prevents penile erections associated with BPH.
(D) blocks seminal fluid production.
(E) blocks prostate cell growth.

View Answer***37. The answer is A[].***38. **BRL37344 is a β_3-agonist. It might be of interest to develop this agent into a clinically usable drug because of the expectation that β_3-agonists would**
(A) constrict blood vessels and increase blood pressure in shock patients.
(B) induce lipolysis and decrease lipocyte mass in obese patients.
(C) increase glycogenolysis and prevent glycogen storage in liver cirrhosis.
(D) enhance renal vasodilation and increase urinary elimination of ethanol in alcoholics.
(E) cause bronchodilation and counteract the negative effects of asthma treatment agents.

View Answer***38. The answer is B[III.B.1.b].***39. **The pharmacologic profile of carvedilol is most similar to that of**
(A) esmolol.
(B) labetalol.
(C) metoprolol.
(D) nadolol.

(E) timolol.

View Answer***39. The answer is B[IV.C.3;].*****40. Besides both of them being phenanthrene derivatives, apomorphine and morphine also have the common property of**

(A) stimulating brain neurogenesis and hence antidepressant activity.

(B) eliciting a potent nerve blockade and hence anesthetic activity.

(C) stimulating μ-opioid receptors and hence analgesic efficacy.

(D) improving immobility and hence antiparkinsonian activity.

(E) inducing rewarding stimuli and hence addiction liability.

View Answer***40. The answer is E[XV.A.2, C].***P.320

ANSWERS AND EXPLANATIONS

1. The answer is B *[V.C.2.b, c; VI.C.1.e-g].*

Ipratropium is a newly approved antimuscarinic agent used to treat bronchospasm. Propantheline and homatropine are antimuscarinic agents used as a gastrointestinal (GI) antispasmodic and as a mydriatic, respectively. Edrophonium and ambenonium are indirect-acting cholinergic agonists and, as such, would be expected to induce bronchospasm.

2. The answer is C *[*VI.D*].*

Xerostomia, or dry mouth, results from reduced salivary secretions and, therefore, is not a manifestation of cholinergic agonist activity. All of the other effects listed in the question are extensions of therapeutic effects of cholinergic agonists to the point of being adverse effects.

3. The answer is C *[*III.C.1*].*

Of the adrenergic agonists listed in the question, only epinephrine, because of its broad, nonselective α- and β-activity, is an agent of choice for anaphylactic reactions. Epinephrine improves circulatory and respiratory function and counteracts the vascular effects of histamine-related anaphylaxis.

4. The answer is B *[VII.D.2].*

Neuromuscular blocking agents interact with nicotinic receptors at the skeletal neuromuscular junction. Succinylcholine is also capable of eliciting autonomic muscarinic responses, such as bradycardia, increased glandular secretions, and cardiac arrest.

5. The answer is A *[*V.B *and* C*].*

Both direct-acting (e.g., pilocarpine) and indirect-acting (e.g., physostigmine) cholinergics may be used in glaucoma to increase cholinergic activity and facilitate outflow of aqueous humor. Similarly, both β-agonists (e.g., epinephrine) and antagonists (e.g., timolol) may be used respectively to increase outflow and decrease production of aqueous humor. Atropine is contraindicated in glaucoma because its anticholinergic effects can block the outflow of aqueous humor and, consequently, increase intraocular pressure.

6. The answer is D *[*VI.D*].*

Classic signs and symptoms of muscarinic blockade, as with atropine, include mydriasis, which may cause light sensitivity (photophobia); dry mouth and constipation by decreasing secretory activity and motility in the GI tract; and tachycardia by inhibiting the normal inhibitory cholinergic control of the cardiac system. Diarrhea is one of the common signs of cholinergic agonists (such as salivation, lacrimation or tearing, urination, and diarrhea).

7. The answer is B *[*VIII.A.1*].*

The general anesthetics are divided into two major classes of drugs: those that are gases or volatile liquids, which are administered by inhalation, and those that are nonvolatile salts, which are administered as intravenous solutions. Halothane is a halogenated hydrocarbon, which belongs to the former class. It has the advantage over older volatile anesthetics (e.g., ethyl ether, cyclopropane) of being nonflammable. Thiopental sodium, alprazolam, buspirone, and phenytoin are all nonvolatile substances that are administered orally or parenterally. Thiopental is a general anesthetic and is sometimes referred to as a basal anesthetic because it does not produce significant third-stage surgical anesthesia. Alprazolam and buspirone are anxiolytics, whereas phenytoin is an anticonvulsant.

8. The answer is A *[*X.A.1; Table 13-6*].*

Fluphenazine, like prochlorperazine, is a piperazinyl phenothiazine antipsychotic and would be likely to cause similar side effects. Whereas thioridazine is also a phenothiazine antipsychotic, it is a piperidyl derivative rather than a piperazinyl derivative. Alprazolam, phenytoin, and pentobarbital are not phenothiazines; therefore, structurally, they are not similar to prochlorperazine.

9. The answer is D *[XII.A.4.c, d;* Figure 13-8*].*

Ultra-short-acting barbiturates are characterized by having branched or unsaturated 5,5-side chains and by having a sulfur atom in place of oxygen in the 2 position of the barbituric acid molecule. These modifications of barbituric acid result in an extremely liposoluble molecule that is very soluble in lipid tissues. After administration, an ultra-short-acting barbiturate readily crosses the blood-brain barrier but then is quickly redistributed into extracerebral tissue, resulting in a rapid loss of activity. While these agents do remain in the body for a long time and seem to have slow rates of metabolism and excretion, their long retention time is due more to their slow rate of leaching out of lipid tissue.

10. The answer is B *[*XIV.B*].*

The H_1-antagonist diphenhydramine possesses antimuscarinic activity, which allows it to be of use in the restoration of striatal dopaminergic-cholinergic neurotransmitter balance. Amantadine appears to stimulate the release of striatal dopamine; it does not mimic the action of dopamine. Trihexyphenidyl is an antimuscarinic, not antihistaminic, agent; it blocks cholinergic, not H_1, receptors. Bromocriptine is a dopaminergic agonist and mimics the activity of striatal dopamine. The neurotransmitter dopamine is not able to cross the blood-brain barrier and is, therefore, not effective as an antiparkinsonian drug.

11. The answer is E *[*XIV.D.1*].*
Livedo reticularis is a circulatory disorder characterized by large, bluish areas on the extremities. It is an adverse effect associated with the use of amantadine and bromocriptine but not with the use of levo-dopa.
12. The answer is E *[XV.A.1, 2;* Figure 13-27E*].*
The *p*-phenyl-*N*-alkylpiperidine moiety is common to the structurally specific opioid analgesics. Meperidine is an opioid analgesic and is an *N*-methyl-*p*-phenylpiperidine derivative. Its chemical name is ethyl 1 -methyl-4-phenylpiperidine-4-carboxylate. Phenobarbital is a barbiturate sedative. Chlorpromazine is a phenothiazine antipsychotic. Diazepam is a benzodiazepine anxiolytic. Imipramine is a tricyclic dibenzazepine antidepressant.
13. The answer is C *[XV.C].*
Unlike the salicylates, opioids do not possess anti-inflammatory activity. Opioids do suppress the cough reflex and are preeminent analgesics. Opioids cause constipation and are, thus, effective antidiarrheal agents. When used as preanesthetic medication, opioids permit a reduction in the amount of general anesthetic required for surgical anesthesia.
14. The answer is A *[*XIII.A.1, C.2*].*
While many analeptics are useful in controlling more than one seizure type, trimethadione is effective primarily against absence (petit mal) seizures. Additionally, its side-effect profile is more extensive than the newer agents (e.g., lamotrigine, gabapentin, felbamate) that are effective in treating partial seizures.
15. The answer is C *[*V.C.2*].*
Cholinesterase inhibitors are indirect-acting cholinergic agonists useful in treating myasthenia gravis and glaucoma. Their effects on GI and urinary bladder smooth muscle would be to increase smooth-muscle tone, not decrease it.
16. The answer is D *[VI.C.1.g, h].*
All three compounds listed in the question are antimuscarinic agents; however, only benztropine and trihexyphenidyl are used to control parkinsonism and some neuroleptic-induced extrapyramidal disorders. Ipratropium is a newly approved agent for the treatment of bronchospasm.
17. The answer is D *[III.B.1.b,* C.1, 2*].*
Dobutamine is a β_1-selective adrenergic agonist. It would be inappropriate to use dobutamine to decrease blood flow at the site of local anesthetic administration. Epinephrine is a nonselective α- and β-agonist, and phenylephrine is an α_1-selective agonist; both of these drugs can be used to limit the systemic absorption of local anesthetics and prolong their activity.
18. The answer is E *[*IX.D.2*].*
Careful administration of a local anesthetic by a knowledgeable practitioner is essential to prevent systemic absorption and consequent toxicity. This is especially important when the patient has cardiovascular disease, poorly controlled diabetes, thyrotoxicosis, or peripheral vascular disease.
19. The answer is E *[*XII.C.1, 2, 3*].*
Benzodiazepines can serve as induction agents for general anesthesia; they also have anxiolytic properties. In addition, intravenous diazepam is used to treat status

epilepticus, whereas clonazepam is used orally for myoclonic and absence (petit mal) seizures. Benzodiazepines also diminish alcohol withdrawal symptoms.

20. The answer is B *[*VI.D*].*

This anticholinergic, if absorbed systemically, could cause classic anticholinergic effects, which include urinary retention.

P.322

21. The answer is A *[IV.D.3].*

Because this is a nonselective β-blocker, there could be some inhibition of β_2-receptors in the bronchial tree, causing bronchoconstriction and possible complication of the patient's asthma.

22. The answer is C *[*III.C.6*].*

Propranolol is a nonselective β-blocker, and prazosin is a selective α_1-blocker. Neither ipratropium nor Proscar works through the adrenergic system. Metaproterenol is a selective β_2-agonist.

23. The answer is D *[*V.A.2, C.2*].*

Pilocarpine acts directly at the muscarinic receptor, whereas epinephrine and timolol both act directly at β-receptors. Isoflurophate inhibits the metabolism of acetylcholine, indirectly increasing levels of the endogenous neurotransmitter.

24. The answers are A and E *[IV.B.3, D.4].*

Metoprolol, a β_1-selective agent, can cause bradycardia alone. The addition of topical timolol, while limiting systemic absorption, could have an additive β-blocking effect to decrease heart rate (negative chronotropy).

25. The answers are B and D *[*V.C.1, 2*].*

Pilocarpine and isoflurophate could limit the effects of each other, because, ultimately, both act via cholinergic receptors. Pilocarpine acts directly on the receptor, while isoflurophate indirectly increases acetylcholine levels. Pilocarpine and acetylcholine could compete for each other at the receptor site, effectively decreasing the effects of both. Epinephrine and timolol are β-agonists and β-antagonists, respectively. Although both agents are effective in treating glaucoma alone, the use of both concomitantly could result in a pharmacological antagonism, effectively decreasing the effects of both.

26-28. The answers are: 26-C *[*XII.B.2*],* **27-B** *[*XI.C.2*],* **28-D** *[*XI.B.3, D.3*].*

Buspirone's mechanism of anxiolytic action is unknown. Unlike the benzodiazepines, buspirone lacks hypnotic and anticonvulsant properties. The tricyclic antidepressant imipramine is useful in the treatment of enuresis, because the compound blocks muscarinic receptors mediating micturition. Trazodone is categorized as an atypical antidepressant that selectively blocks serotonin reuptake.

29-31. The answers are: 29-B *[*IX.A; Figure 13-15*],* **30-D** *[*XII.A; Table 13-7*],* **31-C** *[*XI.A.2; Figure 13-19*].*

The structure shown in question 29 is that of procaine, which is a diethylaminoethyl *p*-aminobenzoate ester. It contains a hydrophilic amino group in the alcohol portion of the molecule and a lipophilic aromatic acid connected by the ester linkage. The procaine molecule is typical of ester-type local anesthetics.

The structure in question 30 is that of diazepam, which has a benzo-1,4-diazepine as its base nucleus. The widely used benzo-1,4-diazepine derivatives have significant anxiolytic, hypnotic, and anticonvulsant activities.
The structure in question 31 is that of desipramine, which has a dibenzazepine as its base nucleus. Dibenzazepine derivatives that have a methyl- or dimethylaminopropyl group attached to the ring nitrogen have significant antidepressant activity. Similarly substituted dibenzocycloheptadienes also have antidepressant activity. Together, these two chemical classes make up the majority of the tricyclic antidepressants.

32. The answer is A *[*X.C*].*

Clozapine, while therapeutically defined as a general antipsychotic, is used almost exclusively in the treatment of schizophrenia.

33. The answer is B *[*XI.A.3, C.2*].*

Fluoxetine is most likely being used in this patient in an attempt to treat depression and obsessive-compulsive disorder with the same drug. Clinical trials have shown fluoxetine to improve both conditions. The use of a single agent for both conditions will minimize the risk of drug-drug interactions, as well as reduce the chances of adverse effects.

34. The answer is C *[*III.A.2, B.3; Table 13-2*].*

Tyramine is an indirectly acting sympathomimetic amine that enters the nerve terminal and displaces norepinephrine from the storage vesicles, thus increasing the quanta of the transmitter released.

35. The answer is C *[*III.A.1, 2*].*

Both aromatic hydroxyl functions are important for both alpha and beta receptor binding. However, removal of one or both of the groups would increase uptake of the resulting compound into the brain and adrenergic nerve terminals, resulting in transmitter displacement from vesicular storage and increased transmitter release.

36. The answer is B *[*XIV.A.2, 3*].*

While levodopa can cross the blood brain barrier to gain access into the brain, a significant portion of an orally administered dose gets converted into dopamine and norepinephrine at peripheral sites, leading to peripheral side effects and decreased brain bioavailability. Carbidopa, a dopa decarboxylase inhibitor that does not cross the blood brain barrier, is coadministered with levodopa to decrease its peripheral conversion, increase central delivery of the drug and hence the therapeutic response.

37. The answer is A *[*IV.C.1*].*

Terazosin blocks alpha receptors on the prostate gland to cause a relaxant effect, which reduces the pressure exerted by the prostate on the urethra, thus easing urinary voidance.

38. The answer is B *[III.B.1.b].*

Stimulation of beta-3 receptors induces the metabolic breakdown of fat stores into free fatty acids that can be further catabolized by the body. The hope is that this

category of pharmacologic agents could, with repeated use, lead to a decrease in the content and number of fat cells, and hence an antiobesity effect.

39. The answer is B *[IV.C.3;* Table 13-3*].*

Like labetalol, carvedilol is a nonselective alpha and beta receptor antagonist used in the treatment of hypertension. Blockade of vascular alpha (alpha-1) receptors would cause vasodilatation and decreased peripheral vascular resistance, while blockade of myocardial beta (beta-1) receptors would decrease cardiac contractility. The resultant decrease in cardiac output would produce a fall in blood pressure (blood pressure = cardiac output × peripheral resistance).

40. The answer is E *[*XIV.A.2, D.2; *XV.A.2, C].*

Despite the similarities in their names and chemical structures, these two agents have very different pharmacological effects and therapeutic uses. The one commonality among them is that both produce rewarding effects and thus abuse liability—morphine primarily through its euphoriant CNS effects and apomorphine primarily through its pro-libido (erectile) effects in males.

Autacoids and Their Antagonists, Nonnarcotic Analgesic-Antipyretics, and Nonsteroidal Anti-inflammatory Drugs

Scott F. Long

I. INTRODUCTION

A. Autacoids, also called autopharmacological agents or local hormones, have widely differing structures and pharmacological actions. Although the term remains poorly defined, the currently accepted criterion that defines a substance as an autacoid is local release and action limited to a specific site. Two of most extensively investigated autacoids are **histamine** and the **prostaglandins.** However, **serotonin, bradykinin,** and **kallidin** also function in a similar manner. While some autacoids (histamine and serotonin) function as neurotransmitters, their autacoid function is the focus of this chapter. Currently, there are no agents that specifically modulate the function of bradykinin or kallidin; however, drugs or analogs that mimic, block, or modulate other autacoid functions have important therapeutic roles.

B. Nonnarcotic analgesic-antipyretics have dissimilar structures but share certain therapeutic actions, including relief of pain, fever, and sometimes inflammation. Mechanistically, these agents act by inhibiting synthesis of prostaglandins.

C. Nonsteroidal anti-inflammatory drugs (NSAIDs) differ in structure and activity from the nonnarcotic analgesic-antipyretics, but possess anti-inflammatory properties. In addition, many of these agents also exhibit antipyretic and analgesic activity. NSAIDs also act by inhibition of prostaglandin synthesis.

II. AUTACOIDS AND THEIR ANTAGONISTS

A. Histamine and antihistaminics

1. Chemistry

a. Histamine is a bioamine derived principally from dietary histidine, which is decarboxylated by L-histidine decarboxylase (Figure 14-1).

b. Antihistaminics (histamine antagonists) can be classified as **H_1- or H_2-receptor antagonists.**

(1) H_1-receptor antagonists, the classic antihistaminic agents, are chemically classified as **ethylenediamines** (e.g., pyrilamine), **alkylamines** (e.g., brompheniramine [Dimetapp], chlorpheniramine [Chlor-Trimeton]), **ethanolamines** (e.g., diphenhydramine [Benadryl], clemastine [Tavist]), **piperazines** (e.g., hydroxyzine [Atarax, Vistaril], cetirizine

[Zyrtec]), **phenothiazines** (e.g., promethazine [Phenergan]), **dibenzocycloheptenes** (cyproheptadine [Periactin]), **phthalazinones**

(azelastine [Optivar, Astelin]), and **piperidines** (e.g., azatadine [Optimine], loratadine [Claritin], desloratadine [Clarinex], and fexofenadine [Allegra]). Cetirizine, azelastine, loratadine, desloratadine, and fexofenadine make up the second-generation antihistaminics, which are less sedating than the older, first-generation drugs, owing to their limited ability to cross the blood-brain barrier (Figure 14-2).

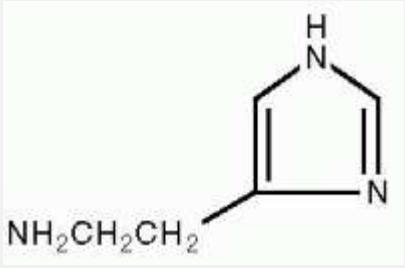

Figure 14-1. Structural formula of histamine, an autacoid.

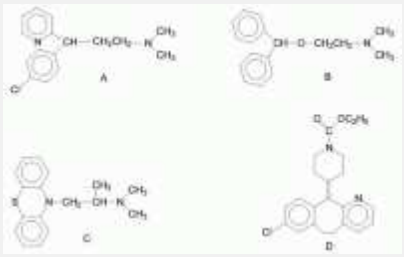

Figure 14-2. Structural formulas of representative H_1-receptor antagonists. (**A**) Chlorpheniramine (alkylamine). (**B**) Diphenhydramine (ethanolamine). (**C**) Promethazine (phenothiazine). (**D**) Loratadine (nonsedating piperidine).

(2) H_2-receptor antagonists are heterocyclic congeners of histamine. These include **cimetidine** (Tagamet), **ranitidine** (Zantac), **famotidine** (Pepcid), and **nizatidine** (Axid) (Figure 14-3).

(3) Alternatives to the H_2-receptor antagonists include **omeprazole** (Prilosec), **lansoprazole** (Prevacid), **rabeprazole** (AcipHex), **pantoprazole** (Protonix), and **esomeprazole**

(Nexium); **specific inhibitors of H^+/K^+-ATPase** (proton pump inhibitors, or PPIs), the ultimate mediator of gastric acid secretion. Structurally, these

agents are substituted **benzimidazoles** linked to a pyridine ring by a sulfinyl bridge, which is required for H^+/K^+-ATPase inhibition.

Figure 14-3. Structural formulas of (**A**) cimetidine, an H_2-receptor antagonist, and (**B**) omeprazole, a proton pump inhibitor.

2. Pharmacology

a. Histamine has powerful pharmacological actions, mediated by two specific receptor types (Table 14-1). A third histamine receptor has been identified. Its function has yet to be elucidated, but it is believed to act, at least in part, as an autoreceptor.

(1) H_1-receptors mediate typical allergic and anaphylactic responses to histamine, such as bronchoconstriction, vasodilation, increased capillary permeability, and spasmodic contractions of gastrointestinal (GI) smooth muscle.

(2) H_2-receptors mediate other responses to histamine, such as increased secretion of gastric acid, pepsin, and Castle's factor (intrinsic factor).

b. H_1-receptor antagonists competitively block H_1-receptors, thus limiting the histamine's effects on bronchial smooth muscle, capillaries, and GI smooth muscle. These antagonists also prevent histamine-induced pain and itching of the skin and mucous membranes.

c. **H_2-receptor antagonists** competitively block H_2-receptors, thus limiting the effects of histamine on gastric secretions.

d. The **PPIs** irreversibly inhibit the proton pump H^+/K^+-ATPase by covalently binding to the protein.

3. Therapeutic indications

a. Exogenous histamine can be used as a **diagnostic agent** for testing gastric function. However, other stimulants of gastric secretion (pentagastrin) are more suitable and safer.

b. H_1-receptor antagonists are used to provide symptomatic relief of **allergic symptoms,** such as seasonal rhinitis, conjunctivitis, and the symptoms of rhinoviral infections (common cold). Their antihistaminic effects also make them useful for symptomatic relief of urticaria. Agents with a high degree of anticholinergic activity (e.g., diphenhydramine) are sometimes used to treat nausea and vomiting associated with motion sickness and vertigo. In addition, promethazine (which also

has a high degree of anticholinergic activity) is sometimes used as an antiemetic, and hydroxyzine pamoate is occasionally employed as a mild anxiolytic. The second-generation drugs (i.e., loratadine, desloratadine,

fexofenadine, acrivastine, cetirizine, and azelastine) provide the added advantage of little to negligible sedation, owing to their relative inability to cross the blood-brain barrier.

Table 14-1. Selected Actions of Endogenous Histamine

Site	Action	Receptor Type
Cardiovascular		
Vascular	Arterial contraction	H_1
	Arteriolar relaxation	H_1 and H_2
	Venule contraction	H_1
	Venule relaxation	H_2
	Endothelial cells, release of EDRF	H_1
	Endothelial cells, contraction	H_1
Heart	Increased heart rate	H_2
	Increased force of contraction	H_2
	Slowed atrioventricular conduction	H_1
Respiratory		
	Bronchiolar smooth-muscle contraction	H_1
Gastrointestinal (GI)		

Gastric mucosa	Increased secretion of acid and pepsin	H_2
GI smooth muscle	Contraction	H_1
Various		
Cutaneous nerves	Pain and itch	H_1
EDRF, endothelium-derived relaxing factor.		

c. **H_2-receptor antagonists** are used to treat **gastric hypersecretory** conditions, such as duodenal ulcer and Zollinger-Ellison syndrome. They are effective in reducing pain associated with gastroesophageal reflux disease, but note that they do not prevent actual reflux.

d. The **proton pump inhibitors** are used to treat **duodenal ulcers** and are the drugs of choice for the treatment of **Zollinger-Ellison syndrome.**

4. Adverse effects

a. Histamine may cause numerous adverse effects related to its basic pharmacology (see II.A.2.a).

b. H_1-receptor antagonists are associated with the following **adverse effects:**

(1) Central nervous system (CNS) effects, such as CNS depression, sedation, fatigue, tinnitus, hallucinations, and ataxia

(2) GI effects, such as nausea and vomiting

(3) Antimuscarinic effects, such as dry mouth, urinary retention, and constipation

(4) Teratogenic effects (possible with piperazine compounds)

c. **Nonsedating H_1-receptor antagonists,** because they possess little anticholinergic activity and do not cross the blood-brain barrier, are relatively free of side effects.

d. H_2-receptor antagonists are associated with the following adverse effects:

(1) CNS effects, such as confusion and dizziness

(2) Hepatic and renal dysfunction

(3) Inhibition of the hepatic microsomal drug-metabolizing enzyme system (with cimetidine)

(4) Androgenic effects (with high doses of cimetidine), such as impotence and gynecomastia in men and galactorrhea in women

e. The **H^+/K^+-ATPase inhibitors** have been reported to cause diarrhea, GI pain, and headache as their most frequent adverse effects. In addition, they may interfere with the metabolism of diazepam, warfarin, phenytoin, and theophylline.

B. Serotonin

1. Chemistry

a. Serotonin (5-hydroxytryptamine) is a bioamine that is synthesized from the amino acid tryptophan by a two-step enzymatic process catalyzed by tryptophan hydroxylase and L-amino acid decarboxylase (Figure 14-4).

b. Serotonin agonists

(1) 5-HT_1-receptor agonists (i.e., sumatriptan [Imitrex], rizatriptan [Maxalt], naratriptan [Amerge], zolmitriptan [Zomig], almotriptan [Axert], eletriptan [Relpax], and frovatriptan [Frova]) are indole derivatives structurally similar to serotonin (Figure 14-4).

(2) Tegaserod (Zelnorm), an **indole** derivative, acts as 5-HT_4-receptor agonist (Figure 14-4).

(3) Ergot alkaloids (ergotamine [Ergomar]) have some activity as a serotonin agonist/partial agonist.

c. **Serotonin antagonists**

(1) Ergot alkaloids and derivatives with antagonist/partial agonist activity include **ergonovine** (Ergotrate), **dihydroergotamine, methysergide,** and **bromocriptine** (Parlodel).

(2) 5-HT_3-antagonists may be either **indole** derivatives (ondansetron [Zofran]) or **benzimidazoles** (granisetron [Kytril]). Other drugs of the class include **dolasetron** (Anzemet), **palonosetron** (Aloxi) and **alosetron** (Lotronex) (Figure 14-4).

2. Pharmacology

a. Serotonin exerts a wide range of effects via a family of receptors that includes at least seven types and several subtypes. Major physiological effects of serotonin include vasoconstriction (5-HT_2); platelet aggregation (5-HT_2); increased release of acetylcholine in the enteric region (5-HT_4); nausea/emesis (5-HT_3); and numerous behavioral actions that influence anxiety, depression, aggression, impulsivity, and appetite (5-HT_1, 5-HT_2, 5-HT_3). In addition, the 5-HT_1-receptor acts as an autoreceptor to inhibit presynaptic activity at both serotonergic and adrenergic neurones in the CNS. Furthermore, it directly contributes to vascular tone through vasoconstriction. Serotonin may also produce numerous other effects, including the opposite of those just stated, depending on the specific receptor that mediates the event.

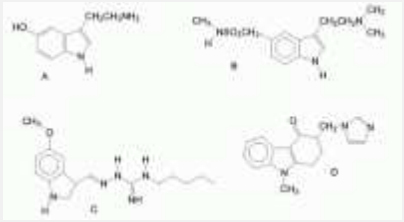

Figure 14-4. Structures of (**A**) serotonin and representative serotonin agonists (**B**) sumatriptan, (**C**) tegaserod, and (**D**) the serotonin antagonist ondansetron.

b. Serotonin agonists

(1) 5-HT_1-agonists mimic the actions of serotonin at this receptor to decrease presynaptic neurotransmitter release. Direct vasoconstriction, decreased release of inflammatory and vasodilating substances (neurokinin A, substance P), and a direct antinociceptive activities are thought to contribute to the efficacy of these drugs.

(2) Tegaserod activates the serotonergic receptor (5-HT_4), causing the release of acetylcholine, other neurotransmitters, and calcitonin gene-related peptide. These, in turn, increase gastric and intestinal motility and tone. In addition, direct actions on the gastrointestinal smooth muscle is thought to contribute it its effect, thus accounting for both the direct and indirect actions of tegaserod.

(3) Ergot alkaloids produce a wide range of pharmacological effects, including both agonistic and antagonistic activity at adrenergic, dopaminergic, and serotonergic receptors. Specific actions dependent on drug and animal models.

c. **Serotonin antagonists** such as **ondansetron** and related drugs block the ion-channel coupled 5-HT_3-receptor, thus inhibiting the ability of serotonin to cause nausea and/or emesis. This action appears to occur both locally at the GI tract and centrally in the area postrema. In addition, activation of peripheral 5-HT_3-receptors will increase pain, abdominal distention, and motor responses of the intestinal tract. Blockade of these actions, thus slowing GI motility, by **alosetron** is responsible for its usefulness in certain cases of irritable bowel syndrome (IBS).

3. Therapeutic indications

a. Serotonin agonists

(1) Numerous CNS active drugs use the serotonergic system to modulate behavior, such as the anorexiants (dexfenfluramine), anxiolytics (buspirone), and selective serotonin reuptake inhibitors for depression (fluoxetine). These drugs are acting more on the neurotransmitter function of serotonin and are discussed here.

(2) Some **ergot alkaloids, sumatriptan,** and similar drugs act to modulate the autacoid function of serotonin. They are used to prevent and treat pain associated with migraine headaches by altering serotonin's actions that result in changes in vascular tone.

(3) In addition, some **ergot alkaloids** are used to prevent postpartum hemorrhaging (through both vasoconstrictive and uterine contractile actions) and to prevent postpartum breast engorgement (**bromocriptine,** through dopaminergic activity).
(4) Tegaserod is used in the treatment of IBS that is constipation predominant.
b. Serotonin antagonists. These agents (e.g., **ondansetron, granisetron, dolasetron, palonosetron**) are used to prevent and treat nausea and emesis secondary to antineoplastic therapy by blocking the actions of serotonin at the 5-HT_3-receptor. **Alosetron** is used for the treatment of IBS that is diarrhea predominant.

4. Adverse effects

a. Serotonin agonists

(1) 5-HT_1-agonists may produce feelings of warmth, paresthesias, dizziness, and tightness or heaviness in the chest. Rarely, patients may experience chest pain. Because these agents may cause coronary vasoconstriction, they are contraindicated in angina patients and should be used cautiously in patients with hypertension or other risk factors for ischemic heart disease.
(2) Tegaserod may produce diarrhea, abdominal cramping and pain, dizziness, and headache as side effects.
(3) Ergot alkaloids may cause GI upset and cold extremities. As toxicity progresses, the patient may experience emesis, diarrhea, peripheral pain secondary to local ischemia, and hallucinations or delusions.
b. Serotonin antagonists. The 5-HT_3-antagonists will produce headache, constipation, and dizziness. In addition, granisetron has been reported to produce somnolence and diarrhea. The use of **alosetron** in patients with diarrhea-associated IBS has resulted in some cases of ischemic colitis and life-threatening complications from severe constipation. Subsequent to a series of adverse drug reactions in this manner, alosetron is generally prescribed only by physicians who have been enrolled in a prescribing programme.

C. Prostaglandins

1. Chemistry

a. Prostaglandins (PGs) are **derivatives** of prostanoic acid, a 20-carbon fatty acid containing a 5-carbon ring (Figure 14-5). In the body, prostaglandins are principally synthesized from arachidonic acid, which is formed from the membrane phospholipids by action of phospholipase A_2. Specifically, prostaglandins are synthesized from arachidonic acid by the enzyme cyclooxygenase (COX), which exists as three isozymes: COX 1, 2, and 3. COX 1 appears to function constantly. Its role seems to be the daily synthesis of prostaglandins, which contribute to normal homeostasis, and includes protection of the gastric mucosa through the prostaglandins and hemostasis through the synthesis of thromboxane. COX 2 is expressed primarily in response to inflammation or injury, contributing to the inflammatory response. It is also important in normal (noninjury) regulation of cardiac and perhaps other functions. COX 3 is thought to be predominantly active within the CNS, contributing to normal thermoregulatory control and pain perception,

through the synthesis of prostaglandins, centrally. Note that the products of cyclooxygenase are then converted into either prostaglandins by prostaglandin synthase or thromboxanes by thromboxane synthase. The thromboxanes differ from the prostaglandins mainly by the substitution of a tetrahydropyran ring structure for the pentane ring found in prostaglandins. The only clinically relevant thromboxane currently identified is thromboxane A_2 (TxA_2), which causes platelet aggregation.

b. Classification of prostaglandins as prostaglandin A (PGA), prostaglandin B (PGB), prostaglandin E (PGE), and so forth relates to the presence or absence of keto or hydroxyl

groups at positions 9 and 11 (Figure 14-5). Subscripts relate to the number and position of double bonds in the aliphatic chains (Figure 14-6).

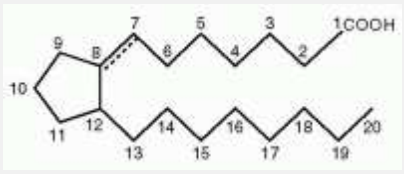

Figure 14-5. Structural formula of prostanoic acid, from which the prostaglandins are derived.

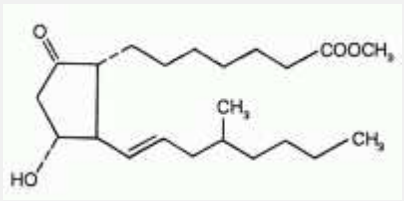

Figure 14-6. Structural formula of misoprostol (Cytotec), a derivative of prostaglandin E_1 (PGE_1).

2. Pharmacology

a. Endogenous prostaglandins appear to affect numerous body functions. They are released in response to many chemical, bacterial, mechanical, and other insults;

and they appear to contribute to the signs and symptoms of the inflammatory process, including pain and edema.

b. Physiological responses to prostaglandins include vasodilation in most vascular beds, although vasoconstriction can occur in isolated areas. PGI inhibits platelet aggregation and stimulates gastric release of bicarbonate and mucus, both of which serve to protect the gastric epithelium. The PGEs inhibit platelet aggregation, relax bronchial and GI smooth muscle, contract uterine smooth muscle, and inhibit gastric acid secretion. Alternatively, the PGDs and PGFs contract bronchial and GI smooth muscle. Prostaglandins also increase renal blood flow, promote diuresis, natriuresis, and kaliuresis; but paradoxically they increase renin secretion. They also possess diverse endocrine and metabolic effects.

3. Therapeutic indications

a. PGE_1 analogs

(1) Alprostadil (Prostin VR Pediatric) is used for temporary maintenance of a patent ductus arteriosus when awaiting corrective surgery for congenital heart defects.

(2) Alprostadil (Caverject) is used in treating impotence owing to erectile dysfunction.

(3) Misoprostol (Cytotec) is used for the prevention of NSAID-induced GI ulcers (Figure 14-6).

b. PGE_2 analogs and derivative dinoprostone (Prostin E_2, Prepidil, Cervidil) are used for their abortifacient effects and to induce cervical-ripening in pregnancy.

c. **$PGF_{2\alpha}$ analogs**

(1) Carboprost (Hemabate), was used for its abortifacient effects. A high incidence of cardiovascular collapse caused its removal from the U.S. market.

(2) Latanoprost (Xalatan), **travoprost** (Travatan), **bimatoprost** (Lumigan), and **unoprostone** (Rescula) are used topically to lower intraocular pressure in glaucoma.

d. PGI analog epoprostenol (prostacyclin, [Flolan]) is used primarily for the treatment of emergent pulmonary hypertension.

4. Adverse effects associated with PGE include the following:

a. CNS effects, such as CNS irritability, fever, seizures, and headache

b. Cardiovascular effects, such as hypotension, dysrhythmias, vasodilation, flushing, and cardiac arrest

c. Respiratory effects, such as respiratory depression and distress

d. Hematological effects, such as anemia, thrombocytopenia, and disseminated intravascular coagulation (DIC)

e. Diarrhea

f. Decreased renal function

g. Spotty bleeding and menstrual irregularities, abortion, and penile pain

D. Leukotrienes

1. Chemistry

a. Leukotrienes. The leukotrienes (LTs) are 20-carbon derivatives of the fatty acids that are formed via the enzymatic pathway catalyzed by lipoxygenase. Unlike the

prostaglandins, they contain no ring structure and are covalently linked to two or three amino acids.

The two important leukotrienes identified to date (LTC_4 and LTD_4) differ only by the presence of glutamine. The nomenclature of the leukotrienes is similar to that used for the prostaglandins.

b. Leukotriene antagonists

(1) Lipoxygenase inhibitors such as **zileuton** (Zyflo) are benzothiophene derivatives.

(2) Leukotriene antagonists such as **zafirlukast** (Accolate) and **montelukast** (Singulair) represent a diverse chemical group that is peptidomimetic-like in its structure.

2. Pharmacology

a. Leukotrienes play a role in numerous physiological functions. They have been identified as the slow-reacting substance of anaphylaxis. Specific actions of the leukotrienes include the following:

(1) Heart

(a) Negative inotropy

(b) Smooth-muscle chemotaxis

(2) GI **tract.** Neutrophil chemotaxis that has been correlated with inflammatory bowel disease

(3) Pulmonary. The actions of the leukotrienes within the pulmonary system appear to be major. These actions are the most important pharmacologically.

(a) Bronchoconstriction

(b) Increased permeability

(c) Increased mucus secretion

(4) Blood/lymph. As noted previously, the leukotrienes act as chemotactic agents for neutrophils and eosinophils and act to modify lymphocyte proliferation and differentiation.

b. Leukotriene antagonists

(1) The lipoxygenase inhibitor zileuton prevents the synthesis of leukotrienes by inhibiting the enzyme responsible for their formation—namely lipoxygenase. This action prevents the formation of all leukotrienes, thus preventing their contribution to various inflammatory processes.

(2) The leukotriene antagonists **zafirlukast** and **montelukast** nonselectively and competitively inhibit the endogenous leukotrienes at their various receptor sites. This action blocks the effects of histamine, most notably the bronchoconstriction and pulmonary edema associated with asthma and allergic reactions.

3. Therapeutic indications for zileuton, zafirlukast, and montelukast are limited to the treatment of asthma. These agents reduce bronchospasm and associated symptoms that are mediated through the leukotrienes.

4. Adverse Effects

a. Zileuton presents with relatively few side effects, predominantly gastrointestinal in nature (i.e., dyspepsia and nausea). However, it does cause transient increases in hepatic enzymes. This potential for hepatotoxicity has limited its use.
b. Zafirlukast may produce GI upset and liver dysfunction (not as great as with zileuton), and may inhibit the metabolism of theophylline, warfarin, and potentially other drugs. Sudden withdrawal of corticosteroids in patients taking zafirlukast has precipitated a Churg-Strauss syndrome of eosinophilic vasculitis. Patients should be counseled to take zafirlukast with food to enhance its absorption.
c. **Montelukast** presents with a side-effect profile similar to that for zafirlukast but typically with less incidence than with zafirlukast. Churg-Strauss syndrome has not been reported; however, this may simply reflect the relatively recent appearance of the drug on the market. Montelukast may be taken without regard to food.

III. NONNARCOTIC ANALGESIC-ANTIPYRETICS AND NSAIDS

A. Salicylates

1. Chemistry

a. Salicylates are **derivatives of salicylic acid,** which is found as the glycoside salicin in willow bark. The prototypical drug is **aspirin,** the acetyl ester of salicylic acid (Figure 14-7).

P.332

A simple ester, aspirin hydrolyzes easily, is unstable in aqueous media, and is affected by moisture.

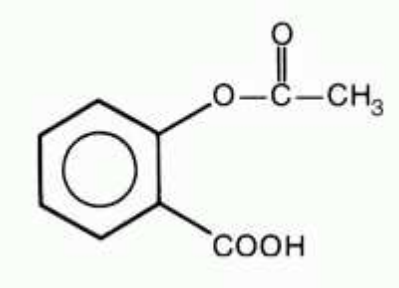

Figure 14-7. Structural formula of aspirin, the prototypical salicylate analgesic-antipyretic.

b. More stable salicylates include **diflunisa**l (Dolobid) and the topical agent **methyl salicylate** (wintergreen oil) (Figure 14-8). Other salicylates are **salsalate** (Disalcid); **sodium thiosalicylate** (Resolute; injectable); **choline salicylate** (Trilisate; oral liquid); and the salicylate **derivatives mesalamine** (Asacol), **olsalazine** (Dipentum), and **sulfasalazine** (Azulfidine).
c. Most salicylates are **weak acids.** Their excretion is influenced by changes in urinary pH.

2. Pharmacology

a. Salicylates **inhibit** the enzyme cyclooxygenase and thus inhibit local prostaglandin synthesis (see II.C.1.a). As a result, they are analgesic for low-intensity integumental pain, antipyretic, and anti-inflammatory. Note that aspirin is the only salicylate that irreversibly inhibits cyclooxygenase by covalent acetylation of the enzyme.

b. Salicylates also **block** platelet cyclooxygenase and subsequent formation of thromboxane A_2. As a result, they inhibit platelet aggregation and eventual thrombus formation.

3. Therapeutic indications

a. Salicylates are indicated for use as:

(1) Analgesics, for relief of musculoskeletal pain, headache, neuralgias, myalgias, and spasmodic dysmenorrhea

(2) Anti-inflammatory agents, for relief of various arthritis symptoms and acute rheumatic fever

(3) Antipyretic agents, for relief of fever. (Children with varicella or influenza-type viral infections should not be given salicylates because of the observed association between salicylate use in these situations and Reye syndrome.)

b. Aspirin is also indicated for **prophylaxis of myocardial infarction.**

c. **Methyl salicylate** (wintergreen oil) is used topically as a **counterirritant.**

d. Sulfasalazine, olsalazine, and **mesalamine** are used to reduce the inflammation associated with inflammatory bowel disease and Crohn disease.

4. Adverse effects

a. Salicylates are associated with the following effects:

(1) GI effects, such as nausea; vomiting; and GI irritation, discomfort, ulceration, and hemorrhage

(2) Increased depth of respirations

(3) Excessive bleeding associated with inhibition of thromboxane synthesis

(4) Uncoupling of oxidative phosphorylation, hyperglycemia, glycosuria, and reduced lipogenesis

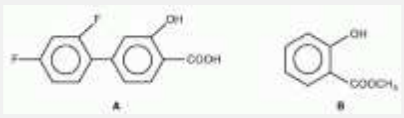

Figure 14-8. Structural formulas of salicylate derivatives. **A.** Diflunisal. **B.** Methyl salicylate.

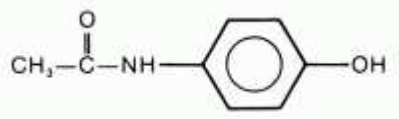

Figure 14-9. Structural formula of acetaminophen, the prototypical *p*-aminophenol derivative.

(5) Delayed onset of labor

(6) Low daily doses of salicylates (2 g) decrease renal urate excretion and increase serum uric acid levels. **High daily doses** (5 g) have the opposite effect.

b. Sulfasalazine has also been shown to have male reproductive effects, causing infertility.

c. **Salicylism** (salicylate toxicity, usually marked by tinnitus, nausea, and vomiting)

d. Ingestion of 1 teaspoon of the topical agent **methyl salicylate** (wintergreen oil) can cause **fatal intoxication.**

B. *p*-Aminophenol derivatives

1. Chemistry. The prototypical *p*-aminophenol derivative is **acetaminophen** (Tylenol), an active metabolite of phenacetin and acetanilid (Figure 14-9).

2. Pharmacology

a. *p*-Aminophenol derivatives inhibit central prostaglandin synthesis (see II.C.I.a), presumably through a selectivity for COX 3 with relatively little or no activity on COX 1 or COX 2. They are analgesic for low-intensity pain and are antipyretic.

b. Because they are less effective than salicylates in blocking peripheral prostaglandin synthesis, they have no anti-inflammatory activity and do not affect platelet function.

3. Therapeutic indications

a. Acetaminophen is primarily used for its **analgesic** and **antipyretic activity,** particularly in a patient unable to tolerate salicylates.

b. Acetaminophen may be safely used as an **alternative antipyretic** in children with varicella or an influenza-type viral infection (see III.A.3.a.(3)).

4. Adverse effects

a. When given in therapeutic doses, adverse effects are limited to:

(1) Skin rash

(2) Hemolytic anemia (with long-term phenacetin use)

(3) Methemoglobinemia

(4) Renal dysfunction and tubular necrosis

b. Acute acetaminophen overdose causes severe hepatotoxicity with necrosis and liver failure.

C. Pyrazolone derivatives

1. Chemistry. The most important pyrazolone derivatives are **phenylbutazone,** its metabolite **oxyphenbutazone,** and the uricosuric agent **sulfinpyrazone** (Anturane). Phenylbutazone is the prototypical agent (Figure 14-10).

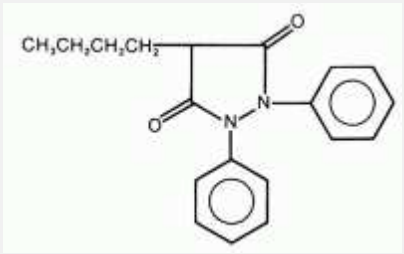

Figure 14-10. Structural formula of phenylbutazone, a pyrazolone derivative.

2. Pharmacology

a. Phenylbutazone, oxyphenbutazone, and **azapropazone** inhibit prostaglandin synthesis (see II.C.I.a) and stabilize lysosomal membranes. As a result, they have analgesic, antipyretic, and anti-inflammatory effects. They also have good uricosuric activity.

b. Sulfinpyrazone inhibits proximal tubular absorption of urate and has a uricosuric effect. However, it is devoid of analgesic, antipyretic, or anti-inflammatory effects.

3. Therapeutic indications

a. Phenylbutazone and **oxyphenbutazone** are used for short-term treatment of acute rheumatoid arthritic conditions and acute gout. However, they should be given only after other therapeutic measures have failed.

b. Sulfinpyrazone is used to control hyperuricemia in the treatment of intermittent and chronic gout.

c. These agents are rarely used, having been replaced with relatively safer compounds.

4. Adverse effects

a. The adverse effects of **phenylbutazone, oxyphenbutazone,** and **azapropazone** (to a much less extent) often limit their use and include

(1) GI effects, such as discomfort, nausea, vomiting, dyspepsia, and peptic ulceration

(2) Blood dyscrasias, such as agranulocytosis, aplastic anemia, hemolytic anemia, thrombocytopenia, and petechiae

(3) Cardiovascular effects, such as congestive heart failure with edema and dyspnea
(4) Renal effects, such as nephrotic lithiasis, renal necrosis, impaired renal function, and renal failure
(5) CNS effects, such as drowsiness, agitation, confusion, headache, lethargy, numbness, weakness, tinnitus, and hearing loss
(6) Hyperglycemia
(7) Skin rash
b. Sulfinpyrazone is associated with the following adverse effects:
(1) GI effects, such as discomfort and upset
(2) Blood dyscrasias, as with phenylbutazone and oxyphenbutazone
(3) Renal failure
D. Agents used for the treatment of gout
1. Chemistry
a. Acute attacks of gout result from an inflammatory response to joint depositions of sodium urate crystals. Therapeutic agents counter this response by reducing plasma uric acid concentrations or inhibiting the inflammatory response.
b. Agents used for the treatment of gout have widely varying structures and include the pyrazolone derivative sulfinpyrazone (see III.C.2.b; III.C.3.b; III.C.4.b); the alkaloid **colchicine;** isopurines, such as **allopurinol** (Zyloprim); and benzoic acid derivatives, such as **probenecid** (Benemid) (Figure 14-11).
2. Pharmacology
a. Colchicine's mechanism of action is presumed to be related to its antimitotic activity. It inhibits tubulin synthesis, which is required for the movement of inflammatory cells.

Through its ability to prevent tubulin polymerization, colchicine appears to inhibit chemotaxis of leukocytes and other inflammatory cells in the affected joint, thus reducing the inflammatory response to deposited urate crystals by inhibiting leukocyte migration and phagocytosis. It also interferes with kinin formation and reduces leukocyte lactic acid production.

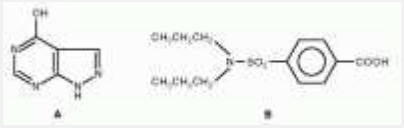

Figure 14-11. Structural formulas of agents used in the treatment of gout. **A.** Allopurinol. **B.** Probenecid.

b. Allopurinol reduces serum urate levels by blocking uric acid production. It competitively inhibits the enzyme xanthine oxidase, which converts xanthine and hypoxanthine to uric acid.

c. **Probenecid,** a uricosuric agent, inhibits the proximal tubular reabsorption of uric acid, increasing uric acid excretion, thus reducing plasma uric acid concentrations.

3. Therapeutic indications

a. Colchicine is used principally for the treatment of acute gout attacks.

b. Allopurinol, which reduces uric acid synthesis and facilitates the dissolution of tophi (chalky urate deposits), is used to prevent the development or progression of chronic tophaceous gout.

c. **Probenecid** is used to treat chronic tophaceous gout. It is also used in smaller doses to prolong the effectiveness of penicillin-type antibiotics by inhibiting their tubular secretion.

4. Adverse effects

a. Chronic use of **colchicine** is associated with these adverse effects:

(1) Agranulocytosis, aplastic anemia, myopathy, hair loss, and peripheral neuritis

(2) Nausea, vomiting, abdominal pain, and diarrhea (indications of impending toxicity)

b. Allopurinol is associated with the following adverse effects:

(1) GI effects, such as GI distress, nausea, vomiting, and diarrhea

(2) Skin rash, Stevens-Johnson syndrome, and hepatotoxicity

(3) Precipitation of an acute gout attack (with initial allopurinol therapy owing to initial mobilization of stored urate)

c. **Probenecid** is associated with the following adverse effects:

(1) Headaches, nausea, vomiting, urinary frequency, sore gums, and dermatitis

(2) Dizziness, anemia, hemolytic anemia, and renal lithiasis

E. NSAIDs

1. Chemistry

a. The classic **NSAIDs** consist of many structurally diverse acids. These include **propionic** acid derivatives (fenoprofen [Nalfon], flurbiprofen [Ocufen], ibuprofen [Motrin], ketoprofen [Orudis], naproxen [Anaprox, Naprosyn], and oxaprozin

[Daypro]), **acetic acid** derivatives (diclofenac [Voltaren], etodolac [Lodine], indomethacin [Indocin], ketorolac [Toradol], sulindac [Clinoril], and tolmetin [Tolectin] and the subclass of the fenamates or anthranilic acid derivatives meclofenamate and mefenamic acid [Ponstel]), and the **enolic acid** derivatives (piroxicam [Feldene], meloxicam [Mobic], and nabumetone [Relafen]) (Figure 14-12).

b. Selective COX 2 inhibitors celecoxib (Celebrex) and **rofecoxib** (Vioxx), and **valdecoxib** (Bextra) are pyrazole derivatives (Figure 14-13).

2. Pharmacology

a. Nonspecific NSAIDs have anti-inflammatory effects, resulting from their ability to inhibit the cyclooxygenase enzyme system and thus reduce local prostaglandin synthesis (see II.C.1.a).

b. NSAIDs also have analgesic and antipyretic effects. In addition, some NSAIDs have mild uricosuric activity. Some agents also have weak inhibitory activity for lipoxygenase, mild selectivity for COX 2, and weak to moderate ability to inhibit leukocyte proliferation and migration and to stabilize lysosomal membranes. The clinical relevance of these secondary actions has not been elucidated.

c. **COX 2 inhibitors** exert anti-inflammatory effects by specifically inhibiting prostaglandin synthesis associated with the inflammatory response. Their ability to decrease pain and inflammation associated with arthritic diseases is approximately equal to that produced by the nonselective NSAIDs. Moreover, by virtue of their selectivity, their actions on gastric mucosa and platelet aggregation are theorized to be less than the nonselective NSAIDs.

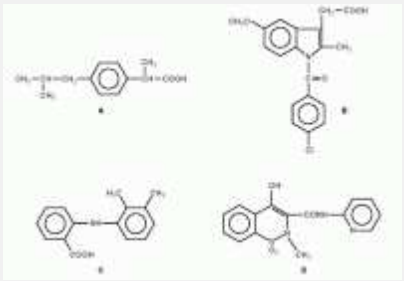

Figure 14-12. Structural formulas of representative nonsteroidal anti-inflammatory drugs (NSAIDs). **A.** Ibuprofen (propionic acid derivative). **B.** Indomethacin (acetic acid derivative). **C.** Mefenamic acid (anthranilic acid derivative). **D.** Piroxicam (enolic acid derivative).

3. Therapeutic indications

a. NSAIDs, like aspirin, are agents of choice for the treatment of rheumatoid arthritis, osteoarthritis, and ankylosing spondylitis. They may also be used as secondary treatments in gouty arthritis.

b. COX 2 inhibitors are approved for use in both rheumatoid arthritis and osteoarthritis.

4. Adverse effects

a. NSAIDs are associated with the following adverse effects:

(1) GI effects, such as GI distress and irritation, erosion of gastric mucosa, nausea, vomiting, and dyspepsia

(2) CNS effects, such as CNS depression, drowsiness, headache, dizziness, visual disturbances, ototoxicity, and confusion

(3) Hematologic effects, such as thrombocytopenia, altered platelet function, and prolonged bleeding time

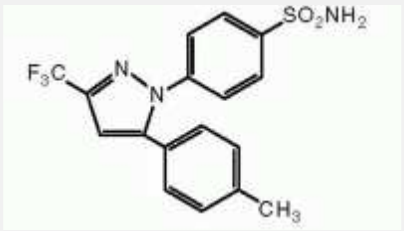

Figure 14-13. Structural formula of celecoxib, a COX 2 specific inhibitor.

(4) Skin rash

(5) Nephrotoxicity

b. COX 2 inhibitors do not appear to cause as great an incidence of GI ulceration or antiplatelet effects as the nonselective NSAIDs. The most commonly reported side effects include GI upset at a lower incidence level. Despite the promise of minimal GI ulceration, many patients experienced gastrointestinal bleeding with these drugs soon after their release. This is thought to have been an instance of overuse/overdosing of the drug. This risk of gastric damage and potential ulceration appears to increase with chronic, high dose use of these drugs. The potential for nephrotoxicity does exist for these drugs, and patients should be monitored for changes in renal function. More recent adverse drug reactions associated with these drugs include an increased risk of thrombotic events, leading to myocardial infarction and stroke, which could be potentially fatal. This is likely the result of an inhibition of cardiovascular COX 2 and subsequent clot formation. This has lead to the voluntary removal of some of these drugs from the market and cautious, closely supervised use of the others.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 45-year-old long-haul trucker suffers from seasonal allergies. He asks advice on which over-the counter product is best to relieve his symptoms. Which of the following choices is the best recommendation for this patient?

(A) diphenhydramine
(B) promethazine
(C) clemastine
(D) chlorpheniramine
(E) loratadine

View Answer***1. The answer is E[see].***2. **Which of the following choices would be most appropriate in treating nausea and vomiting associated with motion sickness?**

(A) diphenhydramine
(B) brompheniramine
(C) ondansetron
(D) omeprazole
(E) ranitidine

View Answer***2. The answer is A[see].***3. **Esomeprazole would be effective in the treatment of**

(A) gastroesophageal reflux disease.
(B) peptic ulcer disease.
(C) Zollinger-Ellison syndrome.
(D) All of the above
(E) None of the above

View Answer***3. The answer is D[see].***4. **Which of the following antiulcer medications is most likely to cause drug interactions and endocrine side effects?**

(A) ranitidine
(B) omeprazole
(C) lansoprazole
(D) cimetidine
(E) famotidine

View Answer***4. The answer is D[see].***5. **A patient has just been diagnosed with recurrent migraine headaches. Which of the following preexisting conditions would preclude the use of sumatriptan for this patient?**

(A) liver disease
(B) renal failure
(C) ischemic heart disease
(D) irritable bowel syndrome (IBS)
(E) gouty arthritis

View Answer***5. The answer is C[see].***6. **Which of the following is an appropriate indication for the drug tegaserod?**

(A) a female patient with constipation-related irritable bowel syndrome (IBS)

(B) a female patient with diarrhea-related IBS
(C) a male patient with Crohn disease
(D) a male patient with diarrhea-related IBS
(E) a patient with Zollinger-Ellison syndrome

View Answer***6. The answer is A[see].*****7. Which of the following prostaglandin analogs is used specifically for the treatment of glaucoma?**
(A) alprostadil
(B) latanoprost
(C) carboprost
(D) dinoprostone
(E) epoprostenol

View Answer***7. The answer is B[see].*****8. The use of misoprostol to prevent nonsteroidal anti-inflammatory drug-induced ulcers could cause which of the following side effects?**
(A) fever
(B) gastrointestinal cramping and diarrhea
(C) headache/pain
(D) All of the above
(E) None of the above

View Answer***8. The answer is D[see].*****9. Which of the following asthma therapies has been associated with an acute vascular syndrome that is associated with sudden withdrawal of corticosteroid anti-inflammatory drugs?**
(A) zafirlukast
(B) zileuton
(C) montelukast
(D) All of the above
(E) None of the above

View Answer***9. The answer is A[see].*****10. Which of the following asthma therapies is effective by decreasing the amounts of released leukotrienes?**
(A) zafirlukast
(B) zileuton
(C) montelukast
(D) All of the above
(E) None of the above

View Answer***10. The correct answer is B[see].***P.339

11. Rizatriptan is effective in treating migraine headache by
(A) directly vasoconstricting involved blood vessels.
(B) inhibiting the release of inflammatory neurotransmitters.
(C) directly blocking pain transmission.
(D) All of the above
(E) None of the above

View Answer***11. The answer is D[see].***12. **Which of the following drugs, based on its mechanism of action, is effective in treating diarrhea-predominant irritable bowel syndrome (IBS)?**

(A) tegaserod

(B) naratriptan

(C) alosetron

(D) All of the above

(E) None of the above

View Answer***12. The correct answer is C[see].***13. **Which of the following salicylates has been linked to male reproductive toxicity with chronic dosing?**

(A) aspirin

(B) diflunisal

(C) sodium thiosalicylate

(D) olsalazine

(E) sulfasalazine

View Answer***13. The correct answer is E[see].***14. **Aspirin exerts its anti-platelet effect by inhibiting**

(A) cyclooxygenase (COX) 1.

(B) COX 2.

(C) COX 3.

(D) prostaglandin synthesis.

(E) leukotriene synthesis.

View Answer***14. The correct answer is A[see].***15. **Acetaminophen has advantages over aspirin or other nonsteroidal anti-inflammatory drugs by virtue of its**

(A) relative lack of anti-platelet effects.

(B) relative lack of gastrointestinal ulcerative effects.

(C) being a safe alternative for children with viral infections.

(D) All of the above

(E) None of the above

View Answer***15. The correct answer is D[see].***16. **Acetaminophen toxicity is characterized by**

(A) profound vasoconstriction and pain.

(B) severe abdominal cramping and diarrhea.

(C) central nervous system stimulation and seizures.

(D) profound liver damage and failure.

(E) All of the above

View Answer***16. The correct answer is D[see].***17. **Which of the following antigout medications is specifically used in acute attacks?**

(A) colchicine

(B) allopurinol

(C) probenecid

(D) All of the above

(E) None of the above

View Answer***17. The correct answer is A[see]*****18. Which of the following antigout medications acts by decreasing serum levels but increasing urine levels of uric acid, thus increasing the risk of kidney stone development?**

(A) colchicine

(B) allopurinol

(C) probenecid

(D) All of the above

(E) None of the above

View Answer***18. The correct answer is C[see]*****19. The nonsteroidal anti-inflammatory drugs, as a class, are anti-inflammatory primarily through their ability to inhibit**

(A) cyclooxygenase (COX) 1.

(B) COX 2.

(C) COX 3.

(D) leukotriene synthesis.

(E) thromboxane synthesis.

View Answer***19. The correct answer is B[see]*****20. The selective cyclooxygenase (COX) 2 inhibitors have been associated with which of the following adverse drug reactions?**

(A) severe ischemic colitis

(B) torsade des pointes

(C) cardiovascular thrombotic events

(D) acute liver failure

(E) Churg-Strauss syndrome

View Answer***20. The correct answer is C[see]***P.340

ANSWERS AND EXPLANATIONS

1. The answer is E *[see* II.A.1.b.(1); II.A.3.b*].*

Diphenhydramine, promethazine, and clemastine all possess moderate to strong anticholinergic activity. This will increase the risk of sedation, which could prove dangerous in this patient. Chlorpheniramine, while the least sedating of the first-generation drugs, still may cross the blood-brain barrier and cause some sedation. Loratadine, as a second-generation drug that has minimal anticholinergic activity and does not cross the blood-brain barrier (thus producing no central effects), is least likely to cause sedation and thus affect his job.

2. The answer is A *[see* II.A.3.b*].*

While ondansetron is used for nausea associated with chemotherapy and anaesthetics, it is not typically used for nausea associated with motion or vertigo. Diphenhydramine, which possesses a high degree of anticholinergic activity, is effective in reducing nausea and vomiting associated with vestibulocochlear activity, vertigo, and motion sickness. None of the other choices directly reduces nausea or vomiting, therefore, diphenhydramine is the best choice.

3. The answer is D *[see* II.A.1.b.(3); II.A.3.d*].*

Because all three of these disease states represent some action of excessive acid secretion, esomeprazole, which also blocks the proton or acid pump, would be effective in reducing the acid-induced pain and damage associated with gastroesophageal reflux disease (GERD), peptic ulcer disease (PUD), and Zollinger-Ellison syndrome.

4. The answer is D *[see* II.A.4.d*].*

Of the drugs listed, and specifically, of the H_2-antagonists, cimetidine is the only drug that inhibits the hepatic microsomal metabolizing system (specifically the 3A4 isozyme) and the only drug that exhibits weak androgenic activity. The former is responsible for numerous drug interactions and some side effects, whereas the latter is responsible for endocrine (specifically androgen-like) side effects.

5. The answer is C *[see* II.B.2.a; II.B.4.a.(1)*].*

Sumatriptan (and other drugs in the class) specifically cause vasoconstriction. This effect, when present in coronory vessels, can cause chest tightness of pain as a normal side effect of the drug. However, in patients with ischemic heart disease, angina, or a risk for coronary artery disease, this action could precipitate attacks of angina or potentially cause myocardial infarction and should not be used in those patients.

6. The answer is A *[see* II.B.1.b.(2); II.B.2.b.(2); II.B.3.a.(4)*].*

Currently, drugs are available specifically for women with IBS characterized by either constipation or diarrhea. The intestinal stimulant action of tegaserod makes it useful for those patients with constipationassociated IBS. Although tegaserod (and alosetron) is (are) being evaluated for use in men with IBS, the current recommendation is primarily for women. Tegaserod, as a prokinetic agent, would worsen IBS that presents primarily with diarrhea. Because it has no anti-inflammatory effect, it would not be effective in treating the primarily inflammatory nature of Crohn disease. Tegaserod has no effect on gastric acid secretion and would, therefore, not be useful in Zollinger-Ellison syndrome.

7. The answer is B *[see* II.C.3.c.(2)*].*

Although most prostaglandin analogs are nonspecific in their sites of action and may produce similar physiological effects, latanoprost is specifically formulated and marketed for use in the treatment of glaucoma. Its relative selectivity for the $PGF_{2\alpha}$ receptor is responsible for its ability to lower intraocular pressure and, therefore, its benefit in treating glaucoma.

8. The answer is D *[see* II.C.2.b; II.C.4*].*

As noted in the answer to question 7, most prostaglandin analogs have activity at receptors throughout the body, causing a prostaglandin-like effect on numerous organ systems. Misoprostol, as a relatively nonselective agonist, would cause contraction of gastrointestinal smooth muscle, stimulate pain fibers, and reset the thermoregulatory center of the CNS, thus causing all the potential side effects listed.

9. The answer is A *[see* II.D.4*].*

Zafirlukast is the only drug that has been associated with Churg-Strauss syndrome, a condition of eosinophilic vasculitis that occurs when a patient who is on both zafirlukast and corticosteroid therapy suddenly discontinues the corticosteroid. This effect has not been observed with the pharmacologically similar drug montelukast. Note that slow withdrawal of the corticosteroid (which should be done anyway, to minimize acute adrenal insufficiency) will prevent this adverse drug reaction.

10. The correct answer is B *[see* II.D.2.b*].*

Zafirlukast and montelukast exert their effect by blocking leukotrienes at their receptor. Zileuton, which acts by inhibiting lipo-oxygenase, will decrease the synthesis of these inflammatory mediators. Therefore, it is the only drug listed that will decrease the synthesis and, consequently, the release of leukotrienes.

11. The answer is D *[see* II.B.1.b.(1); II.B.2.b.(1)*].*

Rizatriptan (and other drugs in the class) are acting as 5-HT_1-agonists. This mechanism results in three distinct and beneficial pharmacodynamic effects. First, it causes direct vasoconstriction, which returns the blood vessel to its preheadache diameter. Second, by acting on neuronal receptors, it inhibits the release of additional vasodilating and pain-transmitting substances, such as neurokinin A and substance P. Third, this action has been shown to have a direct antinociceptive action, preventing the firing of pain neurones directly. Therefore all three answers correctly describe the benefit of rizatriptan.

12. The correct answer is C *[see* II.B.1.c.(2); II.B.2.c; II.B.3.b*].*

Alosetron is the agent useful in treating diarrhea-predominant IBS. By blocking the 5-HT_3-receptor, it inhibits the serotonin-induced increase in intestinal motility, thus slowing peristalsis and gut movement. Tegaserod would worsen diarrhea-predominant IBS, because its serotonergic actions are agonistic and would stimulate GI smooth muscle contraction. Naratriptan, acting as a 5-HT_1-agonist, has little effect on GI motility.

13. The correct answer is E *[see* III.A.4.b*].*

Of the salicylates, sulfasalazine has been most associated with this particular toxicity. It is a toxicity that occurs with chronic use of the drug in men with Crohn disease or other inflammatory conditions of the intestine. Withdrawal of the drug may allow reproductive function to return, although this is not always the case. In addition, it may take an extended period of time, after cessation of therapy, for function to return.

14. The correct answer is A *[see* II.C.1.a; III.A.2.a*].*

Recall that in prostaglandin and thromboxane synthesis, COX 1 is responsible for much of the daily production of maintenance eicosanoids. COX 2, while also contributing to daily production of prostaglandins and thromboxanes, is more important in inflammation. COX 3 is the central source of prostaglandins that contribute to CNS function of the eicosanoids. Also recall that it is thromboxane that specifically has platelet-aggregating ability. Therefore, it is through inhibition of COX 1 and the subsequent decrease in thromboxane (not prostaglandin or leukotriene) synthesis that the antiplatelet effect of aspirin is effected.

15. The correct answer is D *[see* II.C.1.a; III.B.3*].*

The roles of COX 1, 2, and 3 are reviewed in the answer to question 14. Because, mechanistically, acetaminophen is thought to be relatively selective for COX 3, it would not possess any antiplatelet activity, nor would it reduce the synthesis of gastric cytoprotective prostaglandins. Therefore, it would not interfere with platelet function or other antiplatelet therapies and it would not be prone to cause gastric ulceration. In addition, the relationship between aspirin and Reye syndrome in children with viral infections does not apparently exist with acetaminophen, making it a safe antipyretic to use in those patients.

16. The correct answer is D *[see* III.B.4.b*].*

Acetaminophen toxicity is characterized by a profound hepatoxicity, which is mediated by a reactive intermediary formed on saturation and depletion of the normal metabolic pathways. This does not affect the vasculature (as with the ergot derivatives), thus no vasoconstriction is observed. Neither is severe GI upset evident (although mild GI upset may occur early in toxicity). Nor does profound CNS stimulation occur, as it does with aspirin toxicity. Therefore answer D is correct.

17. The correct answer is A *[see* III.D.1.a; III.D.2.a; III.D.3.a*]*

Allopurinol and probenecid, while effective in preventing attacks of gouty arthritis by lowering circulating levels of uric acid, are not effective in treating the acute inflammatory situation that characterizes an acute attack. Colchicine, by inhibiting the migration of proinflammatory cells into the affected joint, will reduce the inflammatory process, thus alleviating the pain and edema associated with acute attacks of gouty arthritis.

18. The correct answer is C *[see* III.D.2.c; III.D.3.c; III.D.4.c.(2)*]*

Probenecid, as a uricosuric and promoting the excretion of uric acid, will effectively lower plasma concentration of urate. However, it also increases the urinary levels of uric acid. If this concentration exceeds the solubility constant of uric acid in the urine, then it may crystallize and precipitate out, causing stone formation or urinary lithiasis. For this reason, patients taking probenecid should always be counseled to drink copious amounts of water.

19. The correct answer is B *[see* II.C.1.a; III.E.2*]*

The roles of COX 1, 2, and 3 are reviewed in the answer to question 14. It is through their inhibition of inflammatory prostaglandin synthesis by inhibiting COX 2, that the NSAIDs exert their anti-inflammatory actions.

20. The correct answer is C *[see* III.E.4.b*]*

The primary side effects that have been associated with the COX 2 specific inhibitors are gastrointestinal bleeding and, more recently, potentially fatal thrombotic events. The latter is thought to reflect a toxicodynamic effect that results from inhibition of vascular COX 2, which contributes to the daily control of platelet and/or vascular function. Severe ischemic colitis has been reported with alosetron; torsade des points, with older, second-generation antihistaminics; and cisapride which are no longer available for use; acute liver failure, with acetaminophen overdose; and Churg-Strauss syndrome with zafirlukast and corticosteroid

withdrawal. None of these adverse drug reactions has been associated with the COX 2 specific inhibitors.

15

Medicinal Chemistry and Pharmacology: Cardiovascular and Diuretic Drugs

Edward J. Moreton

I. INTRODUCTION.

Many categories of drugs affect the cardiovascular (CV) and renal systems. Certain drugs can be used to treat heart failure (e.g., cardiac glycosides and diuretics), relieve angina pectoris (e.g., antianginal agents), and control dysrhythmias (e.g., antiarrhythmic agents). Others can reduce hypertension (e.g., antihypertensives, including a variety of diuretics, β-blocking agents, and arteriolar smooth muscle dilators), treat the hyperlipidemias (e.g., antihyperlipidemic agents), reduce clotting and treat such conditions as venous thrombosis and pulmonary embolism (e.g., anticoagulants, thrombolytics), and treat anemias (e.g., antianemic agents).

II. CARDIAC GLYCOSIDES AND POSITIVE INOTROPES

A. Chemistry

1. Almost all of the cardiac glycosides (also called **cardiotonics**) are naturally occurring steroidal glycosides obtained from plant sources. **Digitoxin** is obtained from *Digitalis purpurea,* **digoxin** from *Digitalis lanata,* and **ouabain** from *Strophanthus gratus.*

2. The cardiac glycosides are closely related structurally, consisting of one or more sugars (i.e., **glycone portion**) and a steroidal nucleus (i.e., **aglycon or genin portion**) bonded through an **ether (glycosidic) linkage.** These agents also have an **unsaturated lactone substituent (cyclic ester)** on the genin portion. The prototypical agent is **digitoxin** (Figure 15-1).

a. Digoxin (Lanoxin) has an additional hydroxyl group at position 12 (Figure 15-1).

b. Ouabain has a rhamnose glycone portion and additional hydroxyl groups at positions 1, 5, 11, and 19 (Figure 15-1).

3. Removing the glycone portion causes decreased activity and increased toxicity from changes in polarity that cause erratic absorption from the gastrointestinal (GI) tract.

4. The **duration of action** of a cardiac glycoside is **inversely proportional to the number of hydroxyl groups,** which increase polarity. Increased polarity results in decreased protein binding, decreased liver biotransformation, and decreased renal tubular reabsorption.

a. Digitoxin has a long duration of action and may accumulate.

b. Ouabain, in contrast, has an extremely short duration of action and is effective only when given intravenously.

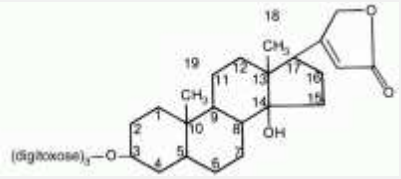

Figure 15-1. Structural formula of digitoxin (Crystodigin), the prototypical cardiac glycoside.

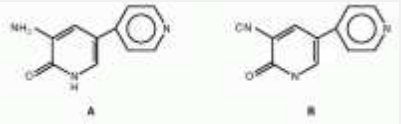

Figure 15-2. Structural formulas of bipyridine derivatives. **A.** Amrinone (Inocor). **B.** Milrinone (Primacor).

5. Amrinone, inamrinone, and milrinone are bipyridine derivatives with positive inotropic action (Figure 15-2).

B. Pharmacology. Cardiac glycosides increase myocardial contractility and efficiency, improve systemic circulation, improve renal perfusion, and reduce edema. The electrophysiological effects of cardiac glycosides are summarized in Table 15-1. Angiotensin-converting enzyme (ACE) inhibitors and perhaps AT_1 angiotensin-receptor antagonists; vasodilators such as nitroprusside, nitroglycerin, and hydralazine; and diuretics may be important adjuncts to cardiac glycosides. ACE inhibitors may be considered as first-line treatment.

1. When given in therapeutic doses, cardiac glycosides produce positive inotropic effects by inhibiting membrane-bound Na^+/K^+-activated adenosine triphosphatase (ATPase). These effects of cardiac glycosides increase the rate of tension development, the contractility, and the rate of relaxation of cardiac muscle. The effects include

a. Increase in intracellular sodium concentration

b. Reduction in calcium transport from the cell by the sodium-calcium exchanger

c. Facilitation of calcium entry via voltage-gated membrane channels

d. Increased release of calcium from sarcoplasmic reticulum

2. Therapeutic doses of cardiac glycosides also cause

a. A negative chronotropic effect from increased vagal tone of the sinoatrial (SA) node

b. Diminished central nervous system (CNS) sympathetic outflow from increased carotid sinus baroreceptor sensitivity

c. Systemic arteriolar and venous constriction, which increases venous return and thus increases cardiac output

3. Amrinone and milrinone produce positive inotropic effects and vasodilation via selective inhibition of type III phosphodiesterase (PDE) isozyme, leading to an increase in cyclic adenosine monophosphate (cAMP) in cardiac and smooth muscle. Inhibition of type III PDE produces

Table 15-1. Effects of Cardiac Glycosides on the Heart

Effects	Atria	AV Node	Ventricles
Direct	Contractility ↑	ERP ↑	Contractility ↑
	ERP ↑	Conduction velocity ↓	ERP ↓
	Conduction velocity ↓		Automaticity ↑
Indirect	ERP ↓	ERP ↑	No effect
	Conduction velocity ↑	Conduction velocity ↓	
On electrocardiogram	P changes	PR interval ↑	QT ↓
			T and ST depressed
Adverse	Extrasystole	AV depression or block	Fibrillation

	Tachycardia		Extrasystole
			Tachycardia

AV, atrioventricular; *ERP,* effective refractory period; ↑, increased; ↓, decreased.

Reprinted with permission from Jacob LS, Pharmacology, 3rd ed. Malvern, PA, Harwal, 1992:96.

a. Vasodilation and fall in vascular resistance

b. Increased force of cardiac contraction

c. Increased velocity of cardiac relaxation

C. Therapeutic indications

1. Heart failure (stage C only)

2. Atrial fibrillation

3. Atrial flutter

4. Paroxysmal atrial tachycardia

5. Amrinone and milrinone are indicated for short-term treatment of congestive heart failure only.

D. Adverse effects

1. Early adverse effects of cardiac glycosides represent the early stages of toxicity, including

a. GI effects, such as anorexia, nausea, vomiting, and diarrhea

b. CNS effects, such as headache, visual disturbances (green or yellow vision), confusion, delirium, neuralgias, and muscle weakness

2. Later adverse effects represent intoxication and include such serious cardiac disturbances as premature ventricular contractions, paroxysmal and nonparoxysmal atrial tachycardia, atrioventricular (AV) dissociation or block, ventricular tachycardia, and ventricular fibrillation.

III. DRUGS FOR TREATMENT OF MYOCARDIAL ISCHEMIA

A. Chemistry

1. Antianginal agents include **nitrites** (i.e., organic esters of nitrous acid) such as amyl nitrite, **nitrates** (i.e., organic esters of nitric acid) such as nitroglycerin and isosorbide, **β-blockers** such as propranolol, and **calcium antagonists** such as verapamil and nifedipine (Figure 15-3).

a. Amyl nitrite is a volatile and flammable liquid administered by inhalation. It requires special precautions (especially restriction of smoking) during administration.

b. Nitroglycerin is also a volatile and flammable liquid and requires great care during storage. It must be dispensed from its original glass containers and protected from body heat.

(1) When given intravenously, nitroglycerin requires the use of special plastic administration sets to avoid absorption and loss of potency.

(2) Nitroglycerin is metabolically unstable and undergoes extensive first-pass metabolism.

2. Peripheral vasodilators include the dipiperidino-dipyrimidine dipyridamole (Figure 15-3).

B. Pharmacology

1. Nitrites and nitrates are fast-acting antianginal agents that directly relax vascular smooth muscle by formation of the free radical nitric oxide (NO), which is identical to endothelium-derived relaxing factor (EDRF). NO activates guanylyl cyclase to increase synthesis of cyclic guanosine monophosphate (cGMP) within smooth muscle, resulting in dephosphorylation of light chain myosin and muscle relaxation. This causes peripheral pooling of the blood, diminished venous return (reduced preload), decreased systemic vascular resistance, and decreased arterial pressure (reduced afterload). These vascular effects:

a. Reduce myocardial oxygen demand

b. Cause redistribution of coronary blood flow along the collateral coronary arteries, improving perfusion of the ischemic myocardium

2. β-Adrenergic blockers decrease sympathetic-mediated myocardial stimulation (see Chapter 13, IV.A.2, IV.C.4). The resulting negative inotropic and negative chronotropic effects reduce myocardial oxygen requirements.

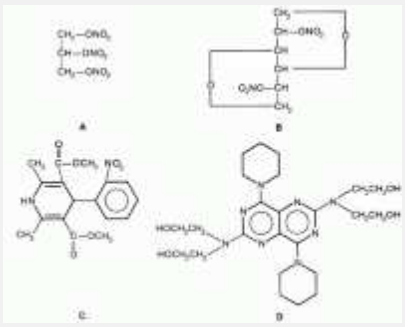

Figure 15-3. Structural formulas of antianginal agents. **A.** Nitroglycerin (Nitrostat). **B.** Isosorbide dinitrate (Isordil). **C.** Nifedipine (Procardia). **D.** Dipyridamole (Persantine).

3. Calcium antagonists (also known as **calcium channel blockers**) block calcium entry through the membranous calcium ion (Ca^{++}) channels of coronary and peripheral vascular smooth muscle.

a. Peripheral arterioles dilate and total peripheral resistance decreases, reducing afterload and reducing myocardial oxygen requirements.

b. Calcium antagonists also increase oxygen delivery to the myocardium by dilating coronary arteries and arterioles.

4. Dipyridamole relaxes smooth muscles, decreasing coronary vascular resistance and increasing coronary blood flow.

C. Therapeutic indications

1. Nitrites and nitrates are used to relieve acute anginal attacks, as prophylaxis during anticipation of an acute anginal attack, and for long-term management of recurrent angina pectoris.

2. β-Adrenergic blockers are used for adjunctive prophylaxis of chronic stable angina pectoris in combination with nitrites or nitrates. They have also been shown to increase survival time in heart failure and after myocardial infarction (MI). Three β-blockers are proven to reduce mortality in heart failure and are now class I recommendations for heart failure.

3. Calcium antagonists are used to treat chronic stable angina pectoris and variant (Prinzmetal) angina.

4. Dipyridamole is now used primarily as a platelet aggregation inhibitor.

D. Adverse effects

1. Nitrites and nitrates are associated with:

a. CNS effects, such as headache, apprehension, dizziness, and weakness

b. CV effects, such as hypotension, tachycardia, palpitations, and syncope

c. Skin effects, such as rash and dermatitis

d. Methemoglobinemia

2. β-Adrenergic blockers are associated with:

a. Worsening of congestive heart failure

b. Bradycardia and hypotension

c. Reduced kidney blood flow and decreased glomerular filtration

3. Calcium antagonists generally produce only mild adverse effects.

a. When given in conjunction with β-adrenergic blockers, the CV effects of calcium antagonists may be enhanced, resulting in bradycardia, hypotension, peripheral edema, congestive heart failure, AV block, and asystole.

b. Verapamil may also cause sleeplessness, muscle fatigue, nystagmus, and emotional depression. During the first week of therapy, verapamil increases serum digitalis concentrations and may cause digitalis toxicity.

4. Dipyridamole is associated with:

a. GI effects, such as nausea, vomiting, and diarrhea

b. CNS effects, such as headache and dizziness

c. CV effects, such as hypotension (with excessive doses)

d. Bleeding

IV. ANTIARRHYTHMIC AGENTS

A. Chemistry. Antiarrhythmic agents have widely diverse chemical structures. They include representatives of the following groups:

1. Cinchona alkaloids—such as quinidine (an optical isomer of quinine)

2. Amides—such as procainamide (Pronestyl), flecainide (Tambocor), and disopyramide (Norpace)

3. Xylyl derivatives—such as lidocaine (Xylocaine) and mexiletine (Mexitil)

4. Quaternary ammonium salts—such as bretylium (Bretylol)

5. Diiodobenzyloxyethylamines—such as amiodarone (Cordarone)

6. β-Blockers—such as, nadolol (Corgard), propranolol (Inderal), esmolol (Brevibloc), and acebutolol (Sectral)

7. Calcium antagonists—such as diltiazem (Cardizem) and verapamil (Calan)

8. Hydantoins—such as phenytoin (Dilantin)

B. Pharmacology. Antiarrhythmic agents are classified according to their ability to alter the action potential of cardiac cells (Tables 15-2 and 15-3). The myocardial action potential curve is shown in Figure 15-4.

1. Class IA drugs (e.g., quinidine, procainamide, disopyramide) produce state-dependent sodium channel blockade to slow the rate of rise of phase 0 (the phase of rapid depolarization and reversal of transmembrane voltage) and prolong repolarization and effective refractory period.

2. Class IB drugs (e.g., lidocaine, tocainide, mexiletine, phenytoin) have a minimal effect on the rate of rise of phase 0 and shorten repolarization.

3. Class IC drugs (e.g., flecainide, propafenone) have a marked effect in slowing the rate of rise of phase 0 and in slowing conduction. They have little effect on repolarization. Encainide was withdrawn from the market but is available on a limited basis.

Table 15-2. Major Effects of Antiarrhythmic Drugs on Electrocardiogram

Drug	QRS	QT	PR[a]
Quinidine	↑	↑	→↑
Procainamide			
Amiodarone			
Disopyramide	↑	↑	→
Lidocaine	→	↓	→↑↓
Phenytoin			
Tocainide			
Mexiletine			
Propranolol	→	↓	→↑

↑, increased; ↓, decreased; →, no change.

[a] All antiarrhythmic drugs have a variable response, usually with little observable effect. However, lidocaine hardly ever affects the PR interval, whereas phenytoin and propranolol usually increase the PR interval.

Table 15-3. Effects of Antiarrhythmic Drugs on Electrophysiologic Properties of the Heart

Drug Class	Automaticity: SA Node	Automaticity: Purkinje Fibers	Effective Refractory Period: AV Node	Effective Refractory Period: Purkinje Fibers	Membrane Responsiveness: Purkinje Fibers
IA	→↑	↓→	↑→↓	↑↓	↓
IB	→	↓	→↓	↓	→↓
IC	→	↓	↑	↓	↓
II	↓	↓	↑	↓→↑	↓
III	↑↓	↑↓	↓→↑	↑	→
IV	↓	→↓	↑	→	→

↑, increased; ↓, decreased; →, no change.

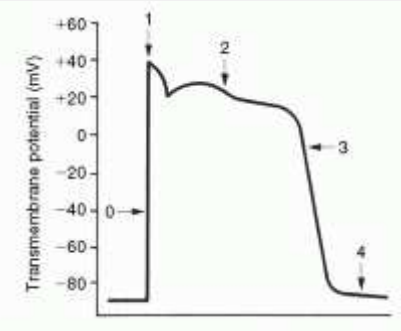

Figure 15-4. Myocardial action potential curve. This curve represents ventricular depolarization/repolarization. *0,* phase 0 (rapid depolarization); *1,* phase 1 (early rapid repolarization); *2,* phase 2 (plateau); *3,* phase (final rapid repolarization); *4,* phase 4 (slow depolarization).

4. Class II drugs (e.g., propranolol, nadolol, esmolol, acebutolol) are β-adrenergic antagonists that competitively block catecholamine-induced stimulation of cardiac β-receptors and depress depolarization of phase 4.

5. Class III drugs (e.g., bretylium, amiodarone, sotalol, ibutilide, dofetilide) increase action potential duration by prolonging repolarization via blockade of the delayed rectifier potassium current I_{Kr}.

6. Class IV drugs (e.g., verapamil, diltiazem, bepridil) are calcium antagonists that block the slow inward current carried by calcium during phase 2 (i.e., long-sustained depolarization or the plateau of the action potential), increase the effective refractory period, and depress phase 4 depolarization.

7. Digoxin and adenosine. Digitalis glycosides (digoxin) elicit a vagotonic response that increases AV nodal refractoriness. Adenosine acts at G-protein-coupled adenosine receptors to increase AV nodal refractoriness.

8. Moricizine is a type I antiarrhythmic but not A, B, or C. It exhibits potent local anesthetic activity and myocardial membrane stabilizing activity. Moricizine reduces fast inward sodium current, decreasing the action potential duration and effective refractory period, and increases the PR, QRS, and QT_e interval.

C. Therapeutic indications. Antiarrhythmic agents are used to reduce abnormalities of impulse generation (ectopic pacemaker automaticity) and to modify the disturbances of impulse conduction within cardiac tissue. (Indications for specific agents are given in Table 15-4.)

Table 15-4. Use of Antiarrhythmic Drugs in Common Cardiac Arrhythmias

Arrhythmia	Treatment of Choice	Alternatives
I. Supraventricular		
Atrial fibrillation or flutter	Digital to control ventricular rate, DC shock for conversion	Quinidine to suppress recurrences after DC shock
Paroxysmal atrial or nodal tachycardia	Vagotonic maneuver; digitalis	Verapamil (quinidine, procainamide, disopyramide, and β-adrenergic antagonists may all be useful, especially prophylactically)
II. Ventricular		
Ventricular premature depolarization	Lidocaine	Procainamide, quinidine, or disopyramide for prolonged suppression
Ventricular	DC shock	Lidocaine, procainamide, or

tachycardia		mexiletine
III. Digitalis-induced		
	Lidocaine or phenytoin	Procainamide is somewhat useful; β-adrenergic antagonists are useful but have a high incidence of adverse effects

DC, direct current.

Reprinted with permission from Jacob LS. Pharmacology, 3rd ed. Malvern, PA, Harwal, 1992:102.

D. Adverse effects

1. Class IA drugs are associated with CV effects (e.g., myocardial depression, AV block, ventricular dysrhythmias, asystole, and hypotension) and with GI effects (e.g., GI upset, nausea, vomiting, and diarrhea). In addition:

a. Quinidine can cause cinchonism, with tinnitus, confusion, photophobia, headache, and psychosis.

b. Procainamide can cause systemic lupus erythematosus- (SLE-) like syndrome.

c. **Disopyramide** can cause congestive heart failure and antimuscarinic effects.

2. Class IB drugs are associated with CNS effects (including CNS depression, drowsiness, disorientation, and paresthesias), CV effects (including hypotension and circulatory collapse), and hepatitis. In addition:

a. Lidocaine can cause seizures and respiratory arrest.

b. Tocainide can cause pneumonitis and blood dyscrasias.

c. **Mexiletine** can cause hepatic injury and blood dyscrasias.

d. Phenytoin can cause nystagmus, decreased mental function, and blood dyscrasias.

3. Class IC drugs are associated with:

a. CV effects, including worsening of arrhythmias in patients with ventricular arrhythmias, particularly patients with a history of MI. They can worsen sinus node dysfunction and heart failure.

b. Visual disturbances such as blurred or double vision

4. Class II drugs are associated with:

a. CV effects, such as hypotension, AV block, and asystole

b. Respiratory effects, such as bronchospasm

5. Class III drugs are associated with:

a. CV effects, such as hypotension and initially increased dysrhythmias

b. GI effects, such as nausea and vomiting

6. Class IV drugs are associated with CV adverse effects, such as hypotension, bradycardia, AV block, congestive heart failure, and asystole.

7. Cardiac glycosides (see II.D). **Adenosine** causes asystole lasting less than 5 sec and is the therapeutic objective.

8. Because of its proarrhythmic activity, **moricizine** is reserved for patients with life-threatening ventricular arrhythmias.

V. ANTIHYPERTENSIVE AGENTS

A. Chemistry. Antihypertensive agents vary so widely in chemical structure that they are usually classified by mechanism of action rather than chemical class (Table 15-5).

B. Pharmacology. Antihypertensive agents lower blood pressure by reducing total peripheral resistance or cardiac output through a variety of mechanisms (Table 15-5).

1. Diuretics such as thiazides create a negative sodium balance, reduce blood volume, and decrease vascular smooth muscle responsiveness to vasoconstrictors (see VI.C).

2. Vasodilators such as diazoxide and minoxidil are potassium channel activators that produce membrane hyperpolarization, whereas hydralazine may stimulate formation of EDRF (NO) to decrease arterial resistance. Human brain natriuretic peptide (BNP) via receptor stimulation and sodium nitroprusside via release of NO activate guanylyl cyclase, forming cGMP to relax both arterioles and veins.

3. Peripheral sympatholytics interfere with adrenergic function by blocking postganglionic adrenergic receptors (e.g., propranolol, prazosin), limiting the release of neurotransmitters from adrenergic neurons (e.g., guanethidine), or depleting intraneuronal catecholamine storage sites (e.g., reserpine).

4. Central α_2-sympathomimetics (e.g., clonidine, methyldopa) appear to mediate their effects by stimulating presynaptic α_2-inhibitory receptors, resulting in a negative sympathetic outflow and lowered peripheral resistance.

Table 15-5. Classification of Antihypertensive Agents by Their Mechanism of Action

Mechanism of Action		Drug
Vasodilators		
	Arteriolar	Diazoxide (Hyperstat IV)
		Hydralazine (Apresoline)
		Minoxidil (Loniten)
	Arteriolar and venous	Nitroprusside (Nipride)
Peripheral sympatholytics		Acebutolol (Sectral)
		Atenolol (Tenormin)
		Betaxolol (Kerlone)
		Bisoprolol (Zebeta)
		Carteolol (Cartrol)
		Carvedilol (Coreg)
		Doxazosin (Cardura)
		Guanadrel (Hylorel)
		Guanethidine (Ismelin)
		Labetalol (Trandate)
		Metoprolol (Lopressor)
		Nadolol (Corgard)

		Penbutolol (Levatol)
		Pindolol (Visken)
		Prazosin (Minipress)
		Propranolol (Inderal)
		Reserpine (Serpasil)
		Terazosin (Hytrin)
		Timolol (Blocadren)
Central α_2-sympathomimetics		Clonidine (Catapres)
		Guanabenz (Wytensin)
		Guanfacine (Tenex)
		Methyldopa (Aldomet)
Calcium channel blockers		Amlodipine (Norvasc)
		Diltiazem (Cardizem) SR
		Felodipine (Plendil)
		Isradipine (DynaCirc)
		Nicardipine (Cardene)
		Nifedipine (Procardia) SR

		Verapamil (Calan)
Angiotensin II receptor antagonists		Candesartan (Atacand)
		Irbesartan (Avapro)
		Losartan (Cozaar)
		Telmisartan (Micardis)
		Valsartan (Diovan)
Angiotensin-converting enzyme inhibitors		Benazepril (Lotensin)
		Captopril (Capoten)
		Enalapril (Vasotec)
		Fosinopril (Monopril)
		Lisinopril (Prinivil)
		Moexipril (Univasc)
		Perindopril (Aceon)
		Quinapril (Accupril)
		Ramipril (Altace)
		Trandolapril (Mavik)
Endothelin receptor antagonist		Bosentan (Tracleer)

5. Calcium channel blockers (e.g., amlodipine, diltiazem, felodipine, isradipine, nicardipine, nifedipine, verapamil) lower vascular resistance and blood pressure via blockade of voltage-gated calcium channels. Arterioles are more sensitive than veins.

6. ACE inhibitors (e.g., captopril) block the conversion of inactive angiotensin I to the potent vasoconstrictor angiotensin II. The reduced angiotensin II concentration also lowers aldosterone concentration, which limits sodium retention.

7. Angiotensin II receptor antagonists (e.g., losartan) are nonpeptide antagonists of the AT1 angiotensin II receptor subtype located in vasculature, myocardium, brain, kidney, and adrenal glomerulosa. They produce vasodilation, cause loss of salt and water to decrease plasma volume, and decrease myogenic activity.

8. Endothelin receptor antagonists (e.g., bosentan) are potent orally active nonpeptide endothelin receptor antagonists.

C. Therapeutic indications

1. Antihypertensive agents are used separately or in combination to **treat high blood pressure.**

2. These agents may also be administered parenterally to **treat hypertensive emergencies** such as malignant hypertension, eclampsia, or the severe hypertension associated with excess catecholamines. Parenteral therapy may include some combination of the following agents:

a. Arteriolar and venous vasodilator such as nitroprusside or bosentan (i.e., pulmonary arterial hypertension)

b. Arteriolar vasodilator such as diazoxide or hydralazine

c. **Dual α-adrenergic-** and **β-adrenergic-receptor blockers** such as labetalol

d. β-Blocking agent such as propranolol

e. Ganglionic-blocking agent such as trimethaphan

D. Adverse effects

1. Diuretics (thiazides) can cause

a. Fluid and solute imbalances, such as hypokalemia, hypercalcemia, hyperuricemia, hypomagnesemia, hyponatremia, and hyperglycemia

b. Increased serum low-density lipoprotein (LDL) cholesterol and triglyceride concentrations

c. Other effects (see VI.C.4)

2. Vasodilators are associated with:

a. GI upset

b. CNS effects, such as headache and dizziness

c. CV effects, such as tachycardia, fluid retention, and worsening of angina

d. Other effects, such as nasal congestion, hepatitis, glomerulonephritis, and SLE-like syndrome

3. Peripheral sympatholytics are associated with a variety of adverse effects, depending on the specific agent.

a. β-Blockers (e.g., propranolol) are associated with:

(1) CV effects, such as bradycardia, congestive heart failure, and Raynaud phenomenon
(2) GI upset
(3) Blood dyscrasias
(4) CNS effects, such as depression, hallucinations, organic brain syndrome, and transient hearing loss
(5) Other effects, such as increased airway resistance, increased serum triglyceride concentrations, decreased high-density lipoprotein (HDL) cholesterol concentrations, and psoriasis
(6) Cardiac arrhythmias if withdrawal is abrupt
b. Prazosin is associated with:
(1) CV effects, such as sudden syncope with the first dose, palpitations, and fluid retention
(2) CNS effects, such as headache, drowsiness, weakness, dizziness, and vertigo
(3) Antimuscarinic effects and priapism
P.353

c. **Guanethidine** is associated with:
(1) CV effects, such as bradycardia, orthostatic hypotension, and sodium and water retention
(2) Diarrhea
(3) Aggravation of bronchial asthma
d. Reserpine is associated with:
(1) CNS effects, such as nightmares, depression, and drowsiness
(2) CV effects, such as bradycardia
(3) GI effects, such as GI upset and activation of peptic ulcer
(4) Nasal stuffiness
4. Central α_2-sympathomimetics also have adverse effects that vary with the specific agent.
a. Clonidine is associated with:
(1) CNS effects, such as sedation and drowsiness
(2) Dry mouth and severe rebound hypertension
(3) Insomnia, headache, and cardiac dysrhythmias (with sudden withdrawal)
b. Methyldopa is associated with:
(1) CV effects, such as orthostatic hypotension and bradycardia
(2) CNS effects, such as sedation and fever
(3) GI effects such as colitis
(4) Other effects, such as hepatitis, cirrhosis, Coombs-positive hemolytic anemia, and SLE-like syndrome
5. Calcium channel blockers are associated with CV effects, resulting in hypotension, dizziness, headache, and flushing. When given with β-adrenergic blockers, their effects may be enhanced, resulting in bradycardia, hypotension, peripheral edema, congestive heart failure, AV block, and asystole. Long-term administration is associated with risk of gingival hyperplasia and Barrett esophagus.

6. ACE inhibitors are associated with:

a. CV effects, such as hypotension and syncope

b. Hematologic effects, such as neutropenia and agranulocytosis

c. Other effects, such as chronic cough, anorexia, polyuria, oliguria, acute renal failure, cholestatic jaundice, and (rarely) angioedema

7. Angiotensin II receptor antagonists are associated with adverse effects similar to ACE inhibitors, except that cough and angioedema, which are independent of angiotensin antagonism, occur less frequently.

8. Endothelin receptor antagonists (Bosentan) have the potential for serious liver injury and damage to a fetus.

VI. DIURETICS

A. Osmotic diuretics

1. Chemistry. Osmotic diuretics (e.g., mannitol, urea, glycerin, isosorbide) are highly polar, water-soluble agents with a low renal threshold (Figure 15-5).

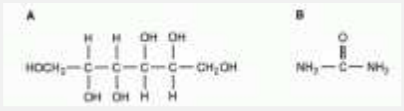

Figure 15-5. Structural formulas of osmotic diuretics. **A.** Mannitol (Osmitrol). **B.** Urea (Ureaphil).

2. Pharmacology

a. Osmotic diuretics are relatively inert chemicals that are freely filtered at the glomerulus and poorly reabsorbed from the renal tubule. By increasing the osmolarity of the glomerular filtrate, they **limit tubular reabsorption of water** and thus **promote diuresis.**

b. Because these agents increase water, sodium, chloride, and bicarbonate excretion, they cause an **increase in urinary pH.**

3. Therapeutic indications. Osmotic diuretics are used to:

a. Help prevent and treat oliguria and anuria

b. Reduce cerebral edema and decrease intracranial pressure

c. Reduce intraocular pressure

4. Adverse effects. Osmotic diuretics are associated with:

a. Headache and blurred vision

b. Increased blood volume that worsens congestive heart failure

B. Carbonic anhydrase inhibitors

1. Chemistry. Carbonic anhydrase inhibitors are aromatic or heterocyclic sulfonamides with a prominent thiadiazole nucleus. **Acetazolamide** is the prototypical agent (Figure 15-6).

2. Pharmacology

a. Carbonic anhydrase inhibitors **noncompetitively inhibit the enzyme carbonic anhydrase.** This prevents the enzyme from providing the tubular hydrogen ions needed for exchange with sodium in the proximal tubule, resulting in sodium bicarbonate diuresis.

b. Because these agents increase water, sodium, potassium, and bicarbonate excretion, they cause an **alkaline urinary pH.**

3. Therapeutic indications. Carbonic anhydrase inhibitors are used to:

a. Reduce edema (as adjunct diuretic therapy)

b. Reduce intraocular pressure (retard aqueous humor formation)

c. Alkalinize the urine, enhancing excretion of acidic drugs and their metabolites

d. Treat motor disorders such as petit mal epilepsy, paroxysmal chorea and dystonia, periodic ataxia, and some cases of essential tremor

4. Adverse effects. Carbonic anhydrase inhibitors are associated with:

a. CNS effects, such as CNS depression, drowsiness, sedation, fatigue, disorientation, and paresthesia

b. GI effects, such as GI upset, nausea, vomiting, and constipation

c. Hematologic effects, such as bone marrow depression, thrombocytopenia, hemolytic anemia, leukopenia, and agranulocytosis

d. Hyperchloremic metabolic acidosis

e. Sulfonamide-type hypersensitivity reactions

C. Benzothiadiazide diuretics

1. Chemistry

a. The commonly used thiazide diuretics are primarily closely related **benzothiadiazides with variable substituents.** The prototypical agent is chlorothiazide (Figure 15-7A).

b. Optimal diuretic activity depends on certain **structural features.**

(1) The benzene ring must have a **sulfonamide** group (preferably unsubstituted) in position 7 and a **halogen** (usually a chloro group) or a **trifluoromethyl group** in position 6 (Figure 15-7).

(2) Saturation of the 3,4-double bond increases potency, as with hydrochlorothiazide (Figure 15-7B).

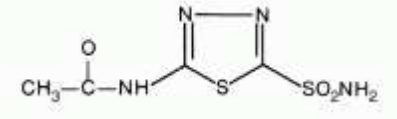

Figure 15-6. Structural formula of acetazolamide (Diamox), the prototypical carbonic anhydrase inhibitor.

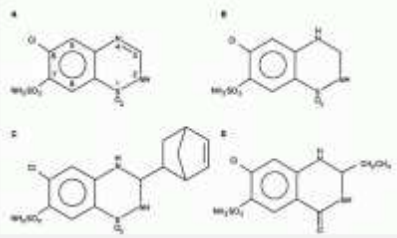

Figure 15-7. Structural formula of (**A**) chlorothiazide (Diuril), the prototypical benzothiadiazide diuretic, and (**B**) hydrochlorothiazide (HydroDIURIL). Structural formulas of (**C**) cyclothiazide (Anhydron) and (**D**) quinethazone (Hydromox), related compounds with substituents that prolong activity and enhance potency.

(3) Lipophilic substituents at position 3 or **methyl groups** at position 2 enhance potency and prolong activity, as with cyclothiazide (Figure 15-7C) and bendroflumethiazide.

(4) Replacement of the sulfonyl group in position 1 by a **carbonyl group** prolongs activity, as with quinethazone (Figure 15-7D).

c. A few **sulfamoylbenzamides** (e.g., indapamide, chlorthalidone) have activity similar to that of the benzothiadiazides (Figure 15-8).

d. Benzothiadiazines without the sulfonamide group (e.g., diazoxide) exhibit antihypertensive activity but lack diuretic activity (Figure 15-9).

2. Pharmacology

a. Benzothiadiazides **directly inhibit sodium and chloride reabsorption** on the luminal membrane of the early segment of the distal convoluted tubule.

b. These agents increase water, sodium, chloride, potassium, and bicarbonate excretion and decrease calcium excretion and uric acid secretion. They may cause an **alkaline urinary pH** by inhibiting carbonic anhydrase.

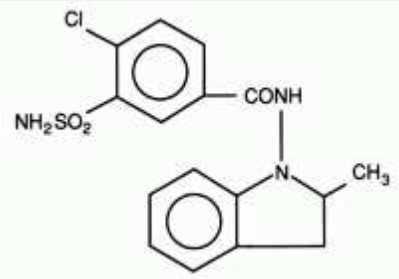

Figure 15-8. Structural formula of indapamide (Lozol), a sulfamoylbenzamide with pharmacological activity similar to that of the benzothiadiazide diuretics.

Figure 15-9. Structural formula of diazoxide (Hyperstat), a benzothiadiazine lacking a sulfonamide group and diuretic action.

3. Therapeutic indications. Benzothiadiazides are used to treat:

a. Chronic edema

b. Hypertension

c. Congestive heart failure (as adjunctive edema therapy)

4. Adverse effects. Benzothiadiazides are associated with:

a. CNS effects, such as headache, dizziness, paresthesias, drowsiness, and restlessness

b. GI effects, such as GI irritation, nausea, vomiting, abdominal bloating, and constipation

c. CV effects, such as orthostatic hypotension, palpitations, hemoconcentration, and venous thrombosis

d. Hematologic effects, such as blood dyscrasias, leukopenia, thrombocytopenia, agranulocytosis, aplastic anemia, hemolytic anemia, and rash

e. Fluid and electrolyte imbalances, such as hypokalemia, hyponatremia, and hypercalcemia

f. Muscular cramps

g. Hyperuricemia and acute gout attacks

h. Hypercholesterolemia and hypertriglyceridemia

i. Sulfonamide-type hypersensitivity reaction

D. Loop diuretics

1. Chemistry. Loop diuretics are anthranilic acid derivatives with a sulfonamide substituent (e.g., furosemide, bumetanide) or aryloxyacetic acids without a sulfonamide substituent (e.g., ethacrynic acid; Figure 15-10).

2. Pharmacology

a. These agents act principally at the thick ascending limb of the loop of Henle, where they **inhibit the cotransport of sodium, potassium, and chloride from the luminal filtrate.**

b. Loop diuretics increase excretion of water, sodium, potassium, calcium, and chloride; decrease uric acid secretion; and cause **no change in urinary pH.**

3. Therapeutic indications. Loop diuretics are used to treat

a. Edema from congestive heart failure, hepatic cirrhosis, and renal disease

b. Pulmonary edema and ascites

4. Adverse effects. Loop diuretics are associated with:

a. Fluid and solute imbalances, such as dehydration, hypokalemia, hyperuricemia, hypercalciuria, and azotemia

b. CNS effects, such as headache, vertigo, blurred vision, tinnitus, and (rarely) irreversible hearing loss

c. Hematologic effects, such as thrombocytopenia and agranulocytosis

Figure 15-10. Structural formulas of loop diuretics. **A.** Furosemide (Lasix). **B.** Ethacrynic acid (Edecrin).

d. CV effects, such as orthostatic hypotension

e. GI effects, such as nausea, vomiting, and diarrhea
f. Leg cramps
g. Hypercholesterolemia and hypertriglyceridemia
h. Sulfonamide-type hypersensitivity reaction

E. Potassium-sparing diuretics

1. Chemistry. The potassium-sparing diuretics are pteridine or pyrazine derivatives (e.g., triamterene, amiloride) or steroid analog antagonists of aldosterone (e.g., spironolactone; Figure 15-11).

2. Pharmacology

a. Spironolactone and **eplerenone** act as **competitive inhibitors of aldosterone** at mineralocorticoid receptors in the late distal tubule and collecting duct. They interfere with aldosterone-mediated sodium-potassium exchange, decreasing potassium secretion.

b. Triamterene and amiloride, which are not aldosterone antagonists, act directly on the late distal tubule and collecting duct. They disrupt sodium exchange with potassium and hydrogen by blocking sodium channels and decreasing the driving force for secretion of potassium and hydrogen.

c. The potassium-sparing diuretics increase bicarbonate excretion and cause an **alkaline urinary pH.**

3. Therapeutic indications. Potassium-sparing diuretics are used

a. As adjunctive therapy to treat edema from congestive heart failure, hepatic cirrhosis, nephrotic syndrome, and hyperaldosteronism (primary and secondary)
b. As adjunctive therapy (with thiazides and loop diuretics) to treat hypertension
c. To treat or prevent hypokalemia

4. Adverse effects

a. Spironolactone is associated with:
(1) Hyperkalemia
(2) GI effects, such as GI upset, GI bleeding, gastritis, nausea, abdominal cramps, and diarrhea
(3) Endocrine effects, such as gynecomastia, menstrual irregularities, and hirsutism
(4) CNS effects, such as mental confusion and lethargy

b. Triamterene and **amiloride** are associated with:
(1) Hyperkalemia
(2) GI effects, such as GI upset, GI bleeding, nausea, and vomiting
(3) CNS effects, such as headache and dizziness
(4) Increased uric acid concentration in patients with gouty arthritis (with triamterene)
(5) Methemoglobinemia in patients with alcoholic cirrhosis (with triamterene, which inhibits dihydrofolate reductase)

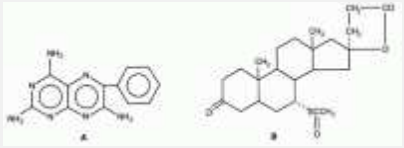

Figure 15-11. Structural formulas of potassium-sparing diuretics. **A.** Triamterene (Dyrenium). **B.** Spironolactone (Aldactone).

VII. ANTIHYPERLIPIDEMIC AGENTS

A. Chemistry. Antihyperlipidemic agents vary in chemical structure and are usually classified by their site of action—locally in the intestine (nonabsorbable agents) or systemically (absorbable agents).

1. Nonabsorbable agents are **bile acid sequestrants.** These agents are hydrophilic, water-insoluble resins that bind to bile acids in the intestine. Examples include colesevelam hydrochloride; **cholestyramine chloride,** a basic anion-exchange resin consisting of trimethylbenzylammonium groups in a large copolymer of styrene and divinylbenzene; **colestipol hydrochloride,** a copolymer of diethylpentamine and epichlorohydrin (Figure 15-12), and **ezetimibe,** a 2-azetidinone blocker of the gastrointestinal cholesterol transporter.

2. Absorbable agents include **nicotinic acid** (but not the structurally similar nicotinamide), the aryloxyisobutyric acid derivatives **fenofibrate** (prodrug) and **gemfibrozil,** the 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitor **lovastatin,** and the fatty fish oils containing large amounts of **eicosapentaenoic acid (EPA)** and **docosahexaenoic acid (DHA;** Figure 15-13).

B. Pharmacology. Antihyperlipidemic agents **increase catabolism** or **reduce lipoprotein production** (e.g., lovastatin, gemfibrozil) or **increase the efficiency of lipoprotein removal** (e.g., cholestyramine, colestipol).

C. Therapeutic indications. These agents are used (in conjunction with appropriate diet and exercise) to reduce plasma lipoprotein concentrations.

D. Adverse effects

1. Nonabsorbable agents (e.g., cholestyramine, colestipol) are associated with GI distress, including abdominal bloating, nausea, dyspepsia, steatorrhea, and constipation or diarrhea.

2. Absorbable agents (e.g., statins, fibrates) are associated with GI distress, skin rash, and leukopenia.

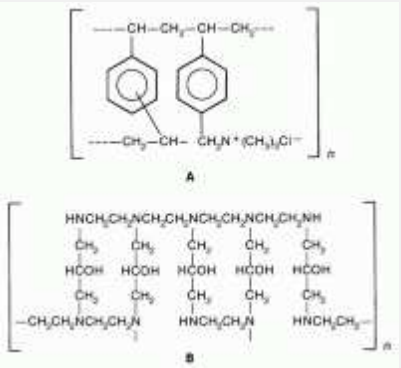

Figure 15-12. Structural formulas of nonabsorbable antihyperlipidemic agents. **A.** Cholestyramine chloride (Questran). **B.** Colestipol hydrochloride (Colestid).

P.359

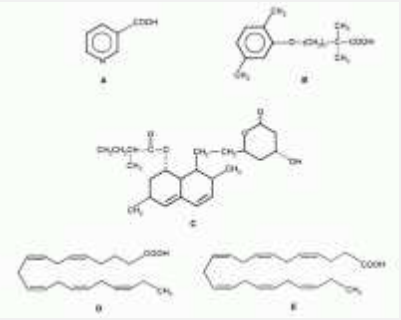

Figure 15-13. Structural formulas of absorbable antihyperlipidemics. **A.** Nicotinic acid (niacin). **B.** Gemfibrozil (Lopid). **C.** Lovastatin (Mevacor). **D.** Eicosapentaenoic acid (found in Promega, Proto-Chol, and others). **E.** Docosahexaenoic acid (found in Promega, Proto-Chol, and others).

a. Lovastatin and other statins (e.g., simvastatin, pravastatin, fluvastatin, atorvastatin,) may increase blood transaminase and creatinine phosphokinase activity associated with myopathy, especially when combined with fibrates or cyclosporins.

b. Gemfibrozil may also cause skeletal muscle pain, blurred vision, and anemia.

c. **Nicotinic acid** produces flushing associated with pruritus, which may be alleviated by one aspirin per day. Tolerance to nicotinic acid develops in 1-2 weeks. High doses of nicotinic acid (2 g/day) may produce hepatic damage.

VIII. ANTICOAGULANT, ANTIPLATELET, AND THROMBOLYTIC AGENTS

A. Anticoagulants. The major anticoagulant agents are **heparin, low molecular weight heparin (LMWH)** and the **oral** anticoagulants.

1. Chemistry

a. Heparin is a large, highly acidic mucopolysaccharide composed of sulfated D-glucosamine and D-glucuronic acid molecules extracted from bovine lung and porcine intestine (Figure 15-14).

b. LMWH fragments (1-10 kDa) **enoxaparin, dalteparin, tinzaparin,** and **ardeparin** are produced through controlled depolymerization of heparin, but they are not interchangeable with heparin in their actions and use.

(1) Because they are highly acidic, heparin and LMWH fragments exist as anions at physiologic pH and are poorly absorbed from the GI tract. Thus they are usually administered parenterally as the sodium salt.

P.360

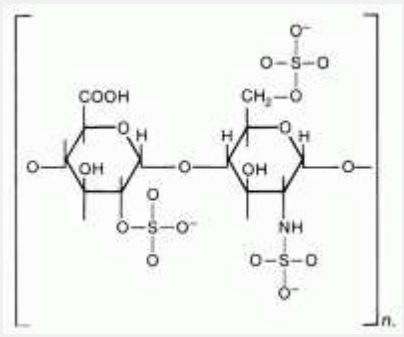

Figure 15-14. Structural formula of heparin, a mucopolysaccharide anticoagulant agent.

(2) The action of heparin and LMWH fragments is quickly terminated by **protamine sulfate,** a highly basic protein that combines chemically with them in approximately equal amounts (mg:mg).

c. **Low molecular weight heparinoids (danaparoid)** are **glycosaminoglycans** extracted from porcine mucosa.

d. Lepirudin is a recombinant-DNA-derived 65 amino acid polypeptide nearly identical to **hirudin,** which belongs to the group of isopolypeptides of the leech *Hirudo medicinalis.*

e. Argatroban is an L-arginine-based structure.

f. Bivalirudin is a 20 amino acid peptide. Lepirudin, bivalirudin, and argatroban are synthetic thrombin inhibitors.

g. Drotrecogin α is a recombinant form of human-activated protein C that inactivates factors Va and VIIIa.

h. **Fondaparinux** is a pentasaccharide that resembles the antithrombin binding region of heparin.

i. Coumarin derivatives, which are highly effective, and the relatively unimportant **indanedione derivatives** are oral anticoagulants.

(1) The **coumarin derivatives** (e.g., **warfarin, dicumarol**) are water insoluble, weakly acidic 4-hydroxycoumarin lactones (Figure 15-15).

(a) These agents are **chemically related to vitamin K,** and their mechanism of action is directly related to their antagonism of the reductase responsible for reducing vitamin K epoxide to the reduced hydroquinone.

(b) These agents are also highly protein bound and extensively metabolized in the liver. These characteristics, in addition to a relatively narrow therapeutic index, make the coumarin derivatives susceptible to significant drug interactions.

(2) Phenindione represents a typical **indanedione derivative** (Figure 15-16).

2. Pharmacology

a. Heparin catalyzes the inhibition of thrombin by antithrombin III (heparin cofactor), preventing the conversion of fibrinogen to fibrin.

Figure 15-15. Structural formulas of coumarin-derivative oral anticoagulants. **A.** Warfarin (Coumadin). **B.** Dicumarol.

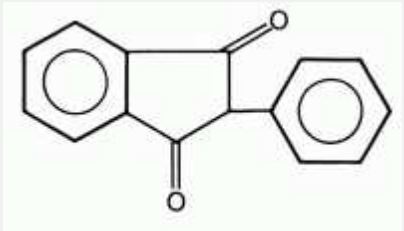

Figure 15-16. Structural formula of the indanedione-derivative oral anticoagulant phenindione (Hedulin).

b. LMWH fragments are unable to catalyze inhibition of thrombin, but they catalyze inhibition by antithrombin III of factor Xa, which is responsible for conversion of prothrombin to thrombin. Heparin prolongs blood clotting time both in vivo and in vitro, whereas LMWH fragments have minimal in vitro effect.

c. **Glycosaminoglycans (Danaparoid)** inhibit fibrin formation by inhibition of clotting factors Xa and IIa (lesser effect).

d. Lepirudin, desirudin, argatroban, and **bivalirudin** bind to and block the catalytic activity of thrombin.

e. Drotrecogin inhibits proteolytic inactivation of factors Va and VIIIa.

f. Fondaparinux facilitates inhibition of factor Xa by antithrombin by 300-fold but has no direct effect on thrombin.

g. Oral anticoagulants interfere with the vitamin K-dependent hepatic synthesis of the active clotting factors II (prothrombin), VII, IX, and X and the anticoagulant proteins C and S. These agents prolong blood clotting time in vivo only.

3. Therapeutic indications

a. Heparin is indicated

(1) For the prophylaxis and treatment of venous thrombosis, pulmonary embolism, peripheral arterial embolism, and atrial fibrillation with embolization

(2) To prevent clotting during arterial surgery and cardiac surgery

(3) To diagnose and treat disseminated intravascular coagulation (DIC)

(4) To prevent postoperative venous thrombosis and pulmonary embolism (in low-dose form)

(5) To prevent cerebral thrombosis during an evolving stroke

(6) As adjunct therapy to prevent coronary occlusion with acute MI

b. LMWH fragments are approved for treatment of thromboembolic complications associated with surgery, unstable angina, and MI.

c. **Danaparoid** is approved for prevention of deep vein thrombosis.

d. Lepirudin and **argatroban** are indicated for treatment of patients experiencing heparin-induced thrombocytopenia.

e. Desirudin is approved of treatment of deep vein thrombosis.

f. Drotrecogin α is approved for reduction of mortality in adult patients with severe sepsis associated with acute organ dysfunction.

g. Fondaparinux is approved for the prophylaxis of deep vein thrombosis in patients undergoing hip fracture surgery and hip or knee replacement surgery. There is no antidote for **fondaparinux**-induced bleeding.

h. **Warfarin sodium** is an oral anticoagulant indicated

(1) For the prophylaxis and treatment of venous thrombosis, pulmonary embolism, and atrial fibrillation with embolization

(2) As adjunct therapy to prevent coronary occlusion with acute MI

4. Adverse effects

a. Heparin

(1) Heparin is associated with:

(a) Hematologic effects, such as hemorrhage, local irritation, thrombocytopenia, hematoma, ulceration, erythema, and pain

(b) Other effects, such as hypersensitivity reactions, fever, chills, and urticaria

(2) Severe adverse effects may be treated by administering protamine sulfate, the specific antidote for heparin.

b. LMWH fragments are absorbed more uniformly than heparin, have a longer biological half-life, and may be associated with a lower incidence of side effects than heparin.

P.362

c. **Danaparoid** is contraindicated in various bleeding disorders and patients hypersensitive to pork products. Danaparoid contains sodium sulfite, which may cause life-threatening allergic reactions.

d. Lepirudin may be associated with cerebral bleeding and allergic, skin, and anaphylactic reactions.

e. Desirudin when employed with epidural/spinal anesthesia or spinal puncture may lead to epidural or spinal hematoma, resulting in long-term or permanent paralysis.

f. Drotrecogin α-induced bleeding is the most common serious adverse reaction.

g. Fondaparinux when employed with epidural/spinal anesthesia or spinal puncture may lead to epidural or spinal hematoma, resulting in long-term or permanent paralysis. The most common adverse reactions associated with **fondaparinux** are bleeding complications.

h. **Warfarin**

(1) The oral anticoagulant warfarin sodium is associated with the following adverse effects:

(a) Hemorrhage

(b) Anorexia, urticaria, purpura, and alopecia

(2) Bleeding may be treated by administering vitamin K (phytonadione), the specific antidote for warfarin sodium.

B. Antiplatelet agents

1. Chemistry. Antiplatelet drugs include aspirin, a salicylate; ticlopidine, a thienopyridine; dipyridamole, a dipiperidino-dinitro pyrimidine; prostacyclin analogs, and the Fab fragments of human monoclonal antibody to the glycoprotein IIb/IIIa (GPIIb/IIIa) receptor.

2. Pharmacology

a. Aspirin in low doses inhibits platelet cyclooxygenase production of thromboxane A2, preventing platelet aggregation. Cyclooxygenase is permanently inhibited for the life of the platelet (7-10 days).

b. Ticlopidine and **clopidogrel** interfere with adenosine diphosphate- (ADP-) induced membrane-mediated platelet-fibrinogen binding, leading to inhibition of platelet-platelet aggregation.

c. **Fab fragments** (e.g., abciximab) are monoclonal antibodies against the GPIIb/IIIa receptor that permanently inhibit platelet-platelet interaction.

d. GPIIb/IIIa-receptor antagonists (e.g., tirofiban, eptifibatide) are reversible antagonists of fibrinogen, von Willebrand factor, and other adhesion ligands at the GPIIb/IIIa receptor, leading to inhibition of platelet aggregation.

e. Anagrelide decreases platelet production.

f. Cilostazol and its metabolites are type III PDE inhibitors that increase cAMP, leading to vasodilation and decreased platelet aggregation.

g. Treprostinil is a prostacyclin analog of prostaglandin I_2 (PGI_2), which is a direct vasodilator and inhibitor of platelet aggregation.

h. **Dipyridamole** may inhibit platelet aggregation via inhibition of:

(1) Red blood cell adenosine, which acts on thromboxane A_2 receptors of platelets

(2) Phosphodiesterase to increase intracellular concentrations of cAMP

(3) Thromboxane A_2 formation

3. Therapeutic indications

a. Aspirin is indicated for reduction of mortality in post-MI, prophylactic treatment of MI to prevent reinfarction, and prophylaxis after transient ischemic attacks and minor stroke.

b. Ticlopidine is approved to reduce the risk of thrombotic stroke in patients with demonstrated risk but who cannot tolerate aspirin. **Clopidogrel** is approved to reduce MI, stroke, and vascular deaths.

c. **Abciximab** is indicated for use with aspirin and heparin in patients undergoing percutaneous transluminal coronary angioplasty (PTCA) or atherectomy.

d. Tirofiban and eptifibatide are approved for treatment of acute coronary syndrome and patients undergoing PTCA.

e. Anagrelide is approved to reduce platelet count in patients with essential thrombocythemia.

f. Cilostazol is approved for treatment of intermittent claudication.

g. Treprostinil is approved for treatment of pulmonary arterial hypertension.

h. **Dipyridamole** is indicated for prophylaxis against thromboembolism after cardiac valve replacement.

4. Adverse effects

a. Aspirin in doses used for treatment of thrombotic disease is associated with epigastric pain, heartburn, nausea, rash, nasal polyps, gout, and anaphylactic reactions in sensitive individuals.

b. Ticlopidine is associated with a high incidence of adverse reactions, including diarrhea, rash, nausea, vomiting, GI pain, and neutropenia.

c. **Abciximab** is associated with major and minor bleeding events, thrombocytopenia, human antichimeric antibody formation, cardiac arrhythmias, AV block, bradycardia, diarrhea, abnormal thinking, and dizziness.

d. Tirofiban and eptifibatide are associated with bleeding events and bleeding complications, nausea, fever, and headaches; in the case of eptifibatide, with hypotension.

e. Anagrelide carries a warning for use in patients with heart disease and may lead to serious adverse effects, including congestive heart failure, MI, heart block, fibrillation, and others.

f. Cilostazol is contraindicated in patients with congestive heart failure. In dogs, cilostazol produced cardiovascular lesions, including endocardial hemorrhage and hemosiderin deposition, necrosis of smooth muscle, intimal thickening, and arteritis in the coronary artery.

g. Treprostinil may produce hypotension and bleeding when combined with vasodilators and antiplatelet drugs. Injections may be extremely painful and associated with infusion site erythema, induration, rash, bleeding and bruising.

h. **Dipyridamole** is associated with nausea, epigastric pain, dizziness, headache, and rash.

C. Thrombolytic agents

1. Chemistry

a. Alteplase, reteplase, and **tenecteplase** are recombinant DNA-derived **tissue plasminogen activators (t-PAs)** consisting of 527, 355, and 527 amino acids, respectively, of the natural t-PA, which catalyzes conversion of plasminogen to plasmin.

b. Streptokinase is a nonenzymatic 47-kDa protein derived from cultures of Group C β-hemolytic streptococci.

c. **Anistreplase** (anisoylated plasminogen streptokinase activator complex; APSAC) is a complex of human lys-plasminogen and streptokinase with an anisoyl group blocking the catalytic site.

d. Urokinase is a two-chain serine protease obtained from cultured human kidney cells.

2. Pharmacology. Thrombolytic agents facilitate the conversion of plasminogen to plasmin, which subsequently hydrolyzes fibrin to dissolve clots.

a. Alteplase and **reteplase** are referred to as clot selective because conversion of plasminogen to plasmin by t-PA is enhanced several hundred-fold in the presence of fibrin.

b. Streptokinase, which has no enzymatic activity, forms a one-to-one complex with plasminogen, resulting in a conformational change that exposes the catalytic site of plasminogen. The stable activated complex subsequently cleaves free plasminogen to form plasmin.

c. **Anistreplase** is a prodrug activated in vivo by deacylation of the anisole moiety from the active site of the plasminogen-streptokinase complex. The activated complex converts plasminogen to plasmin in the bloodstream or thrombus.

d. Urokinase, in contrast to streptokinase, is enzymatic and directly converts plasminogen to plasmin.

3. Therapeutic indications

a. Alteplase and **reteplase** are indicated for treatment of acute MI and acute massive pulmonary embolism.

b. Streptokinase is indicated for acute MI, deep vein thrombosis, arterial thrombosis, and arterial emboli, except those originating from the left side of the heart.

c. **Anistreplase** is indicated for treatment of acute MI and lysis of coronary arterial thrombi.

d. Urokinase is indicated for treatment of coronary artery thrombosis and pulmonary emboli.

4. Adverse effects

a. t-PAs are associated with:

(1) Internal bleeding of the GI and genitourinary tract, retroperitoneal bleeding, and intracranial bleeding

(2) Superficial bleeding at catheter insertion sites, arterial punctures, and surgical sites

(3) Other adverse effects, including hypersensitivity reactions, nausea, vomiting, hypotension, and fever

b. Streptokinase may be associated with:

(1) Internal and superficial bleeding [see VIII.C.4.a.(1) and (2)]

(2) Allergic reactions, including bronchospasm, angioneurotic edema, urticaria, headache, and delayed hypersensitivity reactions

c. **Anistreplase** may be associated with:

(1) Internal and superficial bleeding [see VIII.C.4.a.(1) and (2)]

(2) Cardiac arrhythmias and hypotension

(3) Allergic type reactions such as bronchospasm, angioneurotic edema, urticaria, and delayed purpuric rash

d. Urokinase may be associated with:

(1) Internal and superficial bleeding [see VIII.C.4.a.(1) and (2)]

(2) Allergic reactions leading to bronchospasm and skin rash

IX. ANTIANEMIC AGENTS

A. Chemistry. The major antianemic agents are iron preparations, cyanocobalamin (vitamin B_{12}), folic acid, and hematopoietic growth factors (**erythropoietin, colony-stimulating factors,** and **interleukin 11**).

1. Most iron preparations consist of ferrous salts, which are better absorbed from the GI tract than ferric salts or elemental iron. Parenteral iron preparations—including **sodium ferric gluconate** complex in sucrose (**Ferrlecit**), **iron sucrose (Saccharate),** and **iron dextran (INFeD, Dexferrum)**—should be employed only when clearly indicated.

a. Typical oral preparations include **ferrous sulfate** (Feosol), **ferrous gluconate** (Fergon), and **ferrous fumarate** (Feostat).

b. When parenteral administration is indicated, **sodium ferric gluconate** is preferred over **iron dextran** because it is associated with a lower risk of anaphylactic reaction. **Iron sucrose** may also have a better safety and adverse effect profile than iron dextran.

2. Cyanocobalamin (vitamin B_{12}) is a nucleotide-like macromolecule with a modified porphyrin unit (a corrin ring) containing a trivalent cobalt atom. A cyanide ion is also coordinated to the cobalt atom, as is a benzimidazole group. The benzimidazole group is bonded to an α-ribosyl phosphate.

3. Folic acid consists of three major components: a pteridine nucleus bonded to the nitrogen of *p*-aminobenzoic acid, which is bonded through an amide linkage to glutamic acid (Figure 15-17).

4. Epoetin α and **darbepoetin** α are glycoproteins produced via recombinant DNA technology. Epoetin α (165 amino acids; 30.4 kDa) is identical to natural erythropoietin.

5. Colony-stimulating factors **filgrastim** and **pegfilgrastim** (granulocyte colony-stimulating factor; G-CSF) and **sargramostim** (granulocyte-macrophage colony-stimulating factor; GM-CSF) are glycoproteins produced via recombinant DNA technology.

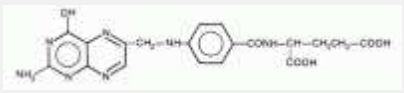

Figure 15-17. Structural formula of folic acid, an antianemic agent.

P.365

6. Oprelvekin (interleukin 11) is a recombinant DNA-produced nonglycosylated polypeptide growth factor that differs from the natural cytokine by one amino acid.

B. Pharmacology

1. Iron preparations (ferrous salts) are readily absorbed from the GI tract and stored in the bone marrow, liver, and spleen as **ferritin** and **hemosiderin.** They are subsequently incorporated as needed into hemoglobin, where the iron reversibly binds molecular oxygen. A lack of body iron causes iron-deficiency anemia with hypochromic, microcytic red blood cells, which transport oxygen poorly.

2. Cyanocobalamin is readily absorbed from the GI tract in the presence of intrinsic factor (Castle factor), a glycoprotein produced by gastric parietal cells that is necessary for GI absorption of cyanocobalamin.

a. Cyanocobalamin is transported to tissue by transcobalamin II. It is essential for cell growth, for maintaining normal nerve cell myelin, and for the metabolic functions of folate.

b. Lack of dietary cyanocobalamin (or lack of intrinsic factor) causes a vitamin B_{12} deficiency and megaloblastic anemia with hyperchromic, macrocytic, immature red blood cells. Demyelination of nerve cells also occurs, causing irreversible CNS damage.

3. Folic acid is readily absorbed from the GI tract, transported to tissue, and stored intracellularly. It is a precursor of several coenzymes (derivatives of tetrahydrofolic acid) that are involved in single carbon atom transfers. A lack of dietary folic acid

causes folic acid deficiency and megaloblastic anemia with hyperchromic, macrocytic, immature red blood cells. Folic acid deficiency causes no neurologic impairment, but folic acid deficiency is associated with birth defects (e.g., spina bifida).

4. Endogenous erythropoietin, whose production in the kidneys is stimulated by blood loss, anemia, and hypoxia, is mimicked by **epoetin α** and **darbepoetin α** to increase proliferation and differentiation of erythroid progenitor cells.

5. Filgrastim and **pegfilgrastim** increase proliferation, differentiation, and activation of neutrophils in patients exhibiting neutropenia after undergoing myelosuppressive chemotherapy. **Sargramostim** stimulates maturation of granulocytes and macrophages and activation of mature cells via cell surface receptors.

6. Oprelvekin increases platelet production via stimulation of hematopoietic stem cells, megakaryocytes progenitor cells, and maturation of megakaryocytes.

C. Therapeutic indications

1. Iron preparations (ferrous salts) are used to treat iron-deficiency anemia.

2. Cyanocobalamin is used to treat megaloblastic anemia resulting from vitamin B12 deficiency.

3. Folic acid is used to treat megaloblastic anemia resulting from folic acid deficiency.

4. Epoetin α and **darbepoetin α** are approved for treatment of anemia resulting from chronic renal failure.

5. Filgrastim and **pegfilgrastim** are approved for treatment of chronic and chemotherapy-induced neutropenia. **Sargramostim** is approved for myeloid reconstitution in patients with non-Hodgkin or Hodgkin disease or who have undergone bone marrow transplantation.

6. Oprelvekin is approved for prevention of chemotherapy-related thrombocytopenia.

D. Adverse effects

1. Iron preparations given orally are associated with GI effects, such as GI distress, nausea, heartburn, diarrhea, and constipation. Parenteral iron administration may be associated with fatal **anaphylactic** and anaphylactoid reactions.

2. Cyanocobalamin only rarely produces adverse effects.

3. Folic acid is associated with only rare allergic reactions after parenteral administration.

4. Epoetin α and **darbepoetin α** may increase blood pressure, which should be monitored and effectively managed.

5. Filgrastim may produce allergic reactions involving skin, respiratory, or cardiovascular systems after initial or subsequent dosing. **Filgrastim** and **pegfilgrastim** are contraindicated in patients allergic to *Escherichia coli*-derived proteins.

6. Oprelvekin produces fluid retention, which may lead to peripheral edema and dyspnea.

STUDY QUESTIONS

Directions for questions 1-7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Calcium channel blockers have all of the following characteristics *except*

(A) they block the slow inward current carried by calcium during phase 2 of the cardiac action potential.

(B) they dilate peripheral arterioles and reduce total peripheral resistance.

(C) they constrict coronary arteries and arterioles and decrease oxygen delivery to the myocardium.

(D) they are useful in treating stable angina pectoris and Prinzmetal angina.

(E) adverse effects include aggravation of congestive heart failure.

View Answer***1. The answer is C[see].*****2. The termination of heparin activity by protamine sulfate is the result of**

(A) a chelating action.

(B) the inhibition of gastrointestinal absorption of heparin.

(C) the displacement of heparin-plasma protein binding.

(D) an acid-base interaction.

(E) the prothrombin-like activity of protamine.

View Answer***2. The answer is D[see].*****3. Which of the following cardiovascular agents is classified chemically as a glycoside?**

(A) Nifedipine

(B) Digoxin

(C) Flecainide

(D) Cholestyramine

(E) Warfarin

View Answer***3. The answer is B[see].Digitalis lanata.Digitalis purpurea,Strophanthus gratus.*****4. Cardiac glycosides may be useful in treating all of the following conditions *except***

(A) atrial flutter.

(B) paroxysmal atrial tachycardia.

(C) congestive heart failure.

(D) ventricular tachycardia.

(E) atrial fibrillation.

View Answer***4. The answer is D[see].*****5. Ingestion of which of the following vitamins should be avoided by a patient taking an oral anticoagulant?**

(A) Vitamin A

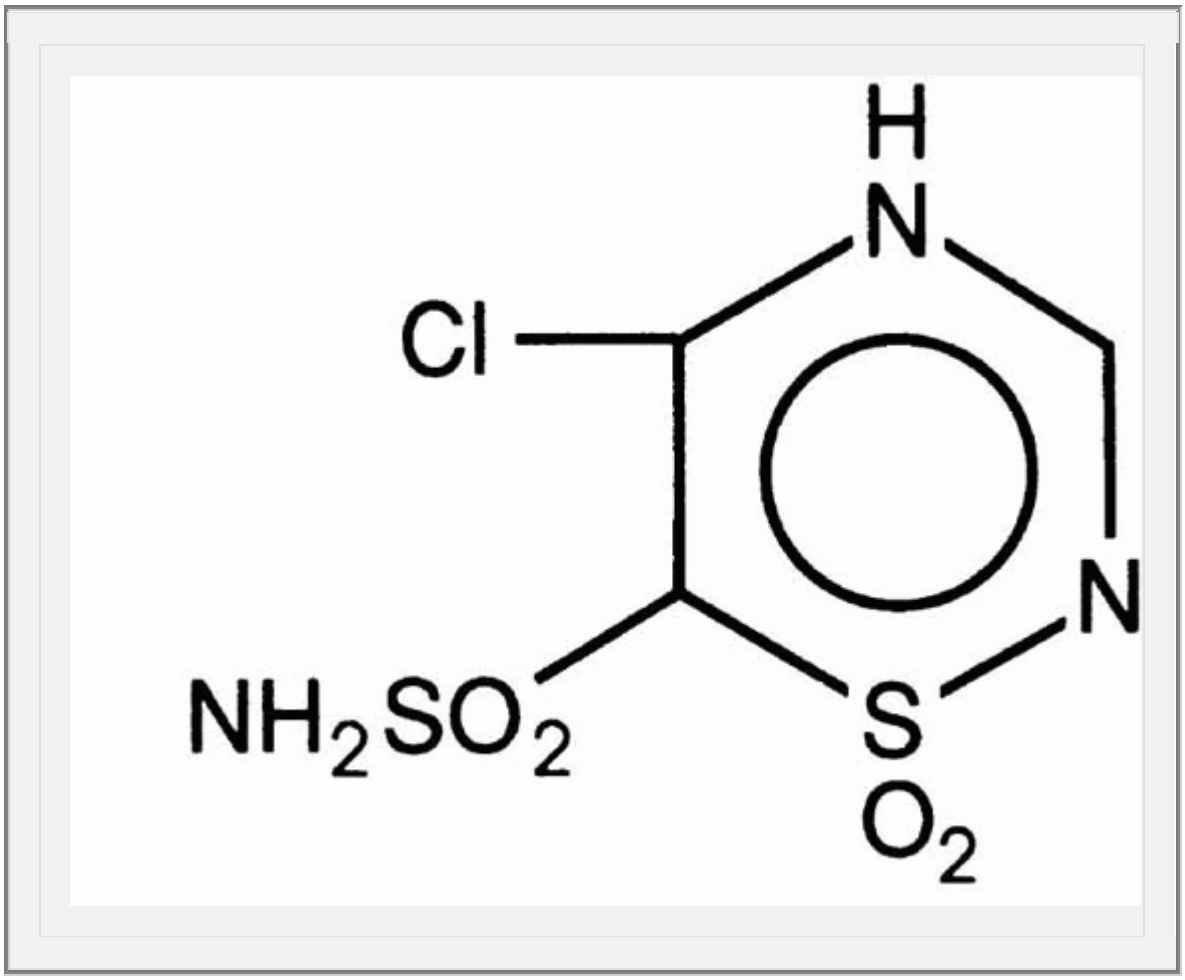
(B) Vitamin B

(C) Vitamin D

(D) Vitamin E

(E) Vitamin K

View Answer***5. The answer is E[seeVIII.4.e].*****6. The structure shown is characteristic of which of the following agents?**



(A) Osmotic diuretics

(B) Carbonic anhydrase inhibitors

(C) Thiazides

(D) Loop diuretics

(E) Potassium-sparing diuretics

View Answer***6. The answer is C[see].*****7. Which of the following diuretics is most similar in chemical structure to the antihypertensive agent diazoxide?**

(A) Furosemide

(B) Spironolactone

(C) Mannitol

(D) Acetazolamide

(E) Chlorothiazide

View Answer***7. The answer is E[seeand].***P.368

Directions for questions 8-11: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

8. In the oral treatment of iron-deficiency anemias, iron is preferably administered as

I. ferrous iron.

II. ferric salts.

III. elemental iron.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***8. The answer is A[see].*****9. Parenterally administered antihypertensive agents used in treating hypertensive emergencies include the**

I. centrally acting antiadrenergic clonidine.

II. arteriolar and venous vasodilator nitroprusside.

III. ganglionic-blocking agent trimethaphan.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***9. The answer is D[see].*****10. Certain factors contribute to the longer duration of action of digitoxin when compared with that of digoxin. These include**

I. greater protein binding.

II. reduced polarity.

III. greater tubular reabsorption.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***10. The answer is E[see].*****11. Oral anticoagulants have which of the following properties?**

I. They interfere with vitamin K-dependent synthesis of active clotting factors II, VII, IX, and X.

II. They have adverse effects that include hemorrhage, urticaria, purpura, and alopecia

III. They prolong the clotting time of blood both in vivo and in vitro.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***11. The answer is C[seeVII.4.e.(1)].*****Directions for questions 12-14:** Each group of adverse effects in this section is most closely related to **one** of the following drug classes. The drug classes may be used more than once or not at all. Choose the **best** answer, **A-E.**

12. Bradycardia, hypotension, increased airway resistance, and congestive heart failure

(A) Cardiac glycosides

(B) Calcium channel blockers

(C) Angiotensin-converting enzyme (ACE) inhibitors

(D) β-Adrenergic blockers

(E) Nitrites and nitrates

View Answer***12. The answer is D[see].*****13. Visual disturbances (yellow or green vision), confusion, anorexia, vomiting, atrioventricular (AV) block, and ventricular tachycardia**

(A) Cardiac glycosides

(B) Calcium channel blockers

(C) Angiotensin-converting enzyme (ACE) inhibitors

(D) β-Adrenergic blockers

(E) Nitrites and nitrates

View Answer***13. The answer is A[see].*****14. Hypotension, acute renal failure, cholestatic jaundice, and agranulocytosis**

(A) Cardiac glycosides

(B) Calcium channel blockers

(C) Angiotensin-converting enzyme (ACE) inhibitors

(D) β-Adrenergic blockers

(E) Nitrites and nitrates

View Answer***14. The answer is C[see].*****Directions for questions 15-17:** Each statement in this group is most closely characterized by **one** of the following drugs. The drugs may be used more than once or not at all. Choose the **best** answer, **A-E.**

15. It interferes with distal tubular aldosterone-mediated sodium-potassium exchange; renders the urine alkaline; and may cause hyperkalemia, gynecomastia, and menstrual irregularities.

(A) Furosemide

(B) Hydrochlorothiazide

(C) Spironolactone

(D) Mannitol

(E) Acetazolamide

View Answer***15. The answer is C[see].*****16. Freely filtered, this drug limits tubular reabsorption of water and is useful in reducing cerebral edema and intracranial pressure.**

(A) Furosemide

(B) Hydrochlorothiazide

(C) Spironolactone

(D) Mannitol

(E) Acetazolamide

View Answer***16. The answer is D[see].*****17. The principal site of action of this drug is on the thick ascending limb of the loop of Henle; it is useful in treating pulmonary edema and ascites.**

(A) Furosemide

(B) Hydrochlorothiazide

(C) Spironolactone

(D) Mannitol

(E) Acetazolamide

View Answer***17. The answer is A[see].***P.369

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* III.B.3; III.C.3; III.D.3*].*

Calcium channel blockers are used in the treatment of angina because they dilate coronary arteries and arterioles, thus decreasing coronary vascular resistance and increasing coronary blood flow.

2. The answer is D *[see* VIII.A.1; VIII.A.4; Figure 15-14*].*

Heparin is a highly acidic mucopolysaccharide, whereas protamine is a highly basic protein. When administered after heparin, protamine chemically combines with it (presumably by an acid-base interaction) and inactivates its anticoagulant effect. Hence it is an effective antidote for heparin. Caution must be employed when using protamine because an excess of protamine can cause an anticoagulant effect itself.

3. The answer is B *[see* II.A.1*].*

Most glycosides are natural products obtained from plant material. Although there are very few medicinal agents that are glycosides, the group known as the cardiac glycosides is extremely important and is widely used for treating congestive heart failure. Digoxin is a cardiac glycoside obtained from *Digitalis lanata.* Other cardiac glycosides include digitoxin, which is obtained from *Digitalis purpurea,* and ouabain, which is obtained from *Strophanthus gratus.*

4. The answer is D *[see* II.C; Table 15-4*].*

Ventricular tachycardia is produced by toxic cardiac glycoside dosage and would not be a therapeutic indication for the agents. Cardiac glycosides increase systolic contraction velocity and increase the refractory period of the AV node. They also have a positive inotropic effect.

5. The answer is E *[see* VIII.A.2.e; *VIII.4.e].*

The oral anticoagulants, such as warfarin, act by inhibiting the liver biosynthesis of prothrombin, which is the precursor of the enzyme thrombin that catalyzes the conversion of soluble fibrinogen to the insoluble polymer fibrin, which results in clot formation. One of the principal factors in the biosynthesis of prothrombin is vitamin K, with which warfarin competes to inhibit this process. Because this is a reversible competition, vitamin K acts as an antagonist to the oral anticoagulants.

6. The answer is C *[see* VI.A; Figure 15-7*].*

The structure can be recognized as a benzothiadiazine, which is known also as a thiazide. It represents the structure of hydrochlorothiazide, a sulfonamide diuretic. Other sulfonamide diuretics include the carbonic anhydrase inhibitors, such as acetazolamide, and the loop diuretics, such as furosemide. Neither of these subclasses contains drugs with a benzothiadiazine nucleus.

7. The answer is E *[see* VI.C; Figures 15-7 *and* 15-9*].*

Diazoxide is a benzothiadiazine derivative; therefore, it would be most similar to chlorothiazide, which is also a benzothiadiazine. Although both the thiazides and the diazoxides have antihypertensive activity, only the thiazides have significant diuretic activity. One of the structural requirements of the thiazide diuretics is an electron-withdrawing group, such as a halogen, ortho to the sulfonamide group on the benzene nucleus. The diazoxide molecule lacks such a group.

8. The answer is A (I) *[see* IX.A.1*].*

Absorption of orally administered iron is significantly improved with ferrous iron than with either ferric salts or elemental iron, presumably because of its better solubility characteristics. Iron preparations (ferrous salts) are more readily absorbed from the gastrointestinal tract and are stored in the bone marrow, liver, and spleen as ferritin and hemosiderin.

9. The answer is D (II, III) *[see* V.B.4; V.C.2.a; V.C.2.e*].*

Clonidine is not recognized as a drug of choice for hypertensive emergencies, possibly because of its central mechanism of action and the latent period required for its effect, compared with other peripheral agents.

10. The answer is E (I, II, III) *[see* II.A; Figure 15-1*].*

Structurally, digitoxin has only one alcohol group on its steroidal nucleus, whereas digoxin has two. This slight difference in structure has a significant effect on the polarity of the molecule. Owing to its greater liposolubility, digitoxin is more likely to undergo tubular reabsorption, to undergo enterohepatic

cycling, to penetrate into the liver microsomes and undergo metabolism, and to be protein bound, all of which contribute to its longer duration of action and potential cumulative effects.

11. The answer is C (I, II) *[see* VIII.A.2.e, *VII.4.e.(1)].*

Oral anticoagulants are effective only in vivo because they block hepatic synthesis of vitamin K-dependent coagulation factors (factors II, VII, IX, and X). This also explains the latency period associated with initiation of oral anticoagulant therapy.

12. The answer is D *[see* III.D.2*].*

13. The answer is A *[see* II.D*].*

14. The answer is C *[see* V.D.6*].*

Nonselective β-adrenergic blockers (e.g., propranolol) produce adverse effects associated with their mechanism of action on the autonomic nervous system. Thus bronchospasm, lowering of blood pressure, and reduced heart rate result from blockade of autonomic β-adrenergic receptors. Visual disturbances (yellow or green vision) are peculiar to cardiac glycoside overdose. AV dissociation and ventricular tachycardia are obviously more significant adverse effects. ACE inhibitors

reportedly may cause blood dyscrasias in addition to cholestatic jaundice and acute renal failure.

15. The answer is C *[see* VI.E.2.a; VI.E.4.a*].*

16. The answer is D *[see* VI.A.3.a; VI.A.3.b*].*

17. The answer is A *[see* VI.D.2.a; VI.D.3.a*].*

Spironolactone interferes with aldosterone-mediated sodium-potassium exchange, reducing the amount of potassium excreted and is often used with other diuretics that promote the excretion of potassium, such as the benzothiadiazides. Mannitol increases the osmolarity of the glomerular filtrate because it is reabsorbed poorly. By increasing the osmolarity of the glomerular filtrate, mannitol limits tubular reabsorption of water, thus promoting diuresis. In this way, it reduces cerebral edema and decreases intracranial pressure. Furosemide is a diuretic of choice for treating acute congestive heart failure because it promotes a significant rapid excretion of water and sodium.

17

Drug Metabolism, Prodrugs, and Pharmacogenetics

Marc W. Harrold

I. INTRODUCTION TO DRUG METABOLISM.

Drug metabolism (also called **biotransformation**) refers to the biochemical changes that drugs and other foreign chemicals **(xenobiotics)** undergo in the body, leading to the formation of different metabolites with different effects. Xenobiotics can undergo a variety of biotransformation pathways, resulting in the production of a mixture of intermediate metabolites and excreted products, including unchanged parent drug. Rarely is only one metabolite produced from a single drug.

A. Inactive metabolites. Some metabolites are inactive (i.e., their pharmacologically active parent compounds become inactivated or detoxified).

1. The hydrolysis of **procaine** to *p*-aminobenzoic acid and diethylethanolamine results in a loss of anesthetic activity.

2. The oxidation of **6-mercaptopurine** to 6-mercapturic acid results in a loss of anticancer activity.

B. Metabolites that retain similar activity. Certain metabolites retain the pharmacological activity of their parent compounds to a greater or lesser degree.

1. Imipramine is demethylated to the essentially equiactive antidepressant, **desipramine.**

2. Acetohexamide is reduced to the more active hypoglycemic, **l-hydroxyhexamide.**

3. Codeine is demethylated to the more active analgesic, **morphine.**

C. Metabolites with altered activity. Some metabolites develop activity different from that of their parent drugs.

1. The antidepressant **iproniazid** is dealkylated to the antitubercular, **isoniazid.**

2. The vitamin **retinoic acid** (vitamin A) is isomerized to the anti-acne agent, **isoretinoic acid.**

D. Bioactivated metabolites. Some pharmacologically inactive parent compounds are converted to active species within the body. These parent compounds are known as **prodrugs.**

1. The prodrug **enalapril** is hydrolyzed to **enalaprilat,** a potent antihypertensive.

2. The prodrug **sulindac,** a sulfoxide, is reduced to the active sulfide.

3. The antiparkinsonian **levodopa (L-dopa)** is decarboxylated in the neuron to active **dopamine.**

II. BIOTRANSFORMATION PATHWAYS

A. Phase I reactions are those in which polar functional groups are introduced into the molecule or unmasked by oxidation, reduction, or hydrolysis.

1. Oxidation is the most common phase I biotransformation.

a. The majority of oxidations occur in the **liver;** however, extrahepatic tissues, such as the **intestinal mucosa, lungs,** and **kidney,** can also serve as metabolic sites.

b. The vast majority of oxidations are catalyzed by a group of mixed-function oxidases known as **cytochrome P_{450} (CYP450).** These oxidases are bound to the smooth endoplastic reticulum of the liver and require both NADPH and a porphyrin prosthetic group. Unlike most enzymes, CYP450 uses a variety of oxidative biotransformations to metabolize a diverse group of substrates.
P.399

c. CYP450 exists in **multiple isoforms** or families. The presence of these different isoforms is responsible for the large substrate variation seen with CYP450.
(1) CYP450 isoforms are named using the root "CYP" followed by an arabic number designating the family, a letter designating the subfamily, and a second arabic number indicating the individual gene (e.g., CYP3A4).
(2) Six mammalian families are involved in steroid and bile acid metabolism: CYP7, CYP11, CYP17, CYP19, CYP21, and CYP27.
(3) Four mammalian families are involved in xenobiotic, or drug, metabolism: CYP1, CYP2, CYP3, and CYP4. Examples of drugs metabolized by these families and subfamilies are shown in Table 17-1. Note that a number of drugs (e.g., tricyclic antidepressants, diazepam, ondansetron, theophylline) are metabolized by multiple isoforms.
d. Additional oxidations (e.g., ethanol to acetaldehyde) are catalyzed by nonmicrosomal oxidases located in cytosol and mitochondria of extrahepatic tissues.
e. CYP450 and nonmicrosomal oxidases catalyze aromatic, aliphatic, olefinic, benzylic, allylic, and α-hydroxylations; *N*-, O-, and *S*-dealkylations; oxidative deamination; *N*- and *S*-oxidations; desulfuration; dehalogenation; and oxidations of alcohols and aldehydes (Table 17-2).
f. The **increased polarity** of the oxidized products (metabolites) enhances their water solubility and reduces their tubular reabsorption to some extent, thus favoring their excretion in the urine. These metabolites are somewhat **more polar** than their parent compounds and very commonly undergo further biotransformation by phase II pathways (see II B).
2. Reduction is less commonly encountered than oxidation; however, the overall goal is the same: to create polar functional groups that can be eliminated in the urine. There is evidence suggesting that the CYP450 system might be involved in some reductions. Additionally, bacteria resident in the GI tract are known to be involved in azo and nitro reductions. Reactions catalyzed by reductases are shown in Table 17-3.
3. Enzymatic hydrolysis, the addition of water across a bond, also results in more polar metabolites (see Table 17-3).
a. Esterase enzymes, usually present in plasma and various tissues, are nonspecific and catalyze de-esterification, hydrolyzing relatively nonpolar esters into two polar, more water-soluble compounds: an alcohol and an acid. Esterases are responsible for converting many prodrugs into their active forms.

b. Amidase enzymes hydrolyze amides into amines and acids (deamidation). Deamidation occurs primarily in the liver.

c. **Ester drugs** susceptible to plasma esterases (e.g., procaine) are usually shorter acting than structurally similar **amide drugs** (e.g., procainamide), which are not significantly hydrolyzed until they reach the liver.

d. Lactones and **lactams** are cyclic esters and amides, respectively, and are thus also susceptible to hydrolytic metabolism.

B. Phase II reactions are those in which the functional groups of the original drug (or metabolite formed in a phase I reaction) are masked by a **conjugation reaction.** Most phase II conjugates are very polar, resulting in rapid drug elimination from the body.

1. Conjugation reactions combine the **parent drug** (or its metabolites) with certain **natural endogenous constituents,** such as glucuronic acid, glycine, glutamine, sulfate, glutathione, the two-carbon acetyl fragment, or the one-carbon methyl fragment. These reactions generally require both a **high-energy molecule** and an **enzyme.**

a. The **high-energy molecule** consists of a **coenzyme** bound to the endogenous substrate, the parent drug, or the drug's phase I metabolite.

b. The **enzymes** (called **transferases**) that catalyze conjugation reactions are found mainly in the liver and, to a lesser extent, in the intestines and other tissues.

c. Most conjugates are **highly polar** and **unable to cross cell membranes,** making them almost always **pharmacologically inactive** and of little or no toxicity. Exceptions to this are acetylated and methylated conjugates. These conjugates do not possess increased polarity; however, they are usually pharmacologically inactive.

2. There are **six conjugation pathways** (Table 17-4).

a. Glucuronidation is the **most common** conjugation pathway because of a readily available supply of glucuronic acid as well as a large variety of functional groups, which can enzymatically react with this sugar derivative.

Table 17-1. Examples of Drugs Metabolized by Specific Cytochrome P450 (CYP) Isoforms

CYP1A2	
	Acetaminophen
	Amitriptyline and other TCAs
	Diazepam
	Methadone
	Olanzapine
	Propranolol
	Riluzole
	Tacrine
	Theophylline
CYP2B1	
	Chlorpheniramine
CYP2B6	
	Bupropion
	Cyclophosphamide and ifosfamide
CYP2C8	
	Diazepam

	Diclofenac
	Mephobarbital
	Omeprazole
	Paclitaxel
	Retinoids
	Tolbutamide
CYP2C9	
	Amitriptyline and other TCAs
	Chlorpheniramine
	Carvedilol
	Dapsone
	Diazepam
	Glimepiride
	Hexobarbital
	Losartan
	NSAIDs
	Phenytoin

	Tolbutamide
	Torsemide
	Verapamil
	Warfarin
	Zafirlukast
CYP2D6	
	Amitriptyline and other TCAs
	β-blockers
	Benztropine
	Captopril
	Chlorpheniramine
	Chlorpromazine
	Clemastine
	Clozapine
	Codeine
	Delavirdine
	Dextromethorphan

	Diphenhydramine
	Dolasetron and Ondansetron
	Donepezil
	Encainide
	Fenfluramine
	Fentanyl
	Flecainide
	Fluphenazine
	Hydrocodone
	Hydroxyzine
	Imipramine
	Lidocaine
	Loratadine
	Meperidine
	Methadone
	Methamphetamine
	Mexiletine

	Morphine
	Ondansetron
	Oxycodone
	Risperidone
	Selegiline
	SSRIs
	Tamoxifen
	Thioridazine

	Salmeterol
	Sildenafil
	SSRIs
	Sulfamethoxazole
	Tacrolimus
	Tadalafil
	Tamoxifen
	Teniposide
	Testosterone
	Theophylline

	Tolterodine
	Tretinoin
	Valproic acid
	Vardenafil
	Verapamil
	Vinca alkaloids
	Warfarin

HMG CoA, β-hydroxy-β-methylglutaryl-coenzyme A; *NSAIDs,* nonsteroidal anti-inflammatory drugs; *SSRIs,* selective serotonin reuptake inhibitors; TCAs, tricyclic antidepressants.

Table 17-2. Phase I Metabolism: Oxidative Pathways

	Type of Reaction (Examples)	Reaction Pathway
1.	Aromatic Hydroxylation (phenytoin, phenylbutazone)	2.	Aliphatic Hydroxylation (pentobarbital, meprobamat	
	e)	
3.	Olefinic Hydroxylation (carbamazepine, cyproheptadine)	4.	Benzylic Hydroxylation (tolbutamide, imipramine)	5.	Allylic Hydroxylation (pentazocine, hexobarbital)	
6.	Hydroxylation-α to a Carbonyl (diazepam, ketamine)	7.	Oxidative Deamination (amphetamine, dopamine)	8.	*N*-Dealkylation (morphine, ephedrine)	
9.	*N*-Oxidation (acetaminophen, guanethidine)	9. 10.	*O*-Dealkylation (codeine, papaverine)	10. 11.	*S*-Dealkylation (6-methylmercaptopurine)	11. 12.	*S*-Oxidation (chlorpromazine, mesoridazine)	12. 13.	Desulfuration (thiopental)	13. 14.	Dehalogenation (halothane, chloramphenicol)	14. 15.	Oxidation of Alcohols (ethanol, estradiol)	15. 

16.	Oxidation of Aldehydes (acetaldehyde, PGE_2)	
Table 17-3. Phase I Metabolism: Reductive and Hydrolytic Pathways

Type of Reaction (Examples)		Reaction Pathway
Reduction		
1.	Carbonyl Reduction (acetohexamide)	2.	Azoreduction (sulfasalazine, olsalazine)	3.	Nitroreduction (chloramphenicol, clonazepam)	
Hydrolysis		
4.	Ester Hydrolysis (procaine, meperidine)	5.	Amide Hydrolysis (lidocaine, indomethacin)	
(1) The high-energy form of glucuronic acid, **uridine diphosphate glucuronic acid,** reacts with a variety of functional groups under the influence of glucuronyl transferase.

(2) Drugs that possess **hydroxyl** or **carboxyl** functional groups readily undergo glucuronidation to form ethers and esters, respectively. In addition, *N*-, *S*-, and *C*-glucuronides are also possible.

(3) As shown in Table 17-4, the addition of glucuronic acid to a drug molecule adds three hydroxyl groups and one carboxyl group. This addition greatly increases the **hydrophilicity** of the drug molecule. As a result, it is unlikely to penetrate cell membranes and elicit pharmacological activity. It is also poorly reabsorbed by the renal tubules and, thus, is readily excreted.

(4) Glucuronides with **high molecular weight** (more than 500) are often excreted into the bile and, eventually, into the intestines. The intestinal enzyme β-glucuronidase can then hydrolyze the conjugate, releasing the unaltered drug (or its primary metabolite) for reabsorption by the intestine.

b. Sulfate conjugation is much less common than glucuronide conjugation because there is no available pool of endogenous sulfate. Additionally, there are fewer functional groups capable of forming sulfate conjugates. The high-energy form of sulfate, **3′-phosphoadenosine-5′-phosphosulfate (PAPS),** reacts with phenols, alcohols, arylamines, and *N*-hydroxyl compounds under the influence of **sulfotransferase** to form highly polar metabolites.

c. **Amino acid conjugation** involves the reaction of either glycine or glutamine with aliphatic or aromatic acids to form amides. A drug molecule is first converted to an acyl coenzyme A intermediate. An *N*-acyltransferase enzyme then catalyzes the conjugation of the activated drug molecule with the amino acid.

d. Glutathione conjugation is extremely important in preventing toxicity from a variety of harmful electrophilic agents. Glutathione, a tripeptide containing a

nucleophilic sulfhydryl group, is present in almost all mammalian tissues. Under the influence of **glutathione S-transferase,** glutathione can react with halides, epoxides, and other electrophilic compounds to form harmless inactive products. When glutathione has reacted with an electrophile, it undergoes a series of reactions to produce a mercapturic acid derivative, which is eliminated.

Table 17-4. Phase II Metabolism: Conjugation Pathways

Type of Conjugate		Reaction Pathway R = Drug Molecule; X = Functional Group
1.	Glucuronide (X = OH, NR_2, CO_2H, SH, acidic carbon atoms)	2.	Sulfate (X = OH, arylamines, NH—OH)	3.	Amino Acid (Occurs only with acid functional groups)	
4.	Glutathione (X = electrophilic center such as halide, epoxide, or Michael acceptor)	5.	Methyl (X = OH, NH_2, SH)	6.	Acetylation (X = NH_2, $NHNH_2$, SO_2NH_2, CO—NH_2)	
e. Methylation of oxygen-, nitrogen-, and sulfur-containing functional groups results in metabolites that are usually less polar than the unaltered drugs. Methylation can inactivate certain compounds [e.g., catechol O-methyl transferase (COMT) methylates a number of catecholamine neurotransmitters], but overall it plays a minor role in the elimination of drugs. Its major role is in the biosynthesis of endogenous compounds (e.g., epinephrine). The high-energy form required for methyltransferase enzymes is *S*-adenosylmethionine (SAM).

f. Acetylation can occur with primary amines, hydrazides, sulfonamides, and, occasionally, amides. It leads to the formation of *N*-acetylated products. These

products are usually less polar than the unaltered drug and can retain pharmacological activity.

(1) *N*-acetylated metabolites can accumulate in tissue or in the kidneys, as in the case of certain antibacterial sulfonamides. Crystalluria and subsequent tissue damage may result.

(2) The high-energy molecule for acetylation is acetyl-CoA. The reaction is catalyzed by *N*-acetyltransferase.

III. FACTORS INFLUENCING DRUG METABOLISM

A. Chemical structure specifically influences a drug's metabolic pathway. The presence or absence of certain functional groups will determine the necessity, route, and extent of metabolism.

B. Species differences

1. Qualitative differences in the actual metabolic pathway. Such a variation can result from a genetic deficiency of a particular enzyme or a difference in a particular endogenous substrate. In general, qualitative differences occur primarily with **phase II reactions.**

2. Quantitative differences are differences in the extent to which the same type of metabolic reaction occurs. Such a variation can result from a difference in the enzyme level, the presence of species specific isozymes, a difference in the amount of endogenous inhibitor or inducer, or a difference in the extent of competing reactions. In general, quantitative differences occur primarily with **phase I reactions.**

C. Physiological or disease state

1. Because the liver is the major organ involved in biotransformation, **pathological factors** that **alter liver function** can affect a drug's hepatic clearance.

2. Congestive heart failure decreases hepatic blood flow by reducing cardiac output, which alters the extent of drug metabolism.

3. An **alteration in albumin production** (the plasma's major drug-binding protein) can alter the fraction of bound to unbound drug. Thus, a decrease in plasma albumin can increase the fraction of unbound (free) drug, which then becomes available to exert a more intense pharmacological effect. The reverse is true when plasma albumin increases.

D. Genetic variations

1. The **acetylation rate** depends on the amount of *N*-acetyltransferase present, which is determined by genetic factors. The general population can be divided into **fast acetylators** and **slow acetylators.** For example, fast acetylators are more prone to **hepatotoxicity** from the antitubercular agent isoniazid than slow acetylators, whereas slow acetylators are more prone to isoniazid's other toxic effects (see VII.B.4.d).

2. The discovery of isoforms and families of CYP450 enzymes has shown that genetic variations exist in isoforms that oxidize **debrisoquine.** Individuals who are

poor metabolizers of this compound **(PM phenotype)** also exhibit impaired metabolism of more than 20 other therapeutic agents, including β-blockers, antiarrhythmics, opioids, and antidepressants. Approximately 5%-10% of whites, 2% of Asians, and 1% of Arabs express the PM phenotype and are at risk for adverse drug reactions.

E. Drug dosage

1. An **increase** in drug dosage results in increased drug concentrations and can saturate certain metabolic enzymes. As drug concentration exceeds 50% saturation for a particular enzyme, drug elimination via this path no longer follows solely first-order kinetics, but rather is a mix of zero- and first-order kinetics. At 100% saturation, metabolism via this enzyme follows zero-order kinetics.

2. When the metabolic pathway is saturated (either because of an exceedingly high drug level or because the supply of an endogenous conjugated agent is exhausted), an alternative pathway may be pursued. For example, at normal doses, 98% of a dose of acetaminophen undergoes conjugation with either glucuronic acid or sulfate; however, at toxic doses, conjugation pathways become saturated and acetaminophen undergoes extensive *N*-hydroxylation, which can lead to hepatotoxicity.

F. Nutritional status

1. The levels of some **conjugating agents** (or endogenous substrates), such as sulfate, glutathione, and (rarely) glucuronic acid, are sensitive to body nutrient levels. For example, a **low-protein diet** can lead to a deficiency of certain amino acids, such as glycine. Low-protein diets also decrease oxidative drug metabolism capacity.

2. Diets **deficient in essential fatty** acids (particularly linoleic acid) reduce the metabolism of ethyl-morphine and hexobarbital by decreasing synthesis of certain drug-metabolizing enzymes.

3. A **deficiency of certain dietary minerals** also affects drug metabolism. Calcium, magnesium, and zinc deficiencies decrease drug-metabolizing capacity, whereas iron deficiency appears to increase it. A copper deficiency leads to variable effects.

4. Deficiencies of vitamins (particularly vitamins A, C, E, and the B group) affect drug-metabolizing capacity. For example, a vitamin C deficiency can result in a decrease in oxidative pathways, whereas a vitamin E deficiency can retard dealkylation and hydroxylation.

G. Age

1. Metabolizing enzyme systems are not fully developed at birth; thus, **infants** and **young children** need to receive smaller doses of drugs than adults to avoid toxic side effects. This is particularly true of drugs that require glucuronide conjugation.

2. In **older children,** some drugs may be less active than in adults, particularly if the dosage is based on weight. The liver develops faster than the increase in general body weight and, thus, represents a greater fraction of total body weight.

3. In the **elderly,** metabolizing enzyme systems decline. The lowered level of enzyme activity slows the rate of drug elimination, causing higher plasma drug levels per dose than in young adults.

H. Gender. Metabolic differences between the sexes have been observed for a number of compounds, suggesting that androgen, estrogen, and/or adrenocorticoid activity might affect the activity of certain CYP450 enzyme isozymes.

1. Metabolism of diazepam, prednisolone, caffeine, and acetaminophen is **slightly faster in women.**

2. Oxidative metabolism of propranolol, chlordiazepoxide, lidocaine, and some steroids occurs **faster in men** than in women.

I. Circadian rhythms. The **nocturnal plasma levels** of drugs, such as theophylline and diazepam, are lower than the **diurnal plasma levels.**

J. Drug administration route

1. Oral administration. The drug is absorbed from the GI tract and transported to the liver through the hepatic portal vein before entering the systemic circulation. Thus, the drug is subject to hepatic metabolism before it reaches its site of action. This is an effect known as the **first-pass effect, or presystemic elimination** (Table 17-5).

a. The first-pass effect can cause **significant clinical problems.** Because drugs are metabolized in the liver from their active forms to inactive forms, this effect must be counteracted to achieve the desired plasma or tissue drug level.

b. A common approach is to **increase the oral dose,** offsetting the loss of drug activity from the first-pass effect.

Table 17-5. Examples of Drugs That Undergo First-Pass Metabolism

Acetaminophen	Fluorouracil	Oxprenolol
Albuterol	Imipramine	Pentazocine
Alprenolol	Isoproterenol	Progesterone
Aspirin	Lidocaine	Propoxyphene
Cortisone	Meperidine	Propranolol
Cyclosporin	Methyltestosterone	Salbutamol
Desipramine	Metoprolol	Terbutaline

Dihydropyridines	Nortriptyline	Testosterone
Estradiol	Organic Nitrates	Verapamil

Table 17-6. Examples of Common CYP3A4 Inhibitors and Inducers

Potent Inhibitors	Moderate Inhibitors	Inducers
Amiodarone	Amprenavir	Carbamazepine
Atazanavir	Ciprofloxacin	Efavirenz
Clarithromycin	Diltiazem	Nevirapine
Indinavir	Erythromycin	Phenytoin
Itraconazole	Fluconazole	Phenobarbital
Ketoconazole	Fluvoxamine	Rifabutin
Nefazodone	Grapefruit juice	Rifapentine
Nelfinavir	Norfloxacin	Rifampin
Ritonavir	Verapamil	St. John's Wort

Telithromycin		
Troleandomycin		
Voriconazole		

2. Intravenous administration bypasses the first-pass effect because the drug is delivered directly to the bloodstream without being metabolized in the liver. Thus, intravenous doses of drugs undergoing considerable first-pass effects are much smaller than oral doses.

3. Sublingual administration and **rectal administration** also bypass first-pass effects, although rectal administration can produce variable effects.

K. Concurrent drug therapy. The co-administration of drugs that are capable of either inhibiting or inducing specific CYP450 isozymes can increase or decrease, respectively, the plasma levels of other drugs that require these isozymes for normal drug metabolism.

1. As indicated on Table 17-1, most drugs are metabolized by the following three isozymes: CYP2C9, CYP2D6, and CYP3A4. The potential for drug interactions due to enzyme inhibition or induction is therefore greater with these compounds.

2. Drugs that alter the activity of CYP450 isozymes are usually substrates of these same isozymes. This can be observed by comparing Tables 17-1 and 17-6.

3. The clinical outcome of these types of drug interactions depends upon three factors:

a. The potency of the inhibitor or inducer (Table 17-6)

b. The availability of alternate elimination pathways

c. The extent to which the higher or lower plasma concentrations of the drug causes symptoms and/or undesirable effects.

IV. EXTRAHEPATIC METABOLISM

A. Definition. Extrahepatic metabolism refers to drug biotransformation that takes place in **tissues other than the liver.** The most common sites include the **portals of entry** (e.g., GI mucosa, nasal passages, lungs) and the **portals of excretion** (e.g., kidneys). However, metabolism can occur throughout the body.

B. Metabolism sites

1. Plasma contains **esterases,** which are responsible primarily for hydrolysis of esters. **Simple esters** (e.g., procaine, succinylcholine) are rapidly hydrolyzed in the blood. Additionally, plasma esterases can activate a variety of ester prodrugs.

2. Metabolizing enzymes in the **intestinal mucosa** are especially important for drugs undergoing microsomal oxidation, glucuronide conjugation, and sulfate conjugation.

a. As a lipid-soluble drug passes through the intestinal mucosa during drug absorption, it can be metabolized into polar or inactive metabolites before entering the blood. The result is **comparable to a first-pass effect.**

b. The intestinal mucosa's drug-metabolizing capacity compares to that of the liver. However, it shows much greater individual variation because of its greater exposure to the environment.

3. Intestinal bacterial flora secrete a number of enzymes capable of metabolizing drugs and other xenobiotics.

a. Any factor that **modifies the intestinal flora** may also **modify drug activity.** Age, diet, disease state, and exposure to environmental chemicals or drugs may all be important.

(1) Certain **diseases,** particularly **intestinal disease,** affect intestinal flora. Ulcerative colitis, for example, promotes bacterial growth. Diarrhea reduces the number of bacteria.

(2) Certain **environmental chemicals** and **drugs** also act on intestinal flora. Antibiotics, for example, decrease the number of bacteria.

b. Bacterial flora **secrete** β-glucuronidase, which hydrolyzes the polar glucuronide conjugates of bile and allows the free, nonpolar bile acids to be reabsorbed. This **enterohepatic circulation** partially maintains the pool of bile acids. This same principle applies to certain glucuronide conjugates of drugs.

c. Certain bacterial flora **convert** vitamin precursors to their **active forms,** as with vitamin K.

d. Bacterial flora can also **convert** certain substances to their **toxic forms,** as with the conversion of the artificial sweetener cyclamate to cyclohexylamine, a suspected carcinogen.

e. Intestinal bacteria produce **azoreductase,** which reduces the prodrug sulfasalazine to the active anti-inflammatory aminosalicylic acid and the active antibacterial sulfapyridine. Sulfasalazine is one of the few agents effective in the treatment of ulcerative colitis.

4. The **acidic environment** of the **stomach** produces nonenzymatic degradation of a number of drug molecules, including penicillin G, carbenicillin, erythromycin, and tetracycline. Additionally, gastric acid assists in the degradation of proteins and peptides (e.g., insulin).

5. The **nasal mucosa** provides a high level of CYP450 activity, which can significantly alter the amount of drug that reaches the systemic circulation. Nasal decongestants, anesthetics, nicotine, cocaine, and other compounds have been shown to undergo nasal metabolism.

6. The **lung** is responsible for first-pass metabolism of drugs administered intravenously, intramuscularly, transdermally, or subcutaneously.

a. The **total amount** of **metabolizing enzymes** present in the lungs is less than that in the liver; however, the specific activities of the enzymes are comparable to those in the liver.

b. The lungs provide **second-pass metabolism** for drugs leaving the liver.

C. Placental and fetal metabolism

1. Placenta. In general, if a drug or other xenobiotic is lipid soluble enough to be absorbed into the circulation when administered to a pregnant woman, it will likely also pass through the placenta.

a. The placenta is not a physical or metabolic barrier to xenobiotics. Very little xenobioticmetabolizing enzyme activity has been demonstrated in the placenta.

b. Drugs present in their **active form** in the maternal circulation likely pass **unchanged** into the fetal circulation.

c. An exception to this lack of enzyme activity in the placenta is the presence of a small amount of **aryl aromatic hydroxylase,** which is **inducible in pregnant women who smoke cigarettes.** A potential consequence is an increase in the production of penultimate carcinogens from the action of this enzyme on the polycyclic aromatic hydrocarbons present in cigarette smoke and other environmental sources.

2. Fetus. In terms of fetal metabolism, there are varying degrees of drug-metabolizing activity dependent upon a number of factors including fetal age.

a. A **major deficiency** is that of **glucuronic acid conjugating activity** both in the **fetus and the neonate.**

b. Two consequences of this are the **gray baby syndrome,** resulting from decreased chloramphenicol glucuronidation, and **neonatal hyperbilirubinemia,** resulting from a decrease in bilirubin glucuronide formation.

P.408

V. STRATEGIES TO MANAGE DRUG METABOLISM.

A variety of methods have been used to circumvent the rapid metabolism of certain drugs. These methods seek to improve drug therapy by decreasing the overall extent of metabolism and increasing the duration of action. In some instances, these methods have provided increased site specificity.

A. Pharmaceutical strategies involve the use of different **dosage forms** to either avoid or compensate for rapid metabolism.

1. Sublingual tablets are useful for delivering drugs directly into the systemic circulation and bypassing hepatic first-pass metabolism. **Nitroglycerin,** a rapidly acting antianginal agent, is essentially ineffective when administered orally due to an extremely high first-pass effect but is very effective in treating acute attacks of angina if given sublingually.

2. Transdermal patches and **ointment formulations** provide a continuous supply of drug over an extended period of time and are useful for rapidly metabolized compounds such as nitroglycerin. These delivery systems, while not suited to treat

acute anginal symptoms, are effective in providing prophylactic concentrations of nitroglycerin.

3. Intramuscular depot injections also provide a continuous supply of drug over an extended period of time. Highly lipid soluble esters of **estradiol** and **testosterone** (e.g., estradiol benzoate, testosterone enanthate) are slowly absorbed from their administration site. Hydrolysis of these prodrugs (see VI) produces a steady supply of these rapidly metabolized hormones.

4. Enteric-coated formulations can protect acid-sensitive drugs as they pass through the acidic environment of the stomach. **Methenamine, erythromycin,** and **omeprazole** are examples of acid-sensitive agents that are available as enteric-coated preparations.

5. Nasal administration allows for the delivery of peptides, such as **calcitonin salmon,** which have very low (if any) oral bioavailability. Characteristics of the lung make it ideal for the administration of peptides. Aerosolized drugs only need to penetrate a thin epithelial layer to reach abundant capillary beds. Additionally, the lungs contain protease inhibitors, which allow for greater stability of the peptides.

B. Pharmacological strategies involve the concurrent use of enzyme inhibitors to decrease drug metabolism. In some instances, the concurrent use of an additional agent does not prevent metabolism but rather prevents the toxicity caused by metabolites of the therapeutic agent.

1. Levodopa (L-dopa), the amino acid precursor of dopamine, is used in the treatment of parkinsonism. Unlike dopamine, L-dopa can penetrate the blood-brain barrier and reach the central nervous system (CNS). When in the brain, it is decarboxylated to dopamine. To ensure that adequate concentrations of L-dopa reach the CNS, peripheral metabolism of the drug must be blocked. The concurrent administration of **carbidopa,** a dopa decarboxylase inhibitor that cannot penetrate the blood-brain barrier, prevents peripheral formation of dopamine and allows site-specific delivery of dopamine to the CNS.

2. β-Lactam antibiotics. The antibacterial activity of a number of β-lactam antibiotics is reduced by microorganisms capable of secreting the enzyme β-lactamase. This enzyme hydrolyzes the β-lactam ring and inactivates the antibiotic. To counter this resistance mechanism, a β-lactamase inhibitor, such as **clavulanic acid,** is used in conjunction with a penicillin, such as **amoxicillin,** to successfully treat infections caused by β-lactamase-producing bacteria.

3. Ifosfamide is an alkylating agent that must undergo in vivo metabolism to produce an active nitrogen mustard. In the process of this metabolic activation, significant concentrations of **acrolein** are produced. These acrolein molecules react with nucleophiles on renal proteins and produce hemorrhagic cystitis. To prevent this toxicity, ifosfamide is always coadministered with **mesna,** a sulfhydryl-containing compound that reacts with and neutralizes any acrolein that is present in the kidney.

4. HIV protease inhibitors are extensively metabolized by CYP3A isozymes. In addition, compounds within this class can inhibit these same isozymes. This latter action has been used to optimize therapy. **Ritonavir** is an HIV protease inhibitor that is known to cause hepatoxicity at therapeutic doses. **Lopinavir** is an HIV

protease inhibitor that is ineffective if used alone due to rapid CYP3A oxidation. A combination of low dose ritonavir with a therapeutic

P.409

dose of lopinavir results in an inhibition of CYP3A, the establishment of adequate plasma levels of lopinavir, and therapeutic efficacy without hepatotoxicity.

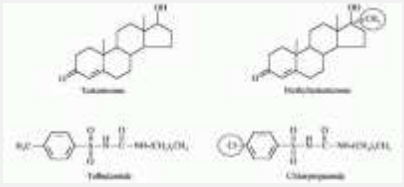

Figure 17-1. Selected examples of chemical modification that eliminate metabolic transformations. Methylation of testosterone blocks the rapid oxidation of the 17-hydroxyl group and allows oral activity, whereas replacement of the metabolically labile *para*-methyl group on tolbutamide with a chloro group allows for a much longer duration of action.

C. Chemical strategies involve the addition, deletion, or isosteric modification of key functional groups. These molecular modifications hinder or completely eliminate metabolic transformations (Figure 17-1).

1. Testosterone is not orally active due to rapid oxidation of its 17-hydroxyl group to a ketone. Addition of a 17α-methyl group converts the labile secondary alcohol to a stable tertiary alcohol. The resulting compound, **methyltestosterone,** is only half as potent as testosterone; however, it is not subject to rapid first-pass metabolism and can be used orally. A similar strategy has been used to make orally active estradiol analogues.

2. Tolbutamide is an oral hypoglycemic with a short duration of action. This sulfonylurea rapidly undergoes oxidation of its para-methyl group. A structurally similar compound, **chlorpropamide,** has a nonmetabolizable para-chloro group and, as a result, has a much longer duration of action.

3. Isoproterenol is a potent β-adrenergic agonist used for the relief of bronchospasm associated with bronchial asthma. Because it is a catechol (i.e., 3,4-dihydroxy-substituted benzene ring), isoproterenol is subject to rapid metabolism by catechol O-methyl transferase (COMT) and, thus, has poor oral activity. Alteration of the 3,4-dihydroxy substitution to a 3,5-dihydroxy substitution produces **metaproterenol,** a bronchodilator that is not susceptible to COMT, is orally active, and has a longer duration of action than isoproterenol.

4. Octreotide is a synthetic octapeptide used to suppress or inhibit severe diarrhea associated with certain tumors. Octreotide mimics the actions of **somatostatin,** a naturally occurring, 14-amino acid peptide. Somatostatin undergoes rapid proteolysis, has a half-life of 1-3 minutes, and must be administered as a continuous intravenous infusion. Octreotide contains the amino acids essential for

clinical efficacy but replaces two of the amino acids with their D-enantiomers. These unnatural D-amino acids are more resistant to hydrolysis. As a result, octreotide has an increased half-life and can be administered as a subcutaneous injection.

VI. PRODRUGS.

These drugs are molecules that are either inactive or very weakly active and require in vivo biotransformation to produce the physiologically active drug. The phase I metabolic

processes discussed previously are used to activate prodrugs. A variety of **advantages** can be gained by using a prodrug instead of the active form of the drug.

A. An **increase in water solubility** is useful for the preparation of ophthalmic and parenteral formulations. **Sodium succinate esters** and **sodium phosphate esters** have been used to make a number of water-soluble steroid prodrugs.

B. An **increase in lipid solubility** is useful for a variety of reasons.

1. Increased duration of action. Lipid-soluble esters of estradiol, such as benzoate, valerate, and cypionate, are used to prolong estrogenic activity. IM injections of these esters in oil result in a deposit of drug that is slowly hydrolyzed, thereby releasing free estradiol over a prolonged period of time (see V.A.3).

2. Increased oral absorption is obtained by converting carboxylic acid groups to esters. These esters can then be rapidly converted to the active acids by plasma esterases. **Enalaprilat** is a potent angiotensin-converting enzyme (ACE) inhibitor that is used for parenteral administration, but, due to its high polarity, it is orally inactive. Its monomethyl ester, **enalapril,** is considerably more lipophilic and, thus, provides good oral absorption. This strategy has been successfully used for a variety of other compounds, including additional ACE inhibitors, fibric acid derivatives, ampicillin, and several cephalosporins.

3. Increased topical absorption of steroids is obtained by masking hydroxyl groups as esters or acetonides. These prodrugs are much less polar than the parent compounds and allow increased dermal permeability for the treatment of inflammatory, allergic, and pruritic skin conditions. Examples include **triamcinolone acetonide, diflorasone diacetate,** and **betamethasone valerate.**

4. Increased palatability. Antibiotics such as **sulfisoxazole** have a bitter taste and are not suitable for administration to young children who cannot yet swallow tablets or capsules. Esterification to produce **sulfisoxazole acetyl** decreases the water solubility of the antibiotic and, thus, decreases its interaction with bitter taste receptors on the tongue. This compound is marketed as a flavored suspension. Similar strategies have been used to mask the bitter taste of **chloramphenicol** and other antibiotics.

C. A decrease in GI **irritation.** Nonsteroidal anti-inflammatory agents (NSAIDs) produce gastric irritation and ulceration via two mechanisms: a direct irritant effect of the acidic molecule and inhibition of gastroprotective prostaglandin production. The prodrugs **sulindac** and **nabumetone** produce less GI irritation because the

gastric and intestinal mucosa are not exposed to high concentrations of active drug during oral administration. Additionally, nabumetone is a ketone, not an acid, and lacks any direct irritant effects.

D. Site specificity is useful for increasing the concentration of drug at the active site and for decreasing side effects.

1. Methyldopa is a prodrug that is structurally similar to L-dopa. As a result, methyldopa is transported into the CNS and metabolized to the active compound, **α-methyldopamine,** via the same path used for the synthesis of dopamine. This allows a significant amount of α-methyldopamine to reach the CNS and bind to central α2-adrenergic receptors.

2. Omeprazole is used to treat gastric ulcers and other hypersecretory disorders. After oral absorption, it is selectively activated at the acidic pH levels (pH less than 1) seen in gastric parietal cells. This allows the active form of the drug to be produced in close proximity to the enzyme H^+/K^+-ATPase (proton pump), resulting in irreversible inhibition of the enzyme and a decrease in gastric acid secretion. Activation in the stomach prior to absorption can be prevented by the use of enteric-coated formulations (see V.A.4).

3. Formaldehyde is an effective urinary tract antiseptic; however, oral administration results in significant toxicity. To avoid this problem, the prodrug **methenamine** is administered instead. Methenamine is stable and nontoxic at normal physiological pH, but is selectively hydrolyzed to formaldehyde and ammonium ions in the acidic urine (pH less than 5.5). As with omeprazole, activation before absorption can be prevented by the use of enteric-coated formulations (see V.A.4).

4. Olsalazine is a highly polar dimer of 5-aminosalicylic acid that is poorly absorbed after oral administration. On reaching the large intestine, colonic bacteria cleave the azo bond and liberate the active anti-inflammatory agent. Olsalazine and a related compound, **sulfasalazine,** are useful in treating inflammatory bowel disease.

E. Increased shelf life of both solids and parenteral admixtures can be obtained by the use of prodrugs. **Cyclophosphamide** is a prodrug that requires in vivo oxidation, followed by nonenzymatic decomposition, to produce the active phosphoramide mustard. As a result, aqueous solutions of cyclophosphamide are much more stable than those of other nitrogen mustards (i.e., mechlorethamine). **Mechlorethamine** is highly reactive, does not require in vivo activation, and can rapidly decompose in aqueous environments before administration.

VII. PHARMACOGENETICS

A. Genes and their involvement in drug response and toxicity

1. Genes can be defined as discrete segments of DNA that are capable of reproduction during cell replication and that are responsible for guiding the biosynthesis of specific proteins and enzymes.

2. Genes encode proteins involved in the **absorption, transport, metabolism, and elimination** of drug molecules. Additionally, they encode proteins that serve as **drug receptors.** It is obvious then that a genetic disposition that would result in either an **over- or an underexpression of these genes** could significantly alter drug response and toxicity.
3. Assuming that a patient has been prescribed a medication that is indicated for his or her condition or disease state, there are several reasons why a patient may not respond or may suffer severe adverse effects:
a. Inappropriate dosing
b. Drug-drug interactions
c. **Drug allergies**
d. Medication errors
e. Genetic predisposition
4. In its most simplistic form, **pharmacogenetics** can be defined as the use of genetic information to select the "right drug for the right patient." This area of study primarily seeks to identify the individual genetic differences and predispositions that influence drug response and safety.
B. Genetic variation in the DNA sequence can cause certain populations of individuals to be **more likely to develop specific disease states,** to be **more likely to follow a specific path of disease progression,** to be **more likely to respond to specific drug therapy,** and/or to be **more likely to develop certain adverse drug effects.**
1. The genetic variation between any two unrelated individuals is approximately one base pair change in every 1000 base pairs.
2. These changes are referred to as **single nucleotide polymorphisms (SNPs)** and are the most common form of genetic variation.
3. The effects of SNPs vary based upon the **type and location** of the variation.
a. An SNP located within the coding region of a gene could produce no discernable effects, negligible effects, or a significant alteration in effects depending upon how the SNP affected the amino acid coding.
(1) An SNP that **did not alter** the amino acid sequence in a protein would produce **no discernable effects.**
(2) An SNP that resulted in one amino acid being replaced by a **similar amino acid** would have a **negligible effect** (e.g., changing a portion of the genetic code from AUU to GUU would result in isoleucine being replaced by valine, a similar hydrophobic amino acid).
(3) An SNP that resulted in one amino acid being replaced by one with **significantly different chemical properties** would cause **a significant alteration of effects** (e.g.,

changing a portion of the genetic code from GUU to GAU would result in valine being replaced with the acidic, and more hydrophilic, aspartic acid).
b. An SNP in a splicing control region could result in the formation of a novel protein that is either larger or smaller in size than that which is naturally occurring.

c. **An SNP in a promoter region** could alter the transcription rate, resulting in either an increase or a decrease in the production of the target protein.
d. An SNP residing outside of any of the above locations is **genetically silent** and does not produce any observable effects.

4. Examples of known genetic variations and their effects on drug efficacy and safety

a. Warfarin. Patients with specific variations in the gene for the metabolizing enzyme CYP2C9 require lower doses and are at an increased risk of bleeding.
b. Salmeterol and albuterol. Genetic variations in the gene coding for the β_2-adrenergic receptor (ADBR2) can result in a decreased efficacy.
c. **6-Mercaptopurine.** Genetic variations affecting the enzyme thiopurine methyltransferase are known to produce increased toxicity.
d. Procainamide, hydralazine, and isoniazid. Genetic variations affecting the rate of *N*-acetylation affect both the efficacy and adverse effect profiles of these agents. The identification of fast and slow acetylators is one of the best known examples of how genetic variation can affect therapeutic safety and efficacy.
e. Quinidine, cisapride, and clarithromycin. Genetic variations in the gene coding for potassium channels can result in increased risk and prevalence of QT-syndrome and arrhythmias.
f. Zileuton. Patients with genetic variations in the gene coding for the enzyme 5-lipoxygenase do not respond to this drug.

C. Clinical pharmacogenetic assays

1. The **goal** of a clinical pharmacogenetic assay is to place patients into one of four categories.
a. Individuals who are most likely to respond and are at a low risk for adverse effects
b. Individuals who are most likely to respond and are at a high risk for adverse effects
c. Individuals who are less likely to respond and are at a low risk for adverse effects
d. Individuals who are less likely to respond and are at a high risk for adverse effects
2. Issues in the development of pharmacogenetic assays include:
a. Improvement in a medically important response (i.e., the assay should allow healthcare providers to make a better decision than would otherwise be possible).
b. False positives for efficacy-based assays should be kept at a minimum in order to prevent nonresponders from being prescribed drugs that will not provide the desired therapeutic outcomes. False negatives (i.e., responders identified as nonresponders) are not as crucial since they would be prescribed appropriate alternative therapy.
c. **False negatives for safety-based assays should be kept at a minimum** in order to prevent at-risk patients from being exposed to potential serious adverse effects. A higher rate of false positives (i.e., patients identified as “at risk”) is acceptable. Excluding a certain percentage of patients in order to avoid serious adverse effects has been proposed to be a reasonable trade-off.

d. The results for the assays must be both interpretable and provide clinically useful results. The assays should be simple to use in a clinical setting and should provide results that are easily understood by the patient, physician, pharmacist, and other health-care providers.

e. Analytical and clinical validation of the assay must meet FDA approval standards.

3. As defined here, pharmacogenetic assays do not test for the presence or absence of a disease-specific mutation, nor do they provide any information that could be used to predict disease states in an individual or his or her family. As such, it has been suggested that legal and ethical issues surrounding disease-specific gene tests should not apply to predictions of safety and efficacy of drugs (i.e., the primary focus of pharmacogenetics).

D. SNP maps and their potential use

1. An SNP map for an individual contains the specific number and locations of base pair variations. Such a map could be used to predict patient response and susceptibility to serious adverse reactions.

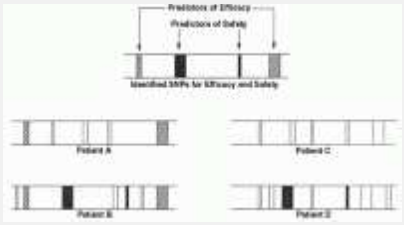

Figure 17-2. Hypothetical single nucleotide polymorphism (SNP) maps. At the top is a composite SNP profile developed by using genetic information from a large database of patients/volunteers. This overall SNP can then be compared to individual SNP maps (i.e., **Patients A-D**) to help determine the overall benefit/risk for the given drug in each of these four patients.

2. A simplified example of this is shown in Figure 17-2. A large database would initially be used to identify SNPs that could be used as predictors of efficacy and safety. At the top of Figure 17-2, the two outside, shaded regions in this **hypothetical model** should be regarded as SNPs that would predict that a patient would favorably respond to the drug. Similarly, the two inner, black regions should be regarded as SNPs that would indicate that a patient was more prone to the development of serious adverse effects. Other SNPs (i.e., the nonhighlighted rectangles shown for the four patients) should be regarded as irrelevant here (i.e., they do not predict either efficacy or safety for the drug in question).

a. Patient A would be predicted to respond to treatment without the development of any serious adverse effects.

b. Patient B would be predicted to respond to treatment but would also be expected to develop serious adverse effects.

c. Patient C would be predicted to be a nonresponder to treatment but would be unlikely to experience any serious adverse effects.
d. Patient D would be predicted to be a nonresponder to treatment but would be expected to develop serious adverse effects.
P.414

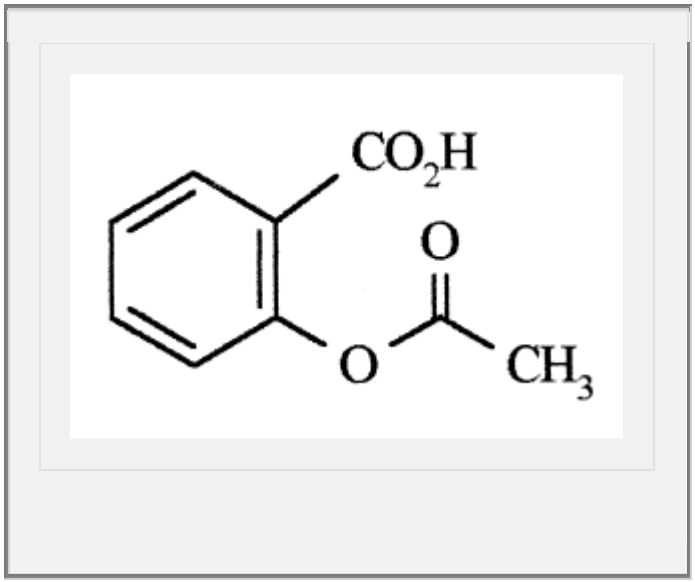
STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the one lettered answer or completion that is **best** in each case.

1. Which of the following statements concerning drug metabolism is true?

(A) Generally, a single metabolite is excreted for each drug administered.
(B) Often, a drug may undergo a phase II reaction followed by a phase I reaction.
(C) Drug-metabolizing enzymes are found only in the liver.
(D) All metabolites are less active pharmacologically than their parent drugs.
(E) Phase I metabolites more likely are able to cross cellular membranes than phase II metabolites.

View Answer***1. The answer is E[].*****2. Which of the following metabolites would be the least likely excretion product of orally administered aspirin (see structure below)?**

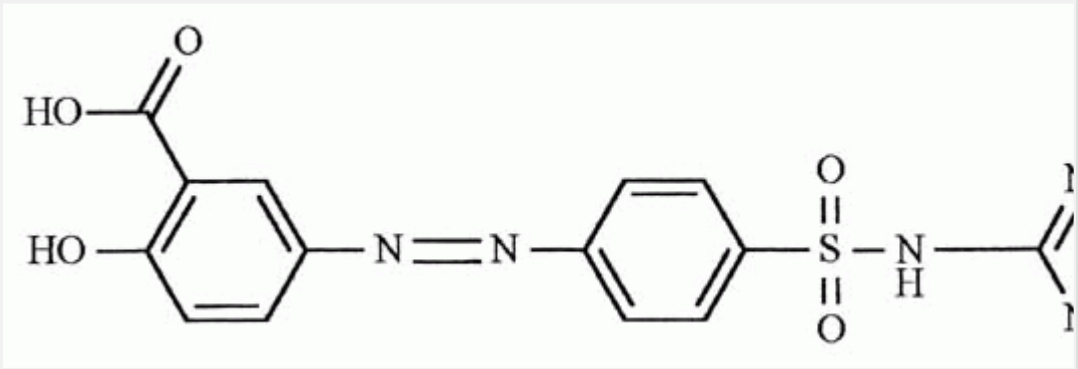


(A) Glycine conjugate
(B) Ester glucuronide
(C) Unchanged drug
(D) Ether glucuronide
(E) Hydroxylated metabolite

View Answer***2. The answer is C[and].*****3. Sulfasalazine (see structure below) is a prodrug that is activated in the intestine by bacterial enzymes. The enzyme most likely responsible is**

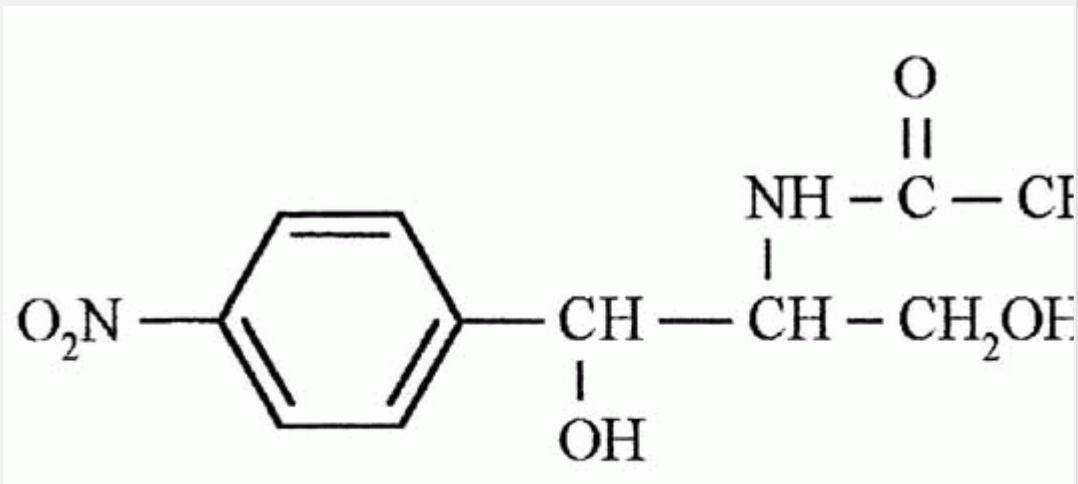
(A) azoreductase

(B) pseudocholinesterase
(C) *N*-acetyltransferase
(D) β-glucuronidase
(E) methyltransferase



View Answer***3. The answer is A[].*****4. Chloramphenicol (see structure below) is considered to be toxic in infants (gray baby syndrome). This is due to tissue accumulation of unchanged chloramphenicol, resulting from an immature metabolic pathway. Which of the following enzymes would most likely be deficient?**

(A) Pseudocholinesterase
(B) Glucuronyl transferase
(C) *N*-Acetyltransferase
(D) Azoreductase
(E) Methyltransferase



View Answer***4. The answer is B[and].*****5. Which of the following therapeutic advantages cannot be obtained by the use of prodrugs? Increased**

(A) oral absorption
(B) water solubility
(C) duration of action
(D) potency
(E) palatability

View Answer***5. The answer is D[and].***P.415

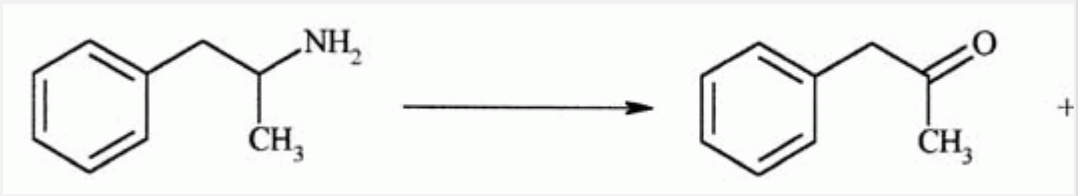
6. Which of the following statements regarding pharmacogenetics is INCORRECT?

(A) Single nucleotide polymorphisms (SNPs) in a promoter region can result in a decreased production of a target protein.
(B) It is crucial that false positives for safety-based assays be kept at a minimum.
(C) The area of pharmacogenetics focuses primarily on the genetic variations that affect drug efficacy and safety.
(D) The effects of SNPs vary based upon the type and location of the variation.
(E) Genetic variation occurs whenever there is a change in the DNA nucleotide base pair sequence.

View Answer***6. The answer is B[and].*****Directions:** Each question below contains three suggested answers, of which **one or more** is correct. Choose the answer.

7. Terms that may be used to describe the following metabolic reaction include

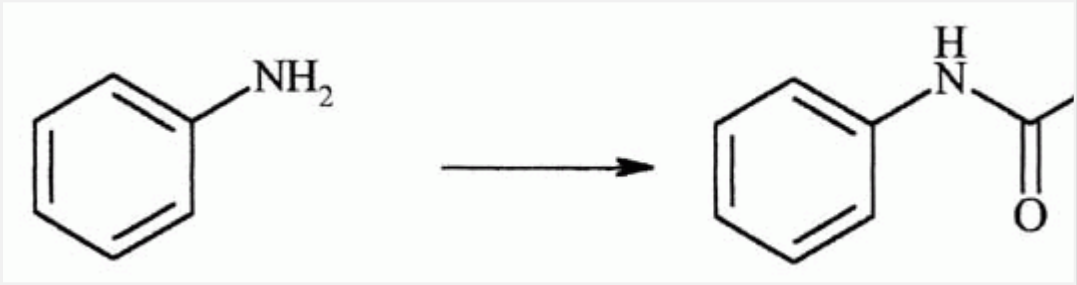
I. *N*-dealkylation
II. oxidative deamination
III. phase I metabolism

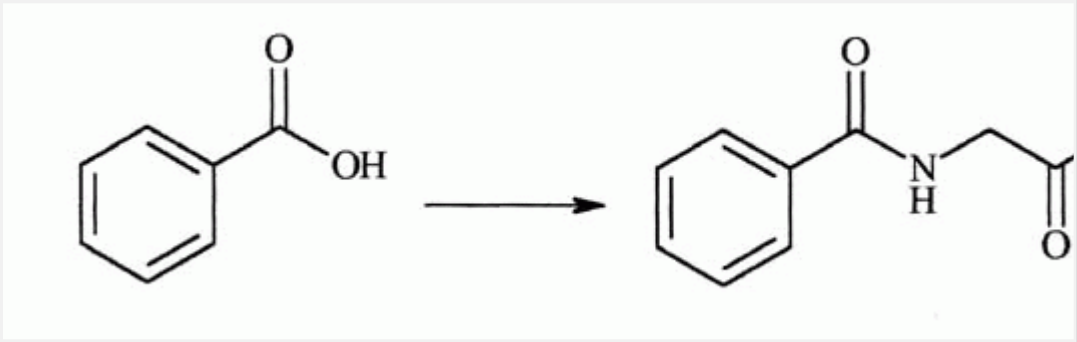


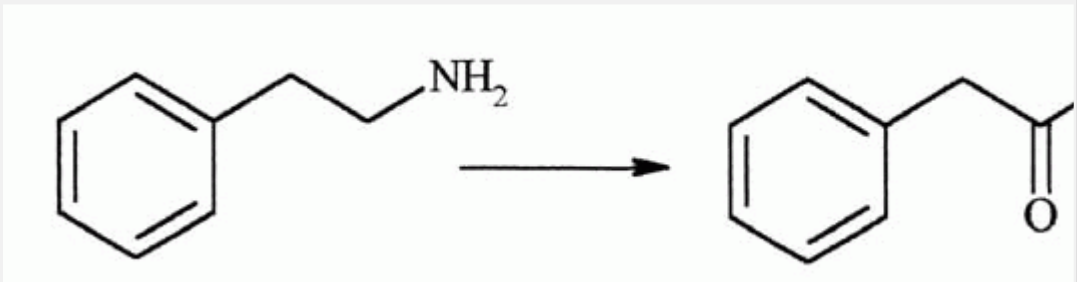
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***7. The answer is D[].N***P.416

8. Which of the following reactions can be classified as phase II metabolism?







A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***8. The answer is C[].***9. Conditions that tend to increase the action of an orally administered drug that undergoes phase II metabolism include

I. enterohepatic circulation
II. enzyme saturation
III. first-pass effect
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***9. The answer is C[].***10. Which of the following statements concerning CYP450 are correct?

I. The CYP7, CYP11, and CYP27 subfamilies are involved in cholesterol metabolism.
II. A single drug may be metabolized by multiple isoforms of CYP450.
III. The majority of xenobiotics, or drugs, are metabolized by the CYP4B and CYP1A subfamilies.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***10. The answer is C[I.A.1.c;].***11. Metabolic reactions likely to be affected by a protein-deficient diet include

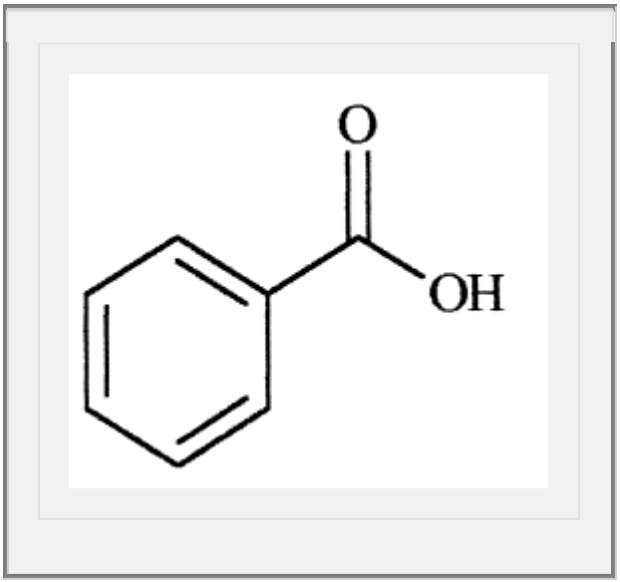
I. glycine conjugation
II. hydrolysis
III. glucuronidation
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***11. The answer is A[].***Directions: The group of items in this section consists of lettered options followed by a set of numbered items. For each item, select the **one** lettered option that is most closely associated with it. Each lettered option may be selected once, more than once, or not at all.

Questions 12-15

For each drug, select its most likely metabolic pathway.

12. Benzoic acid



(A) Ether glucuronidation

(B) Ester glucuronidation

(C) Nitroreduction

(D) Oxidative deamination

(E) Ester hydrolysis

P.417

ANSWERS AND EXPLANATIONS

1. The answer is E *[*I; II.A.1, B*].*

Phase I metabolites are often somewhat more polar than their parents. With the exception of acetylated and methylated metabolites, phase II metabolites are always much more polar than their parents. Thus, phase I metabolites are more likely to retain some liposolubility and are more likely to cross cellular membranes.

It is unusual for a single metabolite to be excreted for a given drug. Most drugs yield a mixture of metabolites. Because of the high polarity and subsequent high excretion of phase II metabolites, they are not likely to undergo further metabolism. Phase I metabolites, on the other hand, are less polar and are very likely to undergo further phase II metabolic reactions.

Whereas the major site of metabolism is the liver, there are many extrahepatic sites that secrete drug-metabolizing enzymes. Although many metabolites are less pharmacologically active than their parents, there are many drugs whose metabolites have equal or greater pharmacological activity and sometimes greater toxicity as well. Prodrugs (i.e., drugs inactive in the form administered) always form at least one active metabolite.

2. The answer is C *[*II.A. 1.e, 3.a, B.2.a.(2), c; Tables 17-2, 17-3, *and* 17-4*].*

Because of the types of functional groups present, aspirin may undergo a number of different metabolic reactions. These include hydroxylation of the aromatic nucleus, conjugation of the carboxyl group with glycine, conjugation of the carboxyl group with glucuronic acid with the formation of an ester glucuronide, hydrolysis of the acetate ester, and conjugation of the phenol group (resulting from hydrolysis of the acetate ester) with glucuronic acid to form an ether glucuronide.

Because the acetate ester is a simple ester, aspirin is susceptible to hydrolysis in the acid media of the stomach before absorption takes place. In addition, any acetylated molecules that are absorbed are subjected to hydrolysis and are catalyzed by the many esterases present in the circulation. Any acetylated molecules not hydrolyzed in the circulation are subject to hydrolysis in the liver. All of these processes occur before the drug reaches the glomerular filtrate; therefore, excretion of the unchanged acetylated drug is highly unlikely.

3. The answer is A *[*II.A.2; Table 17-3*].*

Sulfasalazine has both anti-inflammatory and antibacterial activity when converted to aminosalicylic acid and sulfapyridine in the body. This reaction occurs by reductive cleavage of the “azo” linkage contained in the sulfasalazine molecule and is catalyzed in the intestine by bacterial azoreductase. This is a form of site-specific delivery because the intact drug is not absorbed from the stomach or upper intestine and reaches the colon, where it is metabolized. Sulfasalazine is one of a few drugs that is effective for the treatment of ulcerative colitis.

4. The answer is B *[*II.B.2.a.(2); III.G.1; Tables 17-2, 17-3, *and* 17-4*].*
The chloramphenicol molecule contains an aromatic nucleus, which would be subject to hydroxylation, a nitro group that is subject to reduction, an amide group that is subject to liver hydrolysis, and alcohol groups that are subject to glucuronidation. Of all the enzyme systems responsible for these reactions, the system responsible for glucuronidation is developed poorly in premature infants and infants up to approximately 6-8 weeks of age.
5. The answer is D *[*VI.A, B.1, 2, 3 *and* 4*].*
By definition, prodrugs are inactive or very weakly active molecules that require in vivo activation to the parent molecule. Thus, conversion of a drug molecule to a prodrug does not increase potency because the original molecule, with whatever potency it contains, is produced after administration. A variety of advantages, including increased water solubility, duration of action, oral absorption, and palatability, can be obtained through the use of prodrugs, but none of these advantages results in an increase in potency of the parent molecule.
6. The answer is B *[*VII.A.4, B.1, 2, 3 *and* C.2.c*].*
While keeping false positives and false negatives at a minimum is always desirable, it is most crucial that false negatives be kept at a minimum for safety-based assays in order to prevent at-risk patients from being exposed to potential serious side effects. A higher rate of false positives is acceptable since preventing serious adverse effects is perceived to be more important than excluding some patients from therapy.

Genetic variation occurs whenever there are base pair changes in the DNA nucleotide sequence. The most common form of genetic variation is a single nucleotide polymorphism (SNP). The cumulative effects of these variations vary based on the types and locations of the SNPs. Variations in coding regions can alter protein function, while those in splicing and promoter regions can alter protein size and protein production, respectively. Some SNPs produce no discernable changes and are therefore genetically silent. Pharmacogenetics primarily seeks to use SNPs and other genetic information to predict predispositions that influence drug response and safety in individual patients.
7. The answer is D (II, III) *[*II.A; Table 17-2*].*
The reaction shown in the question involves the conversion of one functional group to another (amine to carbonyl); thus, it is classified as a phase I reaction. The introduction of oxygen into the molecule indicates oxidation, and the loss of the amino group signifies deamination; thus, the reaction also can be classified as oxidative deamination. *N*-Dealkylation implies the removal of an alkyl group from a nitrogen. The nitrogen in the parent molecule does not have an alkyl group attached to it.
8. The answer is C (I, II) *[*II.A, B; Table 17-4*].*
Phase II metabolic reactions involve masking an existing functional group with a natural endogenous constituent. The formulas shown in choices I and II represent

this type of reaction, with choice I being an acetylation reaction and choice II, a glycine conjugation reaction. Choice III represents a change in an existing functional group and, thus, represents a phase I reaction. It is an oxidative deamination reaction.

9. The answer is C (I, II) *[*II.B.2.a.(4), III.E.1, 2; IV.B.3.b*].*

Enterohepatic circulation refers to the process by which glucuronides, which are secreted into the intestine with the bile, are hydrolyzed by intestinal bacterial β-glucuronidase. The hydrolyzed free drug, which is no longer polar, becomes available for intestinal reabsorption into the system and subsequent penetration to its active site.

If an enzyme system becomes saturated, then the active drug cannot be inactivated by that pathway. If the drug cannot undergo an alternative pathway, the increased plasma levels of an unchanged active drug can result in increased activity or toxicity.

The first-pass effect results in metabolism of a drug by the liver before the drug reaches its site of action, resulting in an overall decrease in its activity. Drugs that undergo first-pass metabolism generally are effective in much smaller intravenous doses as compared to oral doses.

10. The answer is C (I, II) *[I.A.1.c;* Table 17-1*].*

There are six mammalian families involved in steroid and bile acid metabolism. These are CYP7, CYP11, CYP17, CYP19, CYP21, and CYP27. Since cholesterol is the common intermediate for the biosynthesis of all endogenous steroids, some of these enzymes are directly involved in cholesterol metabolism. The families listed, CYP7, CYP11, and CYP27, all metabolize cholesterol, while the other three families catalyze additional oxidations of the initial metabolites.

As is evident from Table 17-1, multiple isoforms of CYP450 can metabolize a single drug. An example of this is seen with imipramine, an antidepressant that is metabolized by CYP1A, CYP2C, and CYP2D isoforms. Additionally, Table 17-1 indicates that the subfamilies CYP2C, CYP2D, and CYP3A metabolize the majority of drugs, or xenobiotics.

11. The answer is A (I) *[*III.F.1*].*

Phase II metabolic reactions require natural endogenous substrates, which normally are supplied in the diet. A deficiency of these substances results in a decrease in the biotransformation of drugs that use these pathways. Glycine conjugation is a phase II reaction. Glycine is an amino acid that requires dietary protein. A diet deficient in protein, therefore, could lead to a deficiency of glycine and, thus, a decrease in glycine conjugation. Glucuronidation is also a phase II reaction that requires endogenous glucuronic acid, but this substance is supplied by dietary carbohydrates. Hydroxylation is a phase I metabolic reaction and does not require dietary protein.

12-15. The answers are: 12-B *[*II.B.2.a.(2)*],* **13-E** *[*II.A.3.a*],* **14-A** *[*II.B.2.a.(2)*],* **15-D** *[*II.A.1.e*].*

Benzoic acid contains a carboxylic acid, a functional group that commonly undergoes conjugation with glucuronic acid. The resulting conjugation produces an ester. Carboxylic acids can also undergo conjugation with the amino acids glycine

and glutamine. Additionally, benzoic acid can undergo aromatic hydroxylation, a common phase I pathway for drugs containing unsubstituted aromatic rings. Of these options, ester glucuronidation is the only answer available here.
P.420

Procaine is an ester-containing local anesthetic. Due to the wide physiological distribution of esterase enzymes, it is extremely susceptible to in vivo hydrolysis. This susceptibility to hydrolysis is the major reason why ester-containing local anesthetics have shorter durations of action as compared to those in other chemical classes.
One of the principal functional groups in acetaminophen is the phenol group. Similar to the carboxylic acid in benzoic acid, the phenol commonly undergoes glucuronide conjugation. The one difference is that a phenol (or an alcohol) produces an **ether** glucuronide, while a carboxylic acid produces an **ester** glucuronide. Phenols also commonly undergo sulfate conjugation reactions and occasionally undergo O-methylation reactions.
The principal functional group in amphetamine is its primary amine. Oxidative deamination is a very common metabolic path for primary amines. Occasionally, primary amines undergo phase II acetylation; however, this is a less common pathway. Aromatic hydroxylation, similar to that discussed above for benzoic acid, is also possible for amphetamine.

Drug-Drug and Drug-Nutrient Interactions

Alice C. Engelbrecht

Leon Shargel

I. INTRODUCTION

A. Definition of drug interaction

1. Drug interaction refers to an **adverse** drug response produced by the administration of a drug or coexposure of the drug with another substance, which modifies the patient's response to the drug. Some drug interactions are intentional in order to provide improved therapeutic response or to decrease adverse drug effects. A **precipitant** drug is the drug, chemical, or food element causing the interaction. An **object** drug is the drug affected by the interaction.

2. Drug interactions include:

a. Drug-drug interactions

b. Drug-herbal interactions

c. **Food-drug** interactions

d. Pharmacogenetic interactions

e. Chemical-drug interactions, such as the interaction of a drug with alcohol or tobacco

f. Drug-laboratory test interactions such as chemical interactions.

B. Classification of drug interactions. Drug interactions that occur *in vivo* are generally classified as **pharmacokinetic** or **pharmacodynamic** interactions.

1. Pharmacokinetic or **biopharmaceutical** interactions occur when the absorption, distribution (protein and tissue binding), or elimination (excretion and/or metabolism) of the drug is affected by another drug, chemical, or food element.

2. Pharmacodynamic interactions occur when the pharmacodynamic effect of the drug is altered by another drug, chemical, or food element, producing an antagonistic, synergistic, or additive effect.

3. Pharmacogenetic interactions occur when the pharmacokinetic effect of the drug is altered by genetic polymorphisms in affecting processes.

4. Pharmaceutical interactions are caused by a chemical or physical incompatibility when two or more drugs are mixed together. Pharmaceutical interactions can occur during the extemporaneous compounding of drugs, including the preparation of intravenous (IV) solutions. For example, an IV solution of aminophylline has an alkaline pH and should not be mixed with such drugs as epinephrine, erythromycin gluceptate, or cephalothin sodium, which decompose in alkaline pH. Phenytoin sodium will precipitate from a solution that has an acid pH, such as dextrose 5%. Pharmaceutical interactions are usually considered during the development, manufacturing, and marketing of the drug product. Only drug interactions involving pharmacokinetic, pharmacodynamic, or pharmacogenetic processes will be considered in this chapter.

II. PHARMACOKINETIC INTERACTIONS

A. Absorption

1. Drug interactions can affect the **rate** and the **extent** of systemic drug absorption (bioavailability) from the absorption site, resulting in increased or decreased drug bioavailability (Table 18-1).
P.422

Table 18-1. Drug Interactions That Affect the Bioavailability of the Drug from the Gastrointestinal (GI) Tract

Drug Interaction	Examples (Precipitant drugs)	Effect (Object drugs)
Complexation/chelation	Calcium, magnesium, or aluminum and iron salts	Levofloxacin complexes with divalent cations in the diet or tube feeding, causing a decreased bioavailability
	Sodium polystyrene sulfonate	Cations in antacids bind to sodium polystyrene sulfonate, causing reduced renal clearance of bicarbonate, resulting in systemic acidosis
Adsorption	Cholestyramine	Decreased bioavailability of digoxin, levothyroxine
	Kaolin	Decreased bioavailability of digoxin
	Activated charcoal	Decreased bioavailability of many drugs
	Acarbose	Decreased bioavailability of digoxin

Increased GI motility	Laxatives, cathartics	Increases GI motility, decreases bioavailability for drugs that are absorbed slowly. Will decrease the bioavailability of drugs from controlled-release products.
Decreased GI motility	Anticholinergic agents	Propantheline decreases the gastric emptying of acetaminophen (APAP), delaying APAP absorption from the small intestine.
Alteration of gastric pH	H-2 blockers, antacids, and proton pump inhibitors	H-2 blockers, antacids and PPIs increase gastric pH. The dissolution of ketoconazole is reduced at basic pH, causing decreased drug absorption and therapeutic failure.
Alteration of intestinal flora	Antibiotics	Digoxin has better bioavailability taken after erythromycin. Erythromycin administration reduces bacterial inactivation of digoxin.
		Estrogen/progestin birth control requires intestinal flora to facilitate enterohepatic circulation. Antibiotics reduce intestinal flora and reduce estrogen/progestin levels resulting in

		failure of ovulation suppression and menstrual changes.
Inhibition of drug metabolism in intestinal cells	Monoamine oxidase inhibitors (MAOIs) (e.g., tranylcypromine, phenelzine)	MAOIs inhibit metabolism of albuterol and levalbuterol, leading to hypertension.

2. The most common drug absorption **site** is in the **gastrointestinal (**GI**) tract.** However, drug bioavailability from other absorption sites, such as the skin, can be affected by drug interactions. For example, epinephrine, a vasoconstrictor, will decrease the percutaneous absorption of transdermal lidocaine or transdermal fentanyl.

3. Other **potential** drug-drug and drug-food interactions that affect bioavailability in the GI tract could be due to:

a. Competition for carrier-mediated drug absorption in which the participant drug competes for the same carrier as the object

i. Competition for the P-gp system (an ATP-dependent efflux pump on epithelial cells of the intestines) is involved in transport of cyclosporin and digoxin. Displacement can result in toxicity of those drugs.

ii. Grapefruit juice and orange juice from Seville oranges inhibit OATP (organic anion transporting polypeptides) proteins in the epithelial cells of the small intestine, reducing the bioavailability of oral fexofenadine.

b. Alteration of intestinal blood flow caused by the precipitant drug. In congestive heart disease, the blood flow to the GI tract is poor and an orally administered drug can

have a slower rate of absorption. After digoxin therapy, the perfusion of the GI tract is improved along with bioavailability of the object drug.

B. Distribution. The distribution of the drug may be affected by plasma protein binding and displacement interactions or tissue and cellular interactions.

1. Plasma protein binding and displacement on albumin and alpha1-acid glycoprotein carrier proteins.

a. Valproic acid displaces phenytoin from plasma albumin protein-binding sites and reduces hepatic phenytoin clearance by inhibiting the liver's metabolism of phenytoin, resulting in higher phenytoin levels.

b. Aspirin is 90% to 95% protein bound and displaces warfarin from protein binding sites resulting in higher warfarin levels and increased bleeding.

2. Tissue and cellular interactions. Digoxin toxicity can be enhanced by concurrent administration of quinidine. Quinidine reduces digoxin clearance and displaces digoxin from both alpha-1 glycoproteine and albumin tissue-binding sites, leading to a higher plasma digoxin concentration.

C. Drug elimination and clearance

1. Drug Metabolism and Hepatic Clearance

a. Drug metabolism (hepatic clearance) can be affected by enzyme induction, enzyme inhibition, substrate competition for the same enzyme, and changes in hepatic blood flow (Table 18-2).

b. Many drugs that share the same drug-metabolizing enzymes have a potential for a drug interaction. For example, fluconazole inhibits the hepatic metabolism of warfarin, causing increased risk of bleeding. Carbamazepine is both a substrate and an inducer of the CYP3A4 isoenzyme, thereby inducing its own metabolism and taking 3-5 weeks to reach stable blood levels (Table 18-3). Phenytoin is also a substrate of the CYP3A4 and induces its own metabolism.

c. Over-the-counter (OTC) drugs and herbal preparations can also be involved in CYP450 isoenzyme metabolism and can cause serious drug-herbal interactions. For example, St. John's Wort may induce CYP3A4 isoenzymes and decrease cyclosporin to subtherapeutic levels. Tobacco use (smoking) can induce the CYP1A2 isoenzyme and decrease clozapine levels, increasing the risk of therapeutic failure in treating OCD.

d. Foods may also interfere with hepatic drug metabolism. For example, grapefruit juice is a powerful inhibitor of the CYP3A4 isoenzyme, and will increase blood levels of CYP3A4 substrates such as ritonavir, methadone, amlodipine, alprazolam, cyclosporin, and diltiazem, if taken together.

Table 18-2. Drug Interactions That Affect the Drug Metabolism

Drug Interaction	Examples (Precipitant drugs)	Effect (Objective drugs)
Enzyme induction		
	Smoking (polycyclic aromatic hydrocarbons)	Smoking increases duloxetine metabolism and decreases duloxetine levels
	Phenytoin	Tacrolimus levels are decreased because of increased metabolism
Enzyme inhibition		

Mixed function oxidase	Cimetidine	Decreased atorvastatin clearance and increased drug levels
Induction of UDP-G metabolism	Phenytoin, cimetidine, midazolam, rifabutin	Decreased posaconazole levels due to induction of metabolism
Other enzymes	Monoamine oxidase inhibitors, MAOIs (e.g., pargyline, tranylcypromine)	Serious hypertensive crisis can occur following ingestion of foods with a high content of tyramine or other pressor substances (e.g., cheddar cheese, red wines, avocados), and catecholamines

Table 18-3. Drug/Herb/Food Actions with Cytochrome P450 Enzymes

Enzyme	Inhibitor	Inducer	Substrate
CYP1A2	Ciprofloxacin	Phenytoin	Naproxen
	Levofloxacin	Carbamazepine	Amitriptyline
	Cimetidine	Charbroiled foods	Verapamil
	Citalopram	Tobacco	Clopidogrel
	Ketoconazole	Ritonavir	Duloxetine
	Paroxetine	St. John's Wort	Ramelteon
CYP2C9	Cimetidine	Rifampin	Tamoxifen

	Fluoxetine	Carbamazepine	Losartan
	Voriconazole	Phenytoin	S-Warfarin
	Fluconazole		Celecoxib
	Amiodarone		Phenytoin
	Efavirenz		Carvedilol
	Metronidazole		Voriconazole
			Glyburide
			Sildenafil
CYP2C8	Gemfibrozil	Phenobarbital	Paclitaxel
	Nicardipine	Rifampin	Carbamazepine
	Atazanavir	Carbamazepine	Amiodarone
	Trimethoprim		Pioglitazone
CYP2C19	Ketoconazole	Rifampin	Diazepam
	Omeprazole	Carbamazepine	Phenytoin
	Topiramate	Phenytoin	Citalopram
	Fluoxetine		Omeprazole
	Fluvoxamine		Diphenhydramine

			Duloxetine
			R-Warfarin
CYP2D6	Methadone	Carbamazepine	Amitriptyline
	Cimetidine	Phenytoin	Metoprolol
	Fluoxetine	Ethanol	Paroxetine
	Ritonavir	St. John's Wort	Duloxetine
	Haloperidol	Ritonavir	Haloperidol
	Amiodarone		Venlafaxine
	Paroxetine		Tramadol
	Quinidine		Trazodone
	Sertraline		Narcotic anagesics
CYP2E1	Cimetidine	Ritonavir	Acetaminophen
	Disulfiram	Isoniazid	Caffeine
		Ethanol	Venlafaxine
CYP3A family	Erythromycin	Carbamazepine	Atorvastatin
	Ketoconazole	Phenobarbital	Warfarin

	Saquinavir	St. John's Wort	Lidocaine
	Verapamil	Nevirapine	Ethylestradiol
		Efavirenz	
	Metronidazole	Carbazepine	Cyclosporin
	Amiodarone	Rifampin	Alprazolam
	Cimetidine	Garlic Supplements	Ziprasidone
	Diltiazem	Grapefruit	Doxorubicin
	Posaconazole	Seville Oranges	Amitriptyline
	Metronidazole	Bitter Orange	Methadone
	Nifedipine		Cyclosporin
	Voriconazole		Amlopdipine
	Atazanavir		Indinavir
			Cyclosporin
			Paclitaxel
			Ritonavir
			Lidocaine
			Lovastatin

			Midazolam
			Tamoxifen
			Zaleplon
			Atazanavir

e. Nonhepatic enzymes can be involved in drug interactions. For example, serotonin syndrome has been reported in patients receiving antidepressants such as citalopram (an SSRI inhibitor) in combination with a monamine oxidase inhibitor, such as linezolid. A considerable portion of the CYP3A4 enzymes are found not only in the liver, but also in the GI tract, where some of these substrates are metabolized.

f. A decrease in the hepatic blood flow can decrease the hepatic clearance for high extraction drugs, such as propranolol and morphine.

2. Renal drug clearance can be affected by changes in glomerular filtration, tubular reabsorption, active drug secretion, and renal blood flow and nephrotoxicity (Table 18-4).

III. PHARMACODYNAMIC INTERACTIONS

A. Drugs that have similar pharmacodynamic actions may produce an excessive pharmacological or **toxic response.**

1. For example, central nervous system depressants, such as the combination of narcotics and antihistamines (e.g., diphenhydramine, chlorpheniramine) can produce increased drowsiness in the patient.

2. Drugs having anticholinergic effects, such as promethazine and OTC antihistamines, can cause excessive dryness of the mouth, blurred vision, and urinary retention.

3. Drugs that prolong the QTc interval (such as paliperidone, amiodarone, sotalol, moxifloxacin, and atypical antispychotics such as ziprasidone) have a much greater risk of causing QTc interval arrhythmias when given together.

Table 18-4. Drug Interactions That Affect the Renal Clearance

Drug Interaction	Examples	Effect
Glomerular filtration rate (GFR) and renal blood flow	Methylxanthines (e.g., caffeine, theobromine)	Increased renal blood flow and GFR will decrease time for reabsorption of various drugs, leading to more rapid urinary drug excretion.
Active tubular secretion	Probenecid	Probenecid blocks the active tubular secretion of penicillin and some cephalosporin antibiotics.
Tubular reabsorption and urine pH	Antacids, sodium bicarbonate	Alkalinization of the urine increases the reabsorption of amphetamine and decreases its clearance.
		Alkalinization of urine pH increases the ionization of salicylates, decreases reabsorption, and increases its clearance.

B. The pharmacodynamic effect of one drug can be antagonized by the opposite pharmacodynamic effect of a second drug. For example, the antihypertensive effect of beta blockers can be overcome by the use of vasopressors. Obviously, this can have a deleterious effect, be a therapeutic failure, or be a therapeutic strategy in clinical treatment, depending on the situation

C. Drug therapy can produce an adverse effect that results in an **increased sensitivity** or **toxicity** when another drug is given. For example, the alteration of electrolyte concentrations produced by a diuretic, such as a thiazide derivative, will deplete potassium, resulting in sensitization of the heart to digoxin therapy. Depletion of sodium by a diuretic can also result in lithium toxicity.

D. Therapies that have **intrinsically opposite effects** on the same target system can result in therapeutic failure. For example, naloxone competes with narcotics at the narcotic receptor site, resulting in therapeutic failure of narcotic-based anagesia therapy.

E. Pharmacodynamic drug interactions also can occur with drug-herbal interactions and drug-food interactions. For example, by ingesting large amounts of vitamin K in the diet, the effect of anticoagulation by warfarin is **antagonized.**

F. Starting and stopping therapies that influence metabolism of other drugs can result in therapeutic failure if the induced metabolism reduces the blood levels of the target drug. For example, starting a patient on nicotine patches replaces smoking for a patient. Since the patient is no longer smoking tobacco, the CYP1A2 isoenzymes are no longer induced, and the substrates of the CYP1A2 system (clozapine or haloperidol, for example) may be increased to toxic levels. This effect can occur in several enzyme systems when stopping phenytoin, an inducer for several CYP enzyme systems.

IV. HERBAL-DRUG INTERACTIONS

A. Herbal preparations are various combinations of herbs, sometimes being one herb, or a combination of herbs. Some herbal preparations represent a single herb containing a variety of alkaloids or constituents that may exhibit a variety of pharmacological activities.

1. Some herbs contain a number of different pharmacologically active constituents. For example, St. John's Wort has at least six different constituents: hyperforin, biapigenin, hypericin, quercitin, chlorogenic acid, and pseudohypericin. Each constituent has its own metabolism, binding and pharmacologic action. The predominant effect or interaction depends upon the relative potency of each constituent in the herb. For example, the constituents of St. John's Wort have inhibitory activity of the CYP450 isoenzymes 3A4, 2C9, 1A2, 2D6, and 2D9, but none of these effects are considered clinically significant. St. John's Wort appears overall to be an inducer of CYP3A4, and its constituents have many additional effects on metabolism and binding sites (Table 18-5).

Table 18-5. Pharmacokinetic Activity of the Constituents of St. John's Wort

Activity	Site
Metabolized	CYP450, most notably by the 3A4 isoenzyme
Transported	Intestinal P-glycoprotein
Active at receptor sites	GABA, norepinephrine, dopamine, Lglutamate receptor sites
Active at reuptake sites	Seratonin reuptake and norepinephrine reuptake sites
Inhibits	MAO, and possibly the cellular phosphodiesterase sites
Inhibits	Beta-adrenergic and muscarinic receptor sites

Binding site competition	DNA sites in human leukemia cells

Table 18-6. St. John's Wort Drug Interactions

Pharmacokinetic Process	Site	Action	Results in	Drug
Metabolism	CYP3A4	Induces	Lower levels of	NNRTI
				Protease Inhibitors
				Benzodiazepines
				Calcium channel blockers
				Carbamazepine
				Cyclosporin
				Irninotecan

				Digoxin
	CYP2C9	Induces	Lower levels of	Warfarin
	CYP1A2	Induces	Lower levels of	Warfarin
Transporter proteins	Intestinal P-glycoprotein transporter proteins	Increased catalyzed efflux of substrate drug	Lower levels of	Digoxin Calcium channel blockers Simvastatin
Pharmacodynamic Toxicity	Serotonin reuptake receptor sites	Inhibits serotonin reuptake	Additive SSRI activity	SSRIs
	Serotonin reuptake receptor sites	Serotonin agonist activity	Additive serotonin toxicity	Serotonin agonists (e.g. fenfluamine) and “triptans”
	MAO receptor sites	Increased MAOI and serotonin activity	Additive serotonin toxicity	MAOIs
Pharmacokinetic	Serotonin and norepinephrine reuptake sites	Inhibits reuptake of norepinephrine and serotonin	Norepinephrine and serotonin toxicity	Nefazodone

	DNA binding sites in human leukemia cells	Distorts DNA binding sites	Reverses etoposide-stabilized cleavage complexes	Antagonizes chemotherapy effect of etoposide (in vitro)

2. Many herbal drugs interact at the same transport, metabolism and receptor sites as traditional prescription drugs (Table 18-6).

3. Traditional Chinese medicine (TCM) may contain a combination of herbs. Some imported TCM products have been found to contain unlisted legend drugs. An example is a TCM medication advertised to treat diabetes that was found to contain the pharmaceuticals glyburide and phenformin.

4. Some herbal preparations may contain unrecognized contaminants such as heavy metals, or a similar-appearing herb that is mistakenly harvested. These are quality control issues that are to a large extent unregulated by government agencies.

B. Drug-herbal interactions can occur as pharmacokinetic or pharmacodynamic interactions (Table 18-7).

C. Drugs with narrow therapeutic windows are at greater risk for drug-herbal interactions. For example, important drug-herb interactions occur with patients taking warfarin.

1. Coenzyme Q10 has a chemical structure related to vitamin K. The combination of warfarin and Coenzyme Q10 results in antagonized warfarin activity and inadequate anticoagulation.

Table 18-7. Table of Common Herbs and Potential Drug Interactions

Herb	Drug/Drug Class	Interaction	Effect
Black Cohosh	Antihypertensives	Pharmacodynamic potentiation	Increased effect of antihypertensives (hypotension)
Coenzyme Q10	Warfarin	Pharmacodynamic antagonism	Vitamin K antagonism (increased INR and risk of bleed)
Dong Quai	Beta blockers	Inhibition of CYP450 Enzymes	Increased level of beta blockers (increased hypotension)
	Benzodiazepines	Inhibition of CYP 450 Enzymes	Increased benzodiazepine levels (increased drowsiness and CNS depression)
Echinacea	Immunosuppressants Monoclonal antibodies	Pharmacodynamic antagonism	Decreased immunosuppression (flair of autoimmune disease, transplant graft rejection)
Ephedrine Ma Huang	Beta blockers	Pharmacodynamic antagonism	Sympathomimetic effect (hypertension)
	MAOIs	Blocked metabolism	Increased and prolonged sympathomimetic effect (Hypertensive crisis)

	Corticosteroids	Increased metabolism Induced hepatic metabolism	Decreased corticosteroid levels (decreased steroid effectiveness)
Evening Primrose Oil	Antiplatelets	Pharmacodynamic potentiation	Decreased platelet aggregation (increased risk of bleed)
	Phenothiazines	Additive toxicity	Reduced seizure threshold (seizures)
Ginkgo biloba	Warfarin, LMWH	Pharmacodynamic potentiation	Increased inhibition of platelet aggregation (increased risk of bleed)
Ginseng	MAOI	Pharmacodynamic effect	Increased GABA metabolism and increased dopamine levels (mania symptoms)
Kava Kava	Acetaminophen Azole antifungals Statins	Additive toxicity	Increased otential for hepatic toxicity (elevated LFT, hepatic failure)
	Barbiturates Benzodiazepines	Synergy	Increased GABA receptor binding affinity (increased drowsiness, CNS depression)

	Levodopa	Antagonism	Dopamine blockade (decreased effectiveness of levodopa)
Soy	Lethothyroxine	Impaired absorption	Decreased levels of levothyroxine (hypothyroid symptoms)
St. John's Wort	Irinotecan	Induced CYP3A4 Metabolism	Reduced levels of active irinotecan metabolite for chemotherapy (decreased myelosuppressio n)
Valerian	Sedatives	Pharmacodyna mic	Increased CNS depression (drowsiness and sedation)
	Benzodiazepines	Displacement from binding sites	Displaced benzodiazepine but additive CNS depression (possible increased drowsiness)

2. Ginger, garlic, and feverfew also increase bleeding in patients taking warfarin by directly inhibiting platelets and causing increased risk of bleeding.

3. Wheat grass actually contains high levels of vitamin K which directly antagonizes warfarin causing inadequate anticoagulation and therapeutic failure.

D. Potency of herbal preparations is influenced by a variety of factors:

1. The stage of growth during which the herb was harvested

2. The drying time

3. The solvents used in extraction of the herb
4. The shelf life and storage conditions of the herbal extract

V. Food-drug interactions

A. Food can increase, decrease, or not affect the absorption of drugs (Table 18-8).
B. Food can influence the bioavailability of a drug from a modified-release dosage form (e.g., controlled release, delayed release [enteric coated]) rather than from an immediate-release dosage form. For example, opening the capsule of enteric coated omeprazole beads and giving it in an acidic food such as applesauce or with orange juice, eases administration of the drug while maintaining the enteric coating on the omeprazole beads until the drug reaches the basic pH of the duodenum where the omeprazole beads are uncoated and the drug is absorbed.
C. Complexation and adsorption of the drug in the GI tract with another food element is a common drug interaction that reduces the extent of drug absorption. For example, quinolone antibiotics complex with calcium (found in milk products).
1. Quinolone antibiotics will complex with calcium from the diet and the result will be reduced quinolone antibiotic.
2. Ibandronate for osteoporosis has significantly reduced absorption when given with food. Since absorption is very poor, with less than 0.6% bioavailability in fasting circumstances, and up to 99% protein binding, the significant reduction in ibandronate when given with food may reduce the drug to subtherapeutic levels.
3. A number of drugs such as phenytoin and quinolone antibiotics are adsorbed to calcium and iron in tube feedings.
D. Food can be metabolized by the same liver enzymes that metabolize drugs, causing enzyme inhibition or induction, and resulting in toxic or subtherapeutic drug levels. For example,

grapefruit and valencia oranges inhibit the CYP3A4 isoenzyme system, causing increased levels of substrate drugs such as saquinavir, indinavir, midazolam, nimodipine, nifedipine, lovastatin, cyclosporin, carbamazepine, and verapamil.

Table 18-8. Affect of Food on Drug Bioavailability

Reduced or delayed	Increased	Not affected by food
NSAIDs (nonsteroidal anti-inflammatory drugs) naproxen, naproxen sodium	Griseofulvin	Theophylline*
	Metoprolol	Metronidazole
Aspirin	Phenytoin	
Acetaminophen	Propoxyphene	
Antibiotics (tetracycline and penicillin)	Dicumarol	
Ethanol	Morphine	

* Food does not significantly affect drug absorption of theophylline in an immediate-release dosage form. However, food may affect theophylline absorption from a controlled-release formulation.

E. Food can pharmacodynamically antagonize the effect of some drugs. For example, spinach and broccoli provide dietary sources of vitamin K, which antagonizes the effect of warfarin. Garlic can cause additive antiplatelet effect in combination with warfarin, heparin, and LMWH, and cause increased risk of bleeding.

F. Foods can contain pharmacologically active compounds that interact with drugs meant to inhibit endogenous compounds. Monoamine oxidase inhibitors (MAOIs) prevent normal metabolism of catecholamines. They also inhibit the metabolism of tyramine from tyramine containing foods such as red wine, cheese. The increased levels of tyramine cause hypertensive crisis.

VI. Chemical-drug interactions

A. Smoking by inhaling aromatic polycyclic hydrocarbons (tobacco) can induce the CYP1A2 isoenzyme metabolism and decrease levels of substrate drugs such as theophylline, diazepam, tricyclic antidepressants, duloxetine, and ramelteon.

B. Ethanol can increase or decrease the activity of hepatic drug metabolizing enzymes.

1. Chronic alcoholism can increase the rate of metabolism of tolbutamide, warfarin, and phenytoin.

2. Acute alcohol intoxication can inhibit hepatic enzymes in nonalcoholic individuals.

3. Ethanol induces metabolism in the CYP1A2 and 2E1 isoenzymes. Levels of 1A2 substrates clozapine, cyclobenzaprine, imipramine, naproxen are decreased. Levels of the 2E1 substrates acetaminophen are reduced.
4. Disulfiram inhibits alcohol dehydrogenase, resulting in limited metabolism of ethanol and causing severe ethanol intolerance.

VII. Pharmacogenetics and Drug Interactions

A. Genetic differences in drug metabolism are the result of genetically based variations in **alleles** for genes that code for enzymes responsible for the metabolism of drugs.
1. In normal enzyme function, the gene encoding for the enzyme is composed of two normal alleles. In **Polymorphisms,** the genes contain abnormal pairs or multiples of abnormal alleles leading to altered enzyme function.
2. Polymorphisms can occur in any enzyme system including the CYP450 hepatic enzymes, the mixed oxidase and n-acetyl transferase systems, and the UGT metabolic enzyme systems. In the CYP450 system, the CYP2D6, CYP2C9, and CYP2C19 polymorphisms are the most extensively studied.
3. Differences in enzyme activity occur at different rates according to racial group (Table 18-9).
4. Polymorphisms (differences in the alleles) can also vary within a racial group by geographic distribution. For example, in Western Europeans polymorphism for the CYP2D6 alleles can vary with 10 times as many ultra metabolizers (UM) in Greece as in Austria.
5. The extent of the drug interaction is predicted based upon the baseline activity of the enzyme in an individual. Baseline enzyme efficiency varies greatly among individuals depending upon the type and extent of polymorphic changes to the enzyme.
B. Single Nucleotide Polymorphisms (SNPs) are single changes in one allele of a gene responsible for a variety of metabolic processes including enzymatic metabolism.

Table 18-9. Ethnic Differences in the CYP2D6 Enzyme Activity

Ethnicity	As a Percentage of the Population
Caucasians	7-10% PM / 1% UM
African-Americans	8% PM
Asians	>50% PM / 1% UM

Adapted from Zagaria MAE. The promise of pharmacogenomics. Available online at http://www.uspharmacist.com/index.asp?show=article&page=8_1190.htm. Retrieved January 18, 2006; and Johannson I, Oscarson M, Yue QY, et al. Genetic analysis of the Chinese cytochrome P4502D locus: Characterization of variant CYP2D6 genes present in subjects with diminished capacity for debrisoquine hydroxylation. Mol Pharmacol 1994;46:452-459.

1. The genetic SNPs can be of several different kinds, resulting in many different variants of the enzyme. CYP2D6 has more than 70 variant alleles.

2. The combination of alleles encoding the gene determines the activity of the enzyme. The combinations can include missing alleles, defective alleles, duplicated, and multiple alleles. In addition, alleles can demonstrate amplification, substitution, or defective splicing. Null enzyme activity, or abolished activity can occur from errors in transcription, splicing, start and stop codons, and amino acid changes.

3. The combination of alleles in the affected gene results in differences in the effectiveness of the enzyme. The overall function of the enzyme is the **phenotype** of enzyme function.

a. Poor metabolizers (PM) carry two defective alleles, for example CYP2D6*4/*5 and CYP2D6*4/*4. PMs also include combination of alleles including one resulting in no enzyme, for example CYP2D6*5 and CYP2D6*4/deletion.

b. Intermediate metabolizers (IM) are heterozygous, that is, having one wild type allele and one defective allele.

c. Normal metabolizers carry “wild type” alleles, for example CYP2D6*1/*33. Wild type alleles encode genes for normal enzyme function.

d. Extensive metabolizers (EM) carry one wild type and one amplified gene, for example CYP2D6*1/*2. Another example of EM carry the following pairs: CYP2D6*A/*1a and CYP2D6*1A/*5.

e. Ultra-rapid metabolizers (UM) carry two or more copies of an amplified gene, for example CYP2D6*2/*2.

4. Genetic changes may inactivate or reduce enzymatic activity (e.g., poor metabolizers), leading to increases in the substrate drug.

5. Genetic duplication may increase enzymatic activity (e.g., ultra-rapid metabolizers), resulting in lower levels of the substrate drug.

6. In the CYP2D6 enzyme, genetic variation can cause a 10- to 30-fold difference in the levels of drugs metabolized by that enzyme. Table 18-10 lists a few CYP2D6 variants and their effects of the drug metabolism activity of the enzyme.

C. Polymorphisms affect drug interactions by altering the effect of inhibitors and inducers on the enzymes. The result is an exaggerated effect or minimal effect on the substrate.

1. In an **EM,** the level of substrate drug is normally low because of the rapid metabolism by the enzyme. An **inhibitor** to the enzyme will substantially inhibit the extensive metabolism and cause significant elevations in the substrate drug. The substrate levels rise dramatically because the effect of the inhibitor is much greater in an EM. The drug interaction may occur to a greater extent than it would in normal metabolizers (Table 18-11).

2. In a **PM,** the level of substrate drug remains high because the metabolism of the substrate is much less than normal. When an **inhibitor** is added to the regimen, the additional

inhibition of metabolism is not much greater than is already occurring in a PM. Therefore the effect of an inhibitor on a PM is less than it would be in normal metabolizers. The drug interaction may not occur.

Table 18-10. Allele Activity Patterns in the CYP2D6 Isoenzyme

Gene	Polymorphism	Enzyme activity	Phenotype
CYP2D6*1	Wild-type	Normal	EM or normal
CYP2D6*2	Same as 2D6*1 but possible	Increased enzyme	EM/UM
	Duplication or amplification	Activity	
CYP2D6*4	Defective splicing	Inactive enzyme	PM
CYP2D6*5	Gene depletion	No enzyme	PM
CYP2D6*10	Single AA substitution predominant	Reduction in	PM

	Variant in people of Asian descent	Enzyme activity	
CYP2D6*17	Single AA substitution predominant	Reduction in	PM
	Variant in people of African descent	Enzyme activity	

Adapted from Zagaria MAE. The promise of pharmacogenomics. Available online at http://www.uspharmacist.com/index.asp?show=article&page=8_1190.htm. Retrieved January 18, 2006; Ingelman-Sundberg M. Genetic polymorphisms of cytochrome P4502D6 (CYP2D6): clinical consequences, evolutionary aspects and functional diversity. Pharmacogenomics J 2005;5:6-13; and Lee LS, Nafziger AN, Bertino JS Jr.Evaluation of inhibitory drug interactions during drug development: Genetic polymorphisms must be considered. Clin Pharmacol Ther 2005;78:1-6.

3. In an **EM,** the level of substrate drug is again lower than expected in a normal metabolizer because of the rapid metabolism. The addition of an **inducer** does not cause a great difference in the level of substrate because the metabolism is already increased greatly. The drug interaction may not occur.

4. In a **PM,** the level of substrate drug is again higher than expected in a normal metabolizer because of the lower metabolism of the substrate. The addition of an **inducer** will cause a significant increase in the metabolism of the substrate and cause a much lower level of substrate than expected in a normal metabolizer. The drug interaction may occur to a greater extent than in normal metabolizers, or the drug interaction may result in substrate levels similar to those of normal metabolizers.

5. As a general rule, the effect of inhibitors is greater in EMs than in PMs. The effect of inducers is greater in PMs than in EMs.

6. The difference between EM and UM can be described as the difference between heterozygous and homozygous individuals with duplicated or amplified genes. The addition of an inhibitor to an UM would be expected to show an even greater drug reaction than would be seen with an EM.

7. Complex drug interactions can be seen when a substrate is metabolized through more than one enzyme system where one or more enzymes are affected by polymorphism. In these cases, the substrate is metabolized through a polymorphic enzyme and becomes an active metabolite and an inhibitor or inducer in a second system. Polymorphism in the first enzyme can cause the level of the inhibitor or inducer to be greater or less than

expected, thus causing the extent of the expected inhibition or induction of the second enzyme to be significantly changed.

Table 18-11. The Effect of Inhibition of EM/UM and PM on CYP2D6 Substrates

Enzyme	Inhibitor	Substrate	Effect of EM/UM On the substrate	Effect of PM On the substrate
CYP2D6	Diphenhydramine	Metoprolol	Increased 61%	Little change
CYP2D6	Quinidine	S-venlafaxine	Increased 4x	Little change
CYP2D6		R-venlafaxine	Increased 12x	No change
CYP2D6	Diphenhydramine	Venlafaxine	Increased 2x	Little change
CYP2D6	Fluoxetine	Risperidone	Increased 4x	Increase 1.3x

Adapted from Lee LS, Nafziger AN, Bertino JS Jr.Evaluation of inhibitory drug interactions during drug development: Genetic polymorphisms must be considered. Clin Pharmacol Ther 2005;78:1-6.

D. Specific Pharmacogenomic Drug Interactions from the literature.

1. Omeprazole

In one study of omeprazole activity on the inhibition of moclobemide in CYP2C19 EMs and PMs, the effect of inhibition varied according to the degree of genetic polymorphism. One would expect inhibition of the metabolism of the substrate moclobemide by the inhibitor omeprazole. But in EMs, the AUC level of the substrate moclobemide almost doubled, reflecting the greater effect of inhibition on moclobemide which was originally extensively metabolized. In comparison, PMs already show poor metabolism of the meclobemide. Inhibition of the 2C19 enzyme by omeprazole in PM did not show an extensive change in the AUC levels of moclobemide, because metabolism was already impaired.[1]

2. Fluvoxamine

Fluvoxamine inhibits the metabolism of diphenydramine by the CYP2C19 isoenzyme. When EM taking diphenydramine were given the 2C19 inhibitor fluvoxamine, the

AUC and Cmax levels of diphenhydramine increased significantly over placebo. When PM taking diphenhydramine were given the inhibitor fluvoxamine, the AUC and Cmax of diphenhydramine did not change significantly. The effect of inhibition on the substrate of an EM in the CYP2C19 was greater than it would have been in a normal metabolizer. The effect of inhibition on the substrate of a PM in CYP2C19 is not significant. In addition, those EMs who were homozygous showed greater inhibition than the EMs who were heterozygous. This demonstrates that the degree of inhibition varies by genotype. Homozygous EMs showed greater reduction in enzyme activity that heterozygous EM. In the same way, EM show greater inhibition than PM because PM already have reduced enzyme activity and will not show a great change in Cmax or AUC, even with inhibition.[2]

3. Diphenhydramine

Diphenhydramine inhibits the metabolism of metoprolol. In EM in the CYP2D6, the Cmax and AUC of diphenhydramine increased by 16% and 61%, respectively, as compared to non-polymorphisms. The inhibitor diphenhydramine decreased conversion of metoprolol to its metabolite by a factor of 3. In the PM, the change in metoprolol conversion was insignificant. Again, the effect of inhibition on the substrate in the EM was greater than in PM.[3]

4. Diphenhydramine

Diphenhydramine inhibits the metabolism of venlafaxine by the CYP2D6 isoenzyme. When diphenhydramine is given to a EM who is taking venlafaxine, the levels of venlafaxine rise twofold. Diphenhydramine given to a PM who is taking venlafaxine causes insignificant change in the levels of venlafaxine. As with the example with metoprolol above, the extent of inhibition in EM is much greater than in PM.[4]

E. The effect of polymorphism on drug development and drug safety.

1. Most drug companies during drug development do not genotype their subjects for polymorphisms. In small studies, or in studies of genetically homogenous subjects, the pharmacokinetics described for the drug may be skewed toward the polymorphisms prevalent in the subject population. This can occur when, for example, Asians are the primary subject population for pharmacokinetic studies for a drug metabolized by CYP2C19. CYP2C19 polymorphisms occur in 20% to 25% of the Asian population.

2. When polymorphisms and pharmacogenomics are not considered during drug development, the result can be the development of some drugs that have shown toxicity in certain populations, and have been withdrawn from the market as a result. These drugs include troglitazone (Rezulin) and mibefradil.

3. Pharmacogenomic testing during drug development can identify the dosing variables in certain polymorphic populations and could lead to a greater safety in the use of these

drugs. Clinical trials in warfarin therapy with genetic testing for polymorphisms in CYP2C9 such as the CYP2C9*2 and CYP2C9*3.

4. The identification of polymorphic factors in a specific drug under development may limit the clinical use of that drug to certain pharmacogenomic populations.

5. The FDA may make recommendations, or require labeling for genetic testing of patients to determine polymorphisms that affect drug metabolism or transport.
a. The invader UGT1A1 molecular assay for UGT1A1 detects polymorphisms that can reduce the metabolism of irinotecan, a chemotherapy for colorectal cancer.
b. The FDA has cleared the AmplicChip Cytochrome P450 Genotyping Test for polymorphisms in the CYP450 isoenzyme system which is extensively involved in drug metabolism.
c. The FDA has added labeling to various drugs to test for genetic polymorphisms that affect metabolism, such as antiepileptic drugs.
d. The FDA has also mandated the testing of HIV strains for guidance in using Maraviroc.

VIII. CLINICAL SIGNIFICANCE AND MANAGEMENT OF DRUG INTERACTIONS

A. Potential drug interactions
1. Multiple-drug therapy, including both **prescription** and **nonprescription** (OTC) medication, can potentially lead to drug interactions. The more drugs used by a patient, the greater the potential for a drug interaction.
2. Multiple prescribers. Patients can be seen by different prescribers who prescribe interacting medication.
3. Patient compliance. Patients need to follow proper instructions for taking medications. For example, a patient might take tetracycline with food rather than before meals.
4. Patient risk factors
a. Older patients are at more risk for drug interactions than younger patients. Older patients might have changes in their physiological and pathophysiological condition that lead to altered body composition, altered GI transit time and drug absorption, decreased protein binding, altered distribution, and decreased drug clearance. These changes can exacerbate or increase the risk of a drug interaction.
b. Patients with predisposing illness (diabetes, asthma, AIDS, and alcoholism) and patients who are clinically hypersensitive (atopic) are more at risk for drug interactions than non- atopic patients.
c. Pharmacogenetic polymorphisms in enzyme function can occur at different rates in different racial populations, and to a lesser extent, in different nations. These pharmacogenetic differences can lead to a wide variation in the potential for a drug interaction.
B. Clinical significance
1. Not all drug interactions are clinically significant or cause an adverse effect. In some cases, interacting drugs can be prescribed for patients as long as the patient is given proper instructions and is compliant. For example, cimetidine and an antacid might be prescribed to the patient, but the patient should be instructed to not take both medications at the same time.
2. Combination drug therapy can have beneficial effects. Drug combinations are used to improve the therapeutic objective or to decrease adverse events. Some examples include:

a. Trimethoprim and sulfamethoxazole—combination antibiotic for increased efficacy in urinary tract infections.
b. Amoxicillin and clavulanate potassium—combination containing a beta-lactamase inhibitor (clavulanate) to inhibit the breakdown of amoxicillin.
c. Hydrochlorothiazide and triamterene—combination diuretic and antihypertensive to minimize potassium excretion.
d. Ritonavir is given as a "booster" with tipranavir. Coadministration increased tipranavir levels 30-fold by inhibition of the CYP3A4 enzyme responsible for metabolism of tipranavir.
e. Probenecid inhibits renal tubular secretion of penicillin, thereby prolonging the plasma half-life of the antibiotic.

3. Some drug-food interactions are utilized for their beneficial effects. Phenytoin is given with dietary fats to increase its bioavailability through enhanced absorption.
4. Another type of drug-drug interaction occurs when the conversion of a pro-drug to the active metabolite is inhibited or induced at the metabolizing enzyme.
a. The conversion of inactive codeine to its active metabolite morphine can be reduced by CYP2D6 isoenzyme inhibition caused by cimetidine or citalopram. The reduced metabolism can result in subtherapeutic levels of morphine, and therapeutic failure in pain treatment.
b. The induction of the metabolism of CYP2D6 by phenytoin or St. John's Wort can increase metabolism of codeine to morphine, raise morphine levels, and may result in excessive sedation and narcotic toxicity.
c. Other pro-drug dependent upon metabolic conversion to active metabolites include enalapril, valacyclovir, levodopa, and carisoprodol.
5. The determination of the clinical significance of a potential drug interaction should be documented in the literature. The likelihood of a drug interaction can be classified as follows:
a. Established—a drug interaction supported by well-proven clinical studies
b. Probable—a drug interaction that is very likely but might not be proven clinically
c. **Suspected**—a drug interaction that might occur; some data might be available
d. Possible—a drug interaction that could occur; limited data are available
e. Unlikely—a drug interaction that is doubtful; no good evidence of an altered clinical effect is available
5. The clinical relevance of a potential drug interaction should also consider the:
a. Size of the dose and the duration of therapy
b. Onset (rapid, delayed) and **severity** (major, moderate, minor) of the potential interaction
c. **Extrapolation** to related drugs
6. Polymorphism in pharmacogenetics may affect the toxicity and the clinical efficacy of certain drugs in certain populations. Known inhibitors may pose significant risks to Extensive Metabolizers of enzyme systems.
C. Management of drug interactions

1. Review the patient profile, including drug history and patient risk factors. The patient's past medical history can reveal a tendancy for non-compliance, past therapeutic failures, and evidence for pharmacogenetic considerations.
2. Avoid complex therapeutic drug regimens.
3. Determine the probability of a clinically significant drug interaction. Genetic testing may be useful (Table 18-12).
4. Suggest a different drug if there is a high probability for a clinically significant drug interaction. For example, acetaminophen can be used for headache instead of aspirin for a patient on anticoagulant therapy.
5. Carefully instruct the patient as to the timing of the medication. For example, an antacid and H-2 blocker should not be taken at the same time. The patient should use maximum spacing between drugs. Instruct the patient as to the timing of medications to be taken “on an empty stomach.”

Table 18-12. FDA Encourages Genetic Testing for Patients Who Will Take Specific Drugs

Imatinib	Atomosetine	Venlafaxine
Voriconazole	Tamoifen	Omeprazole
Fluoxetine	Celecoxib	Tramadol
Capecitabine	Beta-blockers	5FU
Rifampin	Dapsone	Irinotecan
Rasburicase	Valproic acid	primaquine

Adapted from http://www.fda.gov/cder/genomics/genomics_biomarkers_table.htm

6. Monitor the patient for adverse events. Sulfonamides, such as sulfisoxazole and sulfamethoxazole, can prolong prothrombin time in patients given warfarin therapy. The prothrombin times should be monitored in these patients.
7. Reevaluate the patient profile and drug history when changing drug therapy. For example, when discontinuing the diuretic of a congestive heart failure patient on digoxin, a review of the profile may reveal a potassium supplement that should be discontinued as well.

8. Evaluate the risks of drug therapy with respect to pharmacogenetic polymorphic status of metabolism. Consider risks identified with racial groups and geographic distribution. Test for enzyme phenotype when feasible. Select drug and adjust doses as indicated, and according to clinical response. Consider genotyping for polymorphisms when unexpected variations in clinical response.

IX. References. A vast number of drug interactions are reported in the literature. Some general references that are updated periodically include:

STUDY QUESTIONS

Directions: Each question below contains three suggested answers, of which **one** or more is correct. Choose the answer

1. Drug interactions may be classed as

I. pharmacokinetic interactions

II. pharmacodynamic interactions

III. pharmaceutical interactions

A I only is correct

B III only is correct

C I and II are correct

D II and III are correct

E I, II, and III are correct

View Answer***1. The answer is E[].*****2. Situations that can potentially lead to drug interactions include**

I. multiple-drug therapy

II. multiple prescribers

III. patient compliance

A I only is correct

B III only is correct

C I and II are correct

D II and III are correct

E I, II, and III are correct

View Answer***2. The answer is E[and].*****Directions:** The question below is followed by four suggested answers. Select the **one** lettered answer that is the **best** response to the question.

3. Which of the following statements regarding drug interactions is true?

(A) All drug interactions can potentially cause an adverse response in the patient.

(B) The clinical significance for each potential drug interaction must be considered individually.

(C) A precipitant drug that inhibits the metabolism of the object drug causes a more serious drug interaction compared to a precipitant drug causing an increase in the bioavailability of the object drug.

(D) If the patient is prescribed drugs that can potentially interact, the prescriber should be called, and a different precipitant drug should be suggested.

View Answer***3. The answer is B[].*****4. A patient on indinavir Anti-Retroviral Therapy (ART) begins taking St. John's Wort for depression and suffers unexpected reduction in CD4 count. This is most likely due to:**

(A) Pharmacodynamic interaction producing additive toxicity.

(B) Pharmacodynamic interaction producing antagonistic therapeutic effect
(C) Enzyme induction by St. John's Wort causing increased metabolism of ART.
(D) Enzyme inhibition by St. John's Wort causing toxic levels of ART.

View Answer***4. The answer is C[].*****5. Which of the following is a valid therapeutic use of a drug interaction?**

(A) The use of probenecid with penicillin G to prolong high penicillin levels to treat a sexually transmitted disease.
(B) Giving aspirin with warfarin to enhance anticoagulation.
(C) Instructing the patient to take levofloxacin with milk or antacid to decrease GI intolerance to oral therapy.
(D) The treatment of depression with a combination of citalopram and an MAOI.

View Answer***5. The answer is A[].*****6. Which of the following is not a harmful food-drug interaction?**

(A) Raw green salads for patients on warfarin DVT prophylaxis.
(B) Grapefruit juice and cyclosporin to prevent graft vs. host rejection of a transplanted kidney.
(C) Omeprazole beads in applesauce for a patient with problems swallowing capsules secondary to GERD.
(D) Milk with doxycycline to treat h. *pylori.*

View Answer***6. The answer is C[].***P.438

7. Which of the following statements regarding pharmacogenetic polymorphisms is not true?

(A) An EM taking metoprolol for hypertension begins to take OTC Tagamet regularly for heartburn. He is at increased risk for bradycardia and cardiac arrhythmias.
(B) An EM taking methadone, begins taking Tegretol for neuropathic pain. He is at risk for treatment failure and pain crisis.
(C) A PM taking atorvastatin for hyperlipidemia is placed on ketoconazole for a fungal infection. He is at increased risk for myalgia and rhabdomyolysis.
(D) A PM taking metoprolol for tachycardia begins taking Benadryl for sleep. He is not at risk for significant bradycardia and cardiac block.

View Answer***7. The answer is C[].*****8. Asians are at greatest risk of all racial groups for genetic polymorphism in which one of the following CYP450 isoenzymes?**

(A) CYP2D6
(B) CYP3A4
(C) CYP2C19
(D) CYP1A2

View Answer***8. The answer is A[].*****9. Which of the following statements regarding pharmacogenetics is false?**

(A) Polymorphisms occur only in the CYP450 hepatic enzymes.
(B) Polymorphisms result in many variations of an isoenzyme.
(C) The overall expression of the combined alleles is the phenotype of the enzyme.

(D) SNPs can occur as errors of transcription, defective splicing, start and stop codones, and amino acid changes.

View Answer***9. The answer is A[].*****10. Which of the following statements regarding allele polymorphisms is false?**

(A) Wild type alleles encode for “normal” metabolism.

(B) UMs have two or more amplified alleles.

(C) PMs carry one defective allele and one amplified allele.

(D) EMs with heterozygous alleles and have slower metabolism than metabolizers with homozygous alleles.

View Answer***10. The answer is C[].***P.439

ANSWERS AND EXPLANATIONS

1. The answer is E *[*I.B*].*

Most drug interactions in vivo are caused by pharmacokinetic and pharmacodynamic interactions. Pharmaceutical interactions can occur during extemporaneous compounding, preparation of intravenous (IV) admixtures, and improper dosing, as in the case of giving aspirin with acidic juices (e.g., orange, cranberry).

2. The answer is E *[*IV.A. 1, 2 *and* 3*].*

Patient profiles might not contain all the drug history information of the patient. Patients who take nonprescription (OTC) medications, go to several different physicians, or purchase drugs at various pharmacies may neglect to inform the pharmacist of all the medications being taken.

3. The answer is B *[*IV.B*].*

Not all drug interactions are clinically significant. Some potential clinically significant drug interactions can be prevented by proper patient instruction and compliance. The potential for a clinically significant drug interaction should be documented before calling a physician concerning the prescribed medication.

4. The answer is C *[*II.C. 1.c; Table 18-3*].*

St. John's Wort induces CYP3A4 isoenzymes increasing the metabolism of the indinavir and resulting in low indinavir levels and therapeutic failure of ART. St. John's Wort itself has no direct effect on CD4.

5. The answer is A *[*II.C.2; Table 18-4*].*

Probenecid is given with penicillin and some cephalosporins in treatment of some sexually transmitted diseases. Probenecid competes with penicillins for renal elimination, prolonging the half-life of the penicillin. Aspirin and warfarin cause additive anticoagulation leading to bleeding. Levofloxacin taken with milk to decrease GI irritation causes complexation of the levofloxacin with the calcium in the milk and results in decreased levofloxacin to be available. Concommittant treatment of depression of citalopram and MAOI results in Serotonin Syndrome, an additive toxicity.

6. The answer is C *[*V.B*].*

Omeprazole beads are enteric coated. Giving an enteric coated bead with an acidic food such as applesauce preserves the enteric coating and allows the drug to pass

intact through the acidic stomach environment and into the basic duodenum environment where it is absorbed. The result is improved drug absorption and decreased drug destruction in the acidic stomach if the beads were not in an acidic food.

7. The answer is C *[*VII.C.2*].*

The PM already has inhibited metabolism of atorvastatin. Additional inhibition will not significantly increase the blood levels of atorvastatin. Therefore dose-related toxicity is unlikely. The EM taking metoprolol and Tagamet (cimetidine) will show a greater increase in the metoprolol levels due to the exaggerated effect of the inhibitor in EM. The EM taking methadone and Tegretol (carbamazepine) will have increased enzyme induction and metabolism of the methadone, lowering methadone levels and putting the patient at risk for treatment failure of his pain. The PM taking metoprolol and Benadryl (diphenhydramine) will show inhibition of the metabolism of the metoprolol and increased levels of metoprolol leading to a higher risk of bradycardia and cardiac block.

8. The answer is A *[*VII.A.3*].*

Polymorphism is highest in the CYP2D6 isoenzyme in Asians, reaching incidence of greater than 50%.

9. The answer is A *[*VII.A.2*].*

Polymorphisms can occur in any enzyme system including mixed oxidase and n-acetyl transferase systems as well as the CYP450 hepatic enzyme system.

10. The answer is C *[*VII.B.3.a*].*

Poor metabolizers (PM) carry a normal allele combined with a defective or deleted allele.

Nuclear Pharmacy

Stephen C. Dragotakes

Jeffrey P. Norenberg

I. INTRODUCTION

A. Overview

1. Nuclear pharmacy is defined as a "patient-oriented service that embodies the scientific knowledge and professional judgment required to improve and promote health through the safe and efficacious use of radioactive drugs for diagnosis and therapy."[1]

2. Radiopharmaceuticals are drug products that contain a biological moiety and a radioactive element. The biological construct targets a physiological or pathophysiological process of interest, allowing the localization of radiation that, in turn, may be imaged or used to effect therapy. Most radiopharmaceuticals are used in diagnostic medical imaging; however, they are also used in therapeutic applications, such as in the treatment of hyperthyroidism, thyroid cancer, polycythemia vera, and in the alleviation of bone pain.

3. Nuclear pharmacy practice entails the:

a. Procurement of radiopharmaceuticals

b. Compounding of radiopharmaceuticals

c. Performance of routine quality control procedures

d. Dispensing of radiopharmaceuticals

e. Distribution of radiopharmaceuticals

f. Implementation of basic radiation protection procedures and practices

g. Consultation with and/or education of the nuclear medicine community, patients, pharmacists, other health professionals, and the general public regarding

(1) Physical and chemical properties of radiopharmaceuticals

(2) Pharmacokinetics and biodistribution of radiopharmaceuticals

(3) Drug interactions and other factors that alter patterns of distribution

h. Monitoring of patient outcomes

i. Research and development of radiopharmaceuticals

B. Properties of radiopharmaceuticals

1. Pharmacological effects. Typically, radiopharmaceuticals lack pharmacological effects because the mass quantities range from picogram (pg) to nanogram (ng) per kilogram (kg) of administered dose.

2. Route of administration. Most radiopharmaceuticals are prepared as sterile, pyrogen-free intravenous (IV) solutions or suspensions to be administered directly to the patient. Other routes of administration include intradermal, oral, interstitial, and inhalation (e.g., radioactive gases, aerosols).

3. Radionuclides

a. The radioactive component of a radiopharmaceutical is referred to as a radionuclide. Nuclides are identified as atoms having a specific number of protons and neutrons in the nucleus. A nuclide is typically identified by the chemical symbol of the element with a mass number shown as a superscript, indicating the sum of protons and neutrons (e.g., iodide-131 is indicated as ^{131}I). When the atom is radioactive, it is called a radionuclide.
b. Radionuclides undergo spontaneous radioactive decay accompanied by the release of energy. The distribution, metabolism, and elimination of the radiopharmaceutical can

be determined by measuring this energy with imaging equipment. There are four major types of radiation emitted through this process: α-, β-, γ-, and x-rays. α- and β-radiations are not useful in medical imaging and are, therefore, undesirable in diagnostic applications. Most diagnostic radiopharmaceuticals use penetrating γ-radiation, which can be easily detected and converted into imaging data.

4. Half-lives of radiopharmaceuticals

a. The **physical half-life** of a radiopharmaceutical is the amount of time necessary for the radioactive atoms to decay to one half their original number. Each radionuclide is characterized by a specific half-life that is a physical constant.
b. The **biological half-life** of a radiopharmaceutical is the amount of time required for the body to metabolize or eliminate one half of the administered dose of any substance through biological processes.
c. The **effective half-life** of a radiopharmaceutical is the time required for an administered radiopharmaceutical dose to be reduced by one half as a result of both physical decay and biological mechanisms. It is defined as:

$$T_e = T_p + (T_b/T_p) \times T_b$$

where T_e is the effective half-life, T_p is the physical half-life, and T_b is the biological half-life.

C. Optimal radiopharmaceuticals

1. Optimal diagnostic radiopharmaceuticals

a. Should contain a radionuclide with a half-life short enough to minimize radiation exposure to the patient, yet long enough to allow for collection of imaging information. The optimal relationship is a physical half-life equal to approximately 67% of the biological process of interest.
b. Should incorporate a γ-emitting radionuclide, which decays with the emission of a photon energy between 100 and 300 kiloelectron volts (keV), which is efficiently detected with current instrumentation
c. Should contain a biological component that allows rapid localization in the organ system of interest and be metabolized or excreted from the nontarget tissues to maximize contrast and minimize the radiation absorbed dose to nontarget organs
d. Should be readily available and cost-effective

2. Optimal therapeutic radiopharmaceuticals, in addition to I.C.1.c and d, should contain α- or β-emitting radionuclides that can effectively deliver radiation in quantities sufficient to cause the desired therapeutic effect. Such effects include apoptosis, DNA damage, or irreparable cell damage leading to tissue effects.

II. SODIUM PERTECHNETATE ^{99M}TC GENERATOR

A. Overview

1. ^{99m}Tc, the most commonly used radionuclide in diagnostic imaging today, is produced by the radioactive decay of molybdenum-99 (^{99}Mo).

a. ^{99m}Tc is obtained via commercially supplied, sterile, pyrogen-free generator systems. A generator is a device used to separate a short half-life radionuclide from the longer-lived parent nuclide while retaining the parent to produce more of the daughter nuclide. In this way, short half-life nuclides can be made available continuously at great distances from the sites of generator production.

b. All of the commercially supplied generators currently use ^{99}Mo obtained from the fission of uranium-235 (^{235}U). This ^{99}Mo parent is absorbed on an alumina ion (Al_2O_3) exchange column, and the ^{99m}Tc formed from its decay is exchanged for the chloride ion (Cl^-) available in the 0.9% saline eluate solution washed through the column, as the sodium pertechnetate $Na^+(^{99m}TcO_4)^-$ form.

2. The chemical valence state of $Na^+(^{99m}TcO_4)^-$ as it is eluted from the column is +7. Typically, it must be reduced to a lower valence state before it is able to react with other compounds. Although many processes can reduce ^{99m}Tc, the stannous ion (Sn^{++}) reduction method is most commonly used in ^{99m}Tc radiopharmaceutical kits.

a. A radiopharmaceutical kit consists of sterile, pyrogen-free vials containing a reducing agent, the biological compound to be labeled, and any additional adjutants necessary to effect the reaction or to stabilize the labeled product.

b. In most cases, they are lyophilized under inert atmospheres, so as to minimize oxidation of the reducing agent (e.g., Sn^{++}).

B. Sodium pertechnetate ^{99m}Tc USP (*United States Pharmacopeia;* $Na^{+99m}TcO_4^-$) as eluted from a generator in 0.9% sodium chloride (NaCl) solution is an isotonic, sterile, nonpyrogenic, diagnostic radiopharmaceutical suitable for IV injection, oral administration, and direct instillation.

1. Physical properties

a. The solution should be clear, colorless, and free of visible foreign material. The pH is 4.5-7.0.

b. $Na^{+}{}^{99m}TcO_4^-$ is itself a radiopharmaceutical, or it may be used to radiolabel all other ^{99m}Tc radiopharmaceuticals.

2. Biodistribution

a. $^{99m}TcO_4^-$ is handled by the body in a fashion similar to ^{131}I—that is, it is taken up and released but not organified by the thyroid.

b. After IV administration, $^{99m}TcO_4^-$ concentrates in the choroid plexus, thyroid gland, salivary gland, and stomach, but remains in the circulation long enough for first-pass blood-pool studies, organ perfusion, and major vessel studies.

c. It is primarily excreted by the kidneys unchanged and is expressed in the urine 15-50% by 24 hr.

d. Between 10 and 55% of the administered dose is eliminated via feces within 3 days.

3. Decay data

a. ^{99m}Tc decays by isomeric transition with a physical half-life of 6 hr.

b. The primary radiation emissions are 140 keV γ energy photons.

4. Purity

a. USP radionuclidic purity requires a ^{99}Mo breakthrough limit of < 0.15 μCi/mCi of ^{99m}Tc at the time of patient administration.

b. USP chemical purity requires an aluminum ion (Al^{+3}) test result of less than 10 μg/mL.

5. Administration and dosage. All of the following imaging studies are administered via IV, except nasolacrimal imaging, which is instilled into the lacrimal canal.

a. Brain imaging: 10-20 mCi (370-740 megabecquerels; MBq)

b. Thyroid imaging: 1-10 mCi (37-370 MBq)

c. Salivary gland imaging: 1-5 mCi (37-185 MBq)

d. Placenta localization: 1-3 mCi (37-111 MBq)

e. Blood-pool imaging: 10-30 mCi (370-740 MBq)

f. Urinary bladder imaging: 0.5-1 mCi (18-37 MBq)

g. Nasolacrimal imaging: < 100 μCi (< 3.7 MBq)

III. RADIOPHARMACEUTICALS FOR CARDIOVASCULAR IMAGING

A. Perfusion agents for cardiac imaging. Radiopharmaceuticals are useful in cardiac imaging as agents that provide information on the regional myocardial blood perfusion. They typically are administered as part of a cardiac stress test so as to provide information at peak cardiac output. The patient will run on a treadmill to “stress” the heart. IV coronary vessel dilating agents are used in place of the treadmill when the patient is not physically able to exercise. Examples of these pharmacological agents are dipyridamole, adenosine, and dobutamine. The patient will also be imaged when the heart is at “rest.”

1. Thallous chloride thallium-201 (^{201}Tl) is a radionuclide that is produced by a cyclotron. It is used for myocardial perfusion imaging in the diagnosis of coronary artery disease and localization of myocardial infarction.

a. Biodistribution

(1) ^{201}Tl is a monovalent cation with distribution analogous to a potassium ion (K^+); myocardial uptake is by active transport via the Na^+/K^+-adenosine triphosphatase (ATPase) pump.

(2) Biodistribution is generally proportional to organ blood flow at the time of injection, with blood clearance by myocardium, kidneys, thyroid, liver, and stomach. The remainder is distributed uniformly throughout the rest of the body.

(3) ^{201}Tl is excreted slowly and equally in both urine and feces.

b. Decay data

(1) Physical half-life: 73 hr

(2) Effective half-life: 2.4 days

(3) Biological half-life: 11 days

(4) Primary radiation emissions: 68-80 keV x-rays and 167 and 135 keV γ energy photons.

c. **Administration and dosage.** IV, 2-4 mCi (74-148 MBq)

2. ^{99m}Tc sestamibi (^{99m}Tc-MIBI) exists as a sterile, pyrogen-free IV injection after kit reconstitution with $Na^{+99m}TcO_4^-$ and heating at 100°C for 10 min.

a. Biodistribution

(1) ^{99m}Tc sestamibi is a cation complex that has been found to accumulate in viable myocardium by passive diffusion into the myocyte with subsequent binding to the mitochondria within the cell.

(2) The major pathway for clearance of ^{99m}Tc sestamibi is the hepatobiliary system. This agent is excreted without any evidence of metabolism via urine and feces.

b. Decay data

(1) Effective half-life: 3 hr (myocardium)

(2) Biological half-life: 6 hr (myocardium)

c. **Administration and dosage.** IV, 10-30 mCi (370-1110 MBq)

3. ^{99m}Tc tetrofosmin exists as a sterile and pyrogen-free IV injection after kit reconstitution with sodium pertechnetate ^{99m}Tc injection USP.

a. Description. ^{99m}Tc tetrofosmin is a lipophilic, cationic ^{99m}Tc complex that has been found to accumulate in viable myocardium.

b. Biodistribution. The major pathways for clearance of ^{99m}Tc tetrofosmin are the renal system and the hepatobiliary system with 26% of the administered dose excreted in the feces and 40% excreted in the urine within 48 hr.

c. **Physical properties.** See II.A; II.B.3.

d. Administration and dosage. IV during exercise, 5-8 mCi (185-296 MBq); during rest, 15-24 mCi (555-1443 MBq)

4. Rubidium-82 (^{82}Rb) chloride is a generator-produced radiopharmaceutical obtained by the decay of its accelerator-produced parent strontium (^{82}Sr; half-life is 25 days) adsorbed on a stannous oxide column.

a. Biodistribution

(1) When eluted with 0.9% NaCl at a rate of 50 mL/min, a solution of the short-lived daughter ^{82}Rb is eluted from the generator for direct IV administration.

(2) After IV administration, ^{82}Rb rapidly clears from the blood and is extracted by the myocardial tissue in a manner analogous to K^+.

(3) Myocardial activity is visualized within 1 min after administration.

b. Decay data

(1) Physical half-life: 75 sec.

(2) The **decay mode** is by positron emission.

(3) The **primary radiation emissions** are annihilation 511 keV γ energy photons.

(4) Parent ^{82}Sr and contaminant ^{85}Sr breakthrough must be closely monitored. Acceptable levels of strontium breakthrough are < 0.02 μCi ^{82}Sr/mCi ^{82}Rb and < 0.2 μCi ^{85}Sr/mCi ^{82}Rb.

c. **Administration and dosage.** IV, 30-60 mCi (1110-2220 MBq)

5. Ammonia ^{13}N exists under a USP monograph as an on site cyclotron produced, sterile IV solution of $^{13}NH_3$, useful as a myocardial perfusion agent.

a. Decay data

(1) Physical half-life: 10 min.

(2) Decay mode: positron emission resulting in the production of two 511 keV annihilation γ photons.

b. Biodistribution

(1) After IV injection, it circulates as $^{13}NH_3$ but localizes into the myocytes via diffusion as $^{13}NH_3$. It is then metabolized to glutamine and retained by the myocytes.

(2) After IV injection, it is cleared rapidly from the blood; < 2% of the administered dose remains after 5 min postinjection.

(3) It is predominantly metabolized to ^{13}N-glutamine by different organs of the body.

(4) Between 10% and 20% is excreted via the renal system.

c. **Administration and dosage.** IV, 15-20 mCi (555-740 MBq)

B. Agents used to measure cardiac function. Regional myocardial wall motion

1. ^{99m}Tc-labeled red blood cells (^{99m}Tc-RBCs) are used for blood-pool imaging, including cardiac first-pass and gated equilibrium imaging (regional cardiac wall motion).

a. Physical properties. Autologous RBCs can be labeled by a number of techniques that use the Sn^{++} radiolabeling method with three general steps.

(1) The cells are treated with Sn^{++} to provide an intracellular source of the reducing agent. This step can be carried out with either in vivo or in vitro labeling procedures.

(2) The next step is the removal of excess Sn^{++} either by chemical oxidation (in vitro method) or by biological clearance (in vivo method).

(3) All of the methods include the addition of sodium pertechnetate ($^{99m}TcO_4^-$). This ^{99m}Tc, while in the +7 valence state, crosses the intact erythrocyte membrane and binds to intracellular hemoglobin (Hb) after being reduced by the available intracellular Sn^{++}.

b. Biodistribution. After IV injection, the labeling RBCs distribute within the blood pool and are well maintained in the blood pool with a bi-exponential whole body clearance of 2.5-2.7 hr and 75-176 hr (e.g., major route of excretion is via the urine).

c. **Administration and dosage.** IV, 10-20 mCi (370-740 MBq)

2. Pyrophosphate injection USP **and phosphates** USP. The major use for these agents in nuclear medicine is as convenient and stable sources of Sn^{++} for the labeling of autologous RBCs. In this application, the kits are reconstituted with normal saline and injected via IV.

3. ^{99m}Tc albumin (^{99m}Tc-HSA) injection

a. Biodistribution

(1) ^{99m}Tc albumin distributes initially within the intravascular space and leaves this space at a rate slow enough to permit imaging of the blood pool.

(2) Plasma clearance is bi-exponential: a fast component clearing with a half-life of 2 hr and a slow component clearing with a half-life of 10-16 hr.

(3) The major route of elimination is via the urine.

b. Administration and dosage. IV, 20 mCi (740 MBq)

C. Agents for imaging myocardial infarction include pyrophosphate injection USP and phosphates USP.

1. Mechanism of localization. The skeletal localizing radiopharmaceutical pyrophosphate has been shown to accumulate also in zones of myocardial infarction. This localization is thought to be the result of binding of the pyrophosphate to microcalcification with hydroxyapatite crystals found in infarcted tissue.

2. Biodistribution of labeled pyrophosphate depends on the ability of phosphates to become involved with calcium ion (Ca^{++}) deposition in necrotic cardiac tissue.

IV. SKELETAL IMAGING

A. Skeletal-imaging agents

1. Overview. ^{99m}Tc-labeled bone agents are useful in the detection of bone lesions that are associated with metastatic neoplasms, metabolic disorders, and infections of the bone. The imaging advantages of ^{99m}Tc, coupled with the sensitivity of bone agent localization in

skeletal bone hydroxyapatite, allows for detection of bone pathology before evidence is shown by conventional x-rays.

2. ^{99m}Tc bone agents. There are many different forms of ^{99m}Tc bone agents, with minor differences in their individual chemical structure. Currently used bone-imaging agents are based on either the P—C—P diphosphonate structure, including ^{99m}medronate disodium and ^{99m}Tc oxidronate, or the inorganic P—O—P phosphate structure, such as ^{99m}Tc pyrophosphate. These bone agents are S^{++} reduction method kits, which exist as sterile, pyrogen-free IV radiopharmaceuticals after reconstitution with $Na^{+}{}^{99m}TcO_4^-$.

a. Physical properties

(1) All of the ^{99m}Tc bone-imaging agents are susceptible to radiological decomposition with reoxidation of the ^{99m}Tc to a higher valence state. These agents sometimes include antioxidants (e.g., ascorbic or gentisic acid) in their formulation to improve their in vitro stability.

(2) They should be stored at room temperature before and after reconstitution.

b. Biodistribution

(1) It is believed that the localization of the diphosphonates occurs by chemisorption onto the hydroxyapatite mineral matrix of skeletal bone with uptake related to bone metabolic activity and bone blood flow.

(2) For ^{99m}Tc medronate disodium and ^{99m}Tc oxidronate, approximately 50% of the administered dose localizes in the skeleton, and 50% is excreted by the kidneys within the first 4-6 hr after IV injection.

c. **Administration and dosage.** IV, 10-20 mCi (370-740 MBq)

B. Bone marrow imaging. See VI.A.1; VI.A.3; VI.B.

V. LUNG IMAGING.

Radiopharmaceuticals are used to evaluate both pulmonary perfusion and pulmonary ventilation, to detect pulmonary embolism and to assess pulmonary function before pneumonectomy.

A. Pulmonary perfusion imaging

1. ^{99m}Tc albumin (^{99m}Tc-MAA)

a. Physical properties

(1) The ^{99m}Tc albumin aggregated kit contains HSA albumin that has been aggregated by heat denaturation.

(2) This Sn^{++} reduction method kit exists as a sterile, pyrogen-free suspension of radiolabeled aggregated particles after reconstitution with $Na^{+}{}^{99m}TcO_4^-$.

(3) It should be stored at 2°-8°C after reconstitution.

b. Biodistribution

(1) After IV administration of ^{99m}Tc albumin aggregated, 80% of the radiolabeled albumin particles become trapped by capillary blockade in the pulmonary circulation.

(2) After trapping, the particles are cleared from the lungs mainly by mechanical breakup. These smaller particles are ultimately cleared from the circulation by the reticuloendothelial system.

(3) Particle size should be controlled—that is, 90% of the particles should be between 10 and 90 μm, and none should be > 150 μm, to ensure adequate trapping by the lung capillary bed but no occlusion of the large-bore vessels.

(4) Particle number should be between 200,000 and 700,000 particles per adult dose to obtain uniform imaging data without compromising capillary blood flow. Neonates should receive < 125,000 particles.

c. **Decay data.** Biological half-life in the lung: 2-3 hr

d. Administration and dosage. IV, 1-4 mCi (37-148 MBq)

B. Pulmonary ventilation imaging with radioactive gases is a routine nuclear medicine procedure that can provide valuable information about regional lung ventilation. Radiopharmaceuticals used are either radioactive gases or radioaerosols.

1. Xenon-133 (^{133}Xe) is supplied as a radioactive gas contained in glass septum vials to be administered by inhalation through a closed respiratory system or a spirometer. It is a byproduct of ^{235}U fission.

a. Biodistribution

(1) ^{133}Xe is a readily diffusible gas, which is neither used nor produced by the body. It passes through membranes and freely exchanges between blood and tissue, tending to concentrate more in body fat.

(2) Inhaled ^{133}Xe distributes within the alveoli and enters the pulmonary venous circulation via the capillaries; most of the absorbed ^{133}Xe ia returned and exhaled from the lungs after a single pass through the peripheral circulation.

(3) In concentrations used for diagnosis, the gas is physiologically inactive.

b. Decay data

(1) Effective half-life in the lung: 2 min

(2) Physical half-life: 5.2 days.

(3) Decay mode: β minus and γ decay.

(4) Primary radiation emissions: 100 keV β energy and 81 keV γ energy photons.

c. **Administration and dosage.** Inhalation, 2-30 mCi (74-1110 MBq)

2. Xenon-127 (^{127}Xe) is supplied as a radioactive gas contained in glass septum vials to be administered by inhalation through a closed respiratory system or a spirometer. It is produced by a cyclotron.

a. Biodistribution. Localization is the same as ^{133}Xe.

b. Decay data

(1) Physical half-life: 36.4 days

(2) Decay mode: by electron capture

(3) Primary radiation emissions: 203 keV, 190 keV, 172 keV, and 375 keV γ energy photons.

c. **Administration and dosage.** Inhalation, 5-10 mCi (185-370 MBq)

3. Radioaerosols have become increasingly used with the advent of nebulizers that produce particles of a consistent size necessary for uniform lung distribution.

a. Biodistribution

(1) ^{99m}Tc pentetate (DTPA) radioaerosols of approximately 0.25 μm mass median aerodynamic diameter are useful in determining lung ventilation.

(2) After deposition of the nebulized droplets within the airways, the ^{99m}Tc pentetate is absorbed into the pulmonary circulation.

(3) The material is subsequently excreted by the kidneys. Clearance from the lungs is sufficiently slow to allow for imaging of the lungs in multiple projections from a single administration.

b. Physical properties. See II.B.3.

c. **Administration and dosage.** Inhalation, 30 μCi (1110 MBq)

VI. HEPATIC IMAGING

A. Overview. Hepatic imaging requires the use of two different classes of radiopharmaceuticals to evaluate the two cell types responsible for hepatic function.

1. Reticuloendothelial system imaging. The liver, spleen, and bone marrow are evaluated with radiolabeled colloidal material, ranging in size from 0.1 to 3.0 μm. These particles are rapidly cleared from the blood by phagocytosis by the Kupffer cells or trapped in the space of Disse, which is found between the polygonal hepatocytes and the Kupffer cells.

2. Liver spleen imaging. Radiopharmaceuticals are useful in imaging space-occupying primary tumors and metastatic neoplasms as well as hepatic defects caused by abscesses, cysts, and trauma.

3. Bone marrow imaging. Images that localize in the bone marrow are useful in the evaluation of pathologies that affect bone marrow.

4. Hepatobiliary imaging. Hepatocyte function can be evaluated by substances meeting requirements of molecular weight, lipophilicity, and chemical structure, to be excreted by the polygonal cells into the hepatobiliary system. Hepatobiliary-imaging radiopharmaceuticals are useful in the diagnosis of cystic duct obstruction in acute cholecystitis as well as defining postcholecystectomy anatomy and physiology.

B. Reticuloendothelial-imaging agents

1. ^{99m}Tc sulfur colloid ($^{99m}Tc_2S_7$) is a sterile, pyrogen-free IV radiopharmaceutical formed via a chemical reaction between $^{99m}TcO_4^-$ and an acidified solution of sodium thiosulfate at 100°C.

a. Physical properties

(1) Tc_2S_7 is thought to remain in the +7 valence state as the heptasulfide coprecipitate of elemental sulfur that occurs during the reaction.

(2) The use of $Na^{+}{}^{99m}TcO_4^-$ with Al^{+3} levels > 10 µg/mL can lead to the formation of particles > 5 µm, which can result in lung uptake.

(3) Heating times should be controlled to preclude large particle formation.

b. Biodistribution. After administration, 80%-90% of the dose is phagocytized by the Kupffer cells of the liver or trapped in the space of Disse, 5%-10% by the spleen, and the balance by the bone marrow. The blood clearance half-life is approximately 2.5 min. Particles are not metabolized and reside in the reticuloendothelial system for a prolonged period.

c. **Administration and dosage.** IV, liver/spleen: 1-8 mCi (37-296 MBq); bone marrow: 3-12 mCi (111-444 MBq)

C. Hepatobiliary-imaging agents

1. Overview

a. Iminodiacetic acid (IDA) derivatives, which are lidocaine analogs, are useful as hepatobiliary-imaging agents because of their lipophilicity, which allows them to be selectively cleared by carrier-mediated hepatocyte metabolic pathways. Because these agents share the same excretion pathway as bilirubin, patients who have increased bilirubin levels exhibit decreased hepatic clearance and an increased renal clearance. Lack of gallbladder visualization is an abnormal finding, suggesting acute cholecystitis.

b. Cholecystokinetic agents, such as sincalide and cholecystokinin, may be used to empty the contents of the gallbladder in fasting patients before injection of IDA compounds in an attempt to promote gallbladder filling and visualization. These agents can also be injected after the injection of the IDA compound to cause a visualized gallbladder to empty.
Cholecystokinetic agents are used to increase the specificity and sensitivity of the imaging procedure.

c. **Narcotic analgesics,** such as morphine, have been used to constrict the sphincter of Oddi to produce increased intraductal pressures to promote retrograde gallbladder filling.

2. ^{99m}Tc disofenin (^{99m}Tc-DISIDA)

a. Physical properties. See II.B.3.

b. Biodistribution

(1) ^{99m}Tc-DISIDA is rapidly cleared from the blood; 8% remains in the blood after 30 min.

(2) Approximately 9% of the administered activity is excreted in the urine during the first 2 hr. The remainder of the activity is cleared through the hepatobiliary system.
(3) Peak liver uptake is within 10 min; peak gallbladder uptake is by 30-40 min.
(4) Gallbladder and intestinal visualization occurs within 60 min postadministration.
c. **Administration and dosage.** IV, nonjaundiced patient: 1-5 mCi (37-185 MBq); IV, jaundiced patient: 3-8 mCi (111-296 MBq)

3. ^{99m}Tc mebrofenin

a. Physical properties. See II.B.3.

b. Biodistribution

(1) ^{99m}Tc mebrofenin is rapidly cleared from the blood; 17% remains after 10 min. Only 1% of the administered activity is excreted in the urine within the first hours; the remainder of the activity clears through the hepatobiliary system.
(2) Peak liver uptake occurs within 10 min; visualization of the hepatic duct and gallbladder, within 10-15 min; then intestinal activity, within 30-60 min.
c. **Administration and dosage.** IV, nonjaundiced patient: 2-5 mCi (74-185 MBq); IV, jaundiced patient: 3-10 mCi (111-370 MBq)

VII. RENAL IMAGING

A. Overview

1. Radiopharmaceuticals are used in renal imaging to determine renal function, renal vascular flow, and renal morphology. They are also useful for the evaluation of renal function in posttransplant patients for complications such as obstruction, infarction, leakage, tubular necrosis, and rejection.
2. The use of radiopharmaceuticals to determine renal function or renal morphology is based on the two physiological mechanisms responsible for excretion: glomerular filtration and tubular secretion.
B. Agents cleared by glomerular filtration are useful in determining the glomerular filtration rate (GFR), renal artery perfusion, and the visualization of the collecting system.

1. ^{99m}Tc pentetate (^{99m}Tc-DTPA)

a. Physical properties. See II.B.3.

b. Biodistribution

(1) After administration, ^{99m}Tc pentetate rapidly distributes throughout extracellular fluid space, from which it is rapidly cleared by glomerular filtration only.
(2) Up to 10% may be protein bound, leading to a decrease in measured GFR.

(3) After administration, 50% of the dose is cleared by the kidneys within 2 hr, and up to 95% is cleared by 24 hr.

c. **Administration and dosage.** IV, 10-20 mCi (370-740 MBq)

2. Sodium iothalamate iodine-125 (^{125}I) injection is a commercially supplied, sterile, pyrogen-free injection containing 1 mg sodium iothalamate per milliliter.

a. Biodistribution

(1) Sodium iothalamate ^{125}I is used for determination of the GFR but not for imaging because of poor imaging emissions of ^{125}I.

(2) Thyroid blockade with oral potassium iodide (KI) is suggested.

b. Decay data

(1) Physical half-life: 59 days

(2) Decay mode: by electron capture

(3) Primary radiation emissions: 35 keV γ energy photons and x-rays.

c. **Administration and dosage.** IV, 10-50 µCi (3.7-18.5 MBq)

C. Tubular secretion agents are used to evaluate renal tubular function and measure effective renal plasma flow.

1. Iodohippurate iodine-131 (^{131}I) hippuran. No longer commercially available

2. ^{99m}Tc mertiatide (^{99m}Tc-MAG3)

a. Description

(1) Supplied as a sterile, pyrogen-free, lyophilized kit containing betiatide, precursor of mertiatide, and chelation adjutants.

(2) After the sodium pertechnetate is added to the kit, it must be heated in a hot water bath or heating block at 100°C for 10 min to form ^{99m}Tc mertiatide from the betiatide precursor.

b. Biodistribution

(1) Mertiatide is renally excreted, 90% of the administered dose is excreted within 3 hr postinjection.

(2) It is primarily cleared via active tubular secretion and to a small extent via glomerular filtration.

c. **Physical properties.** See II.B.3.

d. Administration and dosage. IV, 5-10 mCi (185-370 MBq)

D. Renal cortical imaging agents are used to evaluate renal anatomy because of their ability to accumulate in the kidney and provide anatomical imaging data.

1. ^{99m}Tc gluceptate (^{99m}Tc-GLH)

a. Physical properties. See II.B.3.

b. Biodistribution

(1) ^{99m}Tc-GLH rapidly distributes throughout the body, with rapid blood clearance via glomerular filtration and tubular secretion and reabsorption.

(2) Approximately 25% of the administered dose is excreted within the first hour; 65%, within 6 hr; and 70%, within 24 hr.
(3) After 3-6 hr, a maximum of 5%-15% of the dose administered is concentrated in the proximal renal tubular cells of the renal cortex.
c. **Administration and dosage.** IV, 10-20 mCi (370-740 MBq)

2. ^{99m}Tc succimer (^{99m}Tc-DMSA)

a. Physical properties

(1) See II.B.3.
(2) ^{99m}Tc succimer complex must be allowed to incubate for 10 min postreconstitution and must be used within 4 hr postincubation.

b. Biodistribution

(1) Within 3-6 hr postadministration, 40%-50% of the dose localizes in the renal cortex, where it is taken up by the tubular cells.
(2) Excretion into the urine is slow; 5%-20% is excreted within the first 2 hr, 10%-30% by 6 hr, and < 40% by 24 hr.
c. **Administration and dosage.** IV, 2-6 mCi (74-222 MBq)

VIII. THYROID IMAGING

A. Overview

1. The basic function of the thyroid gland is the production of thyroid hormone for the regulation of metabolism. The thyroid hormones are produced within the gland through the organification of iodine obtained from the oxidation of available iodide circulating in the blood. The inability of the body to distinguish between the isotopes of iodine provides a perfect metabolic tracer for the thyroid biochemical system.
2. The function of the thyroid gland can be evaluated by the uptake of ^{131}I or ^{123}I, allowing the detection of hypothyroidism with decreased uptake and hyperthyroidism with increased uptake.
3. $^{99m}TcO_4^-$ is a monovalent anion with an ionic radius similar to iodide. As a result, the pertechnetate ion is trapped by the thyroid gland in a fashion similar to iodide. The two species are sufficiently different in that $^{99m}TcO_4^-$ is not organified or incorporated into thyroid hormone, and it is subsequently released unchanged.

B. Thyroid imaging agents

1. Sodium iodide iodine-123 (^{123}I) is a radiopharmaceutical available in either solution or capsule form for oral administration. It is produced by a cyclotron.

a. Biodistribution

(1) Orally administered iodine is rapidly absorbed from the gastrointestinal (GI) tract; thyroid gland uptake is evident within minutes.
(2) Sodium iodide ^{123}I is considered an ideal radiopharmaceutical for iodine uptake and imaging studies because of its short half-life and useful 159 keV primary γ emissions.

b. Decay data

(1) Physical half-life: 13.2 hr

(2) Biological half-life: 3.5 days
(3) Decay mode: by electron capture
(4) Primary radiation emissions: 159 keV, 27 keV, and 529 keV γ energy photons
c. **Administration and dosage.** Oral thyroid uptake: 100-200 μCi (3.7-7.4 MBq); thyroid image: 100-500 μCi (3.7-18.5 MBq)
2. Sodium iodide ^{131}I is used for thyroid uptake and imaging studies; however, it is now used less often because of the high radiation dose absorbed.
a. Biodistribution
(1) Orally administered iodine is rapidly absorbed from the GI tract; with thyroid gland uptake is within minutes.

(2) Sodium iodide ^{131}I is not considered an ideal radioiodine radiopharmaceutical for iodine uptake and imaging studies because of its long half-life, poor imaging properties, and the high radiation dose to the thyroid from its β decay component.
(3) The radiation dose from the high-energy β particle with the imaging potential of its γ emissions make this radionuclide the agent of choice for therapeutic treatment of hyperthyroidism and thyroid cancer.
b. Decay data
(1) Physical half-life: 8.08 days
(2) Decay mode: by β decay
(3) Primary radiation emissions: 606 keV and 333 keV β energy; 364 keV, 637 keV, and 284 keV γ energy photons.
c. **Administration and dosage.** ^{131}I is available as either a capsule or in solution for oral administration.
(1) Diagnostics
(a) Thyroid uptake: 2-15 μCi (0.074-0.555 MBq)
(b) Thyroid image: 30-50 μCi (1.11-1.85 MBq)
(c) Whole body image: 1-5 mCi (37-185 MBq)
(2) Therapeutics
(a) Hyperthyroidism: 10-30 mCi (370-1110 MBq)
(b) Thyroid carcinoma: 50-200 mCi (1850-7400 MBq)
3. $Na^{+99m}TcO_4^-$**.** See II.B.
4. ^{201}**Tl.** Parathyroid imaging
a. Biodistribution. ^{201}Tl concentrates in the thyroid and also in parathyroid adenomas, which can be detected by a dual isotope subtraction technique of subtracting thyroid uptake counts from $Na^{+99m}TcO_4^-$ to unmask nonthyroid thallium uptake counts (see III.A.1).
b. Administration and dosage. IV, 2 mCi (74 MBq)

IX. BRAIN IMAGING

A. Cerebral perfusion brain-imaging agents. Radiopharmaceuticals for evaluating brain perfusion must possess a lipophilic partition coefficient sufficient to diffuse passively across the blood-brain barrier (BBB) almost completely within one pass of

the cerebral circulation, as well as being sufficiently retained to permit data collection. The regional uptake of these agents is proportional to cerebral blood flow. This class of radiopharmaceuticals is useful in the diagnosis of altered regional blood perfusion in stroke.

1. ^{99m}Tc exametazime (^{99m}Tc-HMPAO) exists as a sterile, pyrogen-free IV injection after reconstitution with sodium pertechnetate USP, which may be stabilized with the addition of a methylene blue/phosphate buffer stabilizing solution.

a. Description

(1) ^{99m}Tc exametazime is a neutral, lipid-soluble complex that freely crosses the BBB. This is a relatively unstable complex, which rapidly converts to a secondary, less lipophilic complex incapable of penetrating into the brain. The in vitro addition of a methylene blue/phosphate buffer stabilizing solution after preparing the ^{99m}Tc exametazime will stabilize the lipid-soluble complex for 4 hr.

(2) Additional limitations on kit preparation parameters require the use of high mole fraction technetium generator eluates of < 2 hr postelution from a generator previously eluted within 24 hr.

b. Biodistribution

(1) ^{99m}Tc exametazime rapidly clears from the blood, with a maximum brain uptake of 3.5%-7%, and up to 2.5% remaining after 24 hr.

(2) The activity is widely distributed throughout the body; 30% distributes to the GI tract.

(3) Within 48 hr, 40% of the dose is excreted through the urine and 15% is eliminated via the feces.

c. **Physical properties.** See II.B.3.

d. Administration and dosage. IV, 10-20 mCi (370-740 MBq)

2. ^{99m}Tc bicisate (^{99m}Tc-ECD)

a. Description

(1) ^{99m}Tc bicisate exists as a sterile, pyrogen-free IV injection after reconstitution with sodium pertechnetate ^{99m}Tc USP and the addition of a phosphate buffer.

(2) After reconstitution, a stable lipophilic ^{99m}Tc bicisate complex is formed, which is able to cross the BBB by passive diffusion.

b. Biodistribution

(1) ^{99m}Tc bicisate is rapidly cleared from blood; a maximum of 6.5% of the administered dose is localized in the brain, and 5% is left in the blood after 1 hr.

(2) Once located in the brain cells, ^{99m}Tc bicisate is metabolized by endogenous enzymes to a polar compound that is unable to diffuse out of the brain cells.

(3) ^{99m}Tc bicisate is primarily eliminated via the kidneys; 50% is excreted within 2 hr, and 74% in 24 hr. Hepatobiliary excretion accounts for approximately 12.5% of the administered dose after 48 hr.

c. **Radionuclide properties.** See II.B.3.

d. Administration and dosage. IV, 10-30 mCi (370-1110 MBq)

3. Iofetamine hydrochloride ^{123}I. Not commercially available

B. Carrier-mediated transport (cerebral metabolism) mechanisms. These are responsible for transporting glucose across the BBB. Agents such as ^{18}F fludeoxyglucose aid in the evaluation of cerebral function by mapping the distribution of glucose metabolism. ^{18}F fludeoxyglucose is produced by a cyclotron.

1. Biodistribution. Currently, there is a USP monograph for on-site cyclotron-produced ^{18}F fludeoxyglucose, which is a glucose analog. ^{18}F fludeoxyglucose concentrates in the brain, where it is phosphorylated but does not undergo subsequent metabolism because of the replacement of the hydroxyl group in the 2 position with a fluorine atom. It is then metabolically trapped for a sufficient time to allow imaging.

2. Decay data

a. Physical half-life: 109.7 min

b. Decay mode: by positron emission

c. **Primary radiation emissions:** 633 keV energy positrons and 511 keV γ energy photons.

3. Administration and dosage. IV, 5-10 mCi (185-370 MBq)

C. Cerebral neurotransmitter imaging: Fluorodopa fluorine-18 (^{18}F) injection

1. Description

a. Cerebral neurotransmitter synthesis can be studied with fluorodopa ^{18}F injection. The intracerebral distribution of this neurotransmitter tracer can be used in the assessment of neurodegenerative diseases such as parkinsonism.

b. Fluorodopa ^{18}F injection exists under a USP monograph as an on-site-produced sterile IV solution of a levodopa analog in which a portion of the molecule has been replaced with ^{18}F, a positron-emitting radionuclide.

2. Biodistribution

a. After IV injection, plasma activity decreases to 10% of the administered dose within 5 min after injection.

b. Fluorodopa ^{18}F injection is predominantly metabolized in periphery via dopa decarboxylase, and catechol-*O*-methyl transferase. To maximize brain uptake, carbidopa may be used to decrease peripheral metabolism.

c. Rapid excretion via renal system as dopamine metabolites

3. Radionuclide data. See IX.B.2.

4. Administration and dosage. IV, 10-20 mCi (370-740 MBq)

D. Cerebrospinal fluid (CSF) dynamics. Radionuclide cisternography is useful in the evaluation of hydrocephalus and in detecting CSF leaks. In CSF imaging, the radiopharmaceutical **indium-111 pentetate (^{111}In-DTPA)** is introduced intrathecally into the spinal subarachnoid space, ascends through the basal cisterns, proceeds over the cerebral hemispheres, and eventually drains into the superior sagittal sinus. ^{111}In pentetate is commercially supplied as a sterile, pyrogen-free unit dose injection. It is produced by a cyclotron.

1. Biodistribution

a. After intrathecal injection, this radiopharmaceutical normally ascends to the parasagittal region within 24 hr.

b. After absorption into the bloodstream via the arachnoid villi, the major route of elimination is by kidney; 65% of the dose is excreted within 48 hr; and 85%, within 72 hr.

2. Decay data

a. Physical half-life: 67 hr

b. CSF biological half-life: 12 hr

c. **Effective half-life:** 10 hr

d. Decay mode: by electron capture

e. Primary radiation emissions: 171 keV and 245 keV γ energy photons

3. Administration and dosage. Intrathecal, 500 μCi (18.5 MBq)

X. INFECTION AND INFLAMMATION.

Evaluation of sites of infection include the use of agents that can associate with components of the natural defense mechanisms and can accumulate where they localize.

A. Gallium (^{67}Ga) citrate

1. Description

a. It is supplied as a sterile, pyrogen-free radiopharmaceutical with preservatives.

b. The mechanism of localization is thought to depend on the formation of a gallium transferrin complex in the blood and on binding to transferrin receptors associated with infection and inflammation.

c. It accumulates in areas of white blood cell (WBC) localization.

2. Biodistribution

a. After administration, the highest concentration of ^{67}Ga citrate, other than at the site of infection, is in the renal cortex. After 24 hr, the maximum concentration shifts to bone and lymph nodes; but after 1 week, it is mainly concentrated in the liver and spleen.

b. ^{67}Ga citrate is excreted slowly from the body; 26% is via urine, and 9% is via feces. Whole body retention is 65% after 7 days.

3. Radionuclide data

a. Mode of production: by cyclotron

b. Decay mode: by electron capture

c. **Physical half-life:** 78 hr

d. Decay emissions: 93 keV, 185 keV, 300 keV, and 393 keV γ photons

4. Administration and dosage. IV, for infection, 3-8 mCi (111-300 MBq). A daily laxative or an enema should be used by the patient after the injection and before the images to cleanse the bowel of radioactivity that may interfere with the images and possibly lead to a false positive result.

B. WBC labeling agents. Radiolabeled WBCs are used in the detection of a wide variety of infectious and inflammatory processes. Current use includes the diagnosis of intra-abdominal abscesses, inflammatory bowel disease, appendicitis, fever of unknown origin, and osteomyelitis. WBCs can be radiolabeled with ^{111}In oxine or ^{99m}Tc-exametazime.

1. ^{111} In oxyquinoline solution (^{111} In oxine)

a. Description

(1) ^{111}In oxyquinoline is supplied as a sterile preservative-free, pyrogen-free, radiopharmaceutical solution for use in the radiolabeling of autologous leukocytes.

(2) ^{111}In forms a saturated neutral lipophilic complex with oxyquinoline (1:3 ratio), which enables it to penetrate a cell membrane.

(3) After incubation of ^{111}In oxyquinoline with a population of autologous leukocytes, the ^{111}In is thought to become firmly bound to cytoplasmic components, thereby allowing the free oxine to be released by the cell.

b. Biodistribution

(1) After radiolabeling, the autologous leukocytes are reinjected; 30% is taken up by the spleen, and 30% is taken up by the liver, reaching a peak at 2-4 hr postinjection.

(2) Pulmonary uptake is immediately evident postinjection, but it clears, with minimal visible activity, after 4 hr.

(3) There is a biexponential blood clearance; 9%-24% clears with a biological half-life of 2-5 hr, and the remaining 13%-18% clears with a biological half-life of 64-116 hr.

(4) Elimination is mainly through radioactive decay; < 1% is excreted in feces and urine during the first 24 hr.

c. **Radionuclide data**

(1) Mode of production: by cyclotron

(2) Decay mode: by electron capture

(3) Physical half-life: 67 hr

(4) Decay emissions: 245 keV and 171 keV

d. Administration and dosage. IV, 200-500 µCi (7.4-8.5 MBq)

2. ^{99m}Tc-HMPAO. As a sterile and pyrogen-free IV injection after reconstitution with sodium pertechnetate, ^{99m}Tc-HMPAO may be used to radiolabel leukocytes.

a. Description

(1) ^{99m}Tc-HMPAO is a neutral, lipid-soluble complex that is able to penetrate the WBC membrane. This lipophilic complex is relatively unstable and rapidly converts to a secondary complex incapable of penetrating the WBCs.

(2) The methylene blue/phosphate buffer stabilized solution is not able to radiolabel cells and should not be used.

(3) Additional limitations on kit preparation parameters require the use of high mole fraction technetium generator elutes of < 2 hr postelution from a generator previously eluted within 24 hr.

b. Biodistribution

(1) After IV injection, the radiolabeled cells localize in the lungs, liver, spleen, blood pool, bone marrow, and bladder.

(2) Elimination is primarily via the liver.

c. **Radionuclide data.** See II.B.1.b; II.B.3.a and b.

d. Administration and dosage. IV, for infection, 7-25 mCi (260-925 MBq)

XI. BREAST IMAGING

A. ^{99m}Tc-MIBI

1. Description

a. ^{99m}Tc-MIBI is used for both breast and cardiac imaging.

b. ^{99m}Tc-MIBI is indicated for planar imaging as a second line of evaluating breast lesions in patients with an abnormal mammogram or a palpable breast mass.

c. ^{99m}Tc-MIBI may not be used to screen for breast cancer, to confirm the presence or absence of malignancy, or to replace a biopsy.

2. Biodistribution. ^{99m}Tc-MIBI is primarily excreted by the hepatobiliary system.

3. Physical properties. See II.B.3.

4. Administration and dosage. IV, 20-30 mCi (740-1110 MBq)

XII. TUMORS

A. The usefulness of radiopharmaceuticals in the detection of tumors varies in sensitivity and specificity, with differences in tumor location and type.

1. ^{67}Ga

a. Description

(1) ^{67}Ga is supplied as a sterile, pyrogen-free radiopharmaceutical with preservatives.

(2) The mechanism of localization is thought to depend on the formation of a gallium transferrin complex or binding to transferrin receptors on tumor cells.

(3) It accumulates in primary metastatic tumor sites and may detect the presence of Hodgkin disease, lymphoma, and bronchogenic carcinoma.

b. Biodistribution. See X.A.2.

c. **Radionuclide data.** See X.A.3.

d. Administration and dosage. IV, for tumor, 10 mCi (370 MBq)

2. ^{111}In pentetreotide

a. Description

(1) It is supplied as a sterile, pyrogen-free kit for the preparation of ^{111}In pentetreotide. The two-component kit consists of a reaction vial containing a lyophilized mixture of pentetreotide with stabilizer adjutants and a second vial containing an indium ^{111}In chloride/ferric chloride solution.

(a) The pentetreotide molecule is a conjugate of pentetate (diethylenetriamine pentaacetic acid; DTPA) and octreotide, which is a somatostatin analog.

(b) ^{111}In pentetreotide is prepared by adding the ^{111}In/Fe chloride solution to the vial containing the pentetreotide. The pentetate portion of the molecule acts as a bifunctional chelate, linking the ^{111}In radionuclide to the biological active octreotide portion of the agent.

(2) ^{111}In pentetreotide is indicated for localization of primary and metastatic neuroendocrine tumors expressing somatostatin receptors.

b. Biodistribution

(1) Within 1 hr after IV injection, ^{111}In pentetreotide distributes from the plasma to extravascular space; less than one third of the administered dose remains in the plasma 10 min postinjection.
(2) ^{111}In pentetreotide localizes as a function of somatostatin receptor density, with accumulation in normal pituitary, thyroid, liver, spleen, and the urinary bladder.
(3) Elimination is primarily renal; 50% of the administered dose is excreted within 6 hr postinjection; 85%, after 24 hr, and < 90% after 48 hr. Less than 2% of the administered dose is cleared via the feces within 72 hr post-injection.
c. **Radionuclide data**
(1) Mode of production: iby cyclotron
(2) Decay mode: by electron capture
(3) Physical half-life: 67 hr
(4) Decay emissions: 245 keV and 171 keV
d. Administration and dosage. IV, 3-6 mCi (111-222 MBq)
3. Iobenguane ^{131}I injection (^{131}I-MIBG)
a. Description
(1) It is supplied as a sterile, pyrogen-free radiopharmaceutical for use as an adjunctive diagnostic agent for the localization of primary and metastatic pheochromocytomas and neuroblastomas.
(2) Iobenguane (meta-iodobenzylguanidine) labeled with ^{131}I acts as a physiological analog of norepinephrine and is transported and accumulated in the adrenal medulla. This allows for the detection of neuroendocrine tumors via the specific uptake of labeled iobenguane.
(3) Because of its physiological similarities to norepinephrine, many classes of drugs that interfere with catecholamine transport and function may affect the uptake and localization of labeled iobenguane.
b. Biodistribution
(1) After IV injection, there is rapid uptake in the liver, with lesser amounts accumulating in the lungs, heart, and spleen.
(2) Normal adrenal gland uptake is low; but for tumors such as pheochromocytomas and neuroblastomas, the uptake is relatively higher.
(3) Elimination is renal; most of the drug is excreted mainly unchanged. Between 40% and 50% of the administered dose is excreted within 24 hr, and 70%-90% is excreted within 4 days postinjection.
(4) Administration of potassium iodide 1 day before and for 10 days after administration is suggested to reduce thyroid uptake of potential radioiodide contaminants.
c. **Physical data.** See VIII.B.2.b.
d. Administration and dosage. IV, 0.5-1 mCi (18.5-37 MBq)
4. ^{201}Tl. This agent has utility as a tumor-imaging agent because of its accumulation in the rapidly metabolizing cells of certain tumors in accordance with its mechanism of localization (see III.A.1).
a. Administration and dosage. IV, 1.5-3 mCi (55-111 MBq)
5. ^{18}F fludeoxyglucose USP. Currently, there is a USP monograph for on-site cyclotronproduced ^{18}F fludeoxyglucose, which is a glucose analog. This agent has

utility as a tumor-imaging agent because of an increased demand for glucose by tumors with an advanced state of malignancy. Not only can ^{18}F fludeoxyglucose locate and differentiate tumors but

it can also help distinguish between recurrent brain tumor and radiation necrosis in patients receiving radiation therapy (see IX.B).

a. Biodistribution. ^{18}F fludeoxyglucose concentrates in metabolically active cells, where it is phosphorylated but does not undergo subsequent metabolism because of the replacement of the hydroxyl group in the 2 position with a fluorine atom. It is then metabolically trapped for a sufficient time to allow imaging.

b. Administration and dosage. IV, 5-25 mCi (185-370 MBq)

XIII. THERAPEUTIC AGENTS.

The therapeutic use of radiopharmaceuticals is based on the concept of selective localization of radiopharmaceuticals coupled with the lethality of the same because of the tissue damage resulting from highly ionizing particulate emissions such as β particles.

A. Chromic phosphate phosphorus-32 (^{32}P) suspension

1. Description. Available as a sterile, pyrogen-free aqueous suspension used in the treatment of peritoneal or pleural effusions caused by metastatic disease. Also used in the treatment of ovarian and prostate cancer.

2. Biodistribution

a. Colloidal suspension of ^{32}P is rapidly taken up by macrophages adhering to the cavity wall, thereby concentrating and localizing the irradiation effect of the ^{32}P radionuclide β particulate emission.

b. After infusion, the suspension rapidly distributes from within the cavity and may localize in the lungs, adrenal glands, kidneys, lymph nodes, liver, spleen, bone marrow, plasma, erythrocytes, and leukocytes, depending on colloidal particle size.

c. Elimination is primarily renal.

3. Radionuclide data

a. Mode of production: by reactor

b. Decay mode: β

c. **Physical half-life:** 14.3 days

d. Decay emissions: 695 keV mean energy β, 100% abundance

4. Administration and dosage

a. Intraperitoneal instillation: 10-20 mCi (370-740 MBq)

b. Intrapleural instillation: 6-12 mCi (222-444 MBq)

c. Carcinoma interstitial: 0.1-0.5 mCi (3.7-18.5 MBq)

d. Caution is advised for visual inspection to prevent misadministration of the sodium phosphate form (clear, colorless), which is designated for intravascular use only.

B. Sodium phosphate ^{32}P solution

1. Description

a. It is available as a commercially supplied, sterile, pyrogen-free radiopharmaceutical.
b. It is primarily used as an antineoplastic for the treatment of polycythemia rubra vera and is selectively used for the palliative treatment of metastatic bone pain.
c. Its therapeutic effect is owing to cell damage resulting from irradiation produced by beta particulate emission.

2. Biodistribution

a. It concentrates as phosphate within the DNA of rapidly dividing hematopoietic cells in the treatment of polycythemia rubra vera and as phosphate in areas of increased bone formation.
b. After IV administration, it diffuses rapidly into extracellular and intracellular space, concentrating in the bone marrow, spleen, and liver.
c. Elimination is primarily renal; 5%-10% is excreted within 24 hr, and 20% within 1 week.
d. Whole body biological half-life is approximately 39 days.

3. Radionuclide data

a. Mode of production: by reactor
b. Decay mode: by β
c. **Physical half-life:** 14.3 days
d. Decay emissions: 695 keV mean energy β, 100% abundance

4. Administration and dosage

a. Polycythemia rubra vera: IV, 3-5 mCi (111-185 MBq)
b. Metastatic bone lesions: IV, 10-21 mCi (370-777 MBq)
c. Caution is advised for visual inspection to prevent misadministration of the chromic phosphate form (green, cloudy), which is designated for interstitial use only.

C. Sodium iodide ^{131}I (therapeutic)

1. Description

a. It is indicated for treatment of hyperthyroidism and thyroid carcinoma.
b. Its therapeutic action is owing to the accumulation and retention of iodine and its isotope ^{131}I.

2. Biodistribution

a. See VIII.A; VIII.B.2.
b. Biological half-life in the thyroid: euthyroid patient, 80 days; hyperthyroid patient, 5-40 days

3. Radionuclide data. See VIII.B.2.b.

4. Administration and dosage. Oral capsule or oral solution
a. Hyperthyroidism: 10-30 mCi (370-1110 MBq)
b. Thyroid carcinoma: 30-200 mCi (1110-7400 MBq)

D. Strontium-89 (^{89}Sr) chloride

1. Description

a. It is indicated for the alleviation of bone pain arising from metastatic bone disease.
b. As a metabolic analog of calcium, ^{89}Sr concentrates selectively in areas of increased osteogenesis, thus delivering a radiation dose sufficient to provide a palliative effect.
c. Pain relief begins 7-21 days after administration, with maximum relief by 6 weeks and an average duration of 6 months.
d. Reduction in patient analgesic usage occurs in up to 75% of patients treated; complete pain relief is seen in 20% of treated patients, and no pain relief in 20%-25% of treated patients.
e. Bone marrow suppression effects limit ^{89}Sr use to patients with initial WBC counts > 2,400 and platelet counts > 60,000.

2. Biodistribution

a. After administration, ^{89}Sr clears rapidly from blood and localizes in the bone hydroxyapatite.
b. Initial biological half-life in normal bone is 14 days; longer retention is seen in metastatic bone lesions. Between 12% and 90% of the administered dose is retained for up to 3 months after administration.
c. Elimination is primarily renal; 66% of the administered dose clears via GFR within the first 2 days, and 33% is excreted via feces.

3. Radionuclide data

a. Mode of production: by accelerator
b. Decay mode: by β
c. **Emission data:** 1.46 MeV maximum β energy, 100% abundance
d. Physical half-life: 50.5 days

4. Administration and dosage. IV, 4 mCi (148 MBq), 40-60 μCi/kg (1.5-2.2 MBq/kg)

E. Samarium-153 (^{153}Sm) lexidronam

1. Description

a. ^{153}Sm is indicated for the relief of pain in patients who have confirmed metastatic cancer of the bone.
b. ^{153}Sm concentrates in areas of high bone turnover and accumulates more in osteoblastic lesions than in the normal bone.
c. The goal of ^{153}Sm therapy is for patients to be able to reduce the amount of narcotic analgesics needed to control their pain.

2. Biodistribution

a. The lesion to normal bone ratio is 5:1.
b. The percentage of uptake of ^{153}Sm is directly proportional to the number of lesions the patient has.
c. Less than 1% of the dose remains in the blood 5 hr postinjection.
d. ^{153}Sm is 100% renally excreted over 12 hr.
e. The onset is approximately 1 week.

3. Radionuclide data

a. Mode of production: by cyclotron

b. Decay mode: by β and γ decay

c. **Physical half-life:** 46.3 hr

d. Decay emissions: 640 keV, 710 keV, and 840 keV β energy and 103 keV γ energy photons

4. Precautions. ^{153}Sm may cause bone marrow suppression, which should return to baseline within 8 weeks postinjection.

5. Administration and dosage. IV, 1 mCi/kg (37 MBq/kg)

F. Yttrium-90 (^{90}Y) ibritumomab tiuxetan and ^{111}In ibritumomab tiuxetan

1. Overview

a. ^{111}In ibritumomab tiuxetan and ^{90}Y ibritumomab tiuxetan are part of a therapeutic regimen used in the treatment of non-Hodgkin lymphoma (NHL) patients with relapsed refractory low-grade, follicular, or transformed B cell NHL and patients with rituximab refractory NHL.

b. Ibritumomab tiuxetan is an immunoconjugate consisting of a monoclonal antibody ibritumomab, which is linked to the chelator tiuxetan.

c. The ibritumomab antibody is a murine immunoglobulin G1 (IgG1) κ monoclonal antibody produced in Chinese hamster ovary (CHO) cells. The ibritumomab antibody is directed against the CD20 antigen, which is expressed on the surface of normal and malignant B lymphocytes.

d. The linker chelator tiuxetan provides a high-affinity chelation site for ^{111}In in the case of the imaging dose and for ^{90}Y in the case of the therapeutic dose.

e. The therapeutic regimen is administered in two separate doses. This allows for the qualitative evaluation of the biodistribution to avoid potential toxicities such as abnormally high bone marrow localization or prolonged renal excretion. In each administration, patients must be premedicated with diphenhydramine 50 mg and acetaminophen 650 mg 0.5 hr before receiving the rituximab infusion required before administering the radiolabeled antibody.

(1) Step 1 is the administration of rituximab followed by the ^{111}In ibritumomab tiuxetan diagnostic imaging dose.

(2) Step 2 follows step 1 by 7-9 days and consists of a second rituximab infusion followed by the ^{90}Y ibritumomab therapy dose.

2. Description

a. Supplied as two separate kits to produce a single dose of ^{111}In ibritumomab tiuxetan and a single dose of ^{90}Y ibritumomab tiuxetan

b. Each kit consists of four vials containing:

(1) Ibritumomab tiuxetan in saline, 3.2 mg

(2) Sodium acetate, 50 mM

(3) Formulation buffer (contains human serum albumin)

(4) One empty reaction vial

c. Exists as a sterile, nonpyrogenic IV solution after formulation with either ^{111}In or ^{90}Y

3. Biodistribution

a. The mean half-life for ^{90}Y ibritumomab tiuxetan in the blood is 30 hr.

b. Approximately 7.8% of the administered dose is excreted in the urine over 7 days.

c. The estimated biological half-life is 48 hr.

4. Radionuclide data

a. ^{111}**In.** See XIII.B.1.c.

b. ^{90}**Y**

(1) Mode of production: by reactor

(2) Decay mode: by β

(3) Physical half-life: 64.1 hr

(4) Decay emission: 935 mean keV, 100% emission

5. Precautions

a. ^{90}Y ibritumomab tiuxetan should not be administered to patients with altered biodistributions of the ^{111}In ibritumomab tiuxetan imaging and dosimetry dose.

b. ^{90}Y ibritumomab tiuxetan should not be administered to patients with:

(1) ≤ 25% lymphoma marrow involvement

(2) Platelet counts < 100,000 cell/mm^3

(3) Neutrophil count < 1,500 cells/mm^3

(4) Hypocellular bone marrow

(5) History of failed stem cell collection

c. Ibritumomab tiuxetan is contraindicated in patients with known hypersensitivity or anaphylactic reactions to murine proteins.

d. Patients who have previously received murine-based protein therapy should be screened for human antimouse antibodies.

e. Infusion-related adverse events, including asthenia, chills, and nausea, are common and are usually self-limited. Tumor lysis syndrome has been reported after rituximab infusions, which are part of ^{90}Y ibritumomab tiuxetan therapy. Patients should be monitored closely for this potentially fatal adverse event.

G. Tositumomab and Iodine I 131 Tositumomab

1. Overview

a. Tositumomab and Iodine 1131 Tositumomab are part of a therapeutic regimen indicated for the treatment of patients with CD20 antigen-expressing relapsed or refractory, low grade, follicular, or transformed non-Hodgkin's lymphoma, including patients with Rituximab-refractory non-Hodgkin's lymphoma.

b. The Tositumomab and Iodine I 131 Tositumomab therapeutic regimen is an antineoplastic radioimmunotherapeutic monoclonal antibody-based regimen composed of the monoclonal antibody, Tositumomab, and the radiolabeled monoclonal antibody, Iodine I 131 Tositumomab.

c. Tositumomab is a murine IgG2a lambda monoclonal antibody directed against the CD20 antigen, which is found on the surface of normal and malignant B lymphocytes. Tositumomab is produced in an antibiotic-free culture of mammalian cells and is composed of two murine gamma 2a heavy chains of 451 amino acids

each and two lambda light chains of 220 amino acids each. The approximate molecular weight of Tositumomab is 150 kD.

d. The therapeutic regimen is administered in two discrete steps: the dosimetric step and therapeutic step. Each step consists of a sequential infusion of Tositumomab followed by Iodine I 131 Tositumomab. The therapeutic step is administered 7-14 days after the dosimetric step.

e. Tositumomab binds specifically to the CD20 (human B-lymphocyte-restricted differentiation antigen. Bp 35 or B1) antigen. This antigen is a transmembrane phosphoprotein expressed on pre-B lymphocytes and at higher density on mature B lymphocytes. The antigen is also expressed on >90% of B-cell non-Hodgkin's lymphomas (NHL). Possible mechanisms of action of the BEXXAR therapeutic regimen include induction of apoptosis, complement-dependent cytotoxicity (CDC), and antibody-dependent cellular cytotoxicity (ADCC) mediated by the antibody.

2. Description

a. Tositumomab is supplied as a sterile, pyrogen-free, clear to opalescent, colorless to slightly yellow, preservative-free liquid concentrate. It is supplied at a nominal concentration of 14 mg/mL of Tositumomab in 35 mg and 225 mg single-use vials. The formulation contains 10% (w/v) maltose, 145 mM sodium chloride, 10 mM phosphate and Water for Injection, USP. pH is approximately 7.2.

b. Iodine I 131 Tositumomab is a radio-iodinated derivative of Tositumomab that has been covalently linked to Iodine-131. Iodine I 131 Tositumomab is supplied as a sterile, clear, preservative-free liquid for IV administration. The dosimetric dosage form is supplied at nominal protein and activity concentrations of 0.1 mg/mL and 0.61 mCi/mL

(at date of calibration), respectively. The therapeutic dosage form is supplied at nominal protein and activity concentrations of 1.1 mg/mL and 5.6 mCi/mL (at date of calibration), respectively. The formulation for the dosimetric and the therapeutic dosage forms contains 4.4%-6.6% (w/v) povidone, 1-2 mg/mL maltose (dosimetric dose) or 9-15 mg/mL maltose (therapeutic dose), 8.5-9.5 mg/mL sodium chloride, and 0.9-1.3 mg/mL ascorbic acid. pH is approximately 7.0.

3. Biodistribution

a. The median blood clearance following administration of 485 mg of Tositumomab in 110 patients with NHL was 68.2 mg/hr (range: 30.2-260.8 mg/hr). (Patients with high tumor burden, splenomegaly, or bone marrow involvement have a faster clearance, shorter terminal half-life, and larger volume of distribution.)

b. The median total body effective half-life, as measured by total body gamma camera counts, in 980 patients with NHL was 67 hours (range: 28-115 hours).

4. Radionuclidie Data

a. See VIII.B.2.b.

5. Administration & Dosing

a. Dosimetric step

(1) Tositumomab 450 mg intravenously in 50 ml 0.9% Sodium Chloride over 60 minutes.

(2) Iodine I 131 Tositumomab (containing 5.0 mCi Iodine-131 and 35 mg Tositumomab) intravenously in 30 ml 0.9% Sodium Chloride over 20 minutes.

b. Therapeutic step

(1) Tositumomab 450 mg intravenously in 50 mL 0.9% Sodium Chloride over 60 minutes.

(2) The recommended Iodine I 131 Tositumomab dose is the activity of Iodine-131 calculated to deliver 75 cGy total body irradiation and 35 mg Tositumomab, administered intravenously over 20 minutes. (Patients with NCI Grade 1 thrombocytopenia (platelet counts = 100,000 but < 150,000 platelets/mm^3): recommended dose is 65 cGy total body irradiation).

6. Precautions

a. Therapeutic Iodine I 131 Tositumomab should not be administered to patients with altered biodistributions of the Iodine I 131 Tositumomab imaging and dosimetry dose.

b. Thyroid-blocking medications should be initiated at least 24 hours before receiving the dosimetric dose and continued until 14 days after the therapeutic dose.

c. The most common adverse reactions were severe or life-threatening cytopenias.

d. Iodine I 131 Tositumomab is contraindicated in patients with known hypersensitivity oranaphylactic reactions to murine proteins. Patients who have previously received murine-based protein therapy should be screened for human antimouse antibodies.

e. hypersensitivity reactions, including fatal outcome, have been reported. Emergency supplies including medications for the treatment of hypersensitivity reactions, e.g., epinephrine, antihistamines and corticosteroids, should be available for immediate use in the event of an allergic reaction during administration.

STUDY QUESTIONS

Directions for questions 1-7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following emissions from the decay of radionuclides is most commonly used in nuclear medicine diagnostic imaging?

(A) x-ray

(B) β

(C) α

(D) γ

(E) Positron

View Answer***1. The answer is D[see].*****2. Which of the following radionuclides is most commonly used in nuclear pharmacy practice?**

(A) gallium-67 (^{67}Ga)

(B) thallium-201 (^{201}Tl)

(C) technetium-99m (^{99m}Tc)

(D) iodine-123 (^{123}I)

(E) xenon-133 (^{133}Xe)

View Answer***2. The answer is C[see].*****3. Which of the following radionuclides is produced using a generator?**

(A) technetium-99m (^{99m}Tc)

(B) thallium-201 (^{201}Tl)

(C) gallium-67 (^{67}Ga)

(D) xenon-133 (^{133}Xe)

(E) iodine-123 (^{123}I)

View Answer***3. The answer is A[see].*****4. Which of the following radiopharmaceuticals can be used in skeletal imaging?**

(A) technetium-99m albumin aggregated

(B) technetium-99m medronate disodium

(C) xenon-133 gas USP

(D) thallous chloride (^{201}Tl) USP

(E) technetium-99m disofenin

View Answer***4. The answer is B[see].*****5. Which of the following radiopharmaceuticals is used in the diagnosis of acute cholecystitis?**

(A) technetium-99m sulfur colloid

(B) technetium-99m medronate disodium

(C) technetium-99m albumin

(D) technetium-99m exametazime

(E) technetium-99m disofenin

View Answer***5. The answer is E[seeand].*****6. Which of the following cyclotron-produced radiopharmaceuticals is used for assessing regional myocardial perfusion as part of an exercise stress test?**

(A) thallous chloride ^{201}Tl USP

(B) sodium iodide ^{123}I

(C) gallium citrate ^{67}Ga USP

(D) indium-111 pentetate

(E) cobalt-57 cyanocobalamin

View Answer***6. The answer is A[see].*****7. Glomerular filtration and the urinary collection system can best be evaluated using which of the following agents?**

(A) technetium-99m sulfur colloid

(B) technetium-99m albumin

(C) technetium-99m sestamibi

(D) technetium-99m disofenin

(E) technetium-99m pentetate

View Answer***7. The answer is E[see].*****Directions for questions 8-11:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

8. The definition of the optimal radiopharmaceutical includes which of the following attributes?

I. short half-life

II. γ photon with a 100-300 keV energy

III. rapid localization in target tissue and quick clearance from nontarget tissue

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***8. The answer is E[see].*****9. Which of the following statements are true for sodium pertechnetate technetium-99m (^{99m}Tc) USP?**

I. It is used to radiolabel all other ^{99m}Tc radiopharmaceuticals.

II. The molybdenum-99 (^{99}Mo) breakthrough limit is < 0.15 µCi ^{99}Mo/mCi ^{99m}Tc (< 0.15 kBq/MBq).

III. It has a physical half-life of 16 hr.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***9. The answer is C[seeand].***P.461

10. Which of the following organs can be imaged with technetium-99m (^{99m}Tc) sulfur colloid?

I. liver

II. spleen

III. bone marrow

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer*10. The answer is E[see].*11. **Which of the following radiopharmaceuticals may be used to image the thyroid gland?**

I. sodium iodide ^{131}**I**

II. sodium pertechnetate technetium-99m USP

III. sodium iodide ^{123}**I**

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer*11. The answer is E[see].***Directions for questions 12-16:** Each of the following mechanisms of localization is most closely related to one of the following radiopharmaceuticals. The mechanisms may be used more than once or not at all. Choose the **best** answer, **A-E.**

12. thallous chloride ^{201}**Tl** USP

A metabolic trapping

B phagocytosis

C capillary blockade

D active transport

E passive diffusion

View Answer*12. The answer is D[see].*13. **technetium-99m albumin aggregated** USP

A metabolic trapping

B phagocytosis

C capillary blockade

D active transport

E passive diffusion

View Answer*13. The answer is C[see].*14. **technetium-99m sulfur colloid**

A metabolic trapping

B phagocytosis

C capillary blockade

D active transport

E passive diffusion

View Answer*14. The answer is B[see].*15. **technetium-99m exametazime**

A metabolic trapping

B phagocytosis

C capillary blockade

D active transport

E passive diffusion

View Answer*15. The answer is E[see].*16. **fluorine-18 fludeoxyglucose**

A metabolic trapping

B phagocytosis

C capillary blockade

D active transport

E passive diffusion

View Answer***16. The answer is A[see].***P.462

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* I.B.3.b*].*

Current camera technology most efficiently detects γ radiation. α and β emissions are not useful in nuclear medicine imaging because of their harmful particulate emissions and low tissue penetration. Although x-ray emissions can be used as in the case of the mercury daughter of the thallous chloride ^{201}Tl parent, they are not efficiently detected. Annihilation radiation associated with positron decay can be imaged, but this technology is currently limited to a few specialized centers.

2. The answer is C *[see* II.A. 1*].*

^{99m}Tc has become the radionuclide of choice in current nuclear pharmacy practice since its introduction in the mid-1960s. ^{99m}Tc fulfills all of the requirements of the optimal radiopharmaceutical, with its physical half-life of 6 hr, 140 keV γ energy emission, ready availability, cost, and ability to be radiolabeled to a wide variety of biologically active compounds.

3. The answer is A *[see* II.A. 1.a*].*

^{99m}Tc is obtained via commercially supplied, sterile, pyrogen-free generator systems. A generator is a device used to separate a short half-life radionuclide from the longer-lived parent nuclide, while retaining the parent to produce more of the daughter nuclide. In this way, short-half-life nuclides can be made available on a continuous basis at great distances from the sites of generator production.

4. The answer is B *[see* IV.A.2*].*

The ^{99m}Tc diphosphonate compounds are the most popular bone-imaging agents currently used in nuclear medicine imaging. They are rapidly taken up by skeletal bone; 50% of the administered dose is adsorbed onto bone hydroxyapatite and the remainder is excreted by the kidneys. The imaging advantages of the ^{99m}Tc, coupled with the sensitivity of bone agent localization in skeletal bone hydroxyapatite, allow for detection of bone pathology before evidence of pathology can be shown by conventional x-ray.

5. The answer is E *[see* VI.C. 1 *and* 2*].*

^{99m}Tc disofenin is an iminodiacetic acid derivative, which is useful for hepatobiliary imaging due to its ability to be selectively cleared by a carrier-mediated hepatocyte pathway. Lack of gallbladder visualization is an abnormal finding suggestive of acute cholecystitis.

6. The answer is A *[see* III.A. 1*].*

Regional uptake of thallous chloride ^{201}Tl USP is proportional to myocardial blood supply. The injection of ^{201}Tl in concert with a treadmill exercise stress test determines myocardial perfusion at maximum cardiac output when cardiac demand outstrips supply and the distribution of ^{201}Tl is less after affected by collateral blood supply within the myocardium. Regions that do not take up ^{201}Tl are interpreted as areas of infarct or ischemia. If these focal areas of decreased uptake subsequently

fill in with redistributed ^{201}TI, they are interpreted to be areas of ischemia, in contrast with areas of infarct, which remain as diminished areas of activity.

7. The answer is E *[see* VII.B. 1*].*

^{99m}Tc pentetate is cleared through glomerular filtration in the same manner as inulin and can be used to determine the GFR as well as in the evaluation of obstruction of vascular supply and renal morphology.

8. The answer is E (I, II, III) *[see* I.C*].*

The optimal radiopharmaceutical has a half-life short enough to minimize radiation exposure to the patient yet long enough to allow for collection of imaging information. It should incorporate a γ- emitting radionuclide, which decays with the emission of a photon energy between 100 and 300 keV, which is efficiently detected with current instrumentation. The radiopharmaceutical should localize rapidly in the organ system of interest and be metabolized, excreted, or both from the nontarget tissues to maximize contrast and minimize radiation-absorbed dose.

9. The answer is C (I, II) *[see* II.A *and* B*].*

Sodium pertechnetate ^{99m}Tc USP decays by isomeric transition and has a physical half-life of 6 hr. The emission of a γ photon has the energy of 140 keV.

10. The answer is E (I, II, III) *[see* VI.B. 1*].*

^{99m}Tc sulfur colloid localizes within the reticuloendothelial system; 80%-90% of the dose is phagocytized by the Kupffer cells of the liver; 5%-10%, by the spleen; and the balance, by the bone marrow.

11. The answer is E (I, II, III) *[see* VIII.B*].*

Although all of the listed agents accumulate in the thyroid gland, only sodium iodide ^{123}I possesses ideal imaging characteristics and organification into thyroid hormone. While the imaging properties of sodium pertechnetate ^{99m}Tc USP are good, the pertechnetate ion is trapped only by the thyroid and not organified, thus limiting the information provided by the image.

12. The answer is D *[see* III.A. 1*].*

Thallous chloride ^{201}TI USP is a monovalent cation with distribution analogous to potassium ion (K^+). Myocardial uptake is by active transport via the Na^+/K^+-ATPase pump.

13. The answer is C *[see* V.A. 1*].*

After IV administration of ^{99m}Tc albumin aggregated USP, 80% of the radiolabeled albumin particles become trapped by capillary blockade in the pulmonary circulation.

14. The answer is B *[see* VI.B. 1*].*

After the administration of ^{99m}Tc sulfur colloid, 80%-90% of the dose is phagocytized by the Kupffer cells of the liver; 5%-10%, by the spleen; and the balance, by the bone marrow.

15. The answer is E *[see* IX.A. 1*].*

^{99m}Tc exametazime is used for evaluating brain perfusion. It possesses a lipophilic partition coefficient that is sufficient to diffuse passively across the BBB almost

completely within one pass of the cerebral circulation, and that is sufficiently retained to permit data collection.

16. The answer is A *[see* IX.B. 1*].*

^{18}F fludeoxyglucose is used in evaluating cerebral function by mapping the distribution of cerebral glucose metabolism. As an analog of glucose, ^{18}F fludeoxyglucose is transported into the brain by carrier-mediated transport mechanisms responsible for transporting glucose across the BBB. Because the presence of the flourine atom in the 2 position prevents metabolism beyond the phosphorylation step, ^{18}F fludeoxyglucose becomes metabolically trapped within the brain.

Pharmaceutical Care and Disease State Management

Peggy C. Yarborough

I. INTRODUCTION

A. Practice of pharmacy. The practice of pharmacy embraces a variety of settings, patient populations, and specialist and generalist pharmacists. Central to the practice of pharmacy, however, is the provision of clinical services directly to, and for the benefit of, **patients.**

B. Definition. The term **pharmaceutical care** (sometimes called **pharmacist care**) describes specific activities and services through which an individual pharmacist "cooperates with a patient and other professionals in designing, implementing and monitoring a therapeutic plan that will produce specific therapeutic outcomes for the patient."[1]

C. Pharmaceutical care is increasingly being augmented by activities that may be described as **focused areas of practice,** wherein the pharmacist is engaged in:

medicine review
oncology services
dose calcu
drug disconti
ADR monit
precautions
tcm
pk monit
lab monit

1. Drug monitoring, for a specific drug or for therapy for a specific disease state

theophyline,antiepiletics
warfarin,TCA
digoxin
,aminoglycoside

2. Disease monitoring, for a specific disease state

3. Drug therapy and disease management/collaborative practice, by protocol

4. A pharmacist may incorporate one or more areas of focused practice into a general practice of pharmacy or may specialize within a narrow field of practice. Examples of highly specialized practice include pharmacist-directed diabetes management clinics, hypertension clinics, anticoagulation clinics, and hospital-based infectious disease services.

II. SCOPE OF PRACTICE WITHIN PHARMACEUTICAL CARE

A. Role. Pharmaceutical care has evolved from an emphasis on prevention of drug-related problems (basically **drug management**) to the expanded roles of pharmacists in the **triage of patients, treatment of routine acute illnesses, management of chronic diseases,** and **primary disease prevention.**

B. Function. The provision of pharmaceutical care does not imply that the pharmacist is no longer responsible for dispensing functions. In many instances, however, implementation of pharmaceutical care services necessitates a redesign of the professional work flow, with assignment of technical functions to technical personnel under the direct supervision and responsibility of the pharmacist.

Table 20-1. Uniqueness of Pharmaceutical Care

Characteristic	Traditional Pharmacy	Clinical Pharmacy	Pharmaceutical Care
Primary focus	Prescription order or OTC request	Physicians or other health professionals	Patient
Continuity	On demand	Discontinuous	Continuous
Strategy	Obey	Find fault or prevention	Anticipate or improve
Orientation	Drug product	Process	Outcomes

OTC, over the counter.

III. UNIQUENESS OF PHARMACEUTICAL CARE.

Provision of pharmaceutical care overlaps somewhat with other aspects of pharmacy practice (Table 20-1). However, pharmaceutical care is not the same as these other areas, which include

A. Clinical pharmacy

B. Patient counseling

C. Pharmaceutical services; when the activities of a pharmacy or pharmacy department are performed for "faceless" patients or charts, the activity is one of pharmacy service, not pharmaceutical care (i.e., chart or drug profile reviews without input from the patient or caregiver is not pharmaceutical care).

IV. ESSENTIAL COMPONENTS OF PHARMACEUTICAL CARE

empathy
trust
collaborate

A. Pharmacist-patient relationship. The importance of putting a face and personality with the clinical picture is a key component of pharmaceutical care. A pharmacist can have a caring relationship with a patient but not with a chart or drug profile. A pharmacist cannot have empathy for words on a page or on a computer screen. Pharmaceutical care is based on a collaborative effort between pharmacist and patient.

B. Pharmacist's workup of drug therapy (PWDT). The provision of pharmaceutical care is often centered around a process described as the PWDT.[2] The PWDT contains the *thought processes* necessary for pharmaceutical care. The PWDT is too lengthy to be used as the chart note for pharmacist interventions; an abbreviated format known as a FARM (findings, assessment, resolutions/recommendation, and monitoring) note or a SOAP (subjective, objective, assessment, and plan) note is more appropriate for a chart notation (Table 20-2). Nonetheless, it is helpful to the

pharmacy student, or to a pharmacist entering a new field of pharmacy practice, to write out complete PWDTs for a variety of patients as training or orientation exercises. Although the forms and methods used for the PWDT may vary, the components are essentially the same.

1. Data collection. Collect, synthesize, and interpret relevant information, such as:

a. Patient demographic data: age, race, sex

b. Pertinent medical information

(1) Current and past medical history

(2) Family history

(3) Social history

(4) Dietary history

(5) Medication history (prescription, OTC, social drugs; allergies)

(6) Physical findings (e.g., weight, height, blood pressure, edema)

(7) Laboratory or other test results (e.g., serum drug levels, potassium level, serum creatinine as relevant to drug therapy)

c. Patient complaints, symptoms, signs

finding, desired outcomes,endpoints, druug related problems,followup,ther selection,monit parametres

Table 20-2. Components of a FARM Note and a SOAP Note

PWDT Component	FARM Note	SOAP Note
	The identified or suggestive patient-specific information that gives a basis for or leads to the recognition of a pharmacotherapy problem or indication for pharmacist intervention	
Findings	**Findings (F)**	**Subjective data (S)**
	Subjective and objective data incorporated into same section	separated from **objective data (O)**
Desired outcomes	**Assessment (A)**	
Desired end points	*The pharmacist's clinical judgment based on his or her findings*—thus it is no better than the database (the	

Drug-related problems	findings); the assessment forms the basis for the intervention plan	
Therapeutic selection	**Resolutions/Recommendation (R)**	**Plan (P)**
Monitoring parameters	**Monitoring (M)**	
Follow-up		

2. Develop or identify the **CORE pharmacotherapy plan**[3]

a. C = condition or patient need. Note that this may include nonmedical conditions or needs and is thus not a reiteration of the current medical problems.

b. O **= outcome(s)** desired for the conditions or needs.

(1) Patient outcomes (POEMS: patient-oriented evidence that matters). There are generally five categories of patient outcomes:

(a) Mortality

(b) Morbidity

(i) Related to disease process

(ii) Related to medication/treatment plan

(c) Behavior

(d) Economic

(e) Quality of life

condition
outcome
regimen

(2) Therapeutic end points (surrogate markers; DOES: disease-oriented evidence)

(a) A therapeutic end point represents the pharmacological or therapeutic effect that is expected, ultimately, to achieve the desired outcome(s).

(b) More than one end point is usually needed to achieve an outcome—for example, both near-normal glycemic control and normalization of blood pressure are necessary to significantly reduce the risk of end-stage renal disease.

c. R **= regimen** to achieve the desired outcome(s)

(1) Therapeutic regimens

(a) Existing therapy. For example, a pharmacist is asked to work with a patient for whom one or more agents are already prescribed for the disease process or problem.

(i) Evaluate the current drug regimen for its potential to achieve desired end points and to meet the patient's individual needs.

(ii) Revise the regimen as appropriate.

(b) Initial therapy. A pharmacist is asked to work with a patient whose condition was newly diagnosed or is asked to develop an initial treatment plan.

(i) List the therapeutic options (drug and regimen) most likely to achieve the desired end points.

(ii) Select the option best suited for the patient's medical, physical (e.g., handicap), psychosocial (e.g., support system), mental (motivation, denial, fear), and financial well-being.

P.468

(2) Goal setting and behavior regimens. The patient is an essential partner for setting and achieving intermediate- and short-term goals and the behavior changes necessary to achieve those goals. To construct effective behavior regimens, the pharmacist practitioner must incorporate the following concepts:

(a) Identify the **type of goal** being set, such as the following:

(i) Start a new positive action—for example, start an exercise program.

(ii) Increase the frequency or intensity of a positive action—for example, drink two more cups of water daily.

(iii) Stop or decrease the frequency or intensity of a destructive action—for example, stop smoking.

(iv) Continue an action that is "perfect"—for example, continue to exercise 30 min a day, every day.

(b) State the behavior goal in terms that are **clear, specific,** and **reasonable.**

(i) Set **time limits**—for example, "Over the next 3 weeks."

(ii) Target a **specific action**—for example, "I will walk."

(iii) Set **measures and frequency**—for example, "six blocks, three days a week."

(iv) Divide a big task into several small ones, making each change small relative to the current patient behavior. The old saying "It's hard by the yard, but a cinch by the inch" is true.

d. E = evaluation parameters to assess outcome achievement.

(1) Efficacy parameters. What should be monitored, how often, and by whom to ensure that therapeutic end points or patient outcomes are being achieved.

(2) Toxicity parameters. What should be monitored, how often, and by whom to ensure that adverse effects, allergic reactions, or toxicity is not occurring.

3. Identify the PRIME pharmacotherapy problems or indications for pharmacist interventions,[4] sometimes referred to as drug-related problems.[5] The goal is to identify actual or potential problems that could compromise the desired patient outcomes (Table 20-3).

a. P = pharmaceutical-based problems

(1) Patient not receiving a prescribed drug, device, or intervention

(2) Routine monitoring (labs, screenings, exams) missing

Table 20-3. PRIME Pharmacotherapy Problem Types

P = Pharmaceutical-based problems

- Patient not receiving a prescribed drug, device, or intervention
- Routine monitoring (labs, screenings, exams) missing

R = Risks to patient

- Adverse drug reaction/drug allergy
- Potential for overlap of adverse effects (must be kept in mind as part of the workup or evaluation of any new complaint or problem reported by patient)

I = Interactions

- Drug-drug, drug-disease, drug-food interactions

M = Mismatch between medications and condition or patient needs

- No indication for a current drug, device, or intervention
- Indication for a drug, device, or intervention but none prescribed

E = Efficacy issues

- Too much of the correct drug
- Too little of the correct drug
- Wrong drug, device, intervention, or regimen prescribed; more efficacious choice possible

Adapted with permission from Canaday BR, Yarborough PC. Documenting pharmaceutical care: Creating a standard. Ann Pharmacother 1994;28:1292-1296.

b. R **= risks to patient**

(1) Adverse drug reaction/drug allergy

(2) Potential for overlap of adverse effects; must be kept in mind as part of the workup or evaluation of any new complaint or problem reported by patient

c. **I = interactions**

(1) Drug-drug, drug-disease, drug-food, drug-lab interactions

d. M **= mismatch** between medications and condition or patient needs

(1) No indication for a current drug, device, or intervention

(2) Indication for a drug, device, or intervention but none prescribed

(3) Perceived or actual barriers to implementation of medication or behavior regimen, such as financial constraints; lifestyle issues; and intellectual, physical, or emotional limitations.

e. E = efficacy issues

(1) Too much of the correct drug

(2) Too little of the correct drug

(3) Wrong drug, device, intervention, or regimen prescribed or more efficacious choice possible

C. Documentation of pharmaceutical care. Formulate a **FARM note** or **SOAP note** to describe and document the interventions intended or provided by the pharmacist.[6] Some healthcare facilities may specify one format over the other; pharmacists need to become proficient in each.

1. Format of a FARM note

a. F = findings. The patient-specific information that gives a basis for, or leads to, the recognition of a pharmacotherapy problem or indication for pharmacist intervention. Within the FARM format, findings include subjective and objective information about the patient.

b. A = assessment. The pharmacist's evaluation of the findings, including statements of:

(1) Any additional information that is needed to best assess the problem to make recommendations

(2) The severity, priority, or urgency of the problem

(3) The short-term and long-term goals of the intervention proposed or provided.

(a) Examples of **short-term goals:** eliminate symptoms, lower blood pressure (BP) to 140/90 mm Hg within 6 weeks, manage acute asthma flareup without requiring hospitalization

(b) Examples of **long-term goals:** prevent recurrence, maintain BP at <130/80 mm Hg, prevent progression of diabetic nerve disease

c. R **= resolution** (including prevention). The intervention plan includes actual or proposed actions by the pharmacist or recommendations to other healthcare professionals. The rationale for choosing a specific intervention should be stated. Intervention options may include the following:

(1) Observing, reassessing, or following—no intervention necessary at this time. If no action was taken or recommended, the FARM note serves as a record of the event and should constitute part of the patient's pharmacy chart or database.

(2) Counseling or educating the patient or caregiver

(3) Making recommendations to the patient or caregiver
(4) Informing the prescriber
(5) Making recommendations to the prescriber
(6) Withholding medication or advising against use
d. M **= monitoring** and follow-up. The parameters and timing of follow-up monitoring to assess the efficacy, safety, and outcome of the intervention. This portion of the FARM note should include the following:
(1) The parameter to be followed (e.g., pain, depressed mood, serum potassium level)
(2) The intent of the monitoring (e.g., efficacy, toxicity, adverse event)
(3) How the parameter will be monitored (e.g., patient interview, serum drug level, physical examination)
P.470

(4) Frequency of monitoring (e.g., weekly, monthly)
(5) Duration of monitoring (e.g., until resolved, while on antibiotic, until resolved then monthly for 1 year)
(6) Anticipated or desired finding (e.g., no pain, euglycemia, healing of lesion)
(7) Decision point to alter therapy when or if outcome is not achieved (e.g., pain still present after 3 days, mild hypoglycemia more than two times a week)
2. Format of a SOAP note. The SOAP format is the one used most often by medical practitioners; however, when used within the pharmaceutical care context, the content of the sections must be revised to match the pharmacist's legal scope of practice.
a. S = subjective findings. The patient-specific *subjective* information that gives a basis for, or leads to, the recognition of a pharmacotherapy problem or indication for pharmacist intervention. Within the SOAP format, patient findings are delineated into subjective and objective data.
(1) Subjective data are open to individual interpretation, whereas objective data are easily duplicated or quantified. Examples of subjective findings include the patient's statement of complaint (the chief complaint; cc) and duration or severity of symptoms.
(2) Sometimes, the data to be noted are not clearly delineated as subjective or objective or there may be a preponderance of one type of data. In these instances, the subjective and objective data may be combined as a single section, labeled “S/O Findings.”
b. O **= objective findings.** The patient-specific *objective* information that gives a basis for, or leads to, the recognition of a pharmacotherapy problem or indication for pharmacist intervention. Examples of objective information include laboratory data, weight, height, blood pressure, and pulse.
c. **A = assessment.** In the medical model, the assessment states the physician's working diagnosis and/or possible explanations for the patient's medical problem(s). In the pharmaceutical care model, however, diagnosis is not normally within the pharmacist's scope of practice. Instead, the assessment section includes the

pharmacist's evaluation of the subjective and objective findings in a manner similar to the description of the assessment in the FARM format (see IV.C.1.b).

d. P = plan. In the medical model, the plan states the physician's intended drug regimen(s), surgical procedures, and/or diagnostic tests. In the pharmaceutical care model, pharmacists may not have the authority to initiate or alter drug therapy regimens or order laboratory tests. Laboratory or prescriptive authority may be granted on a state-bystate basis, under collaborative protocol with specific physician(s) or within a specific healthcare facility or system. Actions included within the plan section should be identified as *recommended* actions when appropriate. In the pharmaceutical care model, the plan is usually expanded to describe information included in the monitoring and follow-up section of the FARM note (see IV.C.1.d).

V. FOCUSED AREAS OF PRACTICE.

This phrase refers to areas of specialty practice in which pharmacists are increasingly being recognized for their therapeutic or management expertise. As such, pharmaceutical care provided by the pharmacist is augmented by activities not normally provided within the generalist pharmacist role. Categories of focused practice may best be described by the type and extent of specialty activities. *Activities for each descriptive level are additive to, or augment, the previous level*—that is, focused drug monitoring incorporates and expands the activities of pharmaceutical care; focused disease monitoring incorporates the activities of pharmaceutical care plus focused drug monitoring, and so on.

A. Drug monitoring. Specialized monitoring for a specific drug or drug therapy for a specific disease state. Examples are the following:

1. Extensive patient education concerning the drug, the drug monitoring process, and the pharmacist's and patient's responsibilities for focused drug monitoring. It must be stressed to the patient that for the focused drug monitoring program to be effective, the pharmacist must have access to information concerning *all* the medications being taken by, or prescribed for, the patient.

2. Each time the patient returns for a refill of the monitored medication (e.g., for hypertension, diabetes, hyperlipidemia, circulation, cardiovascular disease, glaucoma):

a. Perform a **compliance check** (expected versus actual refill date) and determine *why* the needed medication or supplies are not being refilled. Physical, financial, intellectual, mental, or emotional issues may be involved, requiring referral to other healthcare providers or requiring other innovative solutions. Take the responsibility and appropriate action to resolve these issues.

b. Ask about the occurrence and frequency of **side effects,** especially those related to quality of life—such as orthostatic hypotension, changes in sexual function, energy level, exercise tolerance, hypoglycemia, hyperglycemia, and ability to

concentrate. Counsel the patient about strategies to minimize these effects or contact the prescriber to offer options to resolve the patient's reported problems.

3. With each new **prescription or over-the-counter (**OTC**) medication** added to the monitored drug regimen, observe and counsel the patient concerning the following:

a. Drugs that may affect the efficacy of the monitored drug (drug-disease and drug-drug interactions). For example, with diabetes medications:

(1) Certain drugs may directly change blood glucose levels.

(2) Certain drugs may indirectly change blood glucose levels by interacting with the hypoglycemic agent.

b. Drugs that may affect the course of the disease for the monitored drug. For example, certain drugs added to a diabetes regimen may affect the complications of diabetes by aggravating neuropathy and nephropathy as a result of decreased circulation.

c. Drugs that may affect comorbidity conditions of the disease for the monitored drug. For example, certain drugs added to a diabetes regimen may affect concurrent hypertension, lipid abnormalities, and other conditions that occur more frequently in the diabetic population.

4. Remind and encourage patients to adhere to schedules for recommended **laboratory tests** during the course of the drug therapy. Examples include prothrombin time tests, liver function tests, eye examinations, and renal function tests. Adherence to such monitoring parameters will allow prevention or early detection and treatment of certain adverse drug effects.

B. Disease monitoring. Specialized monitoring for a specific disease state. Disease-monitoring activities are optimally performed at regular intervals (e.g., at set appointment times), but should at least be performed each time the patient returns for refill of a disease-related medication or supply.

1. A focused disease-monitoring program is extensive in time, effort, and patient education. At this level, however, the pharmacist does not initiate changes in pharmacological therapies. Recommendations for changes are relayed to the medical provider, who then directs the pharmacist concerning specific regimen adjustments.

2. Examples of focused disease-monitoring activities are the following:

a. Extensive patient education concerning the disease and its treatment, the disease-monitoring process, and the pharmacist's and patient's responsibilities for focused disease monitoring. Education will likely be needed initially and periodically during the monitoring program.

b. Focused monitoring of a *chronic* disease would include patient education to establish the patient's desired *targets or goals* and strategies to attain them.

(1) Encourage and assist patients to set long-term goals—for example, lose 30 lb or quit smoking.

(2) Encourage and assist patients to set short-term goals that are directed toward meeting the long-term goals—for example, lose 1 lb in 1-2 weeks or decrease smoking by one cigarette per day.

c. Assessment for **subjective evidence** of *improvement or worsening of disease symptoms.*

(1) The frequent or consistent occurrence of certain symptoms (such as asthma attacks, hypoglycemia, chest pain, diarrhea from ulcerative colitis) should be brought to the attention of the medical provider.
P.472

(2) Lack of subjective evidence of efficacy (failure of pain control, minimal or no improvement of nocturia) should also be reported to the prescriber.
(3) The patient's report of days of work or school missed owing to exacerbation of disease symptoms is a valuable assessment of disease control or treatment.
d. Assessment for **objective evidence** or *certain indices of disease control or treatment.* For example, a pharmacist may review and guide a diabetic patient in interpretation of self-monitored blood glucose (SMBG) records. Using these data, the pharmacist can then advise the patient concerning the application of a prescribed insulin adjustment algorithm.
(1) Some data may be patient derived, such as SMBG, weight, measurement of calf circumference, and readings from a peak-flow meter.
(2) Some data may be pharmacist initiated, such as a pharmacy-based lipid-monitoring program, blood glucose testing, and blood pressure measurements. It should be noted that a pharmacy may need to be **Clinical Laboratories Improvement Act** (CLIA) certified before performing certain waived or moderately complex laboratory procedures.
(3) Some data may be obtained through the physician's office; a copy is forwarded to the pharmacist or brought in by the patient.
C. Drug/disease management by protocol. The components of this focused practice include the following:
1. Disease and drug monitoring, including a significant component of patient education
2. Disease and quality-of-life outcomes identified and agreed on by patient, medical provider, and pharmacist
3. Application of a drug-disease-management protocol, developed as a collaborative work relationship between pharmacist and medical provider, which elaborates specific authorizations or limitations for the pharmacist's activities. Components of a drug-disease-management protocol may include the following:
a. Process by which the physician refers the patient to the pharmacist
b. Drugs, devices, medical treatment, tests and procedures that may be prescribed, administered, or ordered, as appropriate for the treatment of the health problem addressed by the protocol
(1) Drug initiation, dosage adjustment and/or discontinuation
(2) Specific laboratory orders and interpretation
c. Limited physical assessment
d. Integration of the pharmaceutical care plan into the total medical care plan for the patient
e. Predetermined plan for emergency services

f. Written communication/documentation to/from medical provider (e.g., chart access and note entry)

VI. CLINICAL SKILLS AND PHARMACIST'S ROLES IN PHARMACEUTICAL CARE.

The skills, activities, and services inherent in the provision of pharmaceutical care include the following:

A. Patient assessment

1. Physical assessment

2. Barriers to adherence

3. Psychosocial issues

B. Patient education and counseling

1. Interview skills

2. Communication skills (e.g., empathy, listening, speaking or writing at the patient's level of understanding)

3. Ability to motivate, inspire

4. Develop and implement a patient education plan based on an initial education assessment

5. Identification and resolution of compliance barriers

C. Patient-specific pharmacist care plans

1. Recognition, prevention, and management of drug interactions

2. Pharmacology and therapeutics (innovative and conventional)

3. Interpretation of laboratory tests

4. Knowledge of community resources, professional referrals

5. Communication and rapport with community medical providers

D. Drug-treatment protocols

1. Develop and maintain (update) protocols.

2. Follow protocols as a pharmacist clinician.

3. Monitor aggregate adherence to treatment protocols (e.g., drug-use evaluations; DUEs), especially for a managed-care or health-system facility.

E. Dosage adjustment

1. Identify patients at risk for exaggerated or subtherapeutic response.

2. Apply pharmacokinetic principles to determine patient-specific dosing.

3. Order and interpret relevant tests at correct time intervals to assess dosage adjustment (e.g., plasma drug concentrations, blood glucose levels, blood pressure measurements).

F. Selection of therapeutic alternatives

1. Use drug information resources effectively.

2. Review and critique drug literature.

3. Construct comparative analyses to support therapeutic decisions.

G. Prescriptive authority in designated practice sites or positions

H. Preventive services

1. Immunizations
2. Screenings
3. Health and wellness education
I. Managerial skills
1. Plan, direct, and implement pharmaceutical-care activities within a variety of practice environments, such as community pharmacy, ambulatory-care settings, managed or contractual care, home-health services, long-term-care facilities, inpatient hospital practice, and others.
2. Allocate resources.

VII. PHARMACEUTICAL CARE AS THE MODEL FOR PHARMACY PRACTICE.

The concepts, activities, and services of pharmaceutical care form the basis for provision of clinical services directly to, and for the benefit of, patients in all pharmacy practice settings. These settings include home-health, hospital, ambulatory-care, primary-care, consultation, long-term-care, and community pharmacy practice. Work flow, staffing patterns, processes, and pharmacy programs might differ, but the core approach to patient care remains pharmaceutical care in all settings.
P.474

VIII. DOCUMENTATION OF PHARMACEUTICAL CARE.

“If it isn't documented, it isn't done!” Documentation of pharmaceutical care is integral to continuity of care, demonstration of clinician competence, communication among health-care providers, evidence of contributions to patient care, and reimbursement of professional services.
A. Pharmaceutical care, including the pharmaceutical care plan process (CORE, PRIME, FARM, or SOAP), is a systematic method for recording the pharmacist's examination of a patient's pharmacotherapy and subsequent identification of medication-related problems.
B. Computer software programs, in most practice settings, maintain patient data and drug-profile records. Thus after documentation of the initial pharmaceutical care plan, patient data or drug regimens are included in subsequent FARM (or SOAP) notes only if a change occurs that is relevant to the therapeutic issue being addressed in the note.
C. Forms that summarize pharmacists' interventions using a **unified coding system** are useful for processing reimbursement or billing forms, but these forms are not adequate documentation of pharmaceutical care. These forms do not communicate to other health professionals the depth and quality of pharmacist interventions or the pharmacist's plan for ongoing pharmaceutical care.

IX. PHARMACEUTICAL CARE: AN ONGOING PROCESS.

The **patient profile** (database) is revised and reassessed each time a new drug is added to or deleted from the medication regimen, a new disease or condition is

diagnosed, or the patient undergoes other clinical intervention, such as surgery. When the patient returns to the pharmacy or is readmitted to the health system facility, the pharmacist uses the patient profile, PWDT, and FARM (or SOAP) notes (maintained in the patient pharmacy chart or in the medical chart) as the basis for ongoing pharmacist-patient interactions.

X. IMPORTANCE OF PHARMACEUTICAL CARE IN TODAY'S PHARMACY PRACTICE

A. The potential for **medication errors** is growing, and one professional group must assume a primary role in addressing this issue, rather than various groups or individuals making fragmented efforts. The pharmacist is trained specifically to address these therapeutic issues.

B. The use of prescription and nonprescription medications is growing and now constitutes the primary therapeutic modality available to healthcare practitioners and patients.

C. The number, complexity, and potency of prescription and nonprescription drug products are increasing.

D. The need for pharmaceutical care secures an enduring role for the pharmacist in the U.S. healthcare system. Every encounter with patients, regardless of practice setting, provides pharmaceutical care.

E. Pharmaceutical-care activities integrate pharmacists into the healthcare system of the future.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following statements best describes FARM?

(A) cultivation of a pharmacist's knowledge to better serve the public

(B) findings, assessment, resolution, monitoring

(C) findings, assessment, recognition, management

(D) the process by which an individual pharmacist interacts with a specific patient to attain pertinent medical information

View Answer***1. The answer is B[see].*****2. An example of an expanded role of the pharmacist is**

(A) community leader.

(B) preparation of compounded prescriptions.

(C) maintaining adequate inventory of orphan drugs.

(D) triage of patients.

View Answer***2. The answer is D[see].*****3. What is the most important focus of pharmaceutical care?**

(A) pharmacist

(B) patient
(C) prescription
(D) patient chart

View Answer***3. The answer is B[see].*****4. Which of the following statements regarding pharmaceutical care is true? Pharmaceutical care**

(A) usually does not overlap into other areas of heath care.
(B) and clinical pharmacy are synonymous.
(C) implies that the pharmacist is no longer responsible for dispensing functions.
(D) is based on strategies to provide continuous patient care to attain desired outcomes.

View Answer***4. The answer is D[see].pharmaceutical care*****5. Essential components of pharmaceutical care include**

(A) patient-pharmacist relationship, legible physician orders, and accurate data collection.
(B) pharmacist-patient relationship and workup of drug therapy.
(C) a software program that accesses medication history and prompts the pharmacist concerning questions to ask the patient.
(D) maintenance of patient medication history for at least 2 years and a focus on acute illness.

View Answer***5. The answer is B[seeand].*****6. In the CORE pharmacotherapy plan, what does the *E* stand for?**

(A) education of patient or caregiver
(B) efficacy issues
(C) elaboration
(D) evaluation parameters

View Answer***6. The answer is D[see].*****7. The most important reason for using the FARM note is to**

(A) collect information for the physician.
(B) document problem-solving and/or interventions performed by the pharmacist.
(C) keep a log of all drug interactions.
(D) create a uniform method of recording patient information.

View Answer***7. The answer is B[see].*****8. Which of the following topics would *not* be included in the assessment portion of the FARM note?**

(A) recommendations made to the patient or caregiver
(B) severity, priority, or urgency of the problem
(C) short-term and long-term goals of the intervention
(D) additional information that is needed to best assess the problem

View Answer***8. The answer is A[see].*****9. Immunizations, screenings, and wellness education are examples of which clinical skill?**

(A) community health overview
(B) patient medication education and counseling
(C) preventive services
(D) managerial services

View Answer***9. The answer is C[see].*****10. The pharmacist's role in the selection of therapeutic alternatives requires which of the following clinical skills?**

(A) review and critique drug literature

(B) motivate and inspire patients

(C) perform drug-use evaluations (DUEs)

(D) knowledge of community resources

View Answer***10. The answer is A[see].***P.476

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* IV.C*].*

A FARM progress note is used to describe and document the interventions intended or provided by the pharmacist. The acronym FARM stands for findings, assessment, resolution, and monitoring and follow-up.

2. The answer is D *[see* II.A*].*

Pharmaceutical care has evolved from an emphasis on prevention of drug-related problems to the expanded roles of triage of patients, treatment of routine acute illnesses, management of chronic diseases, and primary disease prevention.

3. The answer is B *[see* IV.A*].*

Pharmaceutical care is based on a collaborative effort between pharmacist and patient.

4. The answer is D *[see* I.B; IX*].*

The term *pharmaceutical care* describes specific activities and services through which an individual pharmacist cooperates with a patient and other professionals in designing, implementing, and monitoring a therapeutic plan that will produce specific therapeutic outcomes for the patient. The patient profile (database) is revised and the potential for drug-related problems is reassessed each time a new drug is added to or deleted from the medication regimen, a new disease or condition is diagnosed, or the patient undergoes other clinical intervention (e.g., surgery).

5. The answer is B *[see* IV.A *and* B*].*

The essential components of pharmaceutical care are the pharmacist-patient relationship and the pharmacist's workup of drug therapy.

6. The answer is D *[see* IV.B.2*].*

The acronym CORE refers to the components of the pharmacotherapy plan, which is part of the pharmacist's workup of drug therapy. CORE stands for condition (or patient need), outcome (desired for that condition), regimen (selected to achieve that outcome), and evaluation parameters (to assess outcome achievement).

7. The answer is B *[see* IV.C; VIII; IX*].*

The FARM note is the pharmacist's progress note, describing and documenting the interventions intended or provided by the pharmacist. This constitutes the progress note in the medical chart (in health-system facilities) or in the pharmacy patient chart (in community pharmacy or sites without ready access to the medical chart).

8. The answer is A *[see* IV.C*].*

The assessment portion of the FARM note states the pharmacist's evaluation of the findings. Recommendations are made to the patient or caregiver to resolve or prevent an actual or potential problem identified by the pharmacist. Thus such recommendations would be included in the resolution portion of the FARM note.

9. The answer is C *[see* VI.H*].*

Immunizations, screenings, and health and wellness education are examples of clinical skills used in a pharmacist's provision of preventive services.

10. The answer is A *[see* VI.F*].*

For effective selection of therapeutic alternatives, a pharmacist would use certain clinical skills, including use of drug information resources, comparative analyses, and review and critique of drug literature.

Drug Information Resources

Paul F. Souney

Connie Lee Barnes

Valerie B. Clinard

I. DEFINITION.

Drug information is current, critically examined, relevant data about drugs and drug use in a given patient or situation.

A. Current information uses the most recent, up-to-date sources possible.

B. Critically examined information should meet the following criteria:

1. More than one source should be used when appropriate.

2. The extent of agreement of sources should be determined; if sources do not agree, good judgment should be used.

3. The plausibility of information, based on clinical circumstances, should be determined.

C. Relevant information must be presented in a manner that applies directly to the circumstances under consideration (e.g., patient parameters, therapeutic objectives, alternative approaches).

II. DRUG INFORMATION RESOURCES.

There are three sources of drug information: journals (primary sources), indexing and abstracting services (secondary sources), and textbook databases (tertiary sources).

A. Primary sources

1. Benefits. Journal articles provide the most current information about drugs and, ideally, should be the source for answering therapeutic questions. Journals enable pharmacists to:

a. Keep abreast of professional news

b. Learn how another clinician handled a particular problem

c. Keep up with new developments in pathophysiology, diagnostic agents, and therapeutic regimens

d. Distinguish useful from useless or even harmful therapy

e. Enhance communication with other healthcare professionals and consumers

f. Obtain continuing education credits

g. Share opinions with other healthcare professionals through letters to the editor

h. Prepare for the board certification examination in pharmacotherapy, nutrition support, oncology, etc.

2. Limitations. Although publication of an article in a well-known, respected journal enhances the credibility of information contained in an article, this does not guarantee that the article is accurate. Many articles possess inadequacies that become apparent as the ability to evaluate drug information improves.

3. Review articles (narrative reviews, systematic reviews, and meta-analyses), articles of opinion, correspondence, special reports.
All material included in a journal is not considered a primary resource. Original clinical trials are considered primary literature; however, review articles, articles of opinion, correspondence, and special reports are not.

B. Secondary sources

1. Benefits. Indexing and abstracting services are valuable tools for quick and selective screening of the primary literature for specific information, data, citation, and articles (Table 21-1).

In some cases, the sources provide sufficient information to serve as references for answering drug information requests.

Table 21-1. Examples of Abstracting and Indexing Services

Secondary References	Journals Indexed	Approximate Lag Time
CINAHL*	2,717	—
ClinAlert	150	1-6 weeks
Current Contents Connect	8000	1-6 weeks
Embase	7000	10 days
Medline/PubMed	5000	1 week
Inpharma	1800	3 weeks
International Pharmaceutical Abstracts	800	3-4 weeks
Iowa Drug Information System	340	30-60 days
Pharmaceutical News Index	—	2-8 weeks
Reactions	1800	3 weeks

Science Citation Index	3700	3 months

* Cumulative Index to Nursing and Allied Health Literature

2. Limitations. Each indexing or abstracting service reviews a finite number of journals. Therefore, relying on only one service can greatly hinder the thoroughness of a literature search. Another important fact to remember is the substantial difference in lag time (i.e., the interval between the publication of an article and the citation of that article in an index) among the available services. Several examples are given in Table 21-1.

a. Secondary sources usually **describe** only articles and clinical studies from journals. Frequently, readers respond to, criticize, and add new information to published articles and studies through letters. Services such as Medline/PubMed or the Iowa Drug Information Service generally do include pertinent letters to the editor within the scope of coverage.

b. Indexing and abstracting services are primarily used to **locate** journal articles. In general, abstracts should not be used as primary sources of information because they are generally interpretations of a study and may be a misinterpretation of important information. Pharmacists should obtain and evaluate the original article because abstracts may not include enough information to critically evaluate the study.

C. Tertiary sources

1. Benefits.

a. Textbooks. General reference textbooks can provide easy and convenient access to a broad spectrum of related topics. Background information on drugs and diseases is often available. Although a textbook might answer many drug-related questions, the limitations of these sources should not be overlooked.

(1) It could take several years to publish a text, so information available in textbooks might not include the most recent developments in the field. Other resources should be used to update or supplement information obtained from textbooks.

(2) The author of a textbook might not have conducted a thorough search of the literature, so pertinent data could have been omitted. An author also

might have misinterpreted the primary or secondary literature. Reference citations should be available to verify the validity and accuracy of the data.

b. Databases. Computer databases are convenient, easy to use, and referenced. These resources are similar to textbooks, but are typically updated more frequently. Computer databases are easy to search and are often useful resources for drug monographs, pill identifications, drug interactions, and various therapeutic calculations. Additionally, computer databases may address clinical questions. In some instances, a PDA version of the database is available. Examples include Clinical Pharmacology On Hand, Clinical Xpert, Lexi-Comp On-Hand, and e-Pocrates Rx.

2. General considerations when examining and using textbooks and/or databases as sources of drug information include the following:

a. The author, publisher, or both: What are the author's and publisher's areas of expertise?

b. The year of publication (copyright date) or last revision date?

c. The edition of the text: Is it the most current edition?

d. The presence of a bibliography: If a bibliography is included, are important statements accurately referenced? When were the references published?

e. The scope of the textbook or database: How accessible is the information?

f. Alternative resources that are available (e.g., primary and secondary sources, other relevant texts)

III. INTERNET

A. Benefits. The Internet expands the ability to search therapies that have been recently published or discussed in the media. An Internet search may be required for the following: company-specific information, issues currently in the news, alternative medicine, or U.S. government information. The most popular Web browsers are Mozilla Firefox and Microsoft Internet Explorer. A variety of search engines, software tools for searching the Internet, have been developed. General search engines (AltaVista, Google, Yahoo, Ask, Dogpile) attempt to index as much of the Internet as possible.

B. Limitations

1. Unlike information published in journals and textbooks, information obtained from the Internet may not be peer reviewed or edited before release.

2. Information received from the Internet may be only as reliable as the person who posted it and the users who read and comment on its content. A Web site should be evaluated by its source (author) of information. The name, location, and sponsorship should be disclosed. Also, a reputable site

will provide easy access to information and the ability to give feedback. Pharmacists should use traditional literature evaluation skills to determine whether information on Web site is clear, concise, unbiased, relevant, and referenced.

C. Use. To obtain information from the Internet, the user must have an address (referred to as a URL, or uniform resource locator) to type into the browser, which will then find the site automatically. Many associations and organizations have Web sites that are linked to other Web pages. Table 21-2 provides a selection of Web sites.

IV. STRATEGIES FOR EVALUATING INFORMATION REQUESTS.

It is important to obtain as much information as possible about drug information requests before beginning a literature search. Both time and money can be lost doing a vast search. Below are important questions to ask the inquirer or to evaluate before a manual or computerized search.

A. Converse with the inquirer. Before spending time searching for information, talk to the person who is requesting the information and acquire any necessary additional information.

1. Determine the reason for the inquiry. Find out where the inquirer heard or read about the drug. Is he or she taking the medication? If so, why? Because the search can be done by the drug or disease name, determine if the inquirer has a medical condition. Ascertaining the reason for the inquiry helps determine what additional information should be provided. For example, if the inquiry concerns a foreign drug, the inquirer might ask for a domestic equivalent.

2. Clarify the drug's identification and availability. Make sure that the drug in question is available and double-check information about the drug, such as:

a. The **correct spelling** of the drug's name

b. Whether it is a **generic** or **brand name drug**

c. What **pharmaceutical company** manufactures the drug and in what **country** the drug is manufactured

d. Whether the drug is **prescription** or **nonprescription**

e. Whether the drug is still **under investigation** and, if it is on the market, **the length of time on the market**

f. The **dosage form** of the drug

g. The **purpose** of the drug (i.e., what medical condition or symptom the drug is intended to alleviate; this information helps narrow the search if products with similar names are found)

B. To **identify** or **assess product availability,** consider using the following resources (see also Appendix E). Some of these resources are available in an electronic format or in an Internet/Intranet version.

1. For drugs manufactured in the **United States,** the following resources are available:

a. *The American Drug Index,* updated annually

b. *Drug Facts and Comparisons,* updated monthly and bound annually/Facts and Comparison 4.0 (online)
c. *Drug Topics Red Book,* periodically supplemented and updated annually
d. *Physician's Desk Reference (*PDR*),* updated annually
e. *American Hospital Formulary Service (AHFS) Drug Information,* supplemented quarterly and updated annually
f. *Martindale: The Complete Drug Reference,* updated every 3 years
g. *Lexi-Drugs Online (Lexi-Comp Online)*
h. *Clinical Pharmacology*
i. Thomson Healthcare Series (Micromedex)
2. For drugs manufactured in **foreign countries,** the following resources are available:
a. *Martindale: The Complete Drug Reference*
b. *Index Nominum*
c. USP *Dictionary of United States Adopted Names (USAN) and International Drug Names*
d. *Lexi-Drugs International Online (Lexi-Comp Online)*
3. For **investigational drugs,** the following resources are available:
a. *Martindale: The Complete Drug Reference*
b. *Drug Facts and Comparisons/Facts and Comparison 4.0 (online)*
c. *The Pink Sheet* published by FDC Reports
d. *The NDA Pipeline* published by FDC Reports

4. For **orphan drugs**—that is, drugs that are used to prevent or treat a rare disease (affects < 200,000 people in the United States, so the cost of development is not likely to be offset by sales) and for which the U.S. Food and Drug Administration (FDA) offers assistance and financial incentives to sponsors undertaking the development of the drugs—the following resources are available:
a. *Drug Facts and Comparisons/Facts and Comparison 4.0 (online)*
b. The FDA Office of Orphan Products Development (OOPD)
c. The National Institutes of Health (NIH) Office of Rare Diseases
d. National Organization for Rare Disorders
e. *Lexi-Drugs Online (Lexi-Comp Online)*
5. For an **unknown drug** (i.e., one that is in hand but not identified), chemical analysis can be performed or the drug can be identified by physical characteristics, such as color, special markings, and shape. Consult the following sources for help:
a. PDR, *Drug Facts and Comparisons, Facts and Comparison 4.0 (online), Drug Topics Red Book, Ident-A-Drug Reference*
b. *Identidex (Micromedex)*
c. The manufacturer
d. A laboratory

e. *Lexi-Comp Online (Lexi-Drug ID)*
f. *Clinical Pharmacology Product Identification*
6. For a **natural product,** the following resources are available:
a. Facts and Comparison 4.0 (online)
b. Natural Medicines Comprehensive Database
c. Natural Standards
d. Complete German Commission E Monographs
e. Natural Products (Lexi-Comp Online)

V. SEARCH STRATEGIES.

To develop an effective search strategy for locating drug information literature, the following tactics should be followed after determining whether primary or secondary sources are desired.
A. Determine whether the question at hand is **clinical** or **research related.** **Define the question** as specifically as possible. Also, identify appropriate index terms (also called keywords or descriptors) with which to search for the information.
B. Determine the **type of information** and **how much** is needed (i.e., only one fact, the most recent journal articles, review articles, or a comprehensive database search).
C. Ascertain as much information as possible about the drug being questioned and the **inquirer's association** with it. Remember that data on adverse drug effects or drug interactions are often fragmented and inadequately documented. See IV.A.2 for the specific drug information that should be acquired. Determine the answers to the following questions:
1. What is the indication for the prescribed drug?
2. Is the drug's use approved or unapproved? This information can be found in the following resources (remember to check how often these resources are updated to ensure having the latest information).
a. Approved uses of drugs can be checked in:
(1) *AHFS Drug Information*
(2) *Drug Facts and Comparisons/Facts and Comparison 4.0 (online)*
(3) PDR
(4) USP *Drug Information*
(5) *Drugdex (Micromedex)*
(6) *Clinical Pharmacology*
(7) *Drug Information Handbook/Lexi-Drugs Online (Lexi-Comp Online)*
b. Unapproved uses of drugs can be found in:
(1) *AHFS Drug Information*
(2) *Drug Facts and Comparisons/Facts and Comparison 4.0 (online)*

(3) *Martindale: The Complete Drug Reference*
(4) Medline

(5) *Drugdex* (Micromedex)
(6) *Inpharma*
(7) USP *Drug Information*
(8) *Clinical Pharmacology*
(9) *Drug Information Handbook/Lexi-Drugs Online (Lexi-Comp Online)*
3. What are the age, sex, and weight of the patient in question?
4. Does the patient have any other medical conditions or renal or hepatic disease?
5. Is the patient taking any other medications?
6. What drugs has the patient taken during the past 6 months, and what were the dosages?
7. Did the patient experience any signs or symptoms of a possible adverse drug reaction? If so:
a. How severe was the reaction?
b. When did the reaction appear?
c. Has the patient (or any member of the patient's family) experienced any allergic or adverse reactions to medications in the past?
d. Consult the following resources for more information:
(1) Meyler's *Side Effects of Drugs*
(2) A general drug reference (e.g. PDR)
(3) *Reactions*
(4) Medline
e. The manufacturer of the drug may be a useful source for missing information. Most companies request further information regarding a suspected adverse drug reaction.
8. Did the patient experience any signs or symptoms of a drug interaction? If so:
a. What were the specific drugs in question?
b. What were the respective dosages of the drugs?
c. What was the duration of therapy?
d. What was the length of the course of administration?
e. What are the details of the events secondary to the suspected reaction?
f. Consult the following resources for more information:
(1) A drug interactions reference—for example, *Drug Interaction Facts,* Hansten's *Drug Interaction Analysis and Management, Evaluations of Drug Interactions (EDI)*
(2) A general drug reference (e.g., PDR)
(3) *Reactions*
(4) Medline
9. What is the patient's current medication status?
10. Does the patient have any underlying diseases?
11. How has the patient been managed so far?
12. What is the stability of the drug? How is compatibility of the drug with other drugs?

What are the administration techniques? What are appropriate containers for the product?

Resources available with this information include

a. Trissel's *Handbook on Injectable Drugs*

b. King's *Guide to Parenteral Admixtures*

c. Trissel's *Stability of Compounded Formulations*

D. Explore other possible information resources if necessary. For example, it may be useful to find background material in textbooks (tertiary references), and then search the journal literature (primary references) for more current information.

VI. EVALUATING A CLINICAL STUDY.

Resource identification is followed by a critical assessment of the available information. This step is critical in developing an appropriate response for the inquirer.

A. Evaluate the objective of the study. Determine the aim of the research that was performed.

1. What did the researchers intend to examine?

2. Is this goal stated clearly (i.e., is the objective specific)?

3. Was the research limited to a single objective, or were there multiple drugs or effects being tested?

B. Evaluate the subjects of the study. Determine the profile of the study population by assessing the following information:

1. Were healthy subjects or affected patients used in the study?

2. Were the subjects volunteers?

3. What were the criteria for selecting the subjects?

4. How many subjects were included, and what are the demographics of the subjects (age, sex, and race)?

5. If a disease was being treated, did any of the subjects have diseases other than that initially being treated? Were any additional treatments given? Were there any contraindications to the therapy?

6. What was the patient selection method and who was excluded from the study?

7. A patient selection review should be done. You will find that most groups of subjects are homogeneous (i.e., they all have comparable characteristics). If a disease state is studied, patients should exhibit similar severity of symptoms. Researchers aim to eliminate interpatient variability. By selecting patients with similar characteristics, researchers can avoid results that are caused by individual differences among patients. Strong individual differences can obscure the results of the experiment. If studying a group of patients who exhibit significant interpatient variability is necessary, researchers may divide the patients into groups according to the

variables likely to be associated with responsiveness to therapy. This is known as stratification.

C. Evaluate the administration of the drug treatment. For each drug being investigated, determine the following information:

1. Details of treatment with the agent being studied:

a. Daily dose

b. Frequency of administration

c. Hours of day when administered

d. Route of administration

e. Source of drug (i.e., the supplier)

f. Dosage form

g. Timing of drug administration in relation to factors affecting drug absorption

h. Methods of ensuring compliance

i. Total duration of treatment

2. Other therapeutic measures in addition to the agent being studied

D. Evaluate the setting of the study. Try to determine the environment of the study and the dates on which the trial began and ended. Assess the following information:

1. People who made the observations; various professionals who offer different and unique perspectives based on their backgrounds and interests (Were the same people making observations throughout the study?)

2. Whether the study was done on an inpatient or outpatient basis

3. Description of physical setting (e.g., hospital, clinic, ward)

4. Length of the study (i.e., dates on which the trial began and ended)

E. Evaluate the methods and design of the study. The method section of the research paper explains how the research was conducted. The study design (i.e., retrospective, prospective, blind, crossover) and the methods used to complete the study are important in judging whether

the study and the results are reliable and valid. From the study, try to determine answers to the following questions:

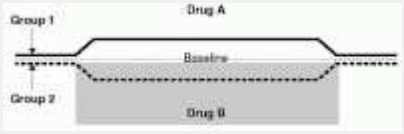

Figure 21-1. Parallel study design.

1. Are the methods of assessing the therapeutic effects clearly described?

2. Were the methods standardized?

a. Retrospective versus prospective

(1) Retrospective studies evaluate events that have already occurred to find some common link among them, require reliance on patient memories and accurate medical records, and are unable to show cause and effect. Retrospective studies are useful for studying rare diseases (or effects) and can help a healthcare professional decide if enough information exists to warrant prospective examination of a problem.

(2) Prospective studies follow identified patients forward in time to answer a specific question. They can be observational or experimental (i.e., clinical trials).

b. Treatment allocation

(1) Parallel study design is a protocol in which two or more patient groups are studied concurrently. The groups are treated identically except for one variable, such as a drug therapy (Figure 21-1).

(2) Crossover design may be used as an additional control for interpatient and intrapatient variability (Figure 21-2). In this type of design, each patient group undergoes each type of treatment. However, the sequence in which the subjects undergo treatment is reversed for one group. Crossover design reduces the possibility that the results were strongly influenced by the order in which therapy was given. And because both groups of patients receive both types of treatment, any differences in responsiveness between the groups as a result of patient selection will be uncovered.

3. Were **control measures** used to reduce variation that might influence the results? Examples of such control methods include

a. Concurrent controls

b. Stratification or matched subgroups

c. A run-in phase

d. The patient as his or her own control (i.e., crossover design)

e. Identical ancillary treatment

4. Were controls used to reduce bias? Examples of such controls include

a. Blind assessment, which means that the people observing the patients do not know who is a subject and who is a control

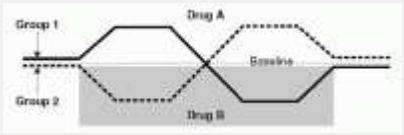

Figure 21-2. Crossover study design.

Table 21-3. Types of Blind Studies

Types of Blinds	Patient Aware of Treatment	Physician Aware of Treatment
Open label (nonblind)	[check mark]	[check mark]
Single-blind	—	[check mark]
Double-blind	—	—

b. Blind patients, which means that the patients do not know whether they received the substance being studied or a placebo (**double-blind** combines this point with point a above [VI.E.4.a]) (Table 21-3)

c. **Random allocation,** which means that patients involved in the study have an even chance of being assigned to either the group of subjects receiving the active drug or the group receiving a placebo

d. Matching dummies, which are placebos that are physically identical to the active agent being studied

e. Comparison of a placebo or a therapy to a recognized standard practice (placebocontrolled)

F. Evaluate the analysis of the study. After assessing specific areas of the study separately, compile the information together to determine whether the trial is acceptable and the conclusions are justified by determining answers to the following questions (Figure 21-3):

1. Were the subjects suitably selected in relation to the aim(s) of the study?

2. Were the methods of measurement valid in relation to the aim(s) of the study?

3. Were the methods adequately standardized?

4. Were the methods sufficiently sensitive?

5. Was the design appropriate?

6. Were enough subjects enrolled?

7. Was the dosage appropriate?

8. Was the duration of treatment adequate?

9. Were carryover effects avoided, or were compensations made for them? Did a wash-out period exist?

10. If no controls were used, were they unnecessary or overlooked?

11. If controls were used, were they adequate?

12. Was the comparability of treatment groups examined?

13. Are the data adequate for assessment?

14. If statistical tests were not done, were they unnecessary or overlooked?

15. If statistical tests are reported, assess the following:

a. Is it clear how the statistical tests were done?

b. Were the tests appropriately used?

c. If results show no significant difference between test groups, were enough patients studied (i.e., statistical power)?

VII. GENERAL GUIDELINES FOR RESPONSES TO DRUG INFORMATION REQUESTS

A. Do not guess!

B. Responses to a member of the public must take several ethical issues into account.

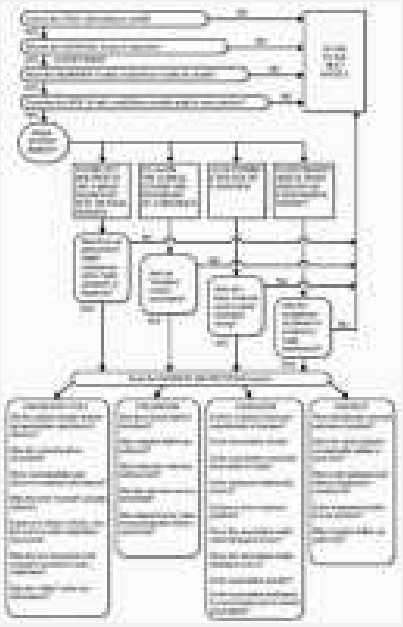

Figure 21-3. Evaluation of study analysis.

P.487

1. Patient privacy must be protected.

2. Professional ethics must be maintained.

3. The patient-physician relationship cannot be breached.

4. Response is not necessary if the inquirer intends to misuse or abuse information that is provided. The inquirer often admits intent or offers clues to potential abuse, such as in the following examples:

a. A patient asks how a certain drug is dosed (i.e., how much the drug can be increased, when it can be increased, what the maximum daily dose is). This kind of inquiry signals that the patient might be adjusting his or her own therapy.

b. A patient asks a pharmacist to identify a tablet that is a prescription product known for a high rate of abuse.

C. Organize information before attempting to communicate the response to the inquirer. Responses should be concise and succinct. Anticipate additional questions.

D. Tailor the response to the inquirer's background. Also, consider the environment of the practice, institutional policy and procedure, and formulary.

E. Tell the inquirer where the information was found. Exercise caution when making statements such as, “There are no reports in the literature.”

F. Use *extreme* caution when making statements such as, “I recommend ...” Do not hesitate to refer consumers to their physicians.

G. Use more than abstracts to answer drug information questions because they might be taken out of context and do not include all of the data available in the original article.

H. Alert the inquirer of a possible delay when it takes longer than anticipated to answer the question.

I. Ask if the information that is provided answers the inquirer's questions.

J. Ask if the inquirer would like to have reprints of articles or a written response.

P.488

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. Primary literature includes which of the following?

(A) Original clinical trials

(B) Letters to the Editor

(C) Systematic reviews

(D) Special reports

View Answer***1. The answer is A[].*****2. Which of the following statements is TRUE regarding tertiary resources?**

(A) Tertiary resources include textbooks and computer databases.

(B) Textbooks typically include the most recent literature and/or information.

(C) Tertiary resources do not typically include a bibliography.

(D) The credentials of the editor of a tertiary resource are not considered important.

View Answer***2. The answer is A[].*****3. Which of the following should NOT be done when developing an effective search strategy?**

(A) Determine if the question is clinical or research-related

(B) Identify appropriate search terms

(C) Disregard other medications the patient may be taking

(D) Ascertain if the inquirer is a healthcare professional

View Answer***3. The answer is C[].*****4. Which of the following resources would be appropriate for identifying a drug manufactured in a foreign country?**

(A) Martindale: The Complete Drug Reference

(B) Clinical Pharmacology

(C) Trissel's Stability of Compounded Formulations

(D) AHFS

View Answer***4. (A) Study objective

(B) Patient demographics

(C) Drug administration

(D) Number of authors

View Answer***9. The answer is D[].*****10. Which of the following statements is TRUE?**

(A) Prospective studies evaluate events that have already occurred.

(B) Retrospective studies are useful for evaluating rare diseases.

(C) A run-in phase typically increases variation.

(D) Crossover design allows patients to undergo only one type of treatment.

View Answer***10. The answer is B[].***P.489

ANSWERS AND EXPLANATIONS

1. The answer is A *[*II.A.3*].*

All material included in a journal is not considered a primary resource. Original clinical trials are considered primary literature; however, review articles, articles of opinion, correspondence, and special reports are not.

2. The answer is A *[*II, II.C*].*

Tertiary resources include both textbooks and databases. Information available in textbooks may not include the most recent data since it could take several years to publish. A bibliography and reference citations should be present in both textbooks and databases so that the reader may refer to a specific reference if desired. Additionally, the areas of expertise for the author and/or publisher should be evaluated when using a tertiary resource.

3. The answer is C *[*V.A, V.C, VII.B, VII.D*].*

One should determine if the question is related to a clinical scenario or is research related to develop an effective search strategy. Appropriate index terms should be identified to assist in the literature search. Other medications, including herbal products, and disease states should be taken into consideration. The background of the inquirer should be determined so that the response can be tailored to the specific inquirer.

4. The answer is A *[*IV.B.2*].*

Martindale: The Complete Drug Reference is one resource that may be used to identify a drug manufactured in a foreign country. Other resources for identifying drugs manufactured in a foreign country include *Martindale: The Complete Drug Reference, Lexi-Drugs International Online (Lexi-Comp Online),* and the USP *Dictionary of United States Adopted Names (USAN) and International Drug Names. Clinical Pharmacology, Trissel's Stability of Compounded Formulations,* and *AHFS* do not contain this type of information.

5. The answer is A *[*IV.B.5*].*

For an unknown drug, the physical characteristics, including an imprint code, may be used to identify the drug in addition to the use of several resources, including *Facts and Comparison 4.0 (Online)* and *Lexi Drugs Online (Lexi-Comp Online).*

6. The answer is C *[*IV.B.6*].*

For a natural product, the following resources are available: *Facts and Comparison 4.0 (online), Natural Medicines Comprehensive Database, Natural Standards, Complete German Commission E Monographs,* and *Natural Products (Lexi-Comp Online).*

7. The answer is B *[*V.C.12*].*

The stability of a drug, the compatibility of a drug with other drugs and/or appropriate containers, and proper administration techniques are included in *Trissel's Handbook on Injectable Drugs, King's Guide to Parenteral Admixtures,* and *Trissel's Stability of Compounded Formulations.*

8. The answer is A *[*V.C.2.b*].*

Unapproved uses of drugs can be found in *Clinical Pharmacology.* This information is not available in the PDR, Index Nominum, or *King's Guide to Parenteral Admixtures.*

9. The answer is D *[*VI.A, VI.B, VI.C*].*

A critical assessment of available information is important in developing an appropriate response. The study objective, the study subjects (via demographics and inclusion and exclusion criteria), and drug administration should be evaluated.

10. The answer is B *[*VI.E*].*

Retrospective studies evaluate events that have already occurred and are useful for studying rare diseases. Prospective studies follow identified patients forward in time to answer a specific question. Crossover design allows for each patient group to undergo each type of treatment. A run-in phase is a control measure used to reduce variation.

22

Adverse Drug Reaction Reporting

Barbara Szymusiak-Mutnick

I. INTRODUCTION.

Adverse drug reactions (ADRs) are a cause of significant morbidity and mortality in patients in all areas of health care today. There is wide variation in the current healthcare literature, but it has been estimated that from one third to as high as one half of ADRs are believed to be preventable. The Institute of Medicine reported in July 2006 that an estimated 1.5 million injuries occur each year as a result of medication errors. Between 44,000 to 98,000 people die from medication errors annually. Medication errors kill more people per year than breast cancer, AIDS, or motor vehicle accidents. The cost of morbidity and mortality owing to drug-related adverse events in hospitalized patients was recently estimated to be at least $3.5 billion annually. There are an estimated 3 million hospital admissions each year caused by the misuse of pharmaceuticals. The suffering that patients experience because of drug-related events cannot be quantified.

II. DEFINITIONS.

The terms *adverse drug reaction, adverse drug event, untoward drug reaction, drug misadventure, side effect, medication errors, misuse of pharmaceuticals,* and *drug-related problem* are many times used interchangeably but do not always describe the same situation.

A. The National Coordinating Council for Medication Error Reporting and Prevention states “A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professionals, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling; packaging; and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use.”[1]

B. The U.S. Food and Drug Administration's (FDA) definition of an **adverse drug** event is “any adverse event associated with the use of a drug in humans, whether or not considered drug related, including the following: an adverse event occurring in the course of the use of a drug in professional practice; an adverse event occurring from a drug overdose, whether accidental or intentional; an adverse event occurring from drug abuse; an adverse event occurring from drug withdrawal; and any significant failure of expected pharmacological action.”[2]

C. Adverse drug reaction is defined by the World Health Organization (WHO) as “one which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function.”[3]

D. The WHO defines a side effect of a drug as: ‘any unintended effect of a pharmaceutical product occurring at doses normally used by a patient which is related to the pharmacological properties of the drug.’

III. TYPES OF ADVERSE DRUG REACTIONS

A. Type A

1. Type A reactions are extensions of the drug's known pharmacology and are responsible for the majority of ADRs.

P.491

2. Type A reactions are usually dose dependent and predictable but can be the result of concomitant disease states, drug-drug interactions, or drug-food interactions.

3. Ways to minimize type A reactions include understanding the pharmacology of the drug being prescribed, monitoring drugs with a narrow therapeutic index, and avoiding polypharmacy when possible.

B. Type B

1. Type B reactions include idiosyncratic reactions, immunological or allergic reactions, and carcinogenic/teratogenic reactions.

2. Type B reactions are usually not the result of a known pharmacology of the drug but seem to be a function of patient susceptibility. They are rarely predictable, are usually not dose dependent, and seem to concentrate in certain body systems such as the liver, blood, skin, kidney, and nervous system.

3. Type B reactions are uncommon but are generally serious and can be life threatening.

4. Except for immediate hypersensitivity reactions, type B reactions usually take 5 days before the patient demonstrates hypersensitivity to a drug. There is no maximum time for the occurrence of a reaction, but most occur within 12 weeks of initiation of therapy.

IV. RECOGNITION

A. Drugs must always be considered as a possible cause of disease or symptoms that are among a patient's list of complaints. Complete drug histories, including nonprescription drugs, must also be carried out.

B. Recognition is often subjective, and it is not always possible to demonstrate strong causality between the drug and the occurrence.

1. Several factors may help in assessing the determination of causality.

a. Did the patient actually ingest the drug in question?

b. Did the onset of symptoms occur after the drug was taken?

c. What is the time interval between taking the drug and the onset of symptoms?

d. Did the symptoms resolve or improve after the drug was stopped or the dose decreased?

e. Did the symptoms reoccur after the drug was reintroduced?

f. Did drug-drug interactions contribute to the symptoms?

g. Were the drugs measured in “toxic levels” in the patient's serum?

h. Has this reaction been previously seen with use of the drug?

i. What is the personal experience of the clinician with previous use of the drug and reactions secondary to the drug?

2. Nomograms have been developed to aid in the assessment of causality.

V. SURVEILLANCE PROGRAMS.

Pharmacists as well as all healthcare professionals should take an active role in monitoring, reporting, and trending ADR information. Some of the activities involved in a concurrent and ongoing ADR surveillance program at an institutional level include the following components:

A. Pharmacy departments should take the lead in the collection of information and should submit all reviews and reports to the pharmacy and therapeutics committees for review and evaluation.

1. Encourage all healthcare professionals to be involved in reporting.

2. Monitor patients who are using high-risk agents.

3. Review patients who have received “antidote”-type drugs.

4. Notify prescribers of suspected ADRs, and encourage thorough documentation of the description of the reaction as well as the outcome in patients' medical records.

5. Report appropriately identified ADRs to the FDA.

6. Develop the use of pharmacy computer systems to track ADRs.

B. Evaluation of the causes of ADRs should be carried out. ADR report information should be used for educational purposes and identification of drug use and medication use processes to prevent further occurrences of such reactions. ADR reporting information should be incorporated into institutional risk management programs.

VI. REPORTING TO THE FDA.

Three of the five major centers at the FDA are involved with evaluating the safety and efficacy of drugs. The largest center is the Center for Drug Evaluation and Research (CDER), which oversees both prescription and nonprescription—over-the-counter (OTC)—drugs. In 2002, CDER established the Adverse Events Reporting System (AERS), a computerized data base designed to support the FDA's postmarketing safety program for drugs and therapeutic biologic products. Annually, the AERS receives about 470,000 reports of adverse experiences possibly associated with drugs. The Center for Biological Evaluation and Research (CBER) ensures the safety and efficacy of blood products, vaccines, allergenics, biological therapeutics, gene therapy, medical devices and tests, xenotransplantation products, and banked human tissue and cellular products. The Center for Food Safety and Applied Nutrition (CFSAN) established the CFSAN Adverse Events Reporting System (CAERS) in 2002. The CAERS provides a monitoring system to identify potentially serious problems secondary to non-FDA-approved herbs, minerals, vitamins, dietary supplements, and other substances.

A. The national **Vaccine Adverse Event Reporting System** (VAERS) is coadministered by the FDA and the Centers for Disease Control and Prevention (CDC). More than 10 million vaccines are given to children and many million more

doses to adults each year. Although vaccines protect many people from dangerous diseases, they do have the potential to cause adverse effects.

1. The National Childhood Vaccine Injury Act (NCVIA) requires health professionals to report

a. Adverse events after the administration of vaccines specified in the act, as described in the “Reportable Events Table,” within the specified time period (available at www.vaers.hhs.gov/ or 1-800-822-7967)

b. Any event listed in the manufacturer's package insert as a contraindication to subsequent doses of the vaccine

2. In 1990, VAERS was set up to receive all reports of suspected adverse events caused by any U.S. licensed vaccine (Figure 22-1).

3. The VAERS depends on voluntary reporting by health professionals to:

a. Identify rare adverse reactions not detected in prelicensing studies

b. Monitor for increases in already known reactions

c. Identify risk factors or preexisting conditions that promote reactions

d. Identify particular vaccine lots with unusually high rates or unusual types of events

B. MedWatch, the FDA's Medical Products Reporting Program established in 1993, is a voluntary system for healthcare providers (Figure 22-2). However, manufacturers and distributors of FDA-approved drugs, biologics, radiation-emitting devices, special nutritional products, dietary supplements, infant formulas, and devices are mandated to report problems to the FDA. The goals of the program are to increase awareness of reporting of medical-product-induced diseases and the importance of reporting, to clarify what should be reported, to make reporting as easy as possible, and to provide feedback to health professionals.

1. Importance of reporting

a. The incidence of ADRs occurs at a high rate in health care today.

(1) Generally, it is reported that 3%-11% of all hospital admissions can be attributable to ADRs, although some studies report the figure to be as high as 29%.

(2) The likelihood that a patient will experience an ADR while hospitalized is reported in the literature to be in a range from 5%-25%.

Figure 22-1. VAERS form for reporting possible adverse drug reactions.

P.494

Figure 22-2. Form for reporting possible adverse drug reactions to the FDA Medical Products Reporting Program.

b. Prevention of ADRs is an important strategy in health care. It has been estimated that at least one third of all ADRs may be preventable. It has been further noted that preventable ADRs tend to be the most costly to treat and cause the greatest degree of patient morbidity.

(1) Future ADRs can be prevented in individual patients by careful and consistent documentation in patient records.

(2) A program that tracks ADRs can help discover previously unidentified trends. These trends can be used within the institution to develop programs of prospective intervention

P.495

to prevent reoccurrence of the reaction in the patient populations that are at similar risk.

c. Recognition of previously undiscovered ADRs attributable to a drug is particularly true in the case of newly marketed products.
(1) Although clinical trials are generally effective in assessing efficacy and risk to benefit ratio, inherent limitations exist in premarketing trials.
(a) The trials are usually relatively short in duration and do not effectively mimic the exposure patients would experience if using the drug as a chronically administered agent.
(b) Drug-drug interactions and use in patients with concomitant disease states may not be tested for in these trials.
(c) The small size of the trials (usually 1000-3500 individuals) is insufficient to detect rarely occurring adverse reactions.
(d) Racial and ethnic groups may not be participating in the same numbers as represented in the general population.
d. Prompt recall in cases of product problems are accomplished when the MedWatch Program is used to report product problems or device defects.
2. What should be reported?
a. ADRs that are serious, even if causality is not proven, including
(1) A patient's death that is suspected of being a direct outcome of an ADR
(2) A life-threatening event
(3) An initial or prolonged hospitalization
(4) A significant, persistent, or permanent change or disability/incapacity
(5) A congenital anomaly (including those occurring in a fetus)
(6) Other problems that aren't listed in the manufacturer's package insert as a known side effect
b. Malfunctioning medical devices such as heart valves, latex gloves, dialysis machines, and ventilators and problems with nutritional products
c. Product problems that can result in compromised safety or quality, including product contamination, mislabeling, unclear labeling, poor packaging, potency problems, and questionable stability
d. Counterfeit or suspected counterfeit drugs
e. Adverse events with food, herbs, vitamins, cosmetics, or dietary supplements, although CAERS is the prefered reporting system
f. Adverse events owing to blood products, allergenics, gene therapy, human tissue and cellular products, and xenotransplantation products
g. Medication errors
3. Confidentiality of both the reporter and the patients whose cases are reported are substantially protected by the FDA.
4. Reporting of problems with OTC medications are required when the product has been marketed with a new drug application (NDA), including drugs formerly marketed as prescription-only drugs. OTC products marketed without an NDA do not require reporting, but reporting is strongly encouraged. Approval of the FDA is not required for the marketing of nonprescription herbs, minerals, vitamins, dietary supplements, and other substances. Because the FDA does not approve these substances, efficacy and safety do not have to be demonstrated, nor is it mandated to report problems to the FDA.

5. Reporting to manufacturers is not described in the FDA's guidelines, although a section of the MedWatch form can be checked off to inform the FDA that a copy of the report has been forwarded to the manufacturer by the reporter.

C. Information on previously reported events

1. The FDA Web site provides on-line safety information at www.fda.gov/medwatch/safety. htm gathered from approximately 25,000 reports that are submitted each year.

2. Clinically important product safety alerts are available via an automated e-mail messagedelivery system from www.fda.gov/medwatch/elist.htm.

P.496

3. FDA alerts also appear on www.Pharmacist.com, a joint venture of the American Pharmacist Association and the National Association of Boards of Pharmacy.

VII. American Society of Health-Systems Pharmacists (ASHP) Guidelines

define criteria for classifying an ADR as significant. They encourage reporting of serious or unexpected ADRs to the FDA, the manufacturer, or both.

VIII. Joint Commission on Accreditation of Healthcare Organizations (JCAHO)

requirements for accreditation describe the need for each healthcare organization to monitor for adverse events involving drugs and devices in a continual, collaborative fashion.

IX. *United States Pharmacopeia (USP).*

Medication Errors Reporting Program at www.usp.org/hqi/patientSafety/mer/and the USP-Institute for Safe Medication Practices (ISMP) Medication Errors Reporting Program at https://www.ismp.org/orderforms/reporterrortoISMP.asp are two programs involved in collection of medication error data.

X. FURTHER INFORMATION

A. Information about the MedWatch program can be obtained by phone at 1-800-FDA-1088 and at www.fda.gov/Medwatch/.

B. Information about VAERS can be obtained by phone at 1-800-822-7967 and at www.fda.gov/cber/vaers/vaers.htm.

C. Information about reporting to the CFSAN program can be obtained by phone at 301-436-2405 or at www.cfsan.fda.gov.

D. Further information about the FDA's reporting systems and programs, such as CDER, can be found on the FDA's Web site (www.fda.gov).

P.497

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The phrase "one which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function," describes

(A) a side effect.

(B) an adverse drug reaction.

(C) an adverse drug event.

(D) a medication error.

View Answer***1. The answer is B[see].*****2. Type A reactions are characterized by which of the following?**

(A) idiosyncratic reactions

(B) a function of patient susceptibility

(C) caused by drug-drug interactions

(D) All of the above

(E) None of the above

View Answer***2. The answer is C[see].*****3. The MedWatch form is *not* the appropriate form to report which of the following events?**

(A) a vaccine event described in the Vaccine Adverse Event Reporting System (VAERS) "Reportable Events Table"

(B) a suspected counterfeit drug

(C) a malfunctioning ventilator

(D) a drug that is contained in a package with unclear labeling

(E) None of the above

View Answer***3. The answer is A[see].*****4. Preventable adverse drug reactions (ADRs)**

(A) generally display mild symptoms.

(B) are always easily recognized.

(C) are problems that are easily medically managed.

(D) All of the above

(E) None of the above

View Answer***4. The answer is E[see].*****5. Reporting problems with vitamins to the FDA is required by law in which of the following situations?**

(A) when the problem is discovered by the consumer

(B) when safety and efficacy have been proven by manufacturers to the FDA

(C) when a healthcare professional discovers the problem

(D) All of the above

(E) None of the above

View Answer***5. The answer is E[see].***P.498

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* II.C*].*

This is the definition from the WHO.

2. The answer is C *[see* III.A.2*].*

Type A reactions can be caused by drug-drug interactions. Idiosyncratic reactions and reactions caused by patient susceptibility are generally in the classification of Type B reactions.

3. The answer is A *[see* VI.A.1*].*

All the others are reportable on the MedWatch form. The National Childhood Vaccine Injury Act requires the use of a VAERS form to report vaccine-related injuries.

4. The answer is E *[see* VI.B.1*].*

Preventable ADRs can be the cause of serious medical problems that require intensive medical care. Although some preventable ADRs may appear obvious on review of a patient's medication history, this is not always the case.

5. The answer is E *[see* VI.B.4*].*

Marketing of these products does not depend on the manufacturers proving efficacy and safety of the products. No law requires reporting of subsequent problems. These products do not require an NDA. Although it is not required for healthcare professionals to report problems, it is essential that voluntary reporting takes place.

23

Medication Errors

Robert Cisneros

I. MEDICATION ERROR PROBLEM

A. The 2000 Institute of Medicine (IOM) report *To Err Is Human* brought the problem of errors in medicine to national attention.[1]

1. An estimated 44,000-98,000 **deaths per year** are caused by medical errors. **Of those deaths,** approximately 7,000 are the result of medication errors.

2. A call to action was given to improve patient safety.

B. In recent years, tragic medication errors have focused attention on concerns regarding patient safety.

1. A chemotherapy mix up at a major cancer center resulted in the death of a patient from a **fourfold overdose** daily for 4 days.

2. A child accidentally received an **intravenous rather than intramuscular** dose of long-acting penicillin and died.

3. A compounding error resulted in death of a child who received a tricyclic antidepressant at a dose **10 times greater than the dose prescribed** by physician.

4. Mixups with heparin vials which had **similar packaging, but different concentrations,** resulted in **overdoses** causing serious injury and several infant deaths.

II. ERROR DEFINITION.

The National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) defines a medication error as follows: “A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use.”[2]

III. TYPES OF ERRORS.

The following categories of errors have been used in numerous research studies.[3]

A. Wrong drug error. A drug that was not ordered for a patient was administered—for example, a patient accidentally received furosemide 40 mg orally. Possible causes: The pharmacist accidentally filled the patient's prescription for an antibiotic with furosemide; the pharmacist reached for the wrong bottle on the shelf and did not check the label carefully enough.

B. Extra dose error. A patient receives more doses of a drug than were ordered—for example, a patient was supposed to receive a medication with breakfast for 3 days but received it for 5 days. Possible cause: The patient's nurse was confused by the medication directions.

C. Omission error. A dose of a drug was not administered as ordered but was skipped—for example, a patient was supposed to receive digoxin 0.25 mg orally in

the morning but did not receive the dose. Possible cause: The patient's nurse was so busy that he or she forgot to administer the dose.
P.500

D. Wrong dose or wrong strength error. Either the wrong dose of a medicine or the wrong strength is administered—for example, the patient was supposed to receive warfarin 0.5 mg but received warfarin 5 mg instead. Possible causes: The pharmacist misread the label; the physician wrote the order as “warfarin .5 mg.” Another example: a patient was supposed to receive timolol 0.25% but was given timolol 0.5%. Possible cause: The pharmacist took the wrong product off of the shelf, confused by the concentrations.
E. Wrong route error. A patient receives a dose of a medication by a route that was not ordered by the physician—for example, a patient was supposed to receive prochlorperazine 10 mg intramuscularly but the drug was administered intravenously. Possible causes: The nurse misread the orders; the physician mistakenly wrote “IV” instead of “IM.”
F. Wrong time error. A patient does not receive a dose of medication at the time at which it was to be administered—for example, a hospitalized patient with diabetes is scheduled to receive a dose of insulin immediately before breakfast (at 7:00 A.M.) but the dose is given 2 hr after breakfast. Possible cause: The nurse was busy and could not give dose on time.
G. Wrong dosage form error. A patient receives a dose of medicine in a dosage form that was not intended—for example, nicotinic acid 500 mg tablets were ordered for a patient who instead receives nicotinic acid 500 mg slow-release capsules. Possible cause: The pharmacist did not carefully check the product or was confused by the label.
H. Other. Errors that do not fit into any of the other categories.

IV. COMMON ERROR HAZARDS

A. Dangerous abbreviations. Numerous common abbreviations and symbols have been associated with errors. Detailed lists are available from the Institute for Safe Medication Practices (ISMP) at http://www.jointcommission.org/SentinelEvents/forms. and the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) at http://www.jointcommission.org/PatientSafety/DoNotUseList/. JCAHO's accredited organizations are required to avoid using the potentially confusing abbreviations on its “Do Not Use” list.
1. U, IU: unit(s). The letter *U* can easily be misinterpreted as a number (e.g., 0 or 4), and serious harm has occurred with insulin and heparin as a result of this confusion. For example, a patient received 66 units of insulin instead of 6 units. The order, which was written for “6U” of regular insulin was misread as 66. The word *units* should be written out in full.

2. QD, Q.D., qd, q.d. **(daily).** These common abbreviations have been misinterpreted as “QID” or “qid” (four times daily) resulting in overdoses. The word *daily* should be written out in full.

3. Q.O.D, QOD, qod (every other day). These common abbreviations have been misinterpreted as QID (four times daily), resulting in overdoses. The words *every other day* should be written out completely.

4. Trailing zero. When a dose is ordered and followed with a decimal point and a zero, such as 2.0 mg or 25.0 mg, errors can occur. The decimal point may be missed and an overdose can occur. For example, warfarin 2.0 mg may be misinterpreted as 20 mg. Trailing zeros should be avoided, and the dose written without the additional zero—for example, warfarin 2 mg (instead of 2.0 mg).

5. Lack of leading zero. A drug's dose may be less than 1 mg, such as for digoxin. Often the dose is written without a leading zero: digoxin .25 mg instead of digoxin 0.25 mg. Errors have occurred because the decimal point is missed—for example, warfarin .5 mg may be interpreted as warfarin 5 mg. Leading zeroes should be included, so the dose is written as digoxin 0.25 mg or warfarin 0.5 mg.

6. MS, MSO_4 (morphine sulfate), $MgSO_4$ (magnesium sulfate). The abbreviations for morphine sulfate and magnesium sulfate are quite similar and can be confused. It is recommend that *morphine sulfate* and *magnesium sulfate* be written in out in full.

P.501

B. Other confusing symbols, abbreviations. There are numerous other hazardous symbols and abbreviations that should be used with caution when writing prescription orders and carefully examined when filling prescriptions. Examples include the following:

1. cc. Stands for cubic centimeters and is often used instead of mL. This has been misinterpreted as a 0 (zero); use mL.

2. µg. Used for micrograms—for example, levothyroxine 250 µg daily. The abbreviation has been mistaken for mg, and overdoses have occurred; better to use mcg or to write out the word *micrograms.*

3. <, >. Symbols for less than (<) and greater than (>) have been mistaken for each other or misinterpreted as numbers. Better to write out the words *less than* or *greater than.*

4. HCT. This abbreviation for “hydrocortisone” has been misinterpreted as hydrochlorothiazide. Better to write the word out completely.

5. HCl. The abbreviation for “hydrochloric acid” has been misinterpreted as KCl (potassium chloride). Better to write out the words completely.

C. Sound-a-like or look-a-like drug names. A detailed list of confusing drug names can be found in the 2004 *United States Pharmacopeia* publication “USP Quality Review” (www.usp.org/pdf/EN/patientSafety/qr792004-04-01.pdf). Another list is available from ISMP (www.ismp.org/Tools/confuseddrugnames.pdf).

1. Examples include the following:

a. Amitriptyline and aminophylline

b. Cisplatin and carboplatin

c. K-Dur and Cardura

2. To avoid these problems, the ISMP offers several suggestions, including the use of computerized reminders, name-alert stickers, and independent checks; opening the bottle in front of the patient, who can confirm the appearance; and reporting errors.

D. High-risk drugs. Certain **potent drugs** have been implicated in many serious and tragic medication errors. These have been called high-risk or high-alert drugs. A list of such medications can be found at www.ismp.org/Tools/highalertmedications.pdf. Examples include the following:

1. Blood-modifying agents such as heparin and warfarin. Errors have resulted in serious injury or death from hemorrhaging as a result of overdose (patient receiving 10 mg instead of 1 mg) or from blood clots as a result of underdose (patient receiving 0.5 mg instead of 5 mg).

2. Narcotics and sedatives. Central nervous system depression and respiratory arrest have resulted from errors with these drugs, such as diazepam 25 mg given intravenously instead of 2.5 mg.

3. Neuromuscular paralyzing agents such as succinylcholine and vecuronium. Accidental use or inadvertent use before adequate ventilation procedures were started have resulted in respiratory arrest and death.

4. Chemotherapy drugs. These drugs are associated with potent adverse effects, affecting numerous body systems, such as the immune, neurologic, and clotting systems. Deaths have occurred as a result of errors with these products. For example, vincristine was accidentally given to a child instead of vinblastine, resulting in death. Confusion over the dosing of cyclophosphamide resulted in a fatal fourfold overdose.

V. SEVERAL SAFETY TECHNIQUES OBSERVED IN COMMUNITY PHARMACIES[4]

A. Keep work procedures organized and simplified.

B. Don't work on several prescriptions at once, just one at a time.

C. Manage interruptions, don't be pressured to rush.

D. Smell check.

E. Bar code check.

F. Use a magnifying glass when needed.

G. Enhance the design of the facility.

VI. ROOT CAUSE ANALYSIS (RCA).

This is a structured process for identifying direct and indirect factors that contributed to a medication error. A framework for conducting an RCA is available at http://www.jointcommission.org/SentinelEvents/forms. See “Framework For Conducting a Root Cause Analysis.”

A. Important questions to ask:

1. What happened and why?

2. What were the contributing factors?

a. Age? Hours worked? Staffing?

b. Workload? Stress? Confusing names? Location on shelf?

c. Inadequate information? Communication?

d. Inadequate equipment?

e. Workplace atmosphere conducive to safety?

f. Inadequate training of pharmacist or technician?

B. Latent defect. A **weakness in a system** that does not immediately result in an error but, under the right set of circumstances, can contribute to a mistake. For example:

1. Stocking look-alike or sound-alike drugs next to each other, contributing to a pharmacist incorrectly filling a prescription.

2. Inadequate training of employees, contributing to an error in which an automated dispensing machine was used improperly and a patient received the wrong medication.

VII. NATIONAL SAFETY EFFORTS

A. JCAHO's National Patient Safety Goals for Accredited Organizations can be found at http://www.jointcommission.org/PatientSafety/NationalPatientSafetyGoals/. Hospital goals include:

1. Improve the accuracy of patient identification. Have two means of identifying the patient other than room number.

2. Improve communication among caregivers. Verify and read back telephone and oral orders.

3. Create a list of “do not use” abbreviations. Standardize the abbreviations used, and prohibit the use of those that are prone to confusion and misinterpretation.

4. Improve the safe use of medicines.

a. Limit the number of different concentrations available per drug product; standardize.

b. Develop methods of identifying and reviewing sound-alike and look-alike drugs, preventing errors with them.

c. All medications and containers should be properly labeled.

d. Reduce the likelihood of patient harm associated with the use of anticoagulation therapy.

5. Reduce the risk of infections.

a. Comply with all Centers for Disease Control and Prevention (CDC) recommendations for hand washing and hygiene.

b. Thoroughly investigate all serious adverse events and deaths associated with infection acquired in a healthcare setting.

Figure 23-1. The medication error form used by the *United States Pharmacopeia.* [Reprinted with permission of the *United States Pharmacopeia.*]

P.504

6. Keep accurate patient medication records and histories throughout the continuum of care.

a. Ensure that a patient's medication records are complete and accurate when he or she is referred or transferred within or between organizations.

b. Proper communication of accurate patient medication information is critical for everyone involved in the patient's care.

B. *The Five Million Lives Campaign* initiated by the Institute for Healthcare Improvement can be found at http://www.ihi.org/IHI/Programs/Campaign.

1. Purpose: "To protect patients from **five million incidents of medical harm** over the next two years (December, 2006-December, 2008)."

2. Twelve interventions were identified and can be found described in more detail at the website above. The interventions included:

a. Preventing **adverse drug events** through **medication reconciliation.**

b. Preventing **surgical site infections** by **appropriate care and anitbiotic use.**

c. Focus on preventing harm from **high risk medications** such as anticoagulants, sedatives, narcotics, and insulin.

d. Reduce **Methicillin-Resistant *Staphylococcus aureus* (MSRA) infections** through appropriate **evidence-based practices.**

C. The IOM in July 2006 released its report "Preventing Medication Errors." Several recommendations were made to improve patient safety including: enhancing role of patient in medication management, improving patient education, and increasing the use of technology, such as e-prescribing. This report can be accessed at www.iom.edu.

D. Medication error reporting. The reporting of medication errors provides critical safety feedback. Figure 23-1 shows the form used in the *United States Pharmacopeia's* error reporting program. Errors can be submitted anonymously via the Internet, by telephone, or by mail.

E. The “Sorry Works Coalition” (www.sorryworks.net) is an organization of various individuals (healthcare professionals, lawyers, insurance executives, concerned citizens, etc.) who promote the necessity of **disclosure and apology** following error. The coalition provides training and education programs.
F. The Institute for Safe Medication Practices (www.ismp.org) focuses its efforts on **medication error prevention and patient safety.** The ISMP publishes four different safety newsletters, provides consulting services, and presents numerous educational programs, services, and activities.
G. The National Patient Safety Foundation (www.npsf.org) represents **stakeholders from a broad array of disciplines,** including patients and families. The NPSF mission is focused on **improving patient safety.** It provides numerous resources, publications, and activities directed at improving the care of patients.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A major result in the 2000 Institute of Medicine (IOM) report is that

(A) pharmacists are not blamed for the majority of medical errors.
(B) surgeons make more mistakes than any other health professional.
(C) pharmacists make more mistakes than any other health professional.
(D) there is now more emphasis on error prevention.

View Answer***1. The correct answer is D[see].*****2. A pharmacist is presented a prescription for 250** mcg **of levothyroxine. Which of the following dosages would be equivalent to that amount?**

(A) 2.5 mg
(B) 0.25 gm
(C) 0.25 mg
(D) 25 gm

View Answer***2. The correct answer is C[see].*****3. A prescription is written for warfarin 1.0 mg. The community pharmacist accidentally dispenses 10 mg. The patient develops severe bleeding within 3 days and nearly dies. Which of the following is the most accurate assessment of this prescription?**

(A) A trailing zero is present in this prescription and could have contributed to the pharmacist's error.
(B) This is an example of a leading zero, which contributed to the error and the patient tragedy.
(C) Sound-alike medications contributed to this error.
(D) This does not qualify as an error based on the National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) definition.

View Answer***3. The correct answer is A[see].*****4. A hospital pharmacy begins stocking new intravenous mini-bags of a neuromuscular-blocking agent.**

The packaging is similar to a commonly used intravenous antibiotic. The addition of the new mini-bags was not widely communicated to all personnel. One weekend, several doses of this new product were accidentally dispensed in place of the intended doses of antibiotic. Several patients suffered respiratory arrest and one of the patients eventually died. What would a root cause analysis of this error find?

(A) The only cause of this error was a pharmacist who was not paying attention. The pharmacist should be dismissed.

(B) Poor communication practices is a latent defect in this pharmacy system and significantly contributed to the error.

(C) The pharmacy technicians are to blame for this error, not the pharmacist, because the technicians obtained the mini-bags from stock and placed the labels on the bags. The pharmacist checked only the technician's work. The technician should be dismissed.

(D) This is an example of an extra dose error.

View Answer***4. The correct answer is B[see].*****5. What do the following abbreviations MS, MSO_4 and $MgSO_4$ have in common?**

(A) common abbreviations for morphine sulfate

(B) common abbreviations for magnesium sulfate

(C) should not be used in JCAHO-accredited institutions

(D) approved abbreviations in most hospitals

View Answer***5. The correct answer is C[see].*****6. A major error in a hospital pharmacy resulted in a total parenteral nutrition solution being mistaken for a cardioplegic solution for coronary bypass surgery. Which of the following is true regarding the root cause analysis that was done at the hospital after the error?**

(A) The primary objective is to find out which pharmacist made the mistake that allowed this to take place.

(B) The result of the analysis would be the admission that an error had taken place.

(C) All factors that could have contributed to this error would be identified and analyzed.

(D) A root cause analysis would be inappropriate in this case.

View Answer***6. The correct answer is C[see].***P.506

ANSWERS AND EXPLANATIONS

1. The correct answer is D *[see* I.A.2*].*

The IOM report revealed alarming data on deaths related to medical errors. The report contributed to increased efforts to improve patient safety.

2. The correct answer is C *[see* III.D*].*

Although this may seem to be an elementary question and answer, a wrong dose error such as this could easily lead to a serious injury or death to a patient.

3. The correct answer is A *[see* IV.A.4*].*

Warfarin 1.0 mg. is an example of a trailing zero. JCAHO has included this in its “Do Not Use” list of abbreviations. However, in the community setting, it is a practice that can still be frequently seen on prescriptions. When a trailing zero is observed, much caution should be exercised in interpreting the prescription.

4. The correct answer is B *[see* VI.A.2*].*

Poor communication was a major contributing factor to this tragic series of errors. The drug was a high-risk drug and had similar packaging as another commonly used drug. These are two major ingredients for the serious error that took place. This does not absolve the technician and pharmacist totally from any blame but emphasizes the significant role that failure of communication played within this pharmacy system. The system was as much or more to blame than any individuals. Firing the individuals does not repair the problem of poor communication in the system but only sets the stage for a similar mistake to occur again.

5. The correct answer is C *[see* IV.A.6*].*

These abbreviations are included in JCAHO's “Do Not Use” list. Errors resulting in serious harm have occurred after mix ups with morphine and magnesium.

6. The correct answer is C *[see* VI.A.2*].*

A root cause analysis is not intended to focus on blame but on all factors that could have been related to this error. Factors might have included training of pharmacist and technicians, the actual drug order, and the label. The contribution of such factors might not be discovered if the focus is on only identifying which pharmacist, technician, or other professional is to blame.

24

Clinical Toxicology

John J. Ponzillo

I. OVERVIEW

A. This chapter is intended to provide the reader with an overview of the management of various toxic exposures. Emergency medical services (EMS) should be immediately contacted to provide advanced life support for patients with unstable vital signs resulting from a poisoning exposure. In addition, these patients should be referred to a hospital for follow-up. A nationwide toll-free poison center number became available. This number, 800-222-1222 is available 24 hr/day and should be used by healthcare professionals and the general public when dealing with exposures to potentially toxic substances.

B. Definitions

1. Clinical toxicology. Focuses on the effects of substances in patients caused by accidental poisonings or intentional overdoses of medications, drugs of abuse, household products, or various other chemicals

2. Intoxication. Toxicity associated with any chemical substance

3. Poisoning. A clinical toxicity secondary to accidental exposure

4. Overdose. An intentional exposure with the intent of causing self-injury or death

C. Epidemiology. In 2004, more than 2.4 million accidental and intentional poisonings were reported to the American Association of Poison Control Centers (AAPCC). The majority of poison exposures (84.1%) were accidental. However, 1183 of these exposures resulted in death. More information can be found at the AAPCC's Web site (www.aapcc.org).

D. Information resources

1. Computerized databases

a. Poisindex is a computerized CD-ROM database that is updated quarterly and is a primary resource for poison control centers.

2. Printed publications. Textbooks and manuals provide useful information regarding the assessment and treatment of patients exposed to various substances, although their usefulness is limited by the lag time of information published in the primary literature reaching updated editions.

a. Ellenhorn MJ, ed. Medical Toxicology: Diagnosis and Treatment of Human Poisonings, 2nd ed. New York, Elsevier Science, 1997.

b. Fraunfelder FT, Fraunfelder FW. Drug-Induced Ocular Side Effects, 5th ed. Little Rock: Butterworth-Heinemann, 2001.

c. Fraunfelder, Fraunfelder and Wiley. Clinical Ocular Toxicology. March 2008 6th edition Saunders

d. Goldfrank L, ed. Toxicologic Emergencies. 8th ed. New York: McGraw Hill, 2006.

e. Grant WM. Toxicology of the Eye, 4th ed. Springfield, IL: Charles C Thomas, 1995.

j. Olson KR, ed., with, Anderson IB, Benowitz NL, Blanc PD, et al. Poisoning and Drug Overdose, 5th ed. Stamford, CT, Appleton & Lange, 2006.

3. Internet[1]
a. Centers for Disease Control and Prevention (CDC) at www.cdc.gov
b. U.S. Food and Drug Administration (FDA) at www.fda.gov
c. National Library of Medicine at www.nlm.nih.gov
d. National Institute for Occupational Safety and Health (NIOSH) at www.cdc.gov/niosh
e. American Society of Health-System Pharmacists at www.ashp.org
f. Material Safety Data Sheets at www.msdssearch.com
g. U.S. Environmental Protection Agency (EPA) at www.epa.gov
h. Chemical Abstracts Service at www.cas.org
4. Poison control centers accredited by the AAPCC provide information to the general public and healthcare providers. These centers are the most reliable and up-to-date sources of information; thus the AAPCC's phone number (800-222-1222) should be readily available.

II. GENERAL MANAGEMENT

A. Supportive care and ABCs. Evaluating and supporting the vital functions (airway, breathing, and circulation [ABCs]) are the mandatory first steps in the initial management of drug ingestions. After the patient is stabilized, the specific issue(s) of poison management should be addressed.[2]

B. Treatment for patients with depressed mental status includes the following:

1. To rule out or treat hypoglycemia, 50 mL of 50% dextrose in adults and 1 mL/kg in children, intravenously (IV)
2. Thiamine 100 mg IV push (glucose can precipitate the Wernicke-Korsakoff syndrome in thiamine-deficient patients)
3. Naloxone (Narcan) 0.4-2 mg IV push, if opiate ingestion is suspected

C. Obtaining a history of exposure

1. Identify the substance(s) ingested, the route of exposure, the quantity ingested, the amount of time since ingestion, signs and symptoms of

overdose, and any associated illness or injury. Corroborate history and other physical evidence (e.g., pill containers) from prehospital providers.
2. Neurological examination evaluates any seizures, alterations in consciousness, confusion, ataxia, slurred speech, tremor, headache, or syncope.
3. Cardiopulmonary examination evaluates any syncope, palpitations, cough, chest pain, shortness of breath, or burning or irritation of the upper airway.
4. Gastrointestinal (GI) examination evaluates any abdominal pain, nausea, vomiting, diarrhea, or difficulty in swallowing.
5. Past medical history should include
a. Medications, including nonprescription (over-the-counter [OTC]) substances
b. Use of herbal medications
c. Alcohol or drug abuse
d. Psychiatric history
e. Allergies
f. Occupational or hobby exposures
g. Travel
h. Prior ingestions
i. Social history with potential for domestic violence or neglect
j. Last normal menstrual period or pregnancy

D. Routine laboratory assessment
1. Complete blood cell (CBC) count
2. Serum electrolytes
3. Blood urea nitrogen (BUN); serum creatinine (SCr)
4. Blood glucose
5. Urinalysis
6. Electrocardiogram (ECG)
7. Chest roentgenogram and/or kidneys, ureters, and bladder (KUB) x-ray
E. Toxicology laboratory tests
1. Advantages
a. Confirm or determine the presence of a particular agent
b. Predict the anticipated toxic effects or severity of exposure to some poisons
c. Confirm or distinguish differential or contributing diagnosis
d. Occasionally help guide therapy
2. Disadvantages
a. These tests cannot provide a specific diagnosis for all patients.
b. All possible intoxicating agents cannot be screened.
c. In critically ill patients, supportive treatment is needed before laboratory results of the toxicology screen are available.

d. Laboratory drug-detection abilities differ.
e. In general, only a qualitative determination of a substance or substances is necessary; however, quantitative levels of the following drugs are necessary to guide therapy:
(1) Acetaminophen
(2) Aminoglycosides
(3) Arsenic
(4) Carbamazepine (Tegretol)
(5) Carboxyhemoglobin
(6) Cyclosporine
(7) Digoxin (Lanoxin)
(8) Ethanol
(9) Ethylene glycol
(10) Iron
(11) Lead
(12) Lithium (Eskalith)
(13) Mercury
(14) Methanol
(15) Methemoglobin
(16) Methotrexate
(17) Phenobarbital
(18) Phenytoin (Dilantin)
(19) Salicylates
(20) Tacrolimus
(21) Theophylline
(22) Valproic acid (Depakene)
(23) Vancomycin
F. Skin decontamination should be performed when percutaneous absorption of a substance may result in systemic toxicity or when the contaminating substance may produce local toxic effects (e.g., acid burns). The patient's clothing is removed, and the areas are irrigated with copious quantities of water. Neutralization should not be attempted. For example, neutralizing acid burns with sodium bicarbonate will produce an exothermic chemical reaction, thereby exacerbating the patient's condition.
G. Gastric decontamination may be attempted when supportive care is begun. GI decontamination involves removal of the ingestant with emesis or lavage, the use of activated charcoal potentially to bind any ingestants, and the use of cathartics to hasten excretion and thereby limit absorption.

1. Emesis
a. Contraindications
(1) Children younger than 6 months of age
(2) Patients with central nervous system (CNS) depression or seizures

(3) Patients who have ingested a strong acid, alkali, or a sharp object
(4) Patients with compromised airway protective reflexes (including coma and convulsions)
(5) Patients who have ingested some types of hydrocarbons or petroleum distillates
(6) Patients who have ingested substances with an extremely rapid onset of action
(7) Patients with emesis after the ingestion
b. Syrup of ipecac. Owing to concerns of safety, efficacy and the delay of antidote administration, syrup of ipecac is no longer recommended for general use. Ipecac may be administered within 30 min of an ingestion and only on the advice of a poison control center.[3] There is no contraindication to the use of ipecac syrup: and There is substantial risk of serious toxicity to the victim: and There is no alternative therapy available or effective to decrease gastrointestinal absorption (e.g., activated charcoal); and There will be a delay of greater than 1 hour before the patient will arrive at an emergency medical facility and ipecac syrup can be administered within 30-90 minutes of the ingestion; and Ipecac syrup administration will not adversely affect more definitive treatment that might be provided at the hospital.
(1) Mechanism of action. The onset of emesis usually occurs within 30 min after syrup of ipecac. The effects last for approximately 2 hr and produce approximately three episodes of emesis in 60 min.
(2) Dosages. Patients 6-12 months of age, 5-10 mL; patients 1-12 years of age, 15 mL; patients older than age 12 years, 30 mL. Each dose of syrup of ipecac should be followed with 120-240 mL of water. The patient should be upright to avoid accidental aspiration and should be supervised.
(3) Adverse effects. Diarrhea, lethargy/drowsiness, and prolonged (> 1 hr) emesis
2. Gastric lavage
a. Use. Gastric lavage is infrequently used in patients who are not alert or have a diminished gag reflex. This procedure should also be considered in patients who are seen early after massive ingestions. This procedure is contraindicated in patients who have ingested acids, alkalis, or hydrocarbons. In addition, patients should not receive gastric lavage if they are at risk for GI perforation or if they are combative.
b. Procedure. Patients are placed in the left lateral decubitus position. Lavage is performed after a cuffed endotracheal tube is in place to protect the airway. After aspiration of the gastric contents, 250-300 mL of tap water or saline is instilled and then aspirated. The sequence should be repeated until the return is continuously clear for at least 2 L.
3. Activated charcoal adsorbs almost all commonly ingested drugs and chemicals and is usually administered to most overdose patients as quickly as possible. Commonly ingested substances not adsorbed include ethanol,

iron, lithium, cyanide, ethylene glycol, lead, mercury, methanol, organic solvents, potassium, strong acids, and strong alkalis.

a. Dosage. Activated charcoal (Actidose with sorbitol) is available as a colloidal dispersion with water or sorbitol. In adults, the dose of activated charcoal is 25-100 g; the dose in children 1-12 years of age is 25-50 g; the dose in children up to 1 year of age is 1 g/kg. Constipation has not been observed after the administration of a single dose of activated charcoal. Multiple doses of any cathartics should be avoided because they can cause electrolyte imbalances and/or dehydration. Toxic ingestions with drugs having an enterohepatic circulation (e.g., carbamazepine, theophylline, phenobarbital, tricyclic antidepressants, phenothiazines, digitalis) generally require that the charcoal be readministered every 6 hr to prevent reabsorption during recirculation.

b. Adverse effects. Charcoal aspiration and empyema have been reported in the literature. As such, charcoal should be withheld if patients are vomiting. Bowel obstruction may

occur with multiple doses of activated charcoal and/or patients who are receiving concomitant therapy with neuromuscular-blocking drugs.[4]

H. Whole-bowel irrigation has been shown to be effective under certain conditions, particularly when activated charcoal lacks efficacy. An isosmotic cathartic solution such as polyethylene glycol (GoLYTELY, Colyte) is used. The dosage is 1-2 L/hr given orally or by nasogastric tube until the rectal effluent is clear.

I. Forced diuresis and urinary pH manipulation may be used to enhance the elimination of substances, whose elimination is primarily renal, if the substance has a relatively small volume of distribution with little protein binding. However, the use of these methods is associated with fluid and electrolyte disturbances.

1. Alkaline diuresis promotes the ionization of weak acids, thereby preventing their reabsorption by the kidney, which facilitates the excretion of such weak acids. This procedure has been used in the management of patients who have ingested long-acting barbiturates such as phenobarbital or salicylic acid. Patients are given 50-100 mEq of sodium bicarbonate IV push, followed by a continuous infusion of 50-100 mEq of sodium bicarbonate in 1 L of 0.25%-0.45% normal saline, maintaining a urine pH of 7.3-8.5. Urine output should be 5-7 mL/kg/hr. Complications include metabolic alkalosis, hypernatremia, hyperosmolarity, and fluid overload.

J. Dialysis. In patients who fail to respond to the measures of decontamination already outlined, hemodialysis, and to a lesser extent peritoneal dialysis, may enhance drug elimination. Substances that are removed by hemodialysis generally are water soluble, have a small volume of distribution (< 0.5 L/kg), have a low molecular weight (< 500 daltons), and are not significantly bound to plasma proteins. Hemodialysis usually is

indicated for life-threatening ingestions of ethylene glycol, methanol, or paraquat. This technique also has been used to enhance the elimination of ethanol, theophylline, lithium, salicylates, and long-acting barbiturates.
K. Hemoperfusion is a technique in which anticoagulated blood is passed through (perfused) a column containing activated charcoal or resin particles. This method of elimination clears substances from the blood more rapidly than hemodialysis, but it does not correct fluid and electrolyte abnormalities, as does hemodialysis. Hemoperfusion, although more effective in removing phenobarbital, phenytoin, carbamazepine, methotrexate, and theophylline than hemodialysis, is less effective in removing ethanol or methanol. Complications of hemoperfusion include thrombocytopenia, leukopenia, hypocalcemia, hypoglycemia, and hypotension.

III. MANAGEMENT OF SPECIFIC INGESTIONS

A. Acetaminophen (Tylenol) is an antipyretic-analgesic that can produce fatal hepatotoxicity in untreated patients through the generation of a toxic metabolite.
1. Available dosage forms. Acetaminophen is available in a variety of OTC and prescription drug products.
2. Toxicokinetics. Acetaminophen is well absorbed from the GI tract and has a half-life between 2 and 3 hr. Less than 5% is excreted unchanged in the urine; the remainder is metabolized in the liver by the cytochrome P450 system.
3. Clinical presentation
a. Phase I (12-24 hr postingestion). Nausea, vomiting, anorexia, and diaphoresis
b. Phase II (1-4 days postingestion). Asymptomatic
c. Phase III (2-3 days in untreated patients). Nausea, abdominal pain, progressive evidence of hepatic failure, coma, and death

4. Laboratory data
a. Serum acetaminophen levels. Patients with levels greater than 150, 70, or 40 mg/mL at 4, 8, or 12 hr after ingestion require antidotal therapy with N-acetyl-L-cysteine (NAC) according to the Rumack-Matthews nomogram.
b. Baseline liver function tests should be done in all patients.
c. Renal function tests, including a BUN and SCr, should be done.
d. Coagulation studies include prothrombin time (PT), partial thromboplastin time (PTT), and bleeding time.
5. Treatment
a. Adult patients who have ingested > 10 g or children who have ingested > 200 mg/kg require treatment. Elderly and alcoholic patients have an increased susceptibility to acetaminophen hepatotoxicity.

b. The recommended treatment is GI decontamination with activated charcoal.

c. Antidotal therapy with NAC is indicated for patients with toxic blood levels of acetaminophen.

(1) NAC dosage is 140 mg/kg as a loading dose followed by 70 mg/kg every 4 hr for a total of 17 doses. NAC is administered either orally or via a nasogastric tube. NAC (Mucomyst) 20% contains 200 mg/mL. Each dose must be diluted 1:3 in either cola or fruit juice to mask the unpleasant taste and smell. The dose of NAC should be repeated if the patient vomits within 30 min of administration. Patients with severe nausea secondary to NAC may be pretreated with IV metoclopramide (Reglan) 10 mg every 6 hr. Metoclopramide acts as an antiemetic while increasing the rate of NAC absorption.

(2) IV NAC (Acetadote)

(a) Loading dose: 150 mg/kg over 60 min

(b) Maintenance dose: 50 mg/kg over 4 hr followed by 100 mg/kg over 16 hr

(c) Anaphylactoid reactions are observed in approximately 20% of patients. Caution should be exercised in patients with a history of asthma.

B. Alcohols[5]

1. Ethylene glycol

a. Available forms. Ethylene glycol commonly is used in antifreeze and windshield deicing solutions. This form is sometimes colorless and has a sweet taste.

b. Toxicokinetics. Ethylene glycol is hepatically metabolized by alcohol dehydrogenase to glycolaldehyde, which is metabolized by aldehyde dehydrogenase to glycolic acid. Glycolic acid is converted to glyoxylic acid, whose most toxic metabolite is oxalic acid.

c. Clinical presentation

(1) Stage I (0.5-12 hrs postingestion). Ataxia, nystagmus, nausea and vomiting, decreased deep tendon reflexes, and severe acidosis (more severe overdoses: hypocalcemic tetany and seizures, cerebral edema, coma, and death)

(2) Stage II (12-24 hrs postingestion). Tachypnea, cyanosis, tachycardia, pulmonary edema, and pneumonitis

(3) Stage III (24-72 hrs postingestion). Flank pain and costovertebral angle tenderness; oliguric renal failure

d. Laboratory data may reveal severe metabolic acidosis, hypocalcemia, and calcium oxalate crystals in the urinalysis.

e. Treatment

(1) Gastric lavage is performed within 30 min of ingestion.

(2) IV ethanol (EtOH) is used in situations in which fomepizole is not available.

(a) Indications include an ethylene glycol level > 20 mg/dL, suspicion of ingestion pending level, or an anion gap metabolic acidosis with a history of ingestion, regardless of the level.

(b) EtOH dosage
(i) An EtOH level of at least 100 mg/dL should be maintained.
(ii) Loading dose is 7.5-10 mL/kg of a 10% ethanol in dextrose 5% in water (D_5W) over 1 hr, followed by a maintenance infusion of 1.4 mL/kg/hr.
(iii) Infusion rates may need to be increased in patients receiving hemodialysis.

(3) Fomepizole (Antizol) is a potent inhibitor of alcohol dehydrogenase that can prevent the formation of the toxic metabolites of either methanol or ethylene glycol.
(a) Administer a loading dose of 15 mg/kg (up to 1 g) in 100 mL of D_5W or 0.9% sodium chloride (NaCl) infused over 30 min.
(b) Maintenance doses: 10 mg/kg every 14 hr for 4 doses, then increase to 15 mg/kg (to offset autoinduction phenomenon) until methanol or ethylene glycol levels are < 20 mg/dL.
(4) Pyridoxine (100 mg IV every day) and thiamine (100 mg IV every day) are cofactors that may convert glyoxylic acid to nonoxalate metabolites.
(5) Sodium bicarbonate is used as needed to correct the acidosis.
(6) Hemodialysis. EtOH infusion must be continued, and the rate of administration may need to be increased. Indications include ethylene glycol level > 50 mg/dL, congestive heart failure, renal failure, and severe acidosis.
2. Methanol
a. Available forms include gas-line antifreeze, windshield washer, and some sterno.
b. Toxicokinetics. Alcohol dehydrogenase converts methanol to formaldehyde, which is then converted to formic acid.
c. Clinical presentation
(1) Stage I. Euphoria, gregariousness, and muscle weakness for 6-36 hr, depending on the rate of formation of formic acid
(2) Stage II. Vomiting, upper abdominal pain, diarrhea, dizziness, headache, restlessness, dyspnea, blurred vision, photophobia, blindness, coma, cerebral edema, cardiac and respiratory depression, seizures, and death
d. Laboratory data include severe metabolic acidosis, hyperglycemia, and hyperamylasemia.
e. Treatment
(1) Gastric lavage. Charcoal has not been shown to absorb alcohols.
(2) IV EtOH (used in situations in which fomepizole is not available)
(a) Indications include any peak methanol level > 20 mg/dL, a suspicious ingestion with a positive history, or any symptomatic patient with an anion gap acidosis.
(b) Administration is the same as per ethylene glycol (see III.B.1).

(3) Folic acid administered at 1 mg/kg (maximum 50 mg) IV every 4 hr for 6 doses increases the metabolism of formate.
(4) Fomepizole (Antizol) (see III.B.1.e.(3))
(5) Sodium bicarbonate is used for severe acidosis.
(6) Hemodialysis is used for methanol levels > 50 mg/dL, severe and resistant acidosis, renal failure, or visual symptoms.
C. Anticoagulants[6], [7], [8] and [9]
1. Heparin/ Low Molecular Weight Heparin (LMWH)
a. Available dosage forms include parenteral dosage forms for IV and subcutaneous administration.
b. Toxicokinetics. Heparin has a half-life of 1-1.5 hr and is primarily metabolized in the liver. The newer LMWHs—enoxaparin (Lovenox), dalteparin (Fragmin), tinzaparin (Innohep)—have a longer half-life, especially in patients with renal failure.
c. Clinical presentation. Look for any signs or symptoms of bleeding or bruising.
d. Laboratory data. Obtain PTT, bleeding time, and platelet counts.
e. Treatment
(1) Stopping heparin administration for 1-2 hr and restarting therapy at a reduced dose can reverse mild over-anticoagulation.

(2) Severe overdoses may require the administration of protamine.
(a) Protamine combines with heparin and neutralizes it: 1 mg protamine neutralizes 100 U heparin.
(b) Protamine should be administered slowly, intravenously over 10 min. The maximum dose of protamine is 50 mg in any 10-min period.
(c) Considerable controversy exists about the method of reversing the over-anticoagulation with LMWHs. Some sources recommend the administration of protamine to neutralize part of the effects of these anticoagulants, whereas case reports reported successes with recombinant factor VII (NovoSeven).
(d) These overdoses should be referred to a hematologist and/or the poison control center.
2. Warfarin (Coumadin)
a. Available dosage forms include oral tablets and a solution for parenteral administration.
b. Toxicokinetics. Warfarin is well absorbed after oral administration. Its mean half-life is 35 hr; protein binding is 99%, with a 5-day duration of activity. Vitamin K-dependent clotting factors begin to decline 6 hr after administration, but therapeutic anticoagulation may require several days.
c. Clinical presentation includes minor bleeding, bruising, hematuria, epistaxis, and conjunctival hemorrhage. More serious bleeding includes GI, intracranial, retroperitoneal, and wound site.

d. Laboratory data include PT, international normalized ratio (INR), and bleeding time.
e. Treatment
(1) If PT or INR is slightly elevated, withhold warfarin for 24-48 hr; then reinstitute therapy with a reduced dosage.
(2) If PT or INR is elevated and bleeding, administer 10 mg of phytonadione (vitamin K) over 30 min. Patients who are bleeding may require the administration of blood products that contain clotting factors.
(3) For mild over-anticoagulation, follow American College of Chest Physicians (ACCP) guidelines.
(4) For patients with life threatening bleeding or intracranial hemorrhage, the American College of Chest Physicians recommends the use of prothrombin complex concentrates or recombinant factor VIIa to immediately reverse the INR.
D. Antidepressants
1. Tricyclic antidepressants (TCAs)
a. Available forms include amitriptyline (Elavil), nortriptyline (Aventyl), imipramine (Tofranil), desipramine (Norpramin), doxepin (Sinequan), protriptyline (Vivactil), and clomipramine (Anafranil).
b. Toxicokinetics. The compounds are hepatically metabolized, undergo enterohepatic recirculation, are highly bound to plasma proteins, and have an elimination half-life of approximately 24 hr.
c. Clinical presentation. Anticholinergic effects include mydriasis, ileus, urinary retention, and hyperpyrexia. Cardiopulmonary toxicity exhibits tachycardias, conduction blocks, hypotension, and pulmonary edema. CNS manifestations range from agitation and confusion to hallucinations, seizures, and coma.
d. Laboratory data. Blood level monitoring does not correlate well with clinical signs and symptoms of toxicity. Some authors suggest that electrocardiographic monitoring is a better guide to assessing the severity of ingestion.
e. Treatment
(1) GI decontamination. Syrup of ipecac is not recommended because patients may quickly become comatose, increasing the risk of aspiration. Activated charcoal is given every 6 hr.
(2) Alkalinization with sodium bicarbonate 1-2 mEq/kg to maintain an arterial pH of 7.45-7.55 decreases the free fraction of the absorbed toxins, while reversing some of the cardiac abnormalities.
(3) Phenytoin (Dilantin) and/or benzodiazepines may be required to control seizures. Phenytoin must be administered at a rate not exceeding 25 mg/min because of hypotensive side effects. (Fosphenytoin [Cerebyx] may be used because it has a lower incidence of hypotension than phenytoin.)

(4) Physostigmine 2 mg IV over 1 min may be used to reverse severe anticholinergic toxicity owing to these drugs. Because this antidote may cause asystole, the use of this antidote for TCA overdoses is declining.
2. Selective serotonin reuptake inhibitors (SSRIs)
a. Available forms (nontricyclic agents) include fluoxetine (Prozac), sertraline (Zoloft), and paroxetine (Paxil).
b. Toxicokinetics. SSRIs are well absorbed after oral administration. Peak levels occur within 2-6 hs. SSRIs are hepatically metabolized with a half-life between 8 and 30 hr.
c. Clinical presentation includes mild symptomatology. Patients may become agitated, drowsy, or confused. Seizures and cardiovascular toxicity are rare.
d. Laboratory data. ECG monitoring is recommended. Blood level monitoring is not recommended.
e. Treatment includes gastric lavage and supportive treatment. Some toxicologists may recommend the use of cyproheptadine (Periactin) to manage the serotonin syndrome, which may manifest as a result of these ingestions.
E. Benzodiazepines
1. Available forms include chlordiazepoxide (Librium), diazepam (Valium), flurazepam (Dalmane), midazolam (Versed), lorazepam (Ativan), alprazolam (Xanax), and triazolam (Halcion).
2. Toxicokinetics. These drugs are hepatically metabolized.
3. Clinical presentation includes drowsiness, ataxia, and confusion. Fatalities are rare.
4. Laboratory data. Drug level monitoring is not indicated.
5. Treatment
a. Supportive treatment includes gastric emptying, activated charcoal, and a cathartic.
b. Flumazenil (Romazicon) is given 0.2 mg IV over 30 sec; repeat doses of 0.5 mg over 30 sec at 1-min intervals for a maximum cumulative dose of 5 mg.
(1) Flumazenil has a short elimination half-life.
(2) Careful observation for resedation is necessary, especially for ingestions of long-acting benzodiazepines.
(3) Flumazenil is contraindicated in mixed overdose patients (particularly involving tricyclic antidepressants) in whom seizures are likely.
F. β-adrenergic antagonists
1. Available dosage forms. Class examples include propranolol (Inderal), metoprolol (Lopressor), and atenolol (Tenormin). Oral and parenteral dosage forms are available.
2. Toxicokinetics. All of the members within this class differ in regard to renal versus hepatic elimination, lipid solubility, and protein binding. Patients may become toxic owing to changes in organ function.

3. Clinical presentation includes hypotension, bradycardia, and atrioventricular block. Bronchospasm may occur, particularly with noncardioselective agents.
4. Laboratory data include serum electrolytes and blood glucose (patients may become hypoglycemic).
5. Treatment
a. GI decontamination includes gastric lavage and activated charcoal.
b. Glucagon is given 50-150 μg/kg as a loading dose over 1 min, followed by a continuous infusion of 1-5 mg/hr.
c. Epinephrine should be used cautiously in β-blocker overdoses. Unopposed α-receptor stimulation in the face of complete β-receptor block may lead to profound hypertension.
d. Calcium salts (see Calcium Channel Antagonists)
e. High Dose Insulin Dextrose (see Calcium Channel Antagonists)
G. Calcium channel antagonists
1. Available forms include verapamil (Calan), diltiazem (Cardizem), and the dihydropyridine class (nifedipine derivatives [Procardia]).

2. Toxicokinetics. Onset of action is approximately 30 min, whereas the duration is 6-8 hr. Several compounds are available as sustained-release dosage forms, which may contribute to prolonged toxicity.
3. Clinical presentation. Hypotension is common to all classes. Bradycardia and atrioventricular block are more commonly seen with ingestions of verapamil or diltiazem. Pulmonary edema and seizures (verapamil) have been reported.
4. Laboratory data include ECG and serum electrolytes.
5. Treatment
a. GI decontamination includes gastric lavage, activated charcoal, and whole-bowel irrigation (especially for ingestions with sustained-release products).
b. Calcium. Calcium chloride 10% (10-20 mL) IV push is given for the management of hypotension, bradycardia, or heart block.
c. Glucagon dosage is the same as for β-blocker overdose.
d. Combined insulin and dextrose administration has been used in selected cases. This should be used only in consultation with a poison control center.
e. Phosphodiesterase Inhibitors. Inamrinone or milrinone.
H. Cocaine
1. Available forms include alkaloid obtained from Erythroxylon coca.
2. Toxicokinetics. Cocaine is well absorbed after oral, inhalational, intranasal, and IV administration. Cocaine is metabolized in the liver and excreted in the urine.

3. Clinical presentation includes CNS and sympathetic stimulation (e.g., hypertension, tachypnea, tachycardia, nausea, vomiting, seizures). Death may result from respiratory failure, myocardial infarction, or cardiac arrest.
4. Laboratory data include cocaine and cocaine metabolite urine screens.
5. Treatment is supportive: benzodiazepines for sedation seizure treatment, Labetalol (Normodyne) for hypertension.

I. Corrosives

1. Available forms include strong acids or alkalis.
2. Toxicokinetics. Corrosives are well absorbed after oral and inhalational administration.
3. Clinical presentation. These compounds produce burns on contact.
4. Laboratory data. Arterial blood gases (ABGs), chest radiographs, and at least 6 hr of observation are required for inhalation exposure.
5. Treatment is decontamination. Exposed skin must be irrigated with water. Neutralization should be avoided because these reactions are exothermic and will produce further tissue damage.

J. Cyanide

1. Available forms include industrial chemicals and some nail-polish removers.
2. Toxicokinetics. The drug is rapidly absorbed after oral or inhalation exposure.
3. Clinical presentation includes headache, dyspnea, nausea, vomiting, ataxia, coma, seizures, and death.
4. Laboratory data include cyanide levels, ABGs, electrolytes, and an ECG.
5. Treatment.

a. Cyanide antidote kit

(1) Amyl nitrite Pearls are crushed and held under the patient's nostrils.
(2) Sodium nitrite 10 mL IV push. Converts hemoglobin to methemoglobin, which binds the cyanide ion.
(3) Sodium thiosulfate 50 mL of a 25% solution IV push. May be repeated if there is no response.

b. Oxygen
c. Sodium bicarbonate. As needed for severe acidosis
d. Hydroxycobalamin (Cyanokit)

(1) Adult dose is 5 grams IV over 15 minutes. Dose may be repeated for a total dose of 10 grams. No data are available for pediatric dosing.[7]

K. Digoxin (Lanoxin)

1. Available dosage forms include oral and parenteral.
2. Toxicokinetics. Digoxin is well absorbed, is primarily renally eliminated, and has a half-life of 36-48 hr. Its volume of distribution is 7-10 L/kg. Equilibration between serum level and myocardial binding requires 6-8 hr.

3. Clinical presentation includes confusion, anorexia, nausea, and vomiting in mild cases. In more severe cases, cardiac dysrhythmias are seen.
4. Laboratory data include serum digoxin levels, electrolytes, particularly serum potassium levels, and an ECG.
5. Treatment
a. Decontamination with activated charcoal is recommended.
b. Supportive therapy includes managing hyperkalemia or hypokalemia and inotropic support as needed.
c. Digoxin-specific Fab antibodies (Digibind). To determine the dosage, use the following formula

$$\text{Dose (vials)} = \frac{[\text{ingested digoxin (mg)} \times 0.8]}{0.6}$$

Each vial contains 40 mg of digoxin antibodies (Digibind) and should be reconstituted with 4 mL of sterile water.
L. Electrolytes
1. Magnesium
a. Available dosage forms include oral, rectal, and parenteral. Magnesium-containing cathartics (e.g., magnesium citrate) have been reported to produce hypermagnesemia in patients receiving repetitive doses with activated charcoal.
b. Toxicokinetics. Magnesium is found intracellularly and is renally eliminated.
c. Clinical presentation
(1) Mild: Deep tendon reflexes may be depressed; lethargy and weakness
(2) Severe: Respiratory paralysis and heart block; prolonged PR, QRS, and QT intervals
d. Laboratory data
(1) Mild: > 4 mEq/L
(2) Severe: > 10 mEq/L
e. Treatment is 10% calcium chloride 10-20 mL to temporarily antagonize the cardiac effects of magnesium. In severe cases, hemodialysis may be required.
2. Potassium
a. Available dosage forms are oral and parenteral.
b. Toxicokinetics. Potassium is primarily an intracellular cation. Changes in acid-base balance produce shifts in serum potassium values (e.g., a 0.1-U increase in serum pH produces a 0.1-0.7 mEq/L decrease in serum potassium values).
c. Clinical presentation includes cardiac irritability and peripheral weakness with minor increases. Cardiac dysrhythmias, including bradycardia, may progress to asystole.
d. Laboratory data. ECG data include peaked T waves and prolongation of the QRS complex.

e. Treatment

(1) Calcium. Administer calcium chloride 10% 10-20 mL to antagonize the cardiac effects of hyperkalemia.

(2) Sodium bicarbonate. 1-2 mEq/kg IV increases serum pH and causes an intracellular shift of potassium.

(3) Glucose and insulin. 50 mL of 50% dextrose and 5-10 U of regular insulin are administered via IV push to shift potassium from the extracellular fluid into the cells.

(4) Cation exchange resins bind potassium in exchange for another cation (sodium). Sodium polystyrene sulfonate (Kayexalate) is given 15 g/60 mL with 23.5% sorbitol in doses 15-30 g by mouth every 3-4 hr as needed until the hyperkalemia resolves. Alternatively, 50 g of sodium polystyrene sulfonate can be given rectally in 200 mL of sodium chloride as a retention enema.

(5) Hemodialysis is reserved for life-threatening hyperkalemia that does not respond to the above measures.

M. Iron (Fe)

1. Available dosage forms. Numerous OTC products are available. Toxicity is based on the amount of elemental iron ingested: sulfate salt 20% elemental Fe; fumarate salt 33% elemental Fe; and gluconate salt 12% elemental Fe.

2. Toxicokinetics. Iron is absorbed in the duodenum and jejunum.

3. Clinical presentation

a. Phase I. Nausea, vomiting, diarrhea, GI bleeding, hypotension

b. Phase II. Clinical improvement seen 6-24 hr postingestion

c. Phase III. Metabolic acidosis, renal and hepatic failure, sepsis, pulmonary edema, and death

4. Laboratory data include serum Fe levels, total iron-binding capacity (TIBC; is controversial), ABGs, liver function tests (LFTs), hemoglobin, and hematocrit. Radiological evaluation of the abdomen notes the presence of radiopaque pills.

5. Treatment

a. Decontamination. For ingestions > 40 mg/kg. Gastric lavage using sodium bicarbonate is of questionable efficacy. Whole-bowel irrigation is used for large ingestions.

b. Supportive treatment

c. Deferoxamine (Desferal) is used to chelate iron. Administer 25-50 mg/kg up to a dose of 1 g, and observe for a red color in the urine. Then administer at a rate of 15 mg/kg/hr up to a maximum dose of 6 g/day. Continue until serum iron is within the therapeutic range.

N. Isoniazid (INH)

1. Available dosage forms include oral and parenteral.

2. Toxicokinetics. INH is well absorbed orally. Peak levels are within 1-2 hr postingestion. Isoniazid is hepatically metabolized.
3. Clinical presentation includes nausea, vomiting, slurred speech, ataxia, generalized tonic-clonic seizures, and coma.
4. Laboratory data include severe lactic acidosis, hypoglycemia, mild hyperkalemia, and leukocytosis.
5. Treatment
a. Decontamination. Avoid emesis because patients are at high risk for developing seizures; for severe ingestions use activated charcoal gastric lavage.
b. Pyridoxine, which reverses INH-induced seizures, is given in gram doses equivalent to the amount of isoniazid ingested. Pyridoxine is mixed as a 10% solution in D5W and infused over 30-60 min.
c. Sodium bicarbonate corrects the acidosis.

O. Lead
1. Available forms include lead-containing paint or gasoline fume inhalation.
2. Toxicokinetics. Lead has slow distribution, with a half-life of approximately 2 months.
3. Clinical presentation includes nausea, vomiting, abdominal pain, peripheral neuropathies, convulsions, and coma.
4. Laboratory data include anemia and an elevated blood-lead level.
5. Treatment
a. Edetate calcium disodium (calcium disodium Versenate) is given 50-75 mg/kg/day intramuscularly (IM) or via slow IV in 4 divided doses.
b. Dimercaprol (BAL) is given 4 mg/kg IM every 4 hr for 3-5 days.
P. Lithium (Eskalith)
1. Available dosage forms include liquid, capsules, and tablets (immediate and sustained release).
2. Toxicokinetics. Lithium is well absorbed after oral administration. It is not appreciably bound to plasma proteins and has a small volume of distribution (V_d) of 0.5 L/kg. Elimination is renal, with a half-life of 14-24 hr.
3. Clinical presentation
a. Mild: Polyuria, blurred vision, weakness, slurred speech, ataxia tremor, and myoclonic jerks
b. Severe: Delirium, coma, seizures, and hyperthermia
4. Laboratory data
a. Therapeutic range: 0.6-1.2 mEq/L
b. Mild toxicity: 1.5-2.5 mEq/L
c. Moderate toxicity: 2.5-3 mEq/L
d. Severe toxicity: > 3 mEq/L
5. Treatment

a. Supportive care, including basic life support and fluid and electrolyte replacement
b. Decontamination
(1) Syrup of ipecac not recommended
(2) Activated charcoal ineffective
(3) Sodium polystyrene sulfonate has been effective in experimental models. Need to monitor potassium levels.
(4) Whole-bowel irrigation for large ingestions, especially those involving sustained-release products
(5) Hemodialysis for severely symptomatic patients with acute exposure levels > 2.5 mEq/L or chronic levels > 1.5 mEq/L. Note: Lithium levels may rise after dialysis owing to a rebound effect.
Q. Opiates
1. Available dosage forms include oral immediate-release and sustained-release preparations as well as parenteral agents.
2. Toxicokinetics. Some agents have prolonged elimination half-lives (e.g., heroin, methadone).
3. Clinical presentation includes respiratory depression and a decreased level of consciousness. Rare effects include hypotension, bradycardia, and pulmonary edema. Seizures have been reported in patients with renal dysfunction in individuals who are receiving meperidine owing to the accumulation of the metabolite normeperidine.
4. Laboratory data include baseline ABGs and toxicology screens.
5. Treatment
a. Naloxone is given 0.4-2 mg every 5 min up to 10 mg and 0.03-0.1 mg/kg in pediatric patients. Naloxone has a very short half-life, and resedation is a concern in patients overdosing on long-acting opioids or sustained-release dosage forms.

b. Nalmefene (Revex) has a half-life of 4-8 hr. Initial dosages are 0.5 mg/70 kg. A follow-up dose 2-5 min later is 1 mg/70 kg.
R. Organophosphates
1. There are a variety of available forms; they are usually pesticides or chemical warfare agents.
2. Toxicokinetics. Organophosphates are absorbed through the lungs, skin, GI tract, and conjunctiva.
3. Clinical presentation includes excessive cholinergic stimulation.
4. Laboratory data include red blood cell acetylcholinesterase activity.
5. Treatment
a. Decontamination
b. Atropine is given 0.5-2 mg IV to reverse the peripheral muscarinic effects.

c. Pralidoxime (2-PAM; Protopam) is given 1 g IV over 2 min and repeated in 20 min as needed.

S. Salicylates

1. Available dosage forms include a variety of OTC products: oral, rectal, and topical.

2. Toxicokinetics. Salicylates are well absorbed after oral administration. The half-life is 6-12 hr at lower doses. In overdose situations, the half-life may be prolonged to more than 20 hr.

3. Clinical presentation includes nausea, vomiting, tinnitus, and malaise (mild toxicity). Lethargy, convulsions, coma, and metabolic acidosis appear in more severe overdoses. Potential complications from therapeutic and toxic doses include GI bleeding, increased PT, hepatic toxicity, pancreatitis, and proteinuria.

4. Laboratory data for the following 6-hr postingestion levels are:

a. 40-60 mg/dL: tinnitus

b. 60-95 mg/dL: moderate toxicity

c. More than 95 mg/dL: severe toxicity

d. With the presence of acidemia and aciduria, evaluate ABGs.

e. In addition, laboratory evaluation may show leukocytosis, thrombocytopenia, increased or decreased serum glucose and sodium, hypokalemia, and increased serum BUN, creatinine, and ketones.

5. Treatment

a. Decontamination. Repetitive doses of activated charcoal every 6 hr, with 1 dose of cathartic for patients who ingested > 150 mg/kg. Whole-bowel irrigation for large ingestions.

b. Alkaline diuresis is given as noted in decontamination section to enhance salicylate excretion. This is indicated for levels> 40 mg/dL.

c. Hemodialysis is used for severe intoxications when serum levels are > 100 mg/dL. This method of decontamination is much better than repetitive doses of activated charcoal.

d. Fluid and electrolyte replacement is administered as needed.

e. Vitamin K (Aquamephyton) and fresh frozen plasma are used to correct any coagulopathy.

T. Snake bites

1. Types. There are numerous species of snakes found worldwide. The venomous snakes found in North America include the following: rattlesnake, cottonmouth, copperhead, and coral. Because patients may be exposed to more exotic snakes, a herpetologist should be consulted for a more definitive identification.

2. Toxicokinetics. Onset of symptomatology depends on the species of snake and the patient's underlying medical condition.

3. Clinical presentation includes nausea; vomiting; diarrhea; syncope; tachycardia; and cold, clammy skin. Local findings include pain, edema, and erythema. More severe envenomations can lead to severe tissue injury, compartment syndrome, and shock.

4. Laboratory data
a. CBC and platelet count
b. Coagulation profile
c. Fibrin degradation products
d. Electrolytes
e. BUN, SCr, and urinalysis
5. Treatment
a. Supportive. Move the patient away from striking distance of the snake. Ideally, the patient should be transported to a medical facility as soon as possible. Constrictive clothing, rings, watches, etc. should be removed. Tetanus immunization should be assessed, and surgical intervention may be necessary for severe cases.
b. Antivenoms
(1) Antivenin (Crotalidae) polyvalent is a horse-derived product that has been reported to produce allergic reactions. For mild bites, the recommended dose is 5-10 vials; moderate, 10-20; and severe envenomations may require 20 or more vials.
(2) Crotalidae polyvalent immune Fab is a polyvalent antivenin made from sheep sources. The initial dose is 4-6 vials diluted in 250 mL of 0.9% normal saline (NS) administered over 1 hr. Additional doses may be required for severe envenomations.
U. Theophylline
1. Available dosage forms include liquid, sustained-release tablets and capsules as well as parenteral forms.
2. Toxicokinetics. Well absorbed orally with a V_d of approximately 0.5 L/kg. Theophylline is hepatically metabolized and has a half-life of 4-8 hr. Theophylline clearance depends highly on age, concomitant disease states, and interacting drugs.
3. Clinical presentation includes nausea, vomiting, seizures, and cardiac dysrhythmias. Chronic toxicity carries a poorer prognosis than acute toxicity.
4. Laboratory data. Therapeutic theophylline levels are 5-20 μg/mL. Hyperglycemia and hypokalemia are seen with acute ingestions. Other useful laboratory tests include serum electrolytes, BUN, creatinine, hepatic function, and ECG monitoring.
5. Treatment
a. Supportive therapy includes maintaining an airway and treating seizures and dysrhythmias as they occur.
b. Decontamination. Syrup of ipecac not recommended.
c. Activated charcoal (repetitive doses) to enhance elimination. Whole-bowel irrigation for massive ingestions (especially with sustained-release products). Charcoal hemoperfusion is used in unstable patients who are in

status epilepticus. Hemodialysis is used when hemoperfusion is unavailable.

d. β-adrenergic antagonists (e.g., esmolol, Brevibloc) are used to treat the hypotension, tachycardia, and dysrhythmias caused by elevated cyclic adenosine monophosphate levels.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

1. A physician receives a call from the parent of a 2-year-old child who has ingested an unknown quantity of morphine controlled-release tablets and is now unconscious. The physician's initial recommendation is to

(A) call emergency medical services (EMS) and have the child taken to the hospital emergency department.
(B) administer 1 g/kg of activated charcoal with sorbitol.
(C) administer syrup of ipecac 15 mL by mouth to induce vomiting.
(D) suggest that the child receive emergency hemodialysis.
(E) suggest that the child receive acid diuresis with ammonium chloride.

View Answer*1. The answer is A***[see**I.A**].2. A grandfather arrives at your pharmacy asking to purchase a bottle of syrup of ipecac to keep in his home in the event of a poisoning when grandchildren are visiting. What should you tell him?**

(A) Administer 15 mL of syrup of ipecac at the first sign of an ingestion.
(B) Syrup of ipecac is no longer recommended by the American Association of Poison Control Centers and the American Academy of Pediatrics.
(C) Provide him with the toll-free number for the poison control center.
(D) Both B and C.

View Answer*2. The answer is D*[seeII.G.1.a].**3. An unconscious patient is brought into the emergency department. The patient is given 50** mL **of 50% dextrose in water, thiamine 100** mg **IV, followed by naloxone 1** mg**, at which point he awakens. This patient most likely has overdosed on which of the following substances?**

(A) methanol

(B) amitriptyline

(C) cocaine

(D) haloperidol

(E) heroin

View Answer*3. The answer is E*[seeIII.Q.5].**4. Contraindications to the administration of syrup of ipecac include which of the following?**

(A) an unconscious patient

(B) a patient who is experiencing a generalized tonic-clonic seizure

(C) a patient who has ingested a caustic substance

(D) All of the above

(E) None of the above

View Answer*4. The answer is D*[seeII.G.1].the answer to question 2**5. An unconscious patient is brought to the emergency department with a history of an unknown drug overdose. Which of the following actions should the physician perform?**

(A) administer 50 mL of 50% dextrose, thiamine 100 mg IV push, and naloxone 0.4 mg IV push

(B) protect the patient's airway and ensure that vital signs are stable

(C) order the following laboratory tests: complete blood count (CBC), electrolytes, and a toxicology screen

(D) All of the above

View Answer*5. The answer is D*[seeII].**6. A patient who overdoses on acetaminophen is admitted to the hospital for antidotal therapy with N-acetyl-L-cysteine (NAC). The patient has the following medication orders: NAC 140** mg**/kg loading dose followed by 70** mg**/kg for a total of 17 doses, ranitidine 50** mg **IV every 8 hr, prochlorperazine 10** mg IM **every 6 hr as needed for nausea, thiamine 100** mg **IV every day for 3 doses, and Darvocet N-100 1-2 tablets every 4 hr as needed for headache. What is the best course of action?**

(A) Call the physician to increase the dosage of ranitidine to 50 mg IV every 6 hr.

(B) Call the physician to have the Darvocet N-100 discontinued.

(C) Call the physician to initiate hemodialysis therapy.

(D) Have the patient prophylactically intubated to protect the airway.

(E) Administer ethanol 10% at a loading dose of 7.5 mL/kg over 1 hr, followed by a continuous infusion of 1.4 mL/kg/hr for 48 hr.

View Answer*6. The answer is B*[seeIII.A].OTCP.524

7. Ethyl alcohol (EtOH) is administered to patients who have ingested either ethylene glycol or methanol because EtOH

(A) helps sedate patients.

(B) increases the metabolism of ethylene glycol and methanol.

(C) blocks the formation of the toxic metabolites of ethylene glycol and methanol.

(D) increases the renal clearance of ethylene glycol and methanol.

(E) is not an antidote for ethylene glycol or methanol overdoses.

View Answer*7. The answer is C***[see**III.B**].8. A patient with renal failure is inadvertently given 3 doses of potassium chloride 40** mEq **IV in 100** mL **of 0.9% sodium chloride over a 3-hr period. This error is immediately discovered and a STAT serum potassium level is 8.0** mEq**/L. The patient is bradycardic with a markedly prolonged QRS complex. The patient should receive which of the following?**

(A) calcium chloride 10% 10 mL IV push

(B) sodium bicarbonate 50 mEq IV push

(C) insulin 10 U and 50% dextrose 50 mL IV push

(D) sodium polystyrene sulfonate 30 g by mouth every 3 hr for 4 doses

(E) None of the above

View Answer*8. The answer is A***[see**III.L.2**].9. Parenteral calcium is used as an antidote for which of the following situations?**

(A) verapamil overdoses

(B) hyperkalemia

(C) cocaine intoxication

(D) verapamil overdoses and hyperkalemia

View Answer*9. The answer is D***[see**III.GIII.L.2**].10. A 65-year-old woman with normal renal function is administered a 0.25** mg **dose of digoxin IV push. A serum level obtained 1 hr after drug administration is 5 ng/**mL**. Your recommendation to the physician is which of the following?**

(A) Administer 2 vials of digoxin immune antibodies STAT.

(B) Administer repetitive doses of activated charcoal.

(C) Call a nephrologist, and put the patient on hemodialysis.

(D) Repeat the serum digoxin level 6-8 hr after the dose, and reassess the patient.

View Answer*10. The answer is D***[see**III.K**].11. A 16-year-old woman is reported to have overdosed on 40 sustained-release theophylline tablets. She is transported to the emergency department, where gastric lavage was performed and she was given one dose of activated charcoal. An initial theophylline level is 42** µg/mL**, but a follow-up level in the intensive care unit (ICU) is 95** µg/mL**. What is the most appropriate course of therapy?**

(A) charcoal hemoperfusion and multiple-dose activated charcoal

(B) syrup of ipecac administration

(C) forced alkaline diuresis

(D) nasogastric administration of sodium-polystyrene sulfonate

View Answer*11. The answer is A* **[see** III.T**].12. A 23-year-old man is admitted to the intensive care unit (ICU) after ingesting 20 acetaminophen tablets 500** mg **with a six-pack of beer. He was initially awake and alert in the emergency department and was given one dose of activated charcoal. His initial acetaminophen level taken approximately 2 hr after ingestion is 90** µg/mL**. What would be the most appropriate course of action?**

(A) Administer repeated doses of activated charcoal and sorbitol.

(B) Administer syrup of ipecac.

(C) Administer a loading dose of N-acetyl-L-cysteine (NAC), and repeat the acetaminophen level in 4 hr.

(D) Discharge the patient to home.

View Answer*12. The answer is C* **[see** III.A**].**mg**13. An overdose victim presents to the emergency department with an elevated heart rate, decreased blood pressure, dilated pupils, and lethargy. Upon arrival to the intensive care unit (ICU), she has a generalized tonic-clonic seizure that is treated with IV diazepam and fosphenytoin. Which of the following is the most likely intoxicant?**

(A) ethyl alcohol

(B) methanol

(C) acetaminophen

(D) oxycodone

(E) amitriptyline

View Answer*13. The answer is E* **[see** III.D**].**P.525

ANSWERS AND EXPLANATIONS

1. The answer is A [see I.A].

Patients with unstable vital signs should be taken to an emergency department for immediate treatment.

2. The answer is D [see II.G.1.a].

Induced vomiting is no longer an acceptable option of managing poisonings at home because it is a relatively ineffective method of removing toxins and results in a delay in administering antidotal therapy. It is important to council patients on poison prevention and to give parents and other friends and relatives the toll-free number for the poison control center. Parents should also know basic first aid and cardiopulmonary resuscitation (CPR).

3. The answer is E [see III.Q.5].

Naloxone reverses the effects of opioid receptor agonists, such as heroin, morphine, and propoxyphene.

4. The answer is D [see II.G.1].

Contraindications to ipecac include the three Cs: caustics, conscious, and convulsions; see also the answer to question 2. The use of syrup of ipecac is reserved for rare circumstances and only under the direction of the poison control center and/or a physician. These are new recommendations and many parents, relatives, and friends may have this product in their medicine cabinets.

5. The answer is D [see II].

The management of unconscious overdose patients involves aggressive support of vital signs and the administration of empiric antidotal therapy, while obtaining various laboratory tests to determine the nature of the overdose.

6. The answer is B [see III.A].

Darvocet N-100 is an acetaminophen-containing product that should not be given to a patient with documented acetaminophen toxicity. Be aware particularly of OTC products containing acetaminophen.

7. The answer is C [see III.B].

Ethanol saturates alcohol dehydrogenase and prevents the formation of the toxic metabolites of either ethylene glycol or methanol, however this antidote is falling out of favor owing to its adverse metabolic and central nervous system effects. Fomepizole (Antizol), a specific inhibitor of alcohol dehydrogenase, is becoming the preferred antidote for methanol or ethylene glycol overdoses. Ethanol may be used in situations in which fomepizole is not available.

8. The answer is A [see III.L.2].

All of the selections are used to manage hyperkalemia. Although, in an unstable patient, the cardiac effects of hyperkalemia must first be reversed with intravenous calcium.

9. The answer is D [see III.G; III.L.2].

Parenteral calcium is used to reverse the cardiac effects of calcium channel blocker overuse and hyperkalemia.

10. The answer is D [see III.K].

The plasma-tissue distribution phase for digoxin is 6-8 hr postadministration. Sampling digoxin levels sooner may give a falsely elevated level. Only symptomatic patients should receive digoxin immune antibodies. Hemodialysis is of no value in managing digoxin overdoses.

11. The answer is A [see III.T].

Large ingestions of sustained-release products may act as drug reservoirs, necessitating aggressive measures to remove the toxin.

12. The answer is C [see III.A].

Large acetaminophen ingestions (> 140 mg/kg) may be fatal if unrecognized. The Rumack-Matthew nomogram requires a 4-hr level to

accurately assess the potential for toxicity. If the 4-hr level is in the toxic range, the full course of NAC therapy should be administered.

13. The answer is E [see III.D].

Tricyclic antidepressant overdoses will produce seizures, hypotension, mydriasis, hypotension, and ventricular dysrhythmias. The cardiac and CNS effects of tricyclic antidepressant toxicity will respond to bicarbonate therapy. Opiates such as oxycodone will produce miosis.

25

Federal Pharmacy Law

Robert C. Pavlan Jr.

James A. Boyd

I. FEDERAL CONTROLLED SUBSTANCES ACT

A. Schedules of controlled substances. Certain drugs have a potential for abuse that leads to physical or psychological dependence. As a result, the U.S. federal government has placed these drugs into schedules (I, II, III, IV, and V) and refers to them as controlled substances. The Attorney General of the United States has the authority to add or remove a drug or substance from one of the federal schedules, or to transfer a drug from one federal schedule to another. The federal schedules are updated and published annually by the federal government.

1. Schedule I (CI; C-I) Schedule I drugs may not be kept in a pharmacy nor dispensed pursuant to a prescription (except for properly registered facilities for investigative or research purposes). A controlled substance analogue of a drug in any federal schedule, commonly referred to as a "designer drug," is considered a schedule I substance to the extent intended for human consumption. Required findings by the government for placement of a drug into schedule I include:

a. The drug or other substance has a high potential for abuse.

b. The drug or other substance has no currently accepted medical use in treatment in the United States.

c. There is a lack of accepted safety for use of the drug or other substance under medical supervision.

2. Schedule II (CII; C-II). Required findings for placement of a drug into schedule II include:

a. The drug or other substance has a high potential for abuse.

b. The drug or other substance has a currently accepted medical use in treatment in the United States or a currently accepted medical use with severe restrictions.

c. Abuse of the drug or other substance may lead to severe psychological or physical dependence.

3. Schedule III (CIII; C-III). Required findings for placement of a drug into schedule III include:

a. The drug or other substance has a potential for abuse less than the drugs or other substances in schedules I and II.

b. The drug or other substance has a currently accepted medical use in treatment in the United States.

c. Abuse of the drug or other substance may lead to moderate or low physical dependence or high psychological dependence.

4. Schedule IV (CIV; C-IV). Required findings for placement of a drug into schedule IV include:

a. The drug or other substance has a low potential for abuse relative to the drugs or other substances in schedule III.

b. The drug or other substance has a currently accepted medical use in treatment in the United States.

c. Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in schedule III.
5. Schedule V (CV; C-V). Required findings for placement of a drug into schedule V include:
a. The drug or other substance has a low potential for abuse relative to the drugs or other substances in schedule IV.
b. The drug or other substance has a currently accepted medical use in treatment in the United States.
c. Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in schedule IV.

B. Registration requirements. This Act regulates the use of controlled substances by requiring all entities that lawfully handle them to register with the federal government, specifically, the Drug Enforcement Administration (DEA).
1. Entities that must register
a. Manufacturers and **wholesalers** of controlled substances must register with the DEA initially and reregister every year thereafter.
b. Dispensers (practitioners and pharmacies) of controlled substances must register with the DEA initially and reregister every 3 years thereafter. Pharmacists, pharmacy interns, pharmacy technicians, and all other employees or agents of a pharmacy do not have to register, providing the pharmacy is properly registered and the employee or agent is acting in the usual course of employment or business.
c. All other entities that lawfully handle any controlled substance must register with the DEA, including researchers, clinics and laboratories, and teaching institutions.
2. Separate registration for separate activities. Every entity that engages in one of the following activities must register with the DEA. A separate registration is required for each activity, with certain exceptions (e.g., a manufacturer of a schedule of a controlled substance is allowed to distribute that schedule without being registered as a distributor).
a. Manufacturing controlled substances
b. Distributing controlled substances
c. Dispensing controlled substances listed in schedules II-V (e.g., practitioners, pharmacies)
d. Conducting research with controlled substances listed in schedules II-V
e. Conducting instructional activities with controlled substances listed in schedules II-V
f. Conducting a narcotic treatment program using any narcotic drug listed in schedules II, III, IV, or V
g. Conducting research and instructional activities with controlled substances listed in schedule I
h. Conducting chemical analysis with controlled substances listed in any schedule
i. Importing controlled substances
j. Exporting controlled substances

k. Participating in maintenance or detoxification treatment and mixing, preparing, packaging, or changing the dosage form of a narcotic drug listed in schedules II, III, IV, or V for use in maintenance or detoxification treatment by another narcotic treatment program.

3. Separate registrations for separate locations. Each principal place of business of a registrant having more than one location must have its own registration certificate. Each pharmacy, chain pharmacy, and hospital that dispenses controlled substances must have its own registration certificate. Registration is not required for an office that is used by a registrant where controlled substances are neither stored nor dispensed.

a. Warehouses. A warehouse where controlled substances are stored by or on behalf of a registrant is not required to register unless one of the following occurs:

(1) Controlled substances are directly distributed from the warehouse to a registered location different than the location from which the substances were shipped.

(2) Controlled substances are directly distributed from the warehouse to a person or entity not required to register under the Act.

4. Registration procedure. Applications to become registered must be submitted to the DEA on the appropriate form with the required fee, information, and signature of one of the following:

a. The individual who owns and operates the entity, if doing business as an individual

b. A partner of the applicant, if a partnership

c. An officer of the applicant, if a corporation, corporate division, association, trust, or other entity

d. One or more individuals who have been granted a power of attorney by an applicant. A **power of attorney** allows one to lawfully act in place of another. The power of attorney must be signed by one of the individuals listed above in a-c and by the individual receiving the power of attorney. The power of attorney remains valid until revoked by the applicant.

5. Registration action by the DEA. If an application is complete, it will be accepted for filing. If it is defective, the DEA will return the application with a statement indicating the reason for its nonacceptance. The application may be corrected and resubmitted at any time.

a. Issuance of certificate of registration. A certificate of registration will be issued by the DEA when it determines that the registration is required by law in order to conduct such activity (e.g., manufacturing, distributing, or dispensing a controlled substance). The certificate must be conspicuously maintained and readily retrievable at the registered location.

b. Denial of registration. If the DEA determines that a registration is not required by law, it will issue an Order To Show Cause why the registration should not be denied. The applicant may request a hearing and explain why the certificate of

registration should be issued. After the hearing, the DEA may deny the application or issue the certificate.

6. Modification of registration. A registrant may submit a letter of request to the DEA seeking to modify its registration. A modification may be sought when there is a change in the name or address that appears on the certificate, or when the pharmacy seeks DEA approval to dispense additional controlled substances [if initially authorized to only dispense a particular schedule(s) of controlled substances].

7. Transfer of registration. A registration to dispense controlled substances may not be transferred to any other person or entity except when the ownership of a pharmacy is being transferred from one entity to another. In such a case, controlled substances in schedules II-V must be properly disposed of or transferred to the new entity.

8. Suspension or revocation of registration. The DEA may suspend or revoke any registration. The DEA must first issue an Order To Show Cause (upon the registrant) why the registration should not be revoked or suspended. The registrant may request a hearing to explain why the registration should not be suspended or revoked. After a hearing, the DEA may suspend, revoke, or take no action on the registration.

a. Order of suspension or revocation. After a registrant has received an order suspending or revoking its registration, it must take the following action:

(1) Immediately deliver its certificate of registration and any DEA 222 order forms in its possession to the nearest office of the DEA

(2) As instructed by the DEA, either:

(a) deliver all controlled substances in its possession to the nearest office of the DEA or to authorized agents of the DEA or

(b) place all controlled substances in its possession under seal.

b. Imminent danger to public health or safety. The DEA may serve on a registrant an order of immediate suspension when it finds that there is an **imminent danger** to the **public health** or **safety.** The immediate suspension remains in effect until the conclusion of all proceedings, either administrative proceedings by the DEA or judicial proceedings. After receiving an order of immediate suspension, the registrant must take the same action as outlined above under I B 8 a.

9. Exemptions from registration. Certain individuals are exempt from registration under the Act. The following are exempt:

a. Military officials. Military officials, including Public Health Service and Bureau of Prisons officials, who are authorized to prescribe, dispense, or administer, but not to procure or purchase, controlled substances in the course of their official duties, are exempt from registering with the DEA. The individual must, however, obtain a registration for such activities conducted during any separate private practice.

b. Law-enforcement officials. Federal and state law-enforcement personnel acting in the course of enforcing any law relating to controlled substances are exempt from registration.

c. **Civil defense officials.** Civil defense and disaster-relief organization officials are exempt from registration in order to maintain and dispense controlled substances during times of proclaimed emergencies or disasters.

d. Agents and employees of registrants. Agents and employees, while acting lawfully in the usual course of their business or employment, are exempt from registration when the business or employment is conducted on behalf of a person (or business) who is registered under the Act. Delivery personnel (e.g., United Parcel Service, Federal Express) are therefore not required to register. Likewise, pharmacists working for a registered pharmacy are not required to register.

10. Termination of registration. The registration of any person or entity will terminate when the person dies, ceases legal existence (e.g., corporate dissolution, partnership dissolution), or discontinues business or professional practice. The DEA must be notified promptly when any of these occurs. In such a case, all controlled substances in schedules II-V must be properly disposed of.

C. Required inventories. The Act requires all pharmacies and hospitals (every separately registered location) to conduct an initial inventory and biennial inventory of all controlled substances in schedules II, III, IV, and V.

1. Initial inventory. The initial inventory must be taken on the date the entity commences business and begins dispensing controlled substances. If the entity has no controlled substances on hand, a record of this fact must be maintained as its initial inventory.

2. Biennial inventory. The biennial inventory must be taken at least every 2 years from the date of the initial inventory.

a. Biennial date. The biennial date may be **any** date that is within 2 years of the previous biennial (or initial) date. This date does **not** have to be reported to the DEA if it is different than the biennial date that would otherwise apply (i.e., on the exact day 2 years after the previous inventory).

3. Inventory procedures

a. All inventories must be maintained in a **written, typewritten,** or **printed form** and be conducted at either the opening of business or the close of business on the inventory date (which must be noted on the inventory).

b. Separate inventory record for schedule II controlled substances. Because all records for schedule II controlled substances must be maintained separately from other records, schedule II inventories must be maintained separately from other controlled-substance inventories.

4. Inventory content. All inventory records must contain the following:

a. Date the inventory is taken

b. Each finished form of the substance (dosage form and strength)

c. Number of units or volume of each finished form in each commercial container (e.g., 100-tablet bottle). For opened commercial containers, inventory must be taken as follows:

(1) For schedule II controlled substances, an exact count or measure must be taken.

(2) For schedule III, IV, and V controlled substances, an estimated count or measure may be taken, except that an exact count must be taken if the container holds more than 1000 tablets or capsules.

d. For each controlled substance maintained for extemporaneous compounding, or for substances that are damaged, defective, or impure and awaiting disposal:

(1) Name of the substance

(2) Total quantity to the nearest metric unit weight or the total number of units of finished form

(3) Reason the substance is being maintained and whether it is capable of use in the manufacture of any controlled substance in finished form

5. Inventory record maintenance. Every inventory record must be maintained at the registered location (e.g., pharmacy, hospital) for at least 2 years from the date of the inventory.

a. Schedule II inventories must be maintained separately from all other records of the pharmacy.

b. Schedule III-V inventory records must be maintained either separately from all other records of the pharmacy or in such a manner that the required information is readily retrievable from ordinary business records of the pharmacy. “Readily retrievable” means that the inventory records can be separated out from all other records in a reasonable time.

6. Perpetual inventories. The Act does not require a dispenser registrant (e.g., pharmacy, hospital) to maintain a perpetual inventory of any controlled substance.

7. Newly controlled substances or changes in scheduling of a substance. An inventory of a substance must be taken when, by order of the DEA, it becomes a newly controlled substance or it shifts into another schedule. The inventory of that particular controlled substance must be taken on the effective date of the change. A complete inventory of all controlled substances is not required, nor is an inventory required when a substance moves from a controlled-substance schedule to a nonfederal schedule.

8. Transfer of business activity. An inventory of controlled substances II-V must be taken at the time a pharmacy or hospital undergoes a change in ownership. The inventory must be taken on the date of transfer and serves as the final inventory of the transferor and the initial inventory of the transferee.

9. Inventory record submission. The Act does not require the submission of inventory records to anyone, including the DEA. The records must be maintained at the registered location for inspection and copying by authorized agents of the DEA.

D. Obtaining controlled substances. Schedule II controlled substances must be obtained from a supplier (wholesaler, manufacturer) by using DEA Form 222. The Act does not require the use of any special form to obtain controlled substances in schedules III-V.

1. DEA Form 222. Only entities that are registered to dispense or handle schedule II controlled substances may obtain Form 222. The forms are serially numbered and

issued by the DEA with the name, address, registration number, authorized activity, and schedules of the registrant. Each form contains an original, duplicate, and triplicate copy (Copy 1, Copy 2, and Copy 3, respectively).

a. Execution of Form 222. Form 222 may be executed only on behalf of the registrant named on the form and only if the registration has not expired nor been revoked or suspended. The form must be prepared in triplicate as provided by the DEA by use of a typewriter, pen, or indelible pencil in the following manner:

(1) Only one item may be ordered on each of the 10 numbered lines on the form. The total number of items ordered must be noted on the form in the space provided.

(2) One item may consist of one or more commercial or bulk containers of a product. A separate item must be made for different commercial or bulk containers of a product. For each item, the form must contain the following information:

(a) Name of the article ordered

(b) Finished or bulk form of the product (dosage form and strength)

(c) Number of units or volume in each commercial or bulk container (e.g., 100-tablet bottle)

(d) Number of commercial or bulk containers ordered

(e) If the article is not in pure form, the name and quantity per unit of the controlled substances contained in the article.

(3) The supplier's name and address must be included on the form. Only one supplier may be listed on any one form.

(4) Each form must include the date of the order, and no form is valid more than 60 days after its execution by the purchaser.

(5) The form must be signed either by the person who signed the most recent application for registration or reregistration, or by a person authorized to obtain and execute order forms by a **power of attorney.**

(a) Any purchaser may authorize one or more individuals (does not have to be an attorney-at-law), whether or not located at the registered location, to obtain and execute 222 Forms by executing a power of attorney for the individual(s).

(b) The power of attorney must be signed by the person who signed the most recent application for registration or reregistration and by the individual(s) receiving the power of attorney. This form must be similar or identical to the DEA's “Power of Attorney for DEA Order Forms.”

(c) Once properly executed, the individual receiving the power of attorney may obtain and sign DEA Form 222 to the same extent as the individual who signed the most recent application for registration or reregistration.

(d) The power of attorney must be filed with the executed 222 Forms of the purchaser and be retained for the same period as any order form bearing the signature of the attorney [see I.D.1.a (8)]. The power of attorney does not have to be submitted to the DEA.

(6) Copies 1 and 2 must be submitted to the supplier. Copy 3 must be retained by the purchaser.

(7) When the ordered schedule II controlled substances are received by the pharmacy, the following information must be recorded on the retained Copy 3:

(a) Number of commercial or bulk containers furnished on each item (or line)

(b) Date on which the containers are received by the pharmacy
(8) DEA 222 Forms must be maintained at the registered location (pharmacy or hospital) for at least 2 years from their execution. The time of execution would be the date the last entry was made on Copy 3.
P.532

b. Cancellation by purchaser. A purchaser may cancel all or part of an order by notifying the supplier in writing. The supplier must indicate the cancellation on Copies 1 and 2 by drawing a line through the canceled items and printing the word “canceled” in the space provided for number of items shipped. Likewise, a supplier may void all or part of an order by notifying the purchaser in writing and printing the word “canceled” in the space provided for number of items shipped.
c. **Maintenance of DEA Form 222.** Executed Copy 3 forms and Copies 1 and 2 of each unaccepted or defective form and the statement of refusal from the supplier must be maintained by the purchaser. They must be kept separate from all other records and be available for inspection for at least 2 years. All forms must be maintained at the registered location preprinted on the form, and not at a central location.
d. Loss or theft of DEA Form 222. Any used or unused form stolen from or lost by a purchaser or supplier must be reported immediately to the DEA. Such notification must include the serial number of each form lost or stolen.
2. Obtaining schedule III-V controlled substances. There is no special form for obtaining schedule III-V controlled substances. Each registrant must, however, maintain a complete and accurate record of receipt for each such substance. The record must be maintained at either the registered location of the pharmacy or hospital, or at a central location, for 2 years. If a central location is used, the pharmacy must first notify the DEA, indicating its intention to keep central records. Central records may then be maintained unless the DEA denies the request to keep such records. An invoice or packing slip will suffice as a record of receipt, providing the following information is included:
a. Name of the controlled substance
b. Finished form of the substance (dosage form and strength)
c. Number of units or volume of the finished form in each commercial container (e.g., 100-tablet bottle)
d. Number of commercial containers of each such finished form received from other persons
e. Date of actual receipt of each commercial container
f. Name, address, and registration number of the person from whom the containers were received
E. Storage of controlled substances. All controlled substances in schedules II-V must be stored in one of the following ways:
1. In a securely locked, substantially constructed cabinet
2. Dispersed throughout the stock of unscheduled prescription medication to prevent any theft or diversion

F. Theft or significant loss of schedule II-V controlled substances. Every registrant must promptly notify the regional office of the DEA of the theft or significant loss of any controlled substance in schedules II-V. This report must be done using DEA **Form 106.**

G. Disposal of controlled substances. Every disposal of a controlled substance must be accomplished by submitting DEA **Form 41** to the DEA (except for disposals pursuant to a valid prescription, discussed below). The form must list the controlled substances earmarked for disposal. The DEA will authorize the disposal and instruct the registrant to dispose of the controlled substances in one of the following ways:

1. By the transfer to a person or entity registered with the DEA and authorized to possess the substance. Schedule II controlled substances must be transferred by use of the transferee's (another pharmacy or hospital, or the wholesaler or manufacturer) DEA Form 222. A written record of the transfer of schedule III-V controlled substances must be kept for at least 2 years and include the following information:

a. Name of the controlled substance

b. Finished form of the substance (dosage form and strength)

c. Number of units or volume of the finished form in each commercial container (e.g., 100-tablet bottle)

d. Number of commercial containers of each finished form transferred

e. Date of the transfer

f. Name, address, and registration number of the transferee

2. By the delivery to an agent of the DEA or to the nearest office of the DEA

3. By the destruction in the presence of an agent of the DEA or other authorized person

4. By any other means that the DEA determines to ensure that the substance does not become available to unauthorized persons or entities

H. Regular disposals of controlled substances. If a registrant (usually a hospital) regularly disposes of controlled substances in schedules II-V the DEA may authorize disposals without prior approval in each instance. If the DEA grants this authority, the registrant must keep records of each disposal and file periodic reports to the regional office of the DEA summarizing the disposals. The DEA may place additional conditions on such disposal, including the method of disposal and the frequency and detail of reports.

I. Disposal of controlled substances pursuant to a valid prescription

1. Persons who may issue prescriptions for controlled substances. A controlled-substance prescription may be issued only by a practitioner who is granted such authority by the state in which that practitioner is licensed. Although the Act is federal legislation, each state determines who will be authorized to dispense controlled substances. Most states allow the following individuals to prescribe: physicians, dentists, podiatrists, and veterinarians. Some states allow the following individuals, referred to as midlevel practitioners, to prescribe (usually with certain

restrictions): physician's assistants, nurse practitioners, certified nurse midwives, psychiatric nurses, mental health clinical specialists. All prescribers must be registered with the DEA or exempted from registration (see I.B.9). **Practitioner** means a physician, dentist, veterinarian, or other person licensed (mid-level practitioners) by the state to prescribe controlled substances, **and** pharmacy, hospital, or other institution licensed to distribute controlled substances. **Individual Practitioner** means a physician, dentist, veterinarian, or other person licensed (mid-level practitioners) by the state to prescribe controlled substances. It is worth noting that the term “individual practitioner” is included in the definition of “practitioner.” Prescribing authority granted by states is limited to professionals within the “individual practitioner” category. The statement like “practitioner who is granted prescribing authority” means the “individual practitioner” who has been granted prescribing authority by the state because the individual practitioner is included in the definition of practitioner. “Pharmacy” is defined as a “practitioner” but, of course, does not have prescribing authority.

a. DEA numbers and authenticity. After registering with the DEA, all registrants are assigned a DEA number by the DEA. A practitioner's DEA number consists of nine characters. The first two characters are letters. The first letter will be either A or B. The second letter will be the first letter of the practitioner's last name. The next six characters are randomly chosen numbers. The last character is a number often referred to as the “check digit.” For example, Dr. Henry Jones may have a DEA number of AJ 4357782.

(1) Authentication of DEA number. The DEA assigns DEA numbers with a quick method of verification built into the number. This allows a dispensing pharmacist to make a cursory review of the number for authenticity. For example, using the above DEA number, the practitioner's last name must start with a J. Also, the following quick calculation can be made to verify that the “check digit” is correct:

(a) The digits in positions 1, 3, and 5 are added together to reach a number. In the above example, that would be 4 + 5 + 7 = 16.

(b) The digits in positions 2, 4, and 6 are added together, then multiplied by 2. In the above example, that would be (3 + 7 + 8) × 2 = 36.

(c) These numbers above are added together: 16 + 36 = 52. The far-right digit becomes the check digit. The check digit must therefore be a 2. If the check digit is anything other than a 2, the number may not be a valid DEA number. In such a case, the DEA should be notified in order to verify the number.

(2) Midlevel practitioner DEA numbers. Midlevel practitioner DEA numbers are similar to practitioner DEA numbers except for the first character. Instead of the letter A or B, midlevel practitioners have the letter M as the first character in their DEA number. The mathematical method for verifying the authenticity of the number is the same.

(3) DEA numbers for practitioners and midlevel practitioners who are employees of institutions. Practitioners and midlevel practitioners who issue prescriptions in the

course of their employment with an institution may issue prescriptions for all controlled substances under the institution's DEA registration. The practitioner's or mid-level practitioner's “DEA number” will be a specific internal code number issued by the institution. The code number must consist of numbers, letters, or a combination of numbers and letters and must be a suffix to the institution's DEA number, preceded by a hyphen (e.g., AP0123456-10 or AP0123456-A12).

2. Purpose of issuance of controlled-substance prescriptions. A controlled-substance prescription may be issued only in good faith for a legitimate medical purpose by a practitioner acting in the usual course of his or her professional practice. The practitioner and the dispensing pharmacist have the responsibility to ensure that a prescription is properly issued and dispensed (referred to as corresponding responsibility of the pharmacist).

a. Legitimate medical purpose. Legitimate medical purpose and good faith are prerequisites for all controlled-substance prescriptions. With respect to a pharmacist, these requirements will be apparent from an objective point of view. As a general rule, if, from all the surrounding facts and circumstances, a reasonably prudent pharmacist would form the opinion that a prescription was issued for a legitimate medical purpose, then the pharmacist has fulfilled his or her responsibility under the Act, and the prescription may be legally dispensed.

b. Usual course of professional practice. A **practitioner-patient relationship** for the purpose of treating and caring for the patient must be present. Usually, such a relationship includes the taking and recording of an appropriate medical history, and an appropriate physical exam. This limits a practitioner's ability to prescribe outside his or her course of professional practice (e.g., a veterinarian may not prescribe a controlled substance for a human). The notion of “usual course of practice” becomes more unclear with respect to medical doctors who specialize. Such specialists often issue prescriptions “outside” their specialty. Generally, all controlled-substance prescriptions from medical doctors are deemed to be “in the usual course of professional practice” as long as it is issued for a human, regardless of whether the problem being treated is within the doctor's specialty.

c. **Restrictions on issuance of a controlled-substance prescription**

(1) A prescription may not be issued by a practitioner in order for that practitioner to obtain controlled substances for the purpose of **general dispensing** to his or her patients.

(2) A prescription may not be issued for the dispensing of controlled substances for **detoxification** or maintenance treatment. Administration and direct dispensing of controlled substances are allowed only when conducted in properly registered treatment programs. A prescription for **methadone** is valid only when issued as an analgesic in cases of severe pain. Methadone may be dispensed in a hospital to maintain a patient's addiction as long as the patient is admitted and being treated for some other medical condition and is not administered methadone solely for detoxification purposes. The 40mg tablets of methadone are only available to facilities authorized for detoxification and maintenance treatment of opioid addiction and hospitals. The other strengths (5mg and 10mg formulations) indicated for the

treatment of pain are available to all authorized registrants, including retail pharmacies.

3. Manner of issuance of a controlled-substance prescription. Schedule II controlled-substance prescriptions must be written with ink or indelible pencil or typewritten (except in cases of oral emergency schedule II prescriptions). Schedule III-V controlled-substance prescriptions may be orally ordered by the practitioner. Prescriptions may be prepared by either the practitioner or an agent of the practitioner, and communicated to the pharmacy by the practitioner or the agent. Authorization for the prescription (or refill) must, however, originate with the practitioner. Both the practitioner and dispensing pharmacist are responsible for the completeness of the prescription. All prescriptions for controlled substances must include the following information:

a. Full name and address of the patient

b. Date the prescription is issued and signed (one and the same)

c. Drug name, dosage form and strength

d. Quantity of drug prescribed

e. Directions for use

f. Name, address, and DEA registration number of the practitioner

g. The signature of the practitioner (no preprinted or stamped signatures) as he or she would sign any legal document (all schedule II controlled-substance prescriptions must be manually signed by the practitioner)

4. Emergency dispensing of schedule II controlled substances

a. An oral schedule II controlled-substance prescription may be received from a practitioner in an emergency situation. An emergency prescription must include all of the information required for any controlled-substance prescription. An emergency situation exists when **all three** of the following factors are present:

(1) The immediate administration of the controlled substance is necessary for proper treatment of the patient.

(2) No appropriate alternative treatment is available, including administration of a controlled substance that is not in schedule II.

(3) It is not reasonably possible for the practitioner to provide a written prescription to be presented to the person dispensing the controlled substance before the dispensing.

b. Proper dispensing. The quantity prescribed and dispensed must be limited to the amount necessary to adequately treat the patient during the emergency period. If the practitioner is not known to the pharmacist, the pharmacist must make a reasonable good-faith effort to determine that the oral authorization came from a registered practitioner.

(1) Delivery of written prescription. The practitioner who authorizes the emergency prescription must, within 7 days of the oral authorization, deliver a written prescription to the dispensing pharmacist. The prescription must contain the information required of all controlled-substance prescriptions, have written on its

face the words “Authorization for Emergency Dispensing,” and the date of the oral authorization. The prescription may be delivered in person or by mail; if delivered by mail, it must be postmarked within the 7-day period. Upon receipt, the dispensing pharmacist must attach it to the oral emergency prescription, which was previously reduced to writing.

(2) Failure to deliver a written prescription. If a practitioner fails to deliver the written prescription as required, the dispensing pharmacist must notify the regional office of the DEA. Failure by the pharmacist to notify the DEA serves to void the pharmacist's authority to dispense an oral emergency schedule II prescription. The pharmacist will be deemed to have unlawfully dispensed a schedule II controlled substance.

5. Facsimile prescriptions. Prescriptions for controlled substances III, IV and V (and nonfederal controlled substances such as penicillin and furosemide) may be delivered to the dispensing pharmacy via facsimile machine. A facsimile prescription is deemed to be the written, signed prescription from the prescriber so long as it contains the information required of all prescriptions under federal law. The prescription must be sent directly from the prescriber or his authorized agent to the pharmacy.

a. Schedule II controlled substances. Prescriptions for schedule II controlled substances may be sent via facsimile to a dispensing pharmacy to facilitate dispensing of the prescription. **No drug may be released** to the patient until the original, signed prescription is presented to the dispensing pharmacist. A schedule II controlled-substance facsimile prescription **will serve** as the original, signed prescription in the following situations:

(1) Injectable home-health prescriptions. A facsimile schedule II narcotic prescription calling for the compounding of a solution for direct administration to a patient in a private residence, long-term-care facility, or hospice setting may serve as the original prescription. The exception applies so long as the solution will be administered by means of parenteral, intravenous, intramuscular, subcutaneous, or intraspinal infusion.

(2) Long-term-care facility prescriptions. Any facsimile schedule II prescription issued for a resident of a long-term-care facility may serve as the original, signed prescription.

(3) Hospice patient prescriptions. Any facsimile schedule II narcotic prescription issued for a patient enrolled in a hospice-care program certified and/or paid for by Medicare under Title XVIII or licensed by state law may serve as the original prescription. The prescriber, or his agent, **must** note on the prescription that the patient is a hospice patient.

6. Electronic data transmission prescriptions for non-controlled substances: Prescription information that is transmitted directly from a practitioner to a pharmacy by electronic means such as via the Internet is referred to as electronic data transmission prescription. Electronic signatures are recognized as legally

acceptable signatures of practitioners. Legend drugs, except for controlled substances, may be transmitted to pharmacies via the Internet if allowed by state law. A state may allow a practitioner and pharmacy to maintain the prescription information in electronic form without reducing it to writing, so long as they comply with state mandated safeguards.

a. Electronic data transmission prescriptions for controlled substances: The DEA does not yet recognize electronic data transmission prescriptions as a means of communicating prescription information for any controlled substance. Therefore, prescription information for controlled substances may not be communicated from a practitioner to a pharmacy by electronic means.

7. Persons who may dispense controlled-substance prescriptions. A **pharmacist** acting in the usual course of his or her professional practice in a DEA-registered pharmacy (or hospital or other registered facility) may dispense a controlled substance pursuant to a prescription. A **pharmacy intern** acting under the direct supervision of his preceptor in a DEA-registered facility may also dispense a controlled substance pursuant to a prescription.

8. Dispensing procedures of controlled substances pursuant to a prescription. Once a controlled-substance prescription has been lawfully issued by a practitioner and presented to a pharmacist, it may be dispensed in accordance with the following:

a. Presentation to the pharmacist. Schedules III and IV controlled-substance prescriptions are valid for 6 months from the date of issuance by the practitioner. Schedule II controlled-substance prescriptions have no time limit for presentation under the Act, although they are often recognized to be valid for up to 6 months. Schedule V controlled-substance prescriptions also have no set time limit for presentation under the Act. Regardless of which schedule of controlled substance is involved, the good-faith and “legitimate medical purpose” limitation will always apply and may serve to otherwise limit the validity of a prescription.

b. Information that must be recorded on the prescription by the dispensing pharmacist.

Under the Act, a filled prescription is considered to be a lawful record of disposition for a controlled substance. As a result, every prescription for a controlled substance must contain certain information. Some of the information will already be contained in the prescription, although the dispensing pharmacist is responsible for ensuring that all of the following information is recorded (usually on the face of the prescription):

(1) Name of the controlled substance

(2) Finished form of the controlled substance (dosage form and strength)

(3) Name and address of the person to whom it was dispensed

(4) Date of dispensing

(5) Number of units or volume dispensed (quantity)

(6) Written or typewritten name or initials of the individual who dispensed the controlled substance

(7) Serial number of the prescription

c. **Required information on prescription labels.** Every prescription label for a controlled substance must include the following information:
(1) Name and address of the pharmacy
(2) Serial number assigned to the prescription
(3) Date of the initial filling of the prescription (for refills, the date originally filled)
(4) Name of the patient
(5) Name of the prescribing practitioner
(6) Directions for use, and cautionary statements, if any
(7) For schedule II, III, and IV controlled substances, the federal crime transfer warning must appear on the container: “Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed.”
d. Allowable quantities that may be dispensed. The Act contains no limitation concerning the quantity of a controlled substance that may be dispensed pursuant to a prescription. All quantities are, of course, limited to the good-faith and “legitimate medical purpose” standards.
e. Filing controlled substance prescriptions. Written controlled-substance prescriptions must be maintained at the pharmacy for a period of 2 years from the date of the original

dispensing or last refill, whichever is later. They must be available for inspection and copying by employees and agents of the DEA and be filed **segregated** from all other records in one of the following ways (state law usually dictates the method to be used):
(1) Using **three separate files** as follows:
(a) One file for schedule II controlled-substance prescriptions
(b) One file for schedule III, IV, and V controlled-substance prescriptions
(c) One file for unscheduled prescription drugs
(2) Using **two separate files** as follows:
(a) One file for all controlled-substance prescriptions (II-V), as long as schedule III, IV, and V prescriptions have the letter “C” stamped in red ink in the lower-right corner no less than 1 inch high
(b) One file for unscheduled prescription drugs
(3) Using **two separate files** as follows:
(a) One file for schedule II controlled-substance prescriptions
(b) One file for all other controlled substances (III-V) and unscheduled prescription drugs, as long as schedule III, IV, and V prescriptions have the letter “C” stamped in red ink in the lower-right corner no less than 1 inch high
(4) In either **(2)** or **(3)** above, if a pharmacy utilizes an electronic record-keeping system for prescriptions (i.e., computerized records), which permits identification by prescription number and retrieval of original documents by prescriber's name, patient's name, drug dispensed, and date filled, then the requirement to mark the hard copy prescription with a red “C” is waived.
f. Refill dispensing of controlled substances. Prescriptions for schedule II controlled substances may not be refilled. Prescriptions for schedules III and IV

controlled substances may be refilled up to five times within 6 months from the date of issue of the prescription. Schedule V controlled-substance prescriptions have no limitations for refilling under the Act; however, once again, the good-faith and "legitimate medical purpose" limitations apply here, as well as to all controlled-substance refills.

(1) Refill information may be maintained either manually or by use of a computer. The Act requires that the information be maintained one way or the other, but not both ways. If **computerized refill records** are maintained, the system must have certain capabilities and the dispensing pharmacist must follow certain procedures.

(a) The computer must be able to provide on-line retrieval of the original prescription information, provide on-line retrieval of the refill history, a refill-by-refill audit trail, and an auxiliary procedure in those cases where the system experiences downtime.

(b) The system must also allow the pharmacist who refills a prescription to document that the information he or she entered into the computer is correct.

(2) When dispensing a refill, the pharmacist must record, on the back of the original prescription or by computer, the following information:

(a) Date of the refill

(b) Name or initials of the refilling pharmacist

(c) Amount of the medication dispensed (if the amount is omitted, the refill will be deemed to have been for the full face amount prescribed by the practitioner)

g. Multiple schedule II prescriptions prescribed on the same day to be filled sequentially. The refill of a prescription for a controlled substance listed in schedule II is prohibited. However, an individual practitioner may issue multiple prescriptions authorizing the patient to receive a total of up to a 90-day supply of a schedule II controlled substance providing each prescription is issued for a legitimate medical purpose by an individual practitioner acting in the usual course of professional practice. The individual practitioner provides written instructions on each prescription (other than the first prescription, if the prescribing practitioner intends for that prescription to be filled immediately) indicating the earliest date on which a pharmacy may fill each prescription.

h. **Partial dispensing of controlled substances.** The Act does not prohibit the partial dispensing of controlled substances in schedules III and IV, provided that each partial filling is recorded in the same manner as refills, the total quantity dispensed in all partial fillings does not exceed the total quantity prescribed, and no partial filling occurs after 6 months from the date of issuance of the prescription. Likewise, all partial fillings of a schedule V prescription must not exceed the total quantity prescribed.

(1) Partial dispensing of a schedule II controlled substance. The partial dispensing of a schedule II prescription is allowed if the pharmacist is unable to supply the full

quantity or the prescription is for a terminally ill patient or a patient in a long-

termcare facility (LTCF). Under no other circumstance may a schedule II prescription be partially dispensed.

(a) Inadequate supply. In cases of an inadequate supply, the dispensing pharmacist must note on the face of the prescription the amount dispensed. The remaining balance of the schedule II prescription must be dispensed within 72 hours of the first partial filling. If, for any reason, the balance is not dispensed within the 72-hour period, the pharmacist must notify the prescribing practitioner of this fact. The pharmacist may not dispense any further amounts pursuant to this prescription beyond the 72-hour period.

(b) Terminally ill and patients in LTCFs. It is the pharmacist's responsibility to ensure that a patient has a medical diagnosis documenting a terminal illness or that the patient is in an LTCF. Before any partial dispensing, the pharmacist must record on the prescription whether the patient is “terminally ill” or an “LTCF patient.” Any partial dispensing without one of these notations shall be deemed to be a dispensing in violation of the Act. The total amount of the schedule II substance dispensed in all partial fillings must not exceed the total quantity prescribed. Schedule II prescriptions for a terminally ill patient or a patient in an LTCF are valid up to 60 days from the date of issuance of the prescription by the practitioner. All of the following information must be recorded, either manually on the back of the prescription or via computer (with similar capabilities required for computerized refill record keeping), when partially dispensing a schedule II prescription for a terminally ill patient or a patient in an LTCF:

(i) Date of the partial filling

(ii) Quantity of drug dispensed

(iii) Remaining quantity authorized to be dispensed

(iv) Identification of the dispensing pharmacist

i. Transfer of refill information for a controlled-substance prescription. Refill information concerning schedules III, IV, and V controlled substances may be transferred to another pharmacy only once (if allowed by state law). Pharmacies electronically sharing a realtime, on-line database (such as chain pharmacies) may transfer refill information for these controlled substances up to the maximum number of refills permitted by law and the prescriber's authorization. The communication must be made directly between two licensed pharmacists. Both the original prescription and the transferred prescription must be maintained for 2 years from the date of the last refill. Certain information must be recorded as follows:

(1) The **transferring pharmacist** must:

(a) Write the word “void” on the face of the original prescription

(b) On the back of the prescription, record the name, address, and DEA registration number of the pharmacy to which it was transferred and the name of the pharmacist receiving the information

(c) Record the date of the transfer and the name of the transferring pharmacist

(2) The **receiving pharmacist** must:

(a) Write the word “transfer” on the face of the transferred prescription

(b) Record all of the information required for any controlled-substance prescription (see I.I.3), and include the following:

(i) Date of issuance of the original prescription
(ii) Original number of refills authorized on the original prescription
(iii) Date the prescription was initially dispensed
(iv) Number of valid refills remaining and the date of the last refill
(v) Pharmacy's name, address, DEA registration number, and original prescription number from which the prescription information was transferred
(vi) Name of the transferring pharmacist

J. Disposal of controlled substances to a patient without a prescription. Controlled substances that are not prescription (or legend) drugs under federal law may be dispensed to a patient at retail without a prescription. These drugs do not have on the manufacturer's label the federal statement: “Caution: Federal law prohibits dispensing without a prescription.” The substances may be dispensed without a prescription in accordance with the following:

1. The dispensing must be made only by a licensed pharmacist. The actual cash transfer or delivery may be made by a nonpharmacist.
2. Not more than 8 oz of any substance containing opium, 4 oz of any other controlled substance, 48 dosage units of any substance containing opium, or 24 dosage units of any other controlled substance may be dispensed to the same purchaser in any 48-hour period.
3. The purchaser is at least 18 years old.
4. Any purchaser not known to the pharmacist must furnish suitable identification.
5. A bound record book must be maintained for 2 years from the date of the last entry. The following information must be recorded for each purchase:
a. Name and address of the purchaser
b. Name and quantity of controlled substance purchased
c. Date of each purchase
d. Name or initials of the pharmacist who dispensed the substance to the purchaser
6. All dispensing of a controlled substance without a prescription must be done in good faith and not to evade the provisions of the Act.

K. Security considerations

1. Controlled-substance seals. Manufacturers must package certain controlled substances in a container with a securely affixed seal to reveal any tampering. Every bottle, multiple-dose vial, or other commercial container of any controlled substance listed in schedule II, or of any narcotic controlled substance listed in schedule III or IV, must be packaged with such a seal.
2. Felony convictions. No DEA registrant may employ an individual who has access to controlled substances if that individual had previously been convicted of a felony offense related to controlled substances.
3. Manufacturer's label. Every commercial container of a controlled substance must have on its label the symbol designating the schedule in which the controlled substance is listed. The symbol must appear in the upper-right corner of the label or be overprinted on the label.

L. Record maintenance. All records required to be maintained under the Act must be kept by the registrant for 2 years. The records may be maintained at a central location (e.g., at a chain pharmacy's regional office) after notifying the DEA. However, executed DEA 222 Forms (Copy 3), all controlled-substance prescriptions, and all inventories must be maintained at the pharmacy, not centrally. All schedule II controlled-substance records must be maintained separately and readily retrievable from all other records.

M. DEA inspections. Inspections by the DEA of any registered facility may be conducted only in a reasonable manner and during regular business hours. Inspection may be conducted after obtaining consent of the registrant or after the DEA has obtained an administrative warrant from a judge. An application for an administrative warrant must state with specificity the nature, extent, and authority to conduct the requested inspection. The scope of an administrative inspection extends to any records required under the Act, equipment and containers used in the handling of controlled substances, and the verification of compliance with any requirement of the Act. If records are removed from the registrant by the DEA, a receipt given to the registrant will list the items taken.

N. Long-term-care facilities (LTCFs). An LTCF is defined as a nursing home, retirement care, mental care, or other facility or institution that provides extended health care to resident patients. LTCFs are not normally registered with the DEA, although they often maintain controlled substances that are dispensed to a patient by prescription from a pharmacy. They are not required to be registered with the DEA because the controlled substance is dispensed to the ultimate user (the patient) and is not issued by or through the LTCF. When disposing of controlled substances, LTCFs must contact the nearest DEA Diversion Field Office for disposal instructions.

1. Emergency kits for LTCFs. An LTCF may maintain controlled substances in emergency kits so long as state law specifically approves of such use and the state sets forth procedures that require the following:

a. Source of supply: The LTCF must obtain controlled substances for the emergency kits from a DEA-registered hospital/clinic, pharmacy, or practitioner.

b. Security safeguards: Access to each emergency kit in the LTCF must be restricted, and the type and quantity of controlled substances that may be placed in the emergency kit must be specifically limited.

c. **Proper control, accountability, and record keeping:** The LTCF and the providing DEA-registered hospital/clinic, pharmacy, or practitioner must maintain complete and accurate records of the controlled substances placed in the emergency kit, including the disposition of these controlled substances, as well as take periodic physical inventories of the drugs.

d. Administration of controlled substances. In emergency medical situations when medication is needed from the emergency kit, only LTCF personnel who are authorized by an individual practitioner can administer the controlled substances.

e. Prohibited activities: Prohibited activities can result in the state revocation, denial, or suspension of having emergency kits containing controlled substances in an LTCF.

O. Violations under the Act. Penalties for violations of the Federal Controlled Substances Act depend on the schedule of controlled substance involved, the unlawful act, **and the knowledge and intent of the violator.** It will also depend on whether it is a first offense or a subsequent offense.

1. Civil penalty. Generally, each violation of the Act may subject an individual to a civil penalty (fine) of up to $10,000. The government must prove that the violator was negligent with respect to compliance under the Act, as opposed to mere mistake or inadvertence.

2. Imprisonment. If an individual knowingly and intentionally violates the Act, he or she may be sentenced to a term of years, in addition to a civil penalty.

II. FEDERAL FOOD, DRUG, AND COSMETIC ACT (FDCA).

In 1937, sulfanilamide elixir containing deadly diethylene glycol (automobile antifreeze) was manufactured without any safety data. There were numerous deaths associated with its use, which prompted the federal government to pass the 1938 FDCA. The FDCA requires that all new drug products intended for use as labeled by the manufacturer in the United States must be proven to the federal government to be safe and effective. Such proof is submitted to the Food and Drug Administration (FDA) by use of a New Drug Application (NDA).

A. Definition. Under the FDCA, the term “drug” is defined as including all of the following:

1. Articles recognized in the official *United States Pharmacopeia (*USP*),* official *Homeopathic Pharmacopoeia of the United States,* or official *National Formulary,* or any supplement to these

2. Articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals

3. Articles (other than food) intended to affect the structure or any function of the body of man or other animals

4. Articles intended for use as a component of any article specified in 1, 2, or 3 above

B. Legend drugs. Legend drugs are those medications that have on their label from the manufacturer the following federally required statement: “**Rx** only.” Such medications may be dispensed directly to the patient by means of a valid written or oral prescription from a practitioner or by a valid refill authorization of either. By law, these medications must bear a label with adequate directions for use, which can only be given by a licensed practitioner and, therefore, the requirement of a prescription. A drug, intended for use by humans, is considered a legend drug (and have the above caution on its label) if any of the following apply:

1. Because of the drug's toxicity or other potential for a harmful effect, or its method of use, or collateral measures necessary to its use, it is **not safe** for use **except under the supervision** of a practitioner licensed by law to administer such drug.

2. The drug is a **new drug** for which an approved NDA limits its use to the professional supervision of a practitioner licensed by law to administer such drug. A new drug is broadly defined as being one that generally is not recognized among experts as safe and effective for use under the conditions prescribed, recommended, or suggested in the labeling. It is also defined as being a drug that, as a result of investigations to determine its safety and effectiveness for use under such conditions, has become so recognized but that has not, other than in the investigations, been used to a material extent or for a material time under such conditions. Finally, a new drug may result from a change in the dosage form, labeling, indications, or any other change in a drug product that is already being marketed. The ultimate decision of whether a drug is a new drug lies with the FDA because of its expertise in resolving technical and scientific questions.

a. NDA. Every new drug marketed in the United States must be safe and effective for its intended use as labeled by the manufacturer. Proof of safety and effectiveness must be submitted to the FDA by the manufacturer via the NDA. When a new chemical entity (NCE) is identified by a manufacturer, the manufacturer must obtain an Investigational New Drug Application (IND) before conducting preclinical animal tests and clinical human investigations.

b. IND. Because an NCE has not yet been approved by the FDA as a safe and effective drug, a manufacturer is required to file an IND with the FDA. The IND allows a manufacturer to conduct research with the NCE and exempts the drug from certain prohibitions of the FDCA in order to facilitate clinical investigations; thus, INDs are sometimes referred to as an Investigational New Drug Exemption. Generally, clinical investigation of an NCE is divided into three phases, with each phase involving a greater number of human subjects.

(1) Phase 1. A phase 1 investigation is the initial introduction of an investigational new drug into humans to determine the metabolism, pharmacology, side effects, mechanism of action, and early evidence on effectiveness.

(2) Phase 2. A phase 2 investigation includes the well-controlled, closely monitored clinical studies in order to evaluate the effectiveness of the drug for a particular indication and to further determine side effects and risks.

(3) Phase 3. A phase 3 investigation includes expanded clinical trials to gather additional information concerning safety, effectiveness, and the overall benefit-risk relationship associated with the drug's use. This phase also includes gathering information to provide an adequate basis for physician labeling.

c. **Treatment INDs (or treatment protocols).** The FDA may allow a treatment IND, which allows a researcher (physician) to use an investigational drug as treatment in serious and life-threatening diseases where no comparable or satisfactory alternative drug or other therapy is available.

C. Over-the-counter (OTC**) medications.** Certain medications may be dispensed OTC at retail distributors without a prescription. The federal government has determined that these medications may be safely and properly self-administered without the supervision of a practitioner licensed by law to administer (or prescribe)

such a drug. Generally, these medications are not habit-forming and have a low toxicity or other potential for a harmful effect. These medications do not have the federal statement "**Rx** only" on their label (see II.B).

1. OTC preparations must have **adequate directions** for use on their label, and the product must comply with the applicable FDA monograph. The FDCA requires all drugs marketed in the United States to be generally recognized as safe and effective. As a result, it convened review panels to review OTC drug effectiveness and create monographs for each therapeutic class of OTC drugs. This review is referred to as the Drug-Efficacy (or Effectiveness) Study Implementation (DESI). All OTC drugs must comply with the applicable drug monograph or be considered misbranded (see II.I) and subject to FDA regulatory action.

2. OTC preparations must have the following information on its label:

a. Identity, in bold face, of the OTC product on the principal display panel

b. Adequate directions for use

c. Ingredients (including inert or inactive ingredients) in the product

d. Net quantity of contents

e. Expiration date of the product

f. Lot number of the product

g. Name and place of business of the manufacturer, packer, or distributor

h. Disclosure of certain contents and the declaration of certain warnings, including habit-forming ingredients and warnings, pregnancy/nursing warnings, and aspirin warnings

3. Prescription drug conversion to OTC. A legend drug will convert to an OTC drug when the FDA finds that the prescription-only limitation is not necessary for the protection of the public health by reason of the drug's toxicity or other potential for harmful effect, the method of its use, or the collateral measures necessary to its use. The FDA must also find that the drug is safe and effective for use in self-medication as directed in proposed labeling.

4. Miscellaneous regulations for OTCs.

a. Ipecac syrup. Although ipecac syrup can only be dispensed pursuant to a prescription, the FDA believes that it should be readily available OTC as an emergency treatment emetic for use in poisonings. The FDA allows the OTC sale of ipecac syrup in 1 fluid ounce containers so that it will be readily available in the household for emergency treatment of poisonings, under medical supervision, and that the drug be appropriately packaged and labeled for this purpose.

b. Pregnancy-nursing warning. All OTC drugs intended for systemic absorption must contain a warning that if the user is pregnant or nursing a baby, she should first seek the advice of a health professional before using the product. Exceptions to this labeling requirement exist when an OTC is intended to benefit the fetus or nursing infant, and for OTC drugs that are labeled exclusively for pediatric use.

c. **Aspirin warnings.** All OTC aspirin containing preparations must have a warning to keep out of children's reach and to contact a physician immediately in case of

accidental overdose. Oral or rectal OTC aspirin containing preparations must also have a warning concerning Reye's syndrome in children and teenagers.

d. Chemicals and precursors. It was discovered that combination drug products containing ephedrine, pseudoephedrine, or phenylpropanolamine are the precursor materials used by illegal methamphetamine laboratories. The Comprehensive Methamphetamine Control Act of 1996 requires all retail distributors of these OTC products to fulfill certain obligations. A retail distributor includes a grocery store, general merchandise store, a pharmacy, or any other entity or person who sells these items to customers for personal use. For regulated transactions, a retailer must maintain a record of these transactions for a period of 2 years, must obtain proof of identity from customers, and must report suspicious regulated sales immediately to the DEA. The record must be maintained separately from other records of controlled substances, and the DEA suggests that the record be made in a bound log book similar to the record kept for the sale of OTC controlled substances (see IJ). The following single transactions of these products in the amounts stated are considered to be “regulated transactions.”

(1) Phenylpropanolamine (PPA). PPA is no longer in any OTC drug product.

(2) Pseudoephedrine. Sales of combination products containing more than 24 g of pseudoephedrine. Blister-pack sales of these products exceeding 24 g are **not** regulated sales.

(3) Ephedrine. Sales of combination products containing more than 24 g of ephedrine **and all** single-entity ephedrine products regardless of the amount of ephedrine (more than zero grams).

D. Generic drugs

1. Definition. The *generic name* of a drug has been defined as its chemical name, a common name, or an official name used in an official compendium. A manufacturer seeking approval from the FDA for a drug that has already been proven to be safe and effective may file an Abbreviated New Drug Application (ANDA).

2. ANDA. A filing of an ANDA allows the approval of a drug for which exhaustive safety and efficacy studies have already been performed. A drug is considered to be the same as an approved drug when the two are identical in active ingredient(s), dosage form, strength, route of administration, indications, and conditions of use. Rigorous animal and human data to determine safety and effectiveness are not required in the ANDA. However, information showing that the generic version of the drug is bioavailable and bioequivalent to the pioneer (original) drug is necessary. Such approved drugs are listed by the FDA in the “Approved Drug Products with Therapeutic Equivalence Evaluations,” commonly referred to as the FDA Orange Book (because it comes from the FDA in an orange binder).

E. Proprietary drugs. The *proprietary name* of a drug is the name given by the manufacturer to designate the drug's source of manufacture and to differentiate it from the same or chemically similar drugs from other manufacturers. Another name for the proprietary name of a drug is its trade name.

F. Established names for drugs. The FDCA authorizes the Commissioner of the FDA to designate an official name for any drug if he determines that such action is necessary or desirable in the interest of usefulness and simplicity. The FDCA also requires that a drug's established name appear on the label and labeling of the drug. A drug's *established name* is defined as follows:

1. It may be an **official name** designated by the Commissioner of Food and Drugs. For NCEs, the name should be simple and useful. In this regard, the FDA recognizes the U.S. Adopted Names Council (USAN) in deriving names for NCEs. The USAN name is considered to be an official name recognized in an official compendium. The FDA may use another name if the USAN or common or usual name is unduly complex, misleading, or is not useful for any other reason.

2. If no official name has been designated for the drug and the drug is an article recognized in an official compendium, then the **official title** contained in the compendium may be the established name.

3. If neither of the above two apply, then the **common** or **usual name** of the drug may be its established name.

G. Dispensing a prescription drug. A prescription drug may be dispensed only by a practitioner or by a pharmacist pursuant to a written or oral prescription of a practitioner, or a refill of either. The prescription label on the container dispensed to the patient must contain certain information, or it will be considered misbranded and dispensed in violation of the FDCA. This information is minimal under the FDCA and is usually supplemented by state laws, which require more information. So long as this information is in English, the dispensing pharmacist will be in compliance with the FDCA. If any of the required information is in another language, then all of the required information must be in that language. The prescription must also be packaged in a child-resistant container as required under the Poison Prevention Packaging Act (see III). The following information must appear on every prescription label:

1. Name and address of the pharmacy

2. Serial number of the prescription

3. Date the prescription is filled or the date of the prescription

4. Name of the prescriber

5. Name of the patient (if stated in the prescription)

6. Directions for use and any cautionary statements contained in the prescription

H. Drug recall. The FDCA allows the FDA to initiate regulatory actions to ensure that unsafe, unfit, or ineffective products do not reach the market, or to promptly remove those products that do reach the marketplace. The enforcement actions that may be initiated include the release of information to the general public and/or professional groups; administrative actions and inspections; the institution of recall; or seizure, injunction, or criminal prosecution.

1. Voluntary action of the manufacturer. After several unsuccessful attempts by the FDA to receive court-ordered recalls, the FDA recognizes that recalls are voluntary actions of the manufacturers and distributors. As a result, a recall may be undertaken at any time, or upon request of the FDA. If the FDA is unsuccessful in persuading a company to recall a product, or when the FDA determines that a recall

is or will be ineffective, it may seek a court order condemning the product and allowing the product's seizure.

2. Drug recall classification. After the FDA has evaluated the problem(s) associated with the product and after the degree of health hazard has been determined, the FDA will assign the recall one of the following classifications:

a. Class I—a situation in which there is a reasonable probability that the use of or exposure to a violative product will cause serious adverse health consequences or death

b. Class II—a situation in which use of or exposure to a violative product may cause temporary or medically reversible adverse health consequences or where the probability of serious health consequences is remote

c. **Class III—**a situation in which use of or exposure to a violative product is not likely to cause adverse health consequences

3. Recall procedure. A recall strategy will be developed that will consider the depth of the recall (consumer level, retail level, wholesale level), the need for public warnings, and the extent of effectiveness checks for the recall. Every recalling company is responsible for notifying each of its affected direct accounts by first-class mail, mailgram, or telegram. Public notification is made by the FDA via the weekly *FDA Enforcement Report,* which publishes each recall according to its classification.

I. Adulteration and misbranding. A misbranding or adulteration of a drug is prohibited by the FDCA. Although the misbranding and adulteration provisions are mainly concerned with the manufacturing of a drug, a pharmacist may also misbrand or adulterate a drug. The purpose of the misbranding and adulteration statutes is to protect the public health of consumers who are largely unable to protect themselves where drugs are involved. The adulteration and misbranding statutes are criminal in nature and may subject a pharmacist to criminal proceedings in federal court, in addition to administrative proceedings.

1. Adulteration. In general, the term *adulteration* refers to a change or variation from official formulary standards or from the manufacturer's standards. A drug is considered adulterated if any of the following conditions occur:

a. If the drug consists in whole or in part of any filthy, putrid, or decomposed substance

b. If the drug has been prepared, packed, or held under unsanitary conditions where it may have been contaminated with filth or rendered injurious to health

c. If the drug's container is composed, in whole or in part, of any poisonous or deleterious substance that may render the contents injurious to health

d. If the drug contains, for purposes of coloring only, a color additive that is unsafe within the meaning of the FDCA

e. If the drug is a new animal drug, or an animal feed containing a new animal drug, that is unsafe within the meaning of the FDCA

f. If the drug is purported to be a drug that is recognized in an official compendium, and its strength differs from, or its quality or purity falls below, the standard set forth in the compendium, unless the deviation is plainly and specifically stated on its label

g. If the drug is not a compound recognized by name in an official compendium; if its strength differs from, or its purity or quality falls below, that which it purports or is represented to possess

h. If the drug has been mixed or packed with another substance so as to reduce the drug's quality or strength

i. If the drug has been substituted, wholly or partially, with another substance

j. If the drug is an OTC drug and it is not packaged in the required tamper-resistant packaging or properly labeled in conformity with the tamper-resistant regulations (see IV)

k. If the drug (or medical device) is an ophthalmic preparation offered or intended for ophthalmic use that is not sterile

2. Misbranding. In general, the term *misbranding* means that a drug is sold or dispensed with a label or labeling that is in violation of the FDCA. *Label* is defined as being a display of written, printed, or graphic matter upon the immediate container of any article (or drug). *Labeling* is more broadly defined to include the label as well as other written, printed, or graphic matter upon any article or any of its containers or wrappers, or accompanying the article (or drug). A drug is considered misbranded if any of the following conditions occur:

a. If the labeling is false or misleading in any particular

b. If the drug is an imitation of another drug, or if it is offered for sale under the name of another drug

c. If the drug is composed wholly or partly of insulin and it is not properly batch certified under the FDCA

d. If the drug is composed wholly or partly of an antibiotic and it is not properly batch certified under the FDCA

e. If the drug is dispensed by a name that is recognized in an official compendium and it is either not packaged or not labeled in conformity with the official compendium

f. If the drug is determined by the federal government to be liable to deterioration and it is not packaged in a proper form and manner, and the label fails to bear a statement of proper precautions

g. If the drug is dispensed in a non-child-resistant container, when a child-resistant container is otherwise required (see III)

h. If the manufacturer fails to place on the label any of the following:

(1) Fact that certain drugs may be habit forming

(2) Name of each active ingredient

(3) Name and place of business of the manufacturer, packer, or distributor

i. If a pharmacist fails to place on a prescription container label any of the following:
(1) Name and address of the pharmacy
(2) Serial number of the prescription
(3) Date of filling the prescription or the date of the prescription
(4) Name of the prescriber
(5) Name of the patient
(6) Directions for use and any cautionary statements contained in the prescription
j. If an oral contraceptive is dispensed without the required patient package insert
k. If an intrauterine device that must be dispensed with a patient package insert is dispensed without the insert
l. If an estrogen product is dispensed without the required patient package insert
m. If a progestogen-containing product is dispensed without the required patient package insert
n. If a legend drug is dispensed (or refilled) without a prescription (or refill authorization) of a licensed practitioner, it is deemed to be misbranded by the dispensing pharmacist
o. If the drug is an OTC drug and it is not packaged in tamper-resistant packaging or properly labeled in conformity with the tamper-resistant regulations (see IV)
p. If the drug is an OTC drug and it is not properly labeled in conformity with the labeling requirements of the FDCA
q. If the drug (or medical device) is an ophthalmic preparation offered or intended for ophthalmic use that is not sterile
3. Violations under the Act. Any misbranding or adulteration of a drug may subject the individual (e.g., a pharmacist) to imprisonment, a fine, or both. A pharmacy and pharmacist will be exempt from criminal sanctions in either of the following cases:
a. Certain cases of good faith. When adulterated or misbranded products are received from a manufacturer or wholesaler in good faith by the pharmacy, the pharmacy may not be held responsible in certain situations. This exemption applies only if it is a first violation and, if requested, the pharmacy or pharmacist furnishes to the government the name and address of the person from whom the drug was received and copies of all documents pertaining to its delivery.
b. Receipt of drug with a signed, written guaranty. A pharmacy and pharmacist will be exempt from misbranding and adulteration violations when a signed, written guaranty is received from the wholesaler or manufacturer. The guaranty must contain the name and address of the person residing in the United States from whom the drug was received in good faith and a statement that the drug is not adulterated or misbranded.
4. Seizures. Any adulterated or misbranded drug will be subject to condemnation and seizure by the U.S. government after a hearing in any district court of the United States (or territory) with proper jurisdiction. A seizure may be done without a hearing if the federal government has probable cause to believe that the violation would be dangerous to health or that the labeling of the misbranded article is fraudulent or would be materially misleading to the injury or damage of the purchaser or consumer.

5. Investigations and inspections

a. The U.S. Secretary of Health and Human Services has the authority to conduct examinations and inspections through federal employees and by officers and employees of any state, territory, or political subdivision duly commissioned by the U.S. Secretary of Health and Human Services as an officer of the U.S. Department of Health and Human Services.

b. Scope of investigation. An investigator may enter a pharmacy or other establishment where adulterated or misbranded drugs are held and inspect all drugs, materials, containers, and labeling. The inspection does not extend to financial data, sales data other

than shipment data, pricing data, personnel data, and other records that have no bearing on adulteration and misbranding. The investigator must present appropriate credentials and a written notice to the owner, operator, or agent in charge that he or she is authorized to conduct an investigation. The inspection must be done at reasonable times, within reasonable limits, and in a reasonable manner.

6. Current Good Manufacturing Practice (cGMP). Under the FDCA, a drug is considered adulterated if it is not manufactured "in conformity with current Good Manufacturing Practice." FDA regulations state with particularity the minimum cGMPs for methods to be used in, and the facilities or controls to be used for, the manufacture, processing, packing, or holding of a drug. The cGMPs ensure that a drug meets the requirements of the FDCA as to safety and has the identity and strength and meets the quality and purity characteristics that it purports.

J. Registration of producers of drugs

1. Manufacturers and businesses that distribute a drug manufactured by another but sold under their own label or trade name must register their establishment with the FDA. They also must submit a list of every drug (prescription and OTC) in commercial distribution, with updates every June and December.

2. Pharmacies properly licensed by state law that do not manufacture or possess drugs for sale other than in the regular course of the practice of pharmacy are not required to register with the FDA. A pharmacy engaged in manufacturing or processing activities that are considered beyond the normal practice of pharmacy must register with the FDA and supply a list of every drug in commercial distribution.

a. Scope of pharmacy practice. A pharmacy or pharmacist may not manufacture drug products. They may only compound drug preparations pursuant to a valid prescription of a practitioner for a particular patient. Large-scale manufacturing of drug products by a pharmacy or pharmacist is outside the scope of pharmacy practice and requires proper registration with the FDA and compliance with cGMPs.

K. Package inserts. The federal government has determined that prescription medication information needs to be disseminated to health professionals and, in the case of certain drugs, to the patient.

1. Manufacturer's insert. An amendment to the FDCA required that all manufacturers provide "full disclosure" concerning prescription medication that they

market. Full disclosure is accomplished by means of a package insert that is enclosed with every commercial container of a drug product. The insert should contain essential scientific information needed for the safe and effective use of the drug and should be informative and accurate. It must not be promotional in tone, false, or misleading.

2. Patient package insert. The FDA has determined that, because of certain side effects associated with the use of particular drug products, patient package inserts must be dispensed to the patient at the time of dispensing the medications. The following products must be dispensed with a patient package insert, which is supplied with the product from the manufacturer:

a. Oral contraceptives. Hospital inpatients or LTCF patients may receive the insert before administration of the first oral contraceptive and every 30 days thereafter, as long as the therapy continues.

b. Intrauterine devices for human use in contraception. Every practitioner dispensing such a device must provide the patient with an informative insert.

c. **Estrogen and estrogen-containing products.** Hospital inpatients or LTCF patients may receive the insert before administration of the first estrogen dose and every 30 days thereafter, as long as the therapy continues.

d. Progestational drug products. Hospital inpatients or LTCF patients may receive the insert before administration of the first progestational drug product and every 30 days thereafter, as long as the therapy continues.

e. Isoproterenol inhalation products require the following warning statement on the immediate container label of such a product: “Warning: Do not exceed the dose prescribed by your physician. If difficulty persists, contact your physician immediately.”

f. Miscellaneous drug products. Certain drug products were approved by the FDA with the provision that they must be dispensed along with a patient package insert that includes a particular warning or statement of benefits and risks associated with the use of the drug. For example, isotretinoin was approved for dispensing with an insert warning about serious fetal harm when administered to pregnant women.

L. Medication Guides

1. The “Medication Guide” bill was signed into law in August 1996. By 2006, 95% of patients receiving a new prescription were to receive written information in non-technical language and in a uniform format. “Medication Guides” or “MedGuides” should not be confused with the patient leaflets generated by most pharmacy computer software programs. Patient leaflets are typically part of the pharmacy software package to process prescriptions and are written and updated by a source other than the manufacturer or FDA. The language of Medication Guides is approved by the FDA while patient leaflets are not approved by the FDA. The manufacturers must make Medication Guides available electronically to pharmacies.

2. The legislation has created significant confusion and controversy within the pharmacy and health care communities. Many pharmacists assume that the patient

leaflet satisfies the MedGuide requirement, but since the language wasn't approved by the FDA, the agency (FDA) says the two are not substitutable. It is not clear if one manufacturer's MedGuide can be given to the patient when another manufacturer's equivalent generic product is dispensed. Each manufacturer is to make the Medication Guides available to pharmacies. If a pharmacy gave the wrong manufacturer's MedGuide for a generic product, assuming the manufacturer's name is on the document, technically this could be construed as a labeling violation. Professional pharmacy organizations and other interested parties (i.e., pharmaceutical manufacturers) are working with the FDA to clarify these requirements.

M. Prescription drug samples

1. An **amendment** to the FDCA (Prescription Drug Marketing Act) severely restricted the distribution of drug samples by manufacturers. Under the FDCA, no person may sell, purchase, or trade, or offer to sell, purchase, or trade any drug sample. Samples may only be distributed upon written request of a practitioner. Manufacturers must maintain records of every sample distribution for a period of three years. Pharmacies may not receive samples from a manufacturer except in certain situations in which a practitioner requests storage of his or her samples in the pharmacy.

2. Importation under the FDCA. The Prescription Drug Marketing Act prohibits the import of prescription drugs once exported. Importation is allowed after notification and approval of the FDA and in cases of an emergency.

N. Medical devices. An amendment to the FDCA in 1976 (Medical Device Amendments) required a device manufacturer to provide reasonable assurance of the safety and effectiveness of the device. The amendment required the FDA to categorize each device on the market in 1976 into one of three classes: Class I, Class II, or Class III, depending on each device's safety and effectiveness. Generally, **Class I** devices are those that have a reasonable assurance of safety and effectiveness. **Class II** devices are those that do not have the reasonable assurance of safety and effectiveness, but there is sufficient information about the device to establish special controls to ensure its safety and effectiveness (and may be marketed with such controls). **Class III** devices are those for which information is not sufficient to provide reasonable assurance of their safety and effectiveness. Class III devices may be marketed only if they are proven to be substantially equivalent to a device on the market before 1976, by approval of a premarket application, or by reclassification into Class I or II.

1. Medical device tracking. Manufacturers of medical devices whose failure would be reasonably likely to have a serious adverse health consequence must track the device down the chain of distribution to the patient. Such tracking allows the manufacturer to take appropriate action with respect to recalls, defects, or other relevant information concerning the device. Every final distributor such as a pharmacy, hospital, or home health-care company must report certain information to the manufacturer. Tracking information must be maintained by the manufacturer and distributor for the useful life of the device and be available for inspection by FDA personnel.

2. Manufacturer's reports. Every device manufacturer must report to the FDA information, when received or made aware of, that reasonably suggests that one of its marketed devices may have caused or contributed to a death or serious injury. Likewise, hospitals and other medical service facilities must provide reports on adverse reactions to, or malfunctioning of, medical devices.

3. Adulteration and misbranding. Medical devices may be adulterated or misbranded in the same way that drugs are adulterated or misbranded (see II.I).

III. POISON PREVENTION PACKAGING ACT (PPPA).

The PPPA of 1970 requires that drugs for human use in an oral dosage form must be packaged for the consumer in special packaging. All such federal controlled substances and drugs dispensed pursuant to a prescription must be dispensed to the consumer in special packaging. ***Special packaging,*** referred to as **child-resistant** containers, is defined as a container that is designed to be significantly difficult for children under 5 years of age to gain access to within a reasonable time. The container must not be too difficult for normal adults (ones with no overt physical or mental handicaps) to use properly and does not include packaging that all such children cannot gain access within a reasonable time. The Consumer Products Safety Commission is responsible for interpreting, establishing rules and regulations for, and enforcing the provisions of the PPPA.

A. Exceptions. The following medications are exempt from the special packaging requirements:

1. Sublingual dosage forms of nitroglycerin; other dosage forms intended for oral administration, such as nitroglycerin sustained-release preparations, must be packaged in child-resistant containers

2. Sublingual and chewable forms of isosorbide dinitrate in dosage strengths of 10 mg or less

3. Erythromycin ethylsuccinate granules for oral suspension and oral suspensions in packages containing not more than 8 g of the equivalent of erythromycin

4. Cyclically administered oral contraceptives in manufacturers' mnemonic (memory-aid) dispenser packages that rely solely on the activity of one or more progestogen or estrogen substances

5. Anhydrous cholestyramine in powder form

6. All unit-dose forms of potassium supplements, including individually wrapped effervescent tablets, unit-dose vials of liquid potassium, and powdered potassium in unit-dose packages, containing not more than 50 mEq of potassium per unit dose

7. Sodium fluoride drug preparations, including liquid and tablet forms, containing no more than 264 mg of sodium fluoride per package and containing no other prescription medication

8. Betamethasone tablets packaged in manufacturers' dispenser packages, containing no more than 12.6 mg betamethasone

9. Pancrelipase preparations in tablet, capsule, or powder form and containing no other prescription medication
10. Prednisone in tablet form, when dispensed in packages containing no more than 105 mg of the drug, and containing no other prescription medication
11. Mebendazole in tablet form in packages containing not more than 600 mg of the drug and no other prescription medication
12. Methylprednisolone in tablet form in packages containing not more than 84 mg of the drug and no other prescription medication
13. Colestipol in powder form in packages containing not more than 5 g of the drug and no other prescription medication
14. Erythromycin ethylsuccinate tablets in packages containing no more than the equivalent of 16 g erythromycin

15. Conjugated estrogen tablets USP, when dispensed in mnemonic packages containing not more than 32 mg of the drug and no other prescription medication
16. Norethindrone acetate tablets USP, when dispensed in mnemonic packages containing not more than 50 mg of the drug and no other prescription medication
17. Medroxyprogesterone acetate tablets
B. Requests for a non-child-resistant container. A prescribing practitioner may make a request in the prescription that the medication be dispensed in a non-child-resistant container. A practitioner may not, however, make a blanket request that all prescriptions issued by him or her be dispensed in non-child-resistant containers. The purchaser, or patient, may also make a request that the medication be dispensed in a non-child-resistant container. The request of the purchaser, or patient, does not (under the PPPA) have to be in writing. The purchaser, or patient, may make a blanket request that none of his or her medications be dispensed in a child-resistant container. A dispensing pharmacist may never make the decision to use non-child-resistant containers.
C. Reuse of child-resistant containers. Reuse of child-resistant containers are prohibited by regulation of the federal Consumer Products Safety Commission. However, the Commission has indicated that glass containers may be reused as long as a new safety closure is used.
D. Manufacturer's packaging. Packaging from the manufacturer that is intended to be dispensed directly to the patient must be in child-resistant packaging. Bulk packaging intended to be repackaged by the pharmacist for each prescription does not have to be in special packaging from the manufacturer. Unit packaging from the manufacturer that will be dispensed directly to the consumer, or patient, must comply with the child-resistant requirements of the PPPA (unless specifically exempted; see III.A).
E. Exemptions for easy access. Special packaging is not required in cases where OTC medication needs to be readily available to the elderly or handicapped persons. A manufacturer may supply a single size of a drug product in non-child-resistant packaging, as long as it also supplies the medication in packages that use

the special packaging. Additionally, the package must be conspicuously labeled with the statement: “This package for households without young children.” For those packages too small for this statement, the statement “Package not child-resistant” may be used.

F. Hospitals and institutions. The special packaging requirements of the PPPA apply to household substances. *Household substance* is defined as “any substance which is customarily produced or distributed for sale for consumption or use, or customarily stored, by individuals in or about the household....” As long as the medication is administered by institutional personnel and is not directly dispensed to the consumer (patient), child-resistant containers are not required.

G. Miscellaneous products requiring special packaging. The PPPA requires that certain household substances be distributed to the consumer in special packaging. Examples of these substances include furniture polish containing petroleum distillates, drain pipe cleaners, turpentine, paint solvents, and lighter fluid.

IV. ANTI-TAMPERING ACT.

The U.S. Congress passed the Anti-Tampering Act in 1984 due to a number of deaths that occurred in the early 1980s from OTC medication capsules contaminated with cyanide.

A. Violations. Unlawful acts involving a consumer product can be broken down into one of the following listed violations. The term *consumer product* includes any food, drug, device, or cosmetic, as well as any article, product, or commodity that is customarily used by individuals for purposes of personal care or to perform services ordinarily done within a household.

1. Tampering. Any individual who tampers or attempts to tamper with any consumer product that affects interstate or foreign commerce, or its labeling or container, may be in violation of the statute. A violation occurs when the individual acts (or threatens to act) with reckless disregard for the risk that another person will be placed in danger of death or bodily injury.

Any individual who taints any consumer product or causes its labeling or container to be materially false or misleading is in violation of the statute if done with intent to cause serious injury to the business of another.

2. False communications. Knowingly communicating false information that a consumer product has been tainted may be a violation. If such tainting, had it occurred, would create a risk of death or bodily injury to another person, then the false communication is deemed a violation.

3. Conspiracy. An agreement between two or more persons to do (or further) either of the above acts is considered a violation.

B. OTC **tamper-resistant packaging.** Certain OTC products must be packaged, by FDA regulation, in tamper-resistant packaging. Examples include contact lens solutions and other ophthalmic solutions. A **tamper-resistant package** is one having one or more indicators or barriers to entry that, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has

occurred. To reduce tampering, the package must have **one** of the following characteristics:

1. Be distinctive by design so that the product cannot be duplicated by commonly available materials or processes or

2. Use one or more indicators or barriers to entry that employ an identifying characteristic

C. OTC **tamper-resistant labeling.** The OTC product must be labeled with a prominently placed statement alerting consumers to the specific tamper-resistant feature of the package. The statement must be placed so that it will be unaffected if the tamper-resistant feature is breached or missing.

D. Medical devices and cosmetics. Certain medical devices and cosmetics must be packaged in tamper-resistant packaging. The packaging requirements are similar to the requirements outlined above for OTC drug products.

V. MAILING PRESCRIPTION MEDICATION

A. All prescription medication, including controlled substances and narcotics in schedules II-V, may be mailed from a physician, or pharmacist pursuant to a prescription, to the patient. Flammable substances (e.g., acetone) and alcoholic beverages may not be sent to a patient through the U.S. mail.

B. The medication must be placed in a plain outer container or be securely overwrapped in plain paper. There must be no markings of any kind on the outside wrapper or container that would indicate the nature of the contents.

VI. OMNIBUS BUDGET RECONCILIATION ACT OF 1990 (OBRA '90).

Under the Constitution of the United States, the federal government has no power or authority to directly regulate the practice of pharmacy. Such power rests with each state. The federal government can, however, indirectly regulate, or affect, the practice of pharmacy by attaching conditions of participation and reimbursement for federally funded programs.

A. Medicaid prescriptions. With respect to prescriptions dispensed to Medicaid patients (paid in part by the federal government along with the state government), the federal government has attached certain conditions for reimbursement. Such conditions were deemed necessary to stem the always increasing cost of the Medicaid programs. It was believed that improved medication compliance by Medicaid recipients would, in the long run, reduce the cost of the programs by reducing subsequent hospitalizations and other subsequent utilization of health care. As a result, pharmacists are required to do the following in the course of dispensing a Medicaid prescription:

1. Make a reasonable good-faith effort to obtain and maintain a history of the patient, including a medication history

2. Conduct a review of every prescription for appropriateness and to screen for potential drug therapy problems

3. Make an offer to counsel each Medicaid recipient concerning the drug (if the offer is accepted, the counseling must include the drug's proper administration, common adverse or severe side effects, techniques for self-monitoring, and proper storage)

B. Manufacturer's best price. OBRA '90 requires manufacturers that wish to participate in the Medicaid program to offer the federal government their best price for prescription drugs. *Best price* is defined as the lowest price at which any purchaser is purchasing that drug product.

VII. HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT OF 1996 (HIPAA).

HIPAA is federal legislation that requires all health-care providers, including pharmacies, to protect patient information from unauthorized use and disclosures. This is referred to as the Privacy Rule and was established as a result of the government's recognition that individually identifiable health information is readily available due to health-care plans, health-care clearinghouses, third-party billing practices, clinical research trials, and the transmission of health information in electronic form. Protected health information (PHI) must be confidentially maintained by a health-care provider to prevent any unauthorized use or disclosure. Other covered entities, such as Organized Health Care Arrangements, HMO's and insurance plans, must also follow the Privacy Rule.

A. Definitions. Under the Privacy Rule, certain terms have specific meanings.

1. "Covered entity" means:

a. a health plan (e.g., group health insurance, Medicaid, Medicare).

b. a health-care clearinghouse (e.g., billing service companies and companies that process health information received from another entity).

c. a health-care provider who transmits any health information in electronic form in connection with a transaction covered by HIPAA. "Health care" is defined as including the sale or dispensing of a drug, device, equipment, or other item in accordance with a prescription.

2. "Individually identifiable health information" is information created or received by a covered entity that relates to the past, present, or future physical or mental health or condition of an individual; the provision of health care to an individual; or any payment for any provision of any health care, **and** that identifies the individual **or** that provides a reasonable basis to identify the individual. The items listed below are deemed sufficient to identify an individual:

a. Name

b. Address, including all geographic subdivisions smaller than a state (e.g., street address, city, county, zip code)

c. Dates (except year), including birth dates, admission dates, discharge dates, dates of death

d. Telephone numbers

e. Fax numbers

f. E-mail addresses

g. Social Security numbers
h. Medical record numbers
i. Health plan beneficiary numbers
j. Account numbers
k. Certificate/license numbers
l. Vehicle identifiers and serial numbers, including license plate numbers
m. Device identifiers
n. Web universal resource locaters (URLs)
o. Internet protocol (IP) address numbers
p. Biometric identifiers, including fingerprints and voice prints
q. Full face photographic images and any comparable images
r. Any other unique identifying number, charactistic, or code, except for codes assigned to reidentify information that has been de-identified
s. Names of any relative, employer, or household member of the individual
P.552

3. "Protected health information" (PHI) is all individually identifiable health information that is transmitted or maintained in **any** form or medium, electronically or otherwise.
4. "Notice of privacy practices for protected health information." An individual has the right to adequate notice of the uses and disclosures of PHI that may be made by the covered entity, and of the individual's rights and the covered entity's legal duties with respect to PHI. Generally, the notice must contain information describing the individual's rights under the Privacy Rule and the covered entity's responsibilities.
a. Header. Every notice must contain the following statement as a header or be otherwise prominently displayed: "THIS NOTICE DESCRIBES HOW MEDICAL INFORMATION ABOUT YOU MAY BE USED AND DISCLOSED AND HOW YOU CAN GET ACCESS TO THIS INFORMATION. PLEASE REVIEW IT CAREFULLY."
b. Individual's rights. An individual has the right to request restrictions on certain uses and disclosures of PHI, the right to receive confidential communications of PHI by alternative means or at alternative locations, the right to inspect and copy his PHI, the right to amend his PHI, the right to receive an accounting of disclosures of PHI, and the right to obtain a paper copy of the notice from the covered entity.
c. **Covered entity's responsibilities.** The notice must include a statement that the covered entity is required by law to maintain the privacy of PHI, a statement of its legal duties and privacy practices with respect to PHI, a statement that it must abide by the notice currently in effect, and a statement that it reserves the right to change the terms of its notice and how it will provide individuals with a revised notice.
d. Miscellaneous contents of notice. The notice must contain a statement that individuals may complain to the covered entity and to the U.S. Department of Health and Human Services if they believe their privacy rights have been violated. The

notice must state a date on which it becomes effective. The effective date must be no later than the date of the first service delivery.

e. Posting of notice. A pharmacy must post the notice in a clear and prominent location where it is reasonable to expect individuals to be able to read the notice.

f. Written acknowledgment of notice. Every covered entity must obtain a written acknowledgment of receipt of the notice by the individual. If one is not obtained, the covered entity must document its good-faith efforts to obtain the acknowledgment and the reason why it was not obtained.

g. Exceptions for inmates. A person incarcerated in or otherwise confined to a correctional institution does not have a right to notice under the Privacy Rule, and the notice requirements do not apply to a correctional institution that is a covered entity.

5. "Authorization" for a covered entity to use or disclose PHI: a patient must give written authorization before a covered entity, including pharmacies and pharmacists, may use or disclose PHI. **No patient consent or authorization** is necessary when PHI use and disclosure is for **treatment, payment, or health-care operations.** This allows a health-care provider to consult with other covered entities (i.e., other health-care providers) to provide proper patient care without being unduly hindered by the Privacy Rule. For uses and disclosures that require an authorization, the **written authorization** must be written in plain language, and a **signed copy** must be provided to the individual. The signed authorization must be maintained by the covered entity for **6 years** from the date of its creation or the date when it was last in effect, whichever is later. The written authorization must at least contain the following core elements and statements:

a. A description of the information to be used or disclosed that identifies the information in a specific and meaningful fashion.

b. The name or other specific identification of the person(s), or class of persons, authorized to make the requested use or disclosure.

c. The name or other specific identification of the person(s), or class of persons, to whom the covered entity may make the requested use or disclosure.

d. A description of each purpose of the requested use or disclosure.

e. An expiration date or an expiration event that relates to the individual or the purpose of the use or disclosure.

f. Signature of the individual and date. If signed by a personal representative, it must also include a description of such representative's authority to act for the individual.

g. The written authorization must contain the following statements:

(1) The individual's right to revoke the authorization in writing along with the exceptions to the right to revoke and a description of how the individual may revoke the authorization.

(2) The ability or inability to condition treatment, payment, enrollment, or eligibility for benefits on the authorization, by stating either that the covered entity cannot

require authorization, or that if the covered entity can require authorization, the consequences to the individual of his or her refusal to sign the authorization.
(3) The potential for the disclosed information to be redisclosed by the recipient and no longer be protected by the Privacy Rule.
6. "Minimum necessary." When using or disclosing PHI or when requesting PHI from another covered entity, a covered entity must make reasonable efforts to limit PHI to the **minimum necessary** to accomplish the intended purpose of the use, disclosure, or request. The minimum necessary rule **does not apply** to disclosures or requests by a health-care provider for treatment, uses or disclosures made pursuant to an authorization, and uses or disclosures that are required by law. "Required by law" means a mandate in a law that compels an entity to make a use or disclosure of PHI. It includes a covered entity's compliance with state and federal laws and regulations that require the production of information; court orders and court-ordered warrants, subpoenas or summons issued by a court, a governmental or tribal inspector general, or an administrative body authorized to require the production of information and Medicare conditions of participation with respect to health-care providers participating in the program.
7. "Business associates." A business associate of a covered entity is a person or business that performs a function or activity on behalf of the covered entity, such as claims processing, billing, utilization review, quality assurance, etc., **and** that requires the use or disclosure of individually identifiable health information. A business associate would also include persons who provide services to the covered entity, **and** the service involves disclosure of individually identifiable health information, such as legal, actuarial, accounting, consulting, data aggregation, management, administrative, accreditation, or financial services. **Excluded** from the definition of business associates are members of the workforce of the covered entity, and functions or services that do not require disclosure of individually identifiable health information.
a. Business associate contracts. Every business associate must enter into an agreement with the covered entity to ensure compliance with the Privacy Rule. Generally, the agreement must establish the required uses and disclosures of PHI by the business associate and require the return or destruction of PHI at termination of the contract.
B. Additional responsibilities of covered entities. Every covered entity must create policies and procedures for compliance with the Privacy Rule, must designate a privacy official responsible for creating such policies and procedures, must designate a contact person or office that is responsible for receiving complaints and that is able to provide further information about matters covered by the notice, and must train all members of its workforce with respect to the Privacy Rule. Every designation must be maintained by the covered entity for 6 years from the date it last was in effect. Lastly, every covered entity must have and apply appropriate sanctions against members of its workforce who fail to comply with the Privacy Rule.
C. State law privacy rules. The federal Privacy Rule is intended as the minimum requirement for privacy standards. If a state law is more stringent, then a covered

entity must follow that state's privacy standards. If a state privacy law is not as stringent, the federal Privacy Rule preempts any contrary state law and a covered entity must abide by the federal Privacy Rule.

D. Penalties for violation of the Privacy Rule. Any person who violates the Privacy Rule may not be fined more than $100 for each violation up to a total of $25,000 per calendar year for all violations of an identical requirement. Additional penalties may be imposed for the following **wrongful disclosure** of individually identifiable health information:

1. Wrongful obtainment or disclosure of PHI: fined not more than $50,000, imprisoned not more than 1 year, or both.

2. Wrongful obtainment or disclosure of PHI under false pretenses: fined not more than $100,000, imprisoned not more than 5 years, or both.

3. Wrongful obtainment or disclosure of PHI committed with intent to sell, transfer, or use same for commercial advantage, personal gain, or malicious harm: fined not more than $250,000, imprisoned not more than 10 years, or both.

VIII. NARCOTIC TREATMENT PROGRAMS.

Methadone use is currently allowed as part of a total treatment program for narcotic addiction. Regulations concerning methadone treatment programs have been jointly established by the DEA and FDA. Narcotic-dependent individuals are those who physiologically need heroin or a morphine-like drug to prevent the onset of signs of withdrawal.

A. Definition. A narcotic treatment program is an organization that administers or dispenses a narcotic drug to a narcotic addict for maintenance or detoxification treatment, and provides, when appropriate or necessary, a comprehensive range of medical and rehabilitative services. The program must be:

1. Approved by the FDA

2. Approved by the appropriate state agency, usually the state's Department of Public Health or equivalent

3. Registered under the Federal Controlled Substances Act with the DEA to use a narcotic drug for the treatment of narcotic addiction

B. Detoxification treatment is defined as dispensing of narcotic drugs in decreasing doses to an individual to alleviate adverse physiological or psychological effects incident to withdrawal of narcotic drug use. Detoxification is for a period not in excess of 180 days.

C. Maintenance treatment is the dispensing of a narcotic drug, at relatively stable dosage levels, in the treatment of an individual for dependence on heroin or other morphine-like drug.

D. Requirements to admit patients into a program. In general, for a patient to be admitted into a comprehensive maintenance program, the following requirements must be met:

1. A program physician must determine that the person is currently physiologically dependent on a narcotic drug and became physiologically dependent at least 1 year before admission to the program.
2. The patient must have voluntarily chosen to participate in the program and must sign a “Consent to Methadone Treatment” (provided by the FDA) after being clearly and adequately informed about the use of methadone.
E. Take-home methadone. Take-home methadone may be given only to patients who, in the clinical judgment of the program physician, are responsible in handling narcotic drugs. The patient must come to the clinic for observation daily or at least 6 days a week. Over time, the program physician may reduce clinical observations to once weekly. Methadone for take-home use must be dispensed similarly to the dispensing of any schedule II controlled substance and include the treatment center's name, address, and telephone number on its label.
P.555

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.
1. All of the following prescription medications may be delivered by mail to the patient via the U.S. Postal Service EXCEPT
(A) procainamide
(B) ampicillin
(C) hydromorphone
(D) diazepam
(E) all of the above may be delivered by mail
View Answer***1. The answer is E[].*****2. Which of the following narcotic drugs has been approved by the FDA for use in the treatment of narcotic addiction?**
(A) Morphine
(B) Codeine
(C) Methadone
(D) Hydrocodone
(E) None of the above
View Answer***2. The answer is C[].*****3. For the U.S. government to place a drug into schedule III, which of the following findings must be made concerning the drug?**
(A) The drug or other substance has a high potential for abuse.
(B) Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in schedule IV.
(C) The drug or other substance has no currently accepted medical use in treatment in the United States.

(D) Abuse of the drug or other substance may lead to moderate or low physical dependence or high psychological dependence.
(E) There is a lack of accepted safety for use of the drug or other substance under medical supervision.

View Answer***3. The answer is D[].*****4. Under the Federal Controlled Substances Act, all of the following items must appear on a controlled-substance prescription label EXCEPT the**

(A) name, address, and DEA number of the pharmacy.
(B) name of the patient.
(C) name of the prescribing practitioner.
(D) serial number assigned to the prescription.
(E) date of the initial filling of the prescription.

View Answer***4. The answer is A[and].*****5. Under the Federal Controlled Substances Act, all of the following entities must register with the DEA EXCEPT**

(A) prescribers of controlled substances.
(B) pharmacists who dispense controlled substances.
(C) distributors of controlled substances.
(D) importers of controlled substances.
(E) universities conducting instructional activities with controlled substances listed in schedules II-V.

View Answer***5. The answer is B[and].*****6. Under the Federal Controlled Substances Act, which of the following statements concerning the emergency dispensing of a schedule II controlled substance is true?**

(A) The practitioner who authorizes the oral prescription must, within 7 days, deliver a written prescription to the dispensing pharmacist.
(B) The quantity prescribed and dispensed must be limited to the amount necessary to adequately treat the patient during the emergency period.
(C) It is not reasonably possible for the practitioner to provide a written prescription to be presented to the person dispensing the controlled substance before the dispensing.
(D) No appropriate alternative treatment is available, including administration of a controlled substance that is not in schedule II.
(E) All of the above statements are true.

View Answer***6. The answer is E[].*****7. Under the Federal Controlled Substances Act, the crime transfer warning, "Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed," must appear on the prescription container label of all controlled substances EXCEPT**

(A) schedule II controlled substances.
(B) schedule III controlled substances.
(C) schedule IV controlled substances.
(D) schedule V controlled substances.

View Answer***7. The answer is D[].***

8. Which of the following statements concerning drug recall classification is true?

(A) A Class I recall is a situation in which use of, or exposure to, a violative product is not likely to cause adverse health consequences.

(B) A Class I recall is a situation in which use of, or exposure to, a violative product may cause temporary or medically reversible adverse health consequences or in which the probability of serious health consequences is remote.

(C) A Class I recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

(D) A Class II recall is a situation in which use of, or exposure to, a violative product is not likely to cause adverse health consequences.

(E) A Class III recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

View Answer***8. The answer is C[and].*****9. Under the Federal Food, Drug, and Cosmetic Act, all of the following statements are considered a misbranding of a drug EXCEPT if**

(A) the labeling is false or misleading in any particular.

(B) an oral contraceptive is dispensed without the required patient package insert.

(C) the drug is an imitation of another drug, or if it is offered for sale under the name of another drug.

(D) the drug consists in whole or in part of any filthy, putrid, or decomposed substance.

View Answer***9. The answer is D[].*****10. All of the following oral medications are exempt from child-resistant packaging EXCEPT**

(A) anhydrous cholestyramine in powder form

(B) nitroglycerin preparations in sustained release form

(C) cyclically administered oral contraceptives in manufacturers' mnemonic (memory-aid) dispenser packages that rely solely upon the activity of one or more progestogen or estrogen substances

(D) pancrelipase preparations in tablet, capsule, or powder form that contain no other prescription medication

View Answer***10. The answer is B[].***P.557

ANSWERS AND EXPLANATIONS

1. The answer is E *[V].*

Narcotics and controlled substances in schedules II-V may be delivered to the patient by mail. The U.S. Postal Service no longer prohibits the mailing of narcotics by a physician or pharmacist (pursuant to a prescription) to the patient.

2. The answer is C *[*VIII; VIII.A; I.I.2.c.(2)*].*

Methadone is approved by the FDA for use in the treatment of narcotic addiction. Only a properly registered narcotic treatment program may dispense methadone for maintenance or detoxification treatment. Pharmacies that are not so registered may only dispense methadone for severe pain.

3. The answer is D *[*I.A.3*].*

To place a drug into schedule III, the U.S. government must make the following findings concerning the drug: (1) it has a potential for abuse less than the drugs or other substances in schedules I and II; (2) it has a currently accepted medical use in treatment in the United States; and (3) abuse of the drug may lead to moderate or low physical dependence or high psychological dependence.

4. The answer is A *[*I.I.8.c.(1), (2), (3), (4), (5), (6) *and* (7)*].*

A pharmacy's DEA number is not required to appear on the medication container label dispensed to the patient.

5. The answer is B *[*I.B.2.a, b, c, d, e, f, g, h, i, j *and* k; I.B.9.d*].*

Agents and employees of DEA registrants, such as pharmacists, are exempt from registering with the DEA. Pharmacies, not the individual pharmacists, must register with the DEA.

6. The answer is E *[*I.I.4.a, b*].*

Emergency dispensing of an oral schedule II controlled-substance prescription must be done in strict compliance with the law. Before dispensing such a prescription, the pharmacist must make the threshold determination that ALL three factors that define an emergency situation (see I.I.4.a) are present. If any one of the three factors is absent, the prescription is not for an emergency situation, and a written prescription must be presented to the pharmacist.

7. The answer is D *[*I.I.8.c.(7)*].*

The federal crime transfer warning label is not required to appear on the prescription container label of schedule V controlled substances.

8. The answer is C *[*II.H.2.a, b *and* c*].*

A Class I recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

9. The answer is D *[*II.I.1, 2*].*

The Federal Food, Drug, and Cosmetic Act states that a drug is considered adulterated if it consists in whole or in part of any filthy, putrid, or decomposed substance. The terms “misbranding” and “adulteration” are often referred to in literature and case law as being the same or similar violations under the law. However, the Act sets forth specific instances of adulteration and specific instances of misbranding.

10. The answer is B *[*III.A.1*].*

Only sublingual dosage forms of nitroglycerin are exempt from child-resistant packaging.

26

Reviewing and Dispensing Prescription and Medication Orders

Todd A. Brown

I. DEFINITIONS

A. Prescriptions are orders for medications, nondrug products, and services that are written by a licensed practitioner or midlevel practitioner who is authorized by state law to prescribe (see Appendix A). Pharmacists are increasingly being given prescribing privileges by enactment of state **collaborative drug therapy management** (CDTM) legislation. This allows pharmacists to change the dose of existing medications or order new medication under established protocols or guidelines agreed on by the pharmacist and physician. Practitioners may prescribe only medications that are within their scope of practice. Prescriptions may be written, presented orally (by telephone), or presented electronically (i.e., via fax or computer network) to the pharmacist. The requirements of the prescription form include security features and tamper-resistant characteristics and vary with state regulations. The prescription serves as a vehicle for communication from the prescriber to the pharmacist about the needs of the patient. The following information should be included on a prescription:

1. Patient information, including full name and address

2. Date on which the prescription was issued

3. Name and dosage form of the product. The name can be any of the following:

a. Proprietary (brand)

b. Nonproprietary (generic)

c. Chemical

4. Product strength. The strength of the product is not required if only one strength is commercially available or if the product contains a combination of active ingredients. It is advisable to include the strength to reduce the chance of misinterpreting the prescription. If the dose is to be calculated by the pharmacist, then the pharmacist can decide the strength of the product dispensed after calculating the patient's dose.

5. Quantity to be dispensed. This should include the amount and the units of measure (e.g., grams, ounces, tablets). If the amount is not specified, the directions should specify the dose to be taken and the duration of therapy so that the pharmacist can calculate the quantity required for the patient.

6. Directions for the pharmacist. Directions may be required for:

a. Preparation (e.g., compounding)

b. Labeling (i.e., information to be put on the prescription label)

7. Directions for the patient. These should include explicit instructions on the quantity, schedule, and duration for proper use. “As Directed” should be avoided. If the directions vary, a minimum and maximum dose can be used.

8. Refill information. If refill information is not supplied, it is generally assumed that no refills are authorized. “As needed” (pro re nata [prn]) refills are usually

interpreted as allowing for refills for 1 year unless laws or regulations restrict the amount or time period in which a prescription is valid.

9. Prescriber information. This should include the name, office address, signature of the prescriber, the Drug Enforcement Administration (DEA) number (for controlled substances only) and the National Provider Identifier (NPI) number.

P.559

B. Medication orders are orders for medications by an individual authorized to prescribe and are intended for use by patients while in an institutional setting. They may be written, presented orally (by telephone), or presented electronically (i.e., via fax or computer network) to the pharmacist. The medication order generally includes

1. Patient information (e.g., full name, identification number)

2. Date and time the order was written

3. Name of the product. The name can be any of the following:

a. Proprietary (brand)

b. Nonproprietary (generic)

c. Chemical

4. Product strength, dosage, and route of administration. The strength of the product is not required if only one strength is commercially available or if the product contains a combination of active ingredients. It is advisable to include the strength to reduce the chance of misinterpreting the order. The pharmacist may decide the strength of the product dispensed after calculating the patient's dose. The dosage and route of administration should be included to reduce the chance of misinterpreting the order and to allow for correct administration to the patient.

5. Prescriber's signature. If the order was taken verbally, the name of the person transcribing the order should be included.

6. Directions for the pharmacist. These can be used for:

a. Preparation (e.g., compounding)

b. Labeling (i.e., information to be put on the label)

7. Instructions for administration, including quantity, route of administration, schedule, and duration of use

II. UNDERSTANDING THE PRESCRIPTION OR MEDICATION ORDER AND EVALUATING ITS APPROPRIATENESS

A. Understanding the order. A complete understanding of all information contained in a prescription or medication order is required. Each piece of information should be appropriate and consistent with the remaining information (i.e., the instructions for use should be appropriate for the medication being ordered). The pharmacist should read the entire prescription or medication order carefully to determine the prescriber's intent by interpreting the following information:

1. The name and address of both the patient and the prescriber

2. The patient's disease or condition requiring treatment

3. The reason the order is indicated, relative to the medical need of the patient (e.g., an antibacterial for an infection)
4. The name of the product, the quantity prescribed, and instructions for use
5. All terminology, including units of measure (apothecary, metric, or English) and Latin abbreviations (see Appendix A for common abbreviations)
B. Evaluating the appropriateness. Complete information is required on the prescription or medication order to provide the necessary information to allow the pharmacist to evaluate the appropriateness of the order. When the order is incomplete, the pharmacist must obtain the required information from either the patient or the prescriber. The following should be considered during an evaluation:
1. The patient's disease or condition requiring treatment
2. The patient's allergies or hypersensitivities
3. The pharmacological or biological action of the prescribed product
4. The prescribed route of administration
5. Whether the prescribed product might result in a drug-drug, drug-disease, or drug-food interaction

6. Whether the dose, dosage form, and dosage regimen are safe and likely to meet the needs of the patient
7. Whether the patient will have any difficulties adhering to the regimen and the potential impact on the therapeutic outcome desired
8. Whether the total quantity of medication prescribed is sufficient to allow proper completion of a course of therapy
9. Whether a physical or chemical incompatibility might result (i.e., if the product requires extemporaneous compounding)
10. Whether a licensed practitioner, acting in the course and scope of practice, issued the prescription in good faith, for a legitimate medical purpose
C. Discovering inappropriate prescriptions or medication orders. Pharmacists are required to review medication profiles to ensure the appropriateness of prescriptions or medication orders. This is commonly called drug utilization review (DUR). Pharmacists should not fill or process prescriptions or medication orders that they have concerns with or that are considered inappropriate but, rather, should contact the prescriber. The process of calling a prescriber to discuss concerns identified during a DUR is commonly called **therapeutic intervention.**
1. When performing a therapeutic intervention, the following information should be provided:
a. A brief description of the problem
b. A reference source that documents the problem
c. A description of the clinical significance of the problem
d. A suggestion of a solution to the problem
2. The following resolutions are possible to solve the problem or concern:
a. The prescription or medication order will be dispensed as written.
b. The prescription or medication order will not be dispensed.

c. The prescription or medication order will be altered and dispensed.

3. Documentation of the results of a therapeutic intervention are required if the prescription or medication order is changed. The name of the prescriber, date of communication, issues discussed, and resolution should be included in the documentation. This information should be kept for the same time period as the prescription or medication order.

4. If the pharmacist feels that, in his or her professional judgment, an order is inappropriate and could harm the patient, the pharmacist should not process the order. The pharmacist may also be required to explain the situation to the patient. If, after a therapeutic intervention, the pharmacist believes the order is still inappropriate, the guidelines of the institution and professional judgment should be followed.

III. PROCESSING PRESCRIPTIONS AND MEDICATION ORDERS

requires that the pharmacist follow appropriate guidelines. An environment that limits distractions and disruptions during these activities will assist in increasing the accuracy of this process. Automation and the use of pharmacy technicians allow the pharmacist to oversee these functions but spend less time performing these activities. The time saved allows the pharmacist greater time for patient-focused activities, such as counseling and patient education.

A. The following information should be recorded on the prescription:

1. The prescription number (for initial filling)

2. The original date of filling

3. The product and quantity dispensed

4. The pharmacist's initials

B. Product selection. Generic substitution statutes, as well as formulary and therapeutic substitution policies, might provide direction in product selection.

C. Product preparation for use by the patient. The following might be necessary for preparation:

1. Obtaining the proper amount of medication to be dispensed

2. Reconstitution (the addition of liquid to make a solution or suspension)

3. Extemporaneous compounding (see Chapter 5)

4. Assembly of the medication delivery unit

D. Selection of the proper package or container is required to ensure product stability, to promote patient compliance, and to comply with legal requirements. This information is commonly found in the *United States Pharmacopeia* (USP).

E. Labeling the prescribed product

1. The **prescription label** typically contains the following information:

a. Name and address of the pharmacy

b. Patient's name

c. Original date of filling

d. Prescription number
e. Directions for use
f. Product's brand name or generic name and manufacturer
g. Product strength (if available in more than one strength)
h. Quantity of medication dispensed
i. Prescriber's name
j. Expiration date of the medication
k. Pharmacist's initials

2. Unit-dose packages contain one dose or one unit of medication. For a medication order that is dispensed in **unit-dose packages,** the label should identify the product's brand or generic name, strength, lot number, and expiration date.

3. Auxiliary and cautionary labels. To ensure proper medication use, storage, and compliance with applicable statutes, and to reinforce information provided during counseling, auxiliary and/or cautionary labels should be affixed when appropriate (see Appendix A).

4. For medication in schedules II-IV (see Chapter 25), a federal transfer warning is required.

F. Record keeping and confidentiality. The pharmacist is required to maintain **prescription files** and **records** in accordance with standards of sound practice and statutory requirements. The implementation of the **Healthcare Insurance Portability and Accountability Act** (HIPAA) has put additional requirements on all health professionals who have access to health information (see Chapter 25). The records include a **patient profile,** containing patient demographic information and a complete chronological record of all medication use and services provided in the delivery of pharmaceutical care.

1. The patient profile should contain the following **patient information:**
a. Patient's name
b. Patient's address (or room number in institutional settings)
c. Any known allergies, sensitivities, or history of idiosyncratic reactions to previous medications
d. Birth date (i.e., to assess the appropriateness of the dose)
e. Clinical condition(s) (to help assess the appropriateness of the medication and to prevent drug-disease interactions)
f. Weight (to assess the appropriateness of the dose)
g. Occupation (to detect conditions associated with a particular occupation and to help determine if the patient will be able to comply with the regimen)
h. Nonprescription medication use (to prevent drug-drug and drug-disease interactions, to assess medication effectiveness, and to detect possible adverse effects)

2. In addition, the patient profile should contain the following information from each prescription or medication order:
a. Name of the medication
b. Medication strength
c. Dosage form
d. Quantity dispensed

e. Directions for use
f. Prescription number
g. Dispensing date
h. Number of refills authorized and remaining
i. Prescriber's name
j. Pharmacist's initials

IV. DISPENSING MEDICATION AND COUNSELING.

The dispensing of medication requires that the pharmacist verify that patients have the necessary knowledge and ability to adhere to the prescribed treatment. This will increase the likelihood of obtaining the desired outcomes.

A. Counseling patients. The pharmacist should evaluate the patient's understanding of each medication and supply additional information when the patient's information is incorrect or insufficient. The pharmacist might need to advise patients regarding the proper dosage, appearance, and name of the medication. Information about the route of administration, instructions for use, duration of use, and the reason the product was prescribed may also be needed. In addition, the following topics might also be appropriate during the counseling session:

1. Special procedures. As appropriate, the pharmacist should advise patients on how to take the medication (e.g., on an empty stomach, with plenty of water) and instruct them on foods to avoid while taking the medication (e.g., alcoholic beverages, dairy products).

2. Potential adverse effects. The pharmacist should ensure that patients are aware of the possible adverse effects associated with the medication. Patients should understand the following:

a. The **frequency** of an adverse effect. This will help patients recognize common adverse effects and not be overly concerned with those that are rare.

b. The **severity** of an adverse effect. This will help patients focus on those adverse effects that are severe and not those that are inconsequential.

c. What action should be taken to **manage** or **minimize** the adverse effect. This will help patients deal with possible adverse effects in the appropriate manner.

3. Proper storage. The pharmacist should counsel patients on how to store medications properly to ensure stability and potency.

4. Over-the-counter (OTC**) products.** The pharmacist should instruct patients about the use of OTC products that might or might not be appropriate when taking a prescribed product.

B. Counseling health professionals. Health professionals (i.e., in an institutional setting) may administer medications to patients. In these cases, the pharmacist should ensure that the health professional has sufficient knowledge to administer the product. Information that health professionals would need to administer medications safely and effectively include the following:

1. The choice of a particular product
2. The proper dosage, dosage regimen, and route of administration
3. The cost of the prescribed product and the costs associated with its use (i.e., administration costs and costs of treating possible adverse effects)
4. The availability of commercially made products
5. Potential adverse effects
6. Drug interactions
7. Physical incompatibilities
8. Safe handling and disposal procedures
9. Nutritional interactions or requirements
10. Drug interference with laboratory tests

V. PATIENT MONITORING.

The provision of pharmaceutical care requires a **pharmaceutical care plan** (see Chapter 20). Monitoring a patient's need for medication and the effect of the medication

on the patient maximizes the effectiveness of the medications being taken. Undesired outcomes associated with drug therapy are frequently called **drug therapy problems.**

A. Pharmaceutical care plan. To increase the frequency and benefits of desired outcomes, a pharmaceutical care plan should include the following:

1. Assessment. A review of the medical conditions and symptoms to determine the need for medication

2. Plan. A decision of an appropriate drug therapy based on the assessment of the patient

3. Monitoring. A review of the outcomes of drug therapy (i.e., goals and end points) to determine if the patient is obtaining the desired outcomes

B. Drug therapy problems are evidence of less-than-optimal drug therapy. Detection of drug-related problems requires an assessment of the need for a change in drug therapy. Possible problems include

1. Unnecessary drug therapy. The medication cannot be associated with a medical condition or the presence of a condition in which nondrug therapy is more appropriate.

2. Wrong drug. The drug is not indicated for the condition or is not delivering the desired outcomes, or a more effective drug is available.

3. Dose too low. Incorrect dose, frequency, administration, or duration of therapy results in an insufficient dose of drug to the patient.

4. Adverse drug reaction. An allergic reaction, drug interaction, or an undesirable effect occurs from a medication.

5. Dose too high. Incorrect dose, frequency, or duration, results in more medication than is required.

6. Inappropriate adherence. The patient is not taking the optimal amount of medication owing to cost, administration difficulties, alternative health beliefs, or a lack of understanding of the need for the medication.

7. Need additional drug therapy. Owing to an undertreated condition, synergism with concurrent drug therapy or prophylactic therapy is required.

P.564

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Medication orders differ from prescriptions in which of the following ways? They

(A) are intended for ambulatory use.

(B) contain only the generic name of the medication.

(C) are intended for institutional use.

(D) may be transmitted electronically.

(E) contain the quantity of medication to be dispensed.

View Answer***1. The answer is C[see].*****2. If a therapeutic intervention is necessary, all of the following information should be communicated to the prescriber *except***

(A) a declaration that “a mistake was made.”

(B) a brief description of the problem.

(C) a reference source that documents the problem.

(D) an alternative or suggestion to resolve the problem.

(E) a description of the clinical significance of the problem.

View Answer***2. The answer is A[see].*****3. The following information should be recorded on a prescription *except* the**

(A) prescription number.

(B) date of filling.

(C) expiration date.

(D) product and quantity dispensed.

(E) pharmacist's initials.

View Answer***3. The answer is C[see].*****4. A prescription label usually contains all of the following *except* the**

(A) quantity dispensed.

(B) lot number.

(C) patient's diagnosis.

(D) expiration date.

(E) prescriber's name.

View Answer***4. The answer is C[see].*****5. Auxiliary and cautionary labels should be used for all of the following purposes *except* to**

(A) substitute for verbal consultation.

(B) ensure proper usage.
(C) inform of storage requirements.
(D) comply with regulatory requirements.
(E) warn against the concomitant use of certain drugs or foods.

View Answer***5. The answer is A[see].*****6. The following items are essential for a patient profile system *except***
(A) the patient's name.
(B) the prescriber's Drug Enforcement Administration (DEA) registration number.
(C) the patient's allergies.
(D) the patient's birth date.
(E) instructions for medication use.

View Answer***6. The answer is B[seeand].*****7. The following are drug therapy problems *except***
(A) an adverse effect from a medication.
(B) symptoms caused by undertreatment.
(C) a drug-drug interaction.
(D) an undiagnosed condition.
(E) an allergic reaction to a medication.

View Answer***7. The answer is D[see].***P.565

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* I.B*].*
Medication orders are written for the care of inpatients. Both medication orders and prescriptions may contain the brand or generic name of the drug and may be transmitted electronically. Only prescriptions contain the quantity of medication to be dispensed.

2. The answer is A *[see* II.C.1*].*
Information provided to the prescriber during a therapeutic intervention should include a description of the problem, reference source, description of the clinical significance, and an alternative. Informing the prescriber that a mistake was made does not encourage cooperation and resolution of the problem.

3. The answer is C *[see* III.A*].*
The prescription number, date of filling, product and quantity dispensed, and pharmacist's initials should be recorded on the prescription. The expiration date of the product being dispensed is not required.

4. The answer is C *[see* III.E.1*].*
The quantity of medication dispensed, lot number, expiration date of the product, and prescriber's name are usually included on the label. The patient's diagnosis, although listed in the patient's profile, is not included on the prescription label.

5. The answer is A *[see* III.E.3; IV.A.1*].*
Auxiliary and cautionary labels are an adjunct to, not a replacement for, verbal consultation. Appropriate uses for such labels include ensuring proper use, storage

requirements, and compliance with statutory requirements, and warning against food and drug interactions.

6. The answer is B *[see* III.F.1 *and* 2*].*

The patient's name is required to identify each patient. Often, the address or room number is required to identify patients with similar names. The patient's allergies, birth date, and instructions for use are required to prevent drug allergies and to assess the appropriateness of the prescription or medication order.

7. The answer is D *[see* V.B*].*

Adverse effects, undertreated conditions, allergic reactions, and drug-drug interactions are all drug therapy problems. An undiagnosed condition may lead to a drug-related problem once diagnosed; however, diagnosis is required before the need for medication can be assessed.

27

Sterile Products

John Fanikos

I. INTRODUCTION.

The United States Pharmacopeia and The National Formulary (USP) published practice standards for compounding sterile preparations after case reports of patient harm and fatality. The procedures and requirements outlined in USP Chapter 797 are intended to prevent patient harm resulting from ingredient errors and microbial contamination. The chapter includes compounding personnel responsibilities, training and evaluation requirements, medication preparation sterility and accuracy verification, classification of microbial contamination risk, and equipment and environmental quality and control. While these standards apply to all facilities (hospitals, nursing homes, pharmacies) and all practitioners (physicians, nurses, technicians), they are especially important for pharmacists who are most often involved with sterile medication preparation. Since the standards require substantial investment in labor, equipment, and supplies, regulatory agencies (Food and Drug Administration, Joint Commission on Accreditation of Health Care Organizations, U.S. state boards of pharmacy) are expecting implementation by January 2006, with evidence of long term compliance and routine monitoring thereafter.

II. DEFINITIONS

A. Sterility, an absolute term, means the absence of living microorganisms.

1. Microbe is a microscopic organisms such as a bacteria, fungus, protazoa or virus

2. Pyrogens are metabolic by-products of live or dead microorganisms that cause a pyretic response (i.e., a fever) upon injection.

3. Sterile products are pharmaceutical dosage forms that are sterile. This includes products like parenteral preparations, irrigating solutions, and ophthalmic preparations (see Chapter 29). Sterile product compounding requires cleaner facilities, personnel training and testing, and a sound knowledge of sterilization and stability principles and practices.

4. Aseptic manipulations refers to the techniques and procedures used during compounding that maintain the sterility of pharmaceutical dosage forms.

5. Compounded Sterile Preparations (CSPs) include;

a. Preparations, when prepared according to manufacturer instructions, expose a sterile agent to potential microbial contamination.

b. Preparations made from nonsterile ingredients that must be sterile before patient administration.

c. Sterile or nonsterile biologicals (vaccines, immune globulins), diagnostics, medications, nutritionals, and radiopharmaceuticals that must be sterile prior to administration or use as an irrigation, bath, implant, inhalation, injection, or for use in the eye or ear.

6. Microbial Contamination Risk Levels are assigned according to the probability of contaminating a preparation with microbial organisms, endotoxins, or with foreign chemical or physical particulate matter.

a. Low Risk Level CSPs are compounded by aseptically transferring a single sterile dosage form from a sterile ampule, vial, bottle, or bag using sterile needles and syringes to a final sterile container or device for patient administration.
b. Medium Risk Level CSPs are compounded by aseptically transferring multiple sterile dosage forms from sterile ampules, vials, bottles, or bags using sterile needles and syringes to a single final sterile container or device for administration to multiple patients or to one patient on multiple occasions.
c. **High Risk Level CSPs** are compounded from nonsterile ingredients and terminally sterilized prior to patient administration or sterile ingredients that are compounded under inferior air quality conditions.

d. Immediate-use CSPs are compounded in emergency situations or where immediate patient administration is mandated to avoid or harm that may result from delays in treatment.
7. Compounded Parenteral Preparations are pharmaceutical dosage forms that are injected through one or more layers of skin. Because the parenteral route bypasses the protective barriers of the body, parenteral preparations must be sterile. The pH of a solution may markedly influence the stability and compatibility of parenteral preparations (see V.B).
B. Design and function of sterile compounding areas
1. Cleanrooms are areas specially constructed and maintained to reduce the probability of environmental contamination of sterile products during the manufacturing process. Engineering controls to reduce the potential for airborne contamination include airflow through high-efficiency particulate-air (HEPA) filters, use of horizontal flow clean benches, vertical flow clean benches, biological safety cabinets, and barrier isolators. Clean room are traditionally designed in multi-compartments or partitioned work areas for aseptic processing (Figure 27-1).
a. Ante-area provides a clean area for personal hygiene and for donning personal protective equipment such as hair covers, gloves, gowns, or full clean room attire (Figure 27-2). Supplies are removed from shipping cartons and decontaminated with a disenfecting agent. The area should provide at least an International Organization for Standardization (ISO) Class 8 or better work environment.
b. Buffer area contains the work surfaces for the staging of supplies and equipment used in CSP preparation. It should provide at least an ISO Class 7 work environment. The buffer area should contain no sinks or drains and be free of objects that shed particles (cardboard, paper, cotton, etc.). Traffic flow in and out is minimized and restricted to qualified compounding personnel.
c. **Primary engineering control** is the room that provides the ISO Class 5 environment for CSP preparation.
d. Direct compounding area is the critical area with the primary engineering control where compounding is performed and critical sites are exposed to HEPA filtered air.

e. HEPA Filters are used to cleanse the air entering the room. These filters remove all airborne particles 0.3 mm or larger, with an efficiency of 99.97%. The reference standards for HEPA-filtered rooms has changed to a metric based system (Table 27-1). HEPA-filtered rooms are classified as ISO Class 3 through 8. An ISO Class 8 room contains no more than 3,520,000 particles of 0.5 µm or larger per cubic meter of air.

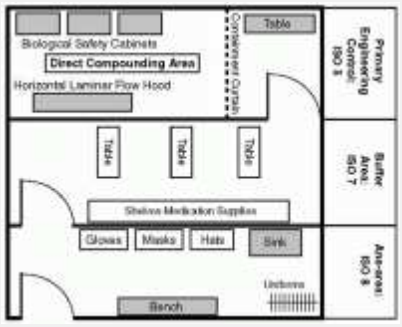

Figure 27-1. Clean room design.

Figure 27-2. Clean room attire.

f. Positive-pressure airflow is used to prevent contaminated air from flowing into the clean room. In order to achieve this, the air pressure inside the clean room must be greater than the pressure outside the room, so that when a door or window to the clean room is opened, the airflow is outward.

g. Counters in the clean room are made of stainless steel or other nonporous, easily cleaned material.

h. **Walls, floors, and ceilings** do not have cracks or crevices and have rounded corners. All surfaces should also be nonporous and washable to enable regular disinfection. If walls or floors are painted, an epoxy paint is used.

i. Airflow. As with the HEPA filters used in clean rooms, the airflow moves with a uniform velocity along parallel lines. The velocity of the airflow is 27 meters (90 feet) per minute.

Table 27-1. International Organization of Standardization (ISO) Classification of Particulate Matter in Room Air

Class Name		Particle Count Number of Particles of 0.5 µm or larger	
ISO Class	U.S. Federal Standard*	ISO (Particles per cubic meter)	U.S. Federal Standard* (Particles per cubic foot)
3	Class 1	35.2	1
4	Class 10	352	10
5	Class 100	3520	100
6	Class 1000	35,200	1,000
7	Class 10,000	352,000	10,000
8	Class 100,000	3,520,000	100,000

* Federal Standard No. 209E, General Services Administration, Washington DC, 20407

j. Critical site is any opening providing a direct path between a sterile product and the environment or any surface coming in direct contact with the sterile product and the environment. Laminar flow work benches are used to provide an adequate critical site environment. USP Chapter 797 requires sterile preparation compounding be performed in at least a ISO Class 5 quality air environment.

2. Laminar flow work benches (LFWB) are generally used in conjunction with clean rooms and are specially designed to create an aseptic environment for the preparation of sterile products. An ISO Class 5 environment exists inside a certified horizontal or vertical LFWB.

a. HEPA filter requirement. Like clean rooms, laminar flow work benches use HEPA filters, but the benches use a higher-efficiency air filter than do clean rooms.

b. Types of laminar flow work benches

(1) Horizontal laminar flow hoods (Figure 27-3) were the first hoods used in pharmacies for the preparation of sterile products. Airflow in horizontal hoods moves across the surface of the work area, flowing first through a prefilter and then through the HEPA filter. The major disadvantage of the horizontal hood is that it offers no protection to the operator, which is especially significant when antineoplastic agents are being prepared (see VII.D.).

(2) Vertical laminar flow hoods (Figure 27-4) provide two major **advantages** over horizontal flow hoods.

(a) The airflow is vertical, flowing down on the work space. This airflow pattern protects the operator against potential hazards from the products being prepared.

(b) A portion of the HEPA-filtered air is recirculated a second time through the HEPA filter. The remainder of the filtered air is removed through an exhaust filter, which may be vented to the outside to protect the operator from chronic, concentrated exposure to hazardous materials.

3. Biological Safety Cabinets (BSCs) are vertical flow hoods with four major types available. They are differentiated by the amount of air recirculated in the cabinet, whether this air is vented to the room or outside, and whether contaminated ducts are under positive or negative pressure.

a. Type A cabinets recirculate 70% of cabinet air through HEPA filters back into the cabinet, the remainder is discharged through a HEPA filter into the cleanroom, contaminated ducts are under positive pressure.

b. Type B1 cabinets recirculate 30% of cabinet air through HEPA filters back into the cabinet, the remainder is discharged through HEPA filters to the outside environment, contaminated ducts are under negative pressure.

c. **Type B2 cabinets** discharged all cabinet air through HEPA filters to the outside environment with contaminated ducts under negative pressure.

Figure 27-3. Horizontal laminar flow hood. (Photo taken by William Salkin.)

Figure 27-4. Vertical laminar flow hood. (Photo taken by William Salkin.)

d. Type B3 cabinets recirculate 70% of cabinet air through HEPA filters back into the cabinet, 30% is discharged through HEPA filters to the outside, and contaminated ducts are under negative pressure.

4. Compounding aseptic isolator (CAI) provide a ISO Class 5 environment for product preparation, with aseptic manipulations occurring inside a closed, pressurized environment accessible only via sealed gloves that reach into the work area (Figure 27-5). **Compounding aseptic containment isolators** protect workers from exposure to undesirable or hazardous drugs during the compounding and material transfer processes. Isolators use unidirectional

or turbulent airflow to remove contaminants from the unit. It uses positive air pressure to keep external airborne particles out of the isolator. This technology represents an acceptable alternative to LFWBs in a clean rooms for aseptic processing.

Figure 27-5. Barrier isolator.

3. Inspection and certification. Clean rooms, LFWBs, BSCs, and barrier isolators are inspected and certified when they are first installed, at least every 6 months thereafter, and, in the case of LFWB, BSCs, and isolators, when moved to a new location.

a. Inspections should be conducted by National Sanitation Foundation (NSF) accredited and certified technicians with expertise and training in contamination control technologies. Equipment used for testing has appropriate tolerance for the specified testing and is calibrated to National Institute of Standards and Technology (NIST) traceable standards.

b. Testing is performed per relevant industry standards and at minimum includes:

(1) HEPA filter integrity testing

(2) Airflow testing: Downflow and inflow where appropriate

(3) Particulate monitoring

(4) Pressurization monitoring (cleanrooms and barrier isolators) ensures that no particle larger than 0.3 mm passes through the HEPA filter. In addition, an anemometer is used to determine airflow velocity, and a particle counter is used to determine the particle count.

III. QUALITY CONTROL AND QUALITY ASSURANCE

A. Definitions

1. Quality control is the day-to-day assessment of all sterile compounding operations. This includes receipt of raw materials, preparation, storage, distribution, patient administration, and analytic testing of the finished product.

2. Quality assurance, an oversight function, involves the auditing of quality control procedures and systems, with suggestions for changes as needed.

B. Testing procedures. Various types of tests are used to ensure that all sterile products are free of microbial contamination, pyrogens, and particulate matter.

1. Clarity testing is used to check sterile products for particulate matter and leaks. Before dispensing a parenteral solution, pharmacy personnel should check it for particulates by swirling the solution and looking at it against both light and dark backgrounds, using a clarity testing lamp or other standard light source.

2. Compound Accuracy Checking is a double check of the used drug products and supplies by a person other than the compounder. This includes an inspection of the label and syringes used to measure the additives.

3. Beyond Use Dating represents the date and time beyond which a product should not be administered because of potency, sterility, or storage concerns. Beyond use dating should be assigned in accordance with the manufacturer's product labeling.

4. End product Testing is sterility and pyrogen testing which should be performed on all high risk CSPs that are prepared in batches of 25 units or more, multidose vials, or preparations where ingredients are exposed longer than 6-12 hours prior to sterilization.

a. Sterility testing ensures that the process used to sterilize the product was successful. The **membrane sterilization method** is often used to conduct sterility testing. Test samples are passed through membrane filters, and a nutrient medium

is then added to promote microbial growth. After an incubation period, microbial growth is determined.

b. Pyrogen testing can be accomplished by means of qualitative fever response testing in rabbits or by in vitro limulus lysate testing. Commercial laboratories are available to perform these tests. Personnel handling sterile products can attempt to avoid problems with pyrogens by purchasing pyrogen-free water and sodium chloride for injection from reputable manufacturers and by using proper handling and storage procedures.

C. Environmental Testing includes air and surface sampling to measure microbiology conditions of the cleanroom and assesses the effectiveness of cleaning and sanitizing procedures.

P.572

1. Viable Air sampling includes volumetric air collection in the controlled environment and evaluation of airborne microorganisms or collection of airborne organisms by exposing sterile nutrient plates containing tryptic soy broth (TSB) or agar (TSA) for a suitable time frame.

2. Non-viable Air Sampling is intended to evaluate the equipment that is used to create clean air. **Total Particle Counts** (Table 27-1) should be within established ISO classifications for a given compounding area.

3. Surface sampling utilizes TSA plates called replicate organism detection and counting (RODAC) plates to capture microorganism.

Both air and surface sampling plates are collected and incubated. The number of discrete colonies of organisms, colony forming units (CFUs), are counted and reported.

D. Practical quality assurance programs for noncommercial sterile products include training, monitoring the manufacturing process, personnel competency assessment, quality control check, and documentation.

1. Training of pharmacists and technicians in proper aseptic techniques and practices is the single most important aspect of an effective quality assurance program. Training should impart a thorough understanding of departmental policies and procedures.

2. By **monitoring the manufacturing process,** a supervisor can check adherence to established policies and procedures and take corrective action as necessary.

3. After training is completed **competency assessment** through performance evaluation and re-evaluation is required for routine tasks like handwashing, gowning, gloving, and aseptic manipulations. Evaluations should occur annually for personnel compounding low and medium risk CSPs and semi-annualy for high risk CSPs.

E. Process validation provides a mechanism for ensuring processes consistently result in sterile products of acceptable quality. This should include a written procedure to follow as well as evaluation of aseptic technique through process simulation.

F. Process simulation testing or Personnel Evaluation duplicates sterile compounding of low, medium, and high risk level CSPs under most stressful conditions except that an appropriate growth media (Soybean-Casein Digest Medium) is used in place of the drug products. After preparation and incubation of the final product, no growth indicates proper aseptic techniques were followed.
G. Quality control checking includes monitoring the sterility of a sample of manufactured products. The membrane sterilization method is practically employed using a commercially available filter and trypticase soy broth media.
H. Documentation of training procedures, quality control results, laminar flow hood certification, and production records are required by various agencies and organizations.

IV. STERILIZATION METHODS AND EQUIPMENT.

Sterilization is performed to destroy or remove all microorganisms in or on a product. Sterilization can be achieved through thermal, chemical, radioactive, or mechanical methods.
A. Thermal sterilization involves the use of either moist or dry heat.
1. Moist-heat sterilization is the **most widely used** and reliable sterilization method.
a. Microorganisms are destroyed by **cellular protein coagulation.**
b. The objects to be sterilized are exposed to saturated steam under 1 atmosphere pressure at a minimum temperature of **121°C** for at least 20-60 minutes.
c. An **autoclave** is commonly used for moist-heat sterilization.
d. Because it does not require as high a temperature, moist-heat sterilization causes **less product and equipment damage** compared to dry-heat sterilization.
P.573

2. Dry-heat sterilization is appropriate for materials that cannot withstand moist-heat sterilization. Objects are subjected to a temperature of at least **160°C** for **120 minutes** (if higher temperatures can be used, less exposure time is required).
B. Chemical (gas) sterilization is used to sterilize surfaces and porous materials (e.g., surgical dressings) that other sterilization methods may damage.
1. In this method, **ethylene oxide** is used generally in combination with heat and moisture.
2. Residual gas must be allowed to dissipate after sterilization and before use of the sterile product.
C. Radioactive sterilization is suitable for the industrial sterilization of contents in sealed packages that cannot be exposed to heat (e.g., prepackaged surgical components, some ophthalmic ointments).
1. This technique involves either **electromagnetic** or **particulate radiation.**
2. Accelerated drug decomposition sometimes results.
D. Mechanical sterilization (filtration) removes but does not destroy microorganisms and clarifies solutions by eliminating particulate matter. For solutions rendered unstable by thermal, chemical, or radiation sterilization, filtration

is the preferred method. A depth filter or screen filter may be used. Personnel should ensure the filter used either during compounding or administration is chemically and physically compatible with the CSP at the temperature and pressure conditions used.

1. Depth filters usually consist of fritted glass or unglazed porcelain (i.e., substances that trap particles in channels).

2. Screen (membrane) filters are films measuring 1-200 mm thick made of cellulose esters, microfilaments, polycarbonate, synthetic polymers, silver, or stainless steel.

a. A **mesh** of millions of microcapillary pores of identical size filter the solution by a process of physical sieving.

b. Flow rate. Because pores make up 70% to 85% of the surface, screen filters have a higher flow rate than depth filters.

c. **Types of screen filters**

(1) Particulate filters remove particles of glass, plastic, rubber, and other contaminants.

(a) Other uses. These filters also are used to reduce the risk of phlebitis associated with administration of reconstituted powders. Filtration removes any undissolved powder particles that may cause venous inflammation.

(b) The **pore size** of standard particulate filters ranges from 0.45-5 mm. Special particulate filters are required to filter blood, emulsions (e.g., fat emulsions), or colloidal dispersions or suspensions because these preparations have a larger particle size.

(2) Microbial filters, with a pore size of 0.22 mm or smaller, ensure complete microbial removal and sterilization. This is referred to as cold sterilization.

(3) Final filters, which may be either particulate or microbial, are often included as part of the tubing used in drug administration. They are referred to as in-line filters and are used to remove particulates or microorganisms from an intravenous (IV) solution during infusion.

V. PACKAGING OF PARENTERAL PRODUCTS.

Parenteral preparations and other sterile products must be packaged in a way that maintains product sterility until the time of use and prevents contamination of contents during opening.

A. Types of containers

1. Ampules, the oldest type of parenteral product containers, are made entirely of **glass.**

a. Intended for **single use only,** ampules are opened by breaking the glass at a score line on the neck.

b. Disadvantages. Because glass particles may become dislodged during ampule opening, the product must be filtered before it is administered. Their unsuitability for multiple-dose

use, the need to filter solutions before use, and other safety considerations have markedly reduced the ampule as a package form.

Figure 27-6. Syringes and vials. (Photo taken by William Salkin.)

2. Vials are glass or plastic containers closed with a rubber stopper and sealed with an aluminum crimp (Figure 27-6).

a. Vials have several **advantages** over ampules.

(1) Vials can be designed to hold multiple doses (if prepared with a bacteriostatic agent).

(2) The drug product is easier to remove from vials than from ampules.

(3) Vials eliminate the risk of glass particle contamination during opening.

b. However, vials also have certain **disadvantages.**

(1) The rubber stopper can become **cored,** causing a small bit of rubber to enter the solution.

(2) Multiple withdrawals (as with multiple-dose vials) can result in microbial contamination.

c. Some drugs that are unstable in solution are packaged in vials unreconstituted and must be **reconstituted** with a diluent before use. Sterile water or sterile sodium chloride for injection are the most commonly used drug diluents.

(1) To accelerate the dissolution rate and permit rapid reconstitution, many powders are lyophilized (freeze dried).

(2) Some of these drugs come in vials that contain a double chamber.

(a) The top chamber, containing sterile water for injection, is separated from the unreconstituted drug by a rubber closure.

(b) To dislodge the inner closure and mix the contents of the compartments, external pressure is applied to the outer rubber closure. This system eliminates the need to enter the vial twice, thereby reducing the risk of microbial contamination.

3. Some drugs come in vials that may be attached to an diluent containing bag for reconstitution and administration (**ADD-Vantage** by Abbott) (Figure 27-7). Premeasured drug and diluent may also be stored in separate compartments within a delivery system then combined at the point of use. (Duplex by B. Braun).

a. The ADD-Vantage vial is screwed into the top of an ADD-Vantage diluent bag, and the rubber diaphragm is dislodged from the vial, allowing the dliuent solution to dissolve the drug.
b. The reconstituted ADD-Vantage vial and IV bag are ready for administration when hung.
c. The Duplex systems has two-compartments where a seal is broken and drug and diluent are mixed to form a solution. The reconstituted drug is ready for patient administration.
4. Prefilled syringes and **cartridges** are designed for maximum convenience (see Figure 27-6).
a. Prefilled syringes. Drugs administered in an emergency (e.g., atropine, epinephrine) are available for immediate injection when packaged in prefilled syringes.
P.575

Figure 27-7. *Left,* Abbott ADDVantage System. *Center,* B. Braun Duplex System. *Right,* prefilled antibiotic piggyback dose. (Photograph by William Salkin.)

b. Prefilled cartridges are ready-to-use parenteral packages that offer improved sterility and accuracy. They consist of a plastic cartridge holder and a prefilled medication cartridge with a needle attached. The medication is premixed and premeasured. Narcotics such as, meperidine (Demerol) and hydromorphone (Dilaudid) are commonly available in prefilled cartridges.
5. Infusion solutions are divided into two categories: **small-volume parenterals** (SVPs), those having a volume less than 100 mL; and **large-volume parenterals** (LVPs), those having a volume of 100 mL or greater. Infusion solutions are used for the intermittent or continuous infusion of fluids or drugs (see VI.B).
B. Packaging materials. Materials used to package parenteral products include glass and plastic polymers.
P.576

1. Glass, the original parenteral packaging material, has superior clarity, facilitating inspection for particulate matter. Compared to plastic, glass less frequently interacts with the preparation it contains.
2. Plastic polymers used for parenteral packaging include polyvinylchloride (PVC) and polyolefin.
a. PVC is flexible and nonrigid.
b. Polyolefin is semirigid; unlike PVC, it can be stored upright.
c. Both types of plastic offer several **advantages** over glass, including durability, easier storage and disposal, reduced weight, and improved safety.

VI. PARENTERAL ADMINISTRATION ROUTES.

Parenteral preparations may be given by a variety of administration routes.
A. Subcutaneous (SC or SQ) administration refers to injection into the subcutaneous tissue beneath the skin layers, usually of the abdomen, arm, or thigh. Insulin is an example of a subcutaneously administered drug.
B. Intramuscular (IM**)** administration means injection into a muscle mass. The mid-deltoid area and gluteus medius are common injection sites.
1. No more than 5 mL of a solution should be injected by this route.
2. Drugs intended for prolonged or delayed absorption such as medroxyprogesterone (Depo-Provera) and methylprednisolone (Depo-Medrol) commonly are administered intramuscularly.
C. Intravenous (IV) administration is the most important and most common parenteral administration route. It allows an immediate therapeutic effect by delivering the drug directly into the circulation. However, this route precludes recall of an inadvertent drug overdose. Antibiotics, cardiac medications, and many other drugs are given intravenously.
D. Intradermal (ID) administration involves injection into the most superficial skin layer. Because this route can deliver only a limited drug volume, its use generally is restricted to skin tests and certain vaccines.
E. Intra-arterial (IA) administration is injection directly into an artery. It delivers a high drug concentration to the target site with little dilution by the circulation. Generally, this route is used only for radiopaque materials, thrombolytic agents, and some antineoplastic agents.
F. Intracardiac (IC) administration is injection of a drug directly into the heart.
G. Hypodermoclysis refers to injection of large volumes of a solution into subcutaneous tissue to provide a continuous, abundant drug supply. This route occasionally is used for antibiotic administration in children.
H. Intraspinal administration refers to injection into the spinal column. Local anesthetics (e.g., lidocaine, bupivacaine) are frequently administered via this route during surgical procedures.
I. Intra-articular administration means injection into a joint space. Corticosteroids (e.g., methylprednisolone, hydrocortisone) use this route for the treatment of arthritis.
J. Intrasynovial administration refers to injection into the joint fluid.

K. Intrathecal (IT) administration is injection into the spinal fluid; it sometimes is used for antibiotics and cancer chemotherapy.
L. Epidural (ED) administration refers to the injection of medications, usually local anesthetics and/or narcotics near or outside the dura mater of the central nervous system. This route is frequently used during childbirth.
P.577

VII. PARENTERAL PREPARATIONS

A. IV admixtures. These preparations consist of one or more sterile drug products added to an IV fluid, generally dextrose or sodium chloride solution alone or in combination. IV admixtures are used for drugs intended for continuous infusion. Drugs that may cause irritation or toxicity when given as a rapid direct IV injection are also prepared as IV admixtures.
B. IV fluids and electrolytes
1. Fluids used in the preparation and administration of parenteral products include sterile water and sodium chloride, dextrose, and Ringer's solutions, all of which have multiple uses. These fluids serve as vehicles in IV admixtures, providing a means for reconstituting sterile powders. They serve as the basis for correcting body fluid and electrolyte disturbances and provide a caloric source in parenteral nutrition.
a. Dextrose (D-glucose) solutions are the most frequently used glucose solutions in parenteral preparations.
(1) Uses. Generally, a solution of dextrose 5% in water (d5w) is used as a vehicle in IV admixtures. D5W may also serve as a hydrating solution. In higher concentrations (e.g., a 10% solution in water), dextrose provides a source of carbohydrates in parenteral nutrition solutions.
(2) Considerations. Because the pH of D5W ranges from 3.5-6.5, instability may result if it is combined with an acid-sensitive drug.
(a) Dextrose concentrations greater than 15% must be administered through a central vein.
(b) Dextrose solutions should be used cautiously in patients with diabetes mellitus.
b. Sodium chloride usually is given as a 0.9% solution. Because it is isotonic with blood, this solution is called normal saline solution (NSS). A solution of 0.45% sodium chloride is termed half-normal saline. A solution of 0.225% sodium chloride is termed quarternormal saline.
(1) Sodium chloride for injection, which is a solution of 0.9% sodium chloride, is used as a vehicle in IV admixtures and for fluid and electrolyte replacement. In smaller volumes, it is suitable for the reconstitution of various medications.
(2) Bacteriostatic sodium chloride for injection, which is also a 0.9% solution, is intended solely for multiple reconstitutions. It contains an agent that inhibits bacterial growth (e.g., benzyl alcohol, propylparaben, methylparaben), which allows for its use in multiple-dose preparations.

c. **Waters** are used for reconstitution and for dilution of such IV solutions as dextrose and sodium chloride. Waters suitable for parenteral preparations include sterile water for injection and bacteriostatic water for injection.

d. Ringer's solutions, which are appropriate for fluid and electrolyte replacement, commonly are administered to postsurgical patients.

(1) Lactated Ringer's injection (i.e., Hartmann's solution, Ringer's lactate solution) contains sodium lactate, sodium chloride, potassium chloride, and calcium chloride. Frequently, it is combined with dextrose (e.g., as 5% dextrose in lactated Ringer's injection).

(2) Ringer's injection differs from lactated Ringer's injection in that it does not contain sodium lactate and has slightly different concentrations of sodium chloride and calcium chloride. Like lactated Ringer's injection, it may be combined in solution with dextrose.

2. Electrolyte preparations. With ions present in both intracellular and extracellular fluid, electrolytes are crucial for various biological processes. Surgical and medical patients who cannot take food by mouth or who need nutritional supplementation require the addition of electrolytes in hydrating solutions or parenteral nutrition solutions.

a. Cations are positively charged electrolytes.

(1) Sodium is the chief extracellular cation.

(a) Importance. Sodium plays a key role in interstitial osmotic pressure, tissue hydration, acid-base balance, nerve-impulse transmission, and muscle contraction.

(b) Parenteral sodium preparations include sodium chloride, sodium acetate, and sodium phosphate.

(2) Potassium is the chief intracellular cation.

(a) Importance. Potassium participates in carbohydrate metabolism, protein synthesis, muscle contraction (especially of cardiac muscle), and neuromuscular excitability.

(b) Parenteral potassium preparations include potassium acetate, potassium chloride, and potassium phosphate.

(3) Calcium

(a) Importance. Calcium is essential to nerve-impulse transmission, muscle contraction, cardiac function, bone formation, and capillary and cell membrane permeability.

(b) Parenteral calcium preparations include calcium chloride, calcium gluconate, and calcium gluceptate.

(4) Magnesium

(a) Importance. Magnesium plays a vital part in enzyme activities, neuromuscular transmission, and muscle excitability.

(b) Parenteral preparation. Magnesium is given parenterally as magnesium sulfate.

b. Anions are negatively charged electrolytes.

(1) Chloride is the major extracellular anion.

(a) Importance. Along with sodium, it regulates interstitial osmotic pressure and helps to control blood pH.

(b) Parenteral chloride preparations include calcium chloride, potassium chloride, and sodium chloride.

(2) Phosphate is the major intracellular anion.

(a) Importance. Phosphate is critical to various enzyme activities. It also influences calcium levels and acts as a buffer to prevent marked changes in acid-base balance.

(b) Parenteral phosphate preparations include potassium phosphate and sodium phosphate.

(3) Acetate

(a) Importance. Acetate is a bicarbonate precursor that may be used to provide alkali to assist in the preservation of plasma pH.

(b) Parenteral acetate preparations include potassium acetate and sodium acetate.

C. Parenteral antibiotic preparations are available as sterile unreconstituted powders, which must be reconstituted with sterile water, normal saline, or d5w, or as a sterile, ready-to-use liquid parenteral.

1. Administration methods. Parenteral antibiotics may be given intermittently by direct IV injection, short-term infusion, intramuscular injection, or intrathecal injection.

2. Uses. Parenteral antibiotics are used to treat infections that are serious and require high antibiotic blood levels or when the gastrointestinal tract is contraindicated, such as in ileus.

3. Dosing frequencies of parenteral antibiotics vary from once daily to as often as every 2 hours, depending on the kinetics of the drug, seriousness of the infection, the site of infection, and the patient's disease or organ status (e.g., renal disease).

D. Parenteral antineoplastic agents. Studies suggest that these medications may be toxic to the personnel who prepare and administer them. The evidence is not conclusive, which necessitates special precautions to ensure safety and minimize risks. In response to concerns, the Occupational Safety and Health Administration (OSHA) has published a technical manual, “Controlling Occupational Exposure to Hazardous Drugs.” Every facility must have a written plan that includes drug preparation precautions, storage, transport, personal protective equipment (gloves, gowns,masks), work equipment, waste disposal, spill management, and personnel medical surveillance,

1. Administration methods. Parenteral antineoplastics may be given by direct IV injection, short-term infusion, or long-term infusion. Some are administered by a non-IV route, such as the subcutaneous, intramuscular, intra-arterial, or intrathecal routes.

2. Safe antineoplastic handling guidelines. All pharmacy and nursing personnel who prepare or administer antineoplastics should receive special training in the following guidelines to reduce the risk of exposure to these drugs.

a. A **vertical laminar flow hood** should be used during drug preparation, with exhaust directed to the outside.

b. All syringes and IV tubing should have **Luer-Lok fittings** (see IX.B.4.a).
c. **Clothing.** Personnel should wear personal protective equipment including closed-front cuffed surgical gowns and double-layered latex surgeon's gloves.
d. Negative-pressure technique should be used during withdrawal of medication from vials. This will prevent pressure from building up inside the vial and causing the drug to spray around the needle.
e. Final dosage adjustment should be made into the vial, ampule, or directly into an absorbent gauze pad.
f. Priming equipment. Special care should be taken when IV administration sets are primed. The IV tubing should be primed before adding the drug, or the tubing can be primed with drug-free fluid before connecting it to the chemotherapy drug container. If these are not available, prime the tubing into sterile gauze in a sealable plastic bag.
g. Proper procedures should be followed for **disposal** of materials used in the preparation and administration of antineoplastics.
(1) Needles should not be clipped or recapped.
(2) Preparations should be discarded in containers that are puncture-proof, leak-proof, and properly labeled.
(3) Hazardous waste. There is no completely acceptable method for disposing of hazardous waste. High-temperature incineration may be the preferred method. These materials may also be buried in an EPA-licensed hazardous waste dump or chemically deactivated.
h. After removal of gloves, personnel should **wash hands** thoroughly.
i. Personnel and equipment involved in the preparation and administration of antineoplastic agents should be **monitored** routinely.
3. Patient problems. Infusion phlebitis and extravasation are the most serious problems that may occur during the administration of parenteral antineoplastics.
a. Infusion phlebitis (inflammation of a vein) is characterized by pain, swelling, heat sensation, and redness at the infusion site. Drug dilution and filtration can eliminate or minimize the risk of phlebitis.
b. Extravasation (infiltration of a drug into subcutaneous tissues surrounding the vein) is especially harmful when antineoplastics with vesicant properties are administered. Measures must be taken immediately if extravasation occurs.
(1) Depending on the drug involved, emergency measures may include stopping the infusion, injecting hydrocortisone or another anti-inflammatory agent directly into the affected area, injecting an antidote (if available), and applying a cold compress (to facilitate a drug-antidote reaction).
(2) A warm compress may then be applied to increase the flow of blood, and thus the vesicant, away from damaged tissue.
E. Parenteral biotechnology products are created by the application of recombinant technology to the generation of therapeutic agents, such as monoclonal antibodies, various vaccines, and colony-stimulating factors.

1. Uses of these agents include cancer therapy, infections, transplant rejection, rheumatoid arthritis, inflammatory bowel disease, respiratory diseases, and malaria as well as vaccines against cancer, HIV infection, and hepatitis B.
2. Characteristics. Protein and peptide biotechnology drugs have a shorter half-life, often require special storage such as refrigeration or freezing, and must not be shaken vigorously to avoid destroying the protein molecules.
3. Administration. Many biotechnology products require reconstitution with sterile water or normal saline and may be parenterally administered by direct IV injection or infusion, or by intramuscular or subcutaneous injection.

VIII. IRRIGATING SOLUTIONS.

Although these sterile products are manufactured by the same standards used to process IV preparations, they are **not intended for infusion into the venous system.** Labeling differences between irrigation solutions and injections are specified in the *United States Pharmacopeia* (USP) and reflect differences in acceptable particulate matter levels, volume of solution available for use, and the container design.
P.580

A. Topical administration. Irrigating solutions for topical use are packaged in pour bottles so that they can be applied directly onto the desired area. These solutions are intended for such purposes as irrigating wounds, moistening dressings, and cleaning surgical instruments.
B. Infusion of irrigating solutions. This procedure, using an administration set attached to a Foley catheter, is commonly used for many surgical patients. Surgeons performing urological procedures often use irrigating solutions to perfuse tissues in order to maintain the integrity of the surgical field, remove blood, and provide a clear field of view. To decrease the risk of infection, 1 mL of Neosporin G.U. Irrigant, an antibiotic preparation, often is added to these solutions.
C. Dialysis. Dialysates are irrigating solutions used in the dialysis of patients with such disorders as renal failure, poisoning, and electrolyte disturbances. These products remove waste materials, serum electrolytes, and toxic products from the body.
1. In **peritoneal dialysis,** a hypertonic dialysate is infused directly into the peritoneal cavity via a surgically implanted catheter. The dialysate, which contains dextrose and electrolytes, removes harmful substances by osmosis and diffusion. After a specified period of time, the solution is drained. Antibiotics and heparin may be added to the dialysate.
2. In **hemodialysis,** the patient's blood is transfused through a dialyzing membrane unit that removes the harmful substances from the patient's vascular system. After passing through the dialyzer, the blood reenters the body through a vein.

IX. NEEDLES AND SYRINGES

A. Hypodermic needles are stainless-steel or aluminum devices that penetrate the skin for the purpose of administering or transferring a parenteral product (Figure 27-8).

1. Needle gauge is the outside diameter of the needle shaft; the larger the number, the smaller the diameter. Gauges in common use range from 13 (largest diameter) to 27. Subcutaneous injections usually require a 24-gauge or 25-gauge needle. Intramuscular injections require a needle with a gauge between 19 and 22. Needles between 18 gauge and 20 gauge are commonly used for compounding parenterals.

2. Bevels are slanting edges cut into needle tips to facilitate injection through tissue or rubber vial closures.

a. Regular-bevel needles are the most commonly used type, and they are suitable for subcutaneous and intramuscular injections and hypodermoclysis.

b. Short-bevel needles are used when only shallow penetration is required (as in IV injections).

c. **Intradermal-bevel needles** are designed for intradermal injections and have the most beveled edges.

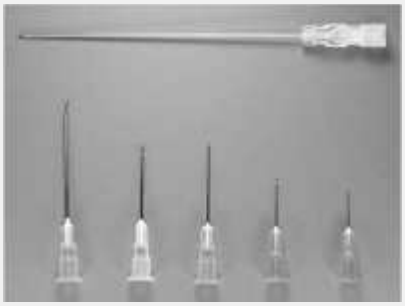

Figure 27-8. Needles. *Top,* 20 gauge-3½ inch. *Left to right,* 18 gauge-1½ inch, 20 gauge-1 inch, 23 gauge-1 inch, 25 gauge-5/8 inch, and 27 gauge-½ inch.

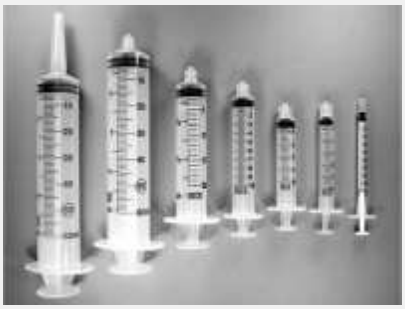

Figure 27-9. Syringes. *Left to right,* 60 mL catheter tip, 60 mL, 30 mL, 10 mL, 5 mL, 3 mL, and 1 mL.

3. Needle lengths range from ¼ inch to 6 inches. Choice of needle length depends on the desired penetration.

a. For **compounding parenteral preparations,** 1½-inch-long needles are commonly used.

b. Intradermal and subcutaneous injections necessitate a short needle length, usually ¼ inch to 5/8 inch.

c. **Intraspinal injection** requires a needle length of 3½ inches.

d. IV infusion requires needles that range in length from 1¼ inches to 2½ inches.

B. Syringes are devices for injecting, withdrawing, or instilling fluids. Syringes consist of a glass or plastic barrel with a tight-fitting plunger at one end; a small opening at the other end accommodates the head of a needle (Figure 27-9).

1. The **Luer syringe,** the first syringe developed, has a universal needle attachment accommodating all needle sizes.

2. Syringe volumes range from 0.3 to 60 mL. Insulin syringes have unit gradations (100 units/mL) rather than volume gradations.

3. Calibrations are in the metric system, and vary in specificity depending on syringe size. The smaller the syringe, the smaller the measurement scale.

4. Syringe tips come in several types.

a. Luer-Lok tips are threaded to ensure that the needle fits tightly in the syringe. Antineoplastic agents should be administered with syringes of this type (see VII.D.).

b. Luer-Slip tips are unthreaded so that the syringe and needle do not lock into place. Because of this, the needle may become dislodged.

c. **Eccentric tips,** which are set off center, allow the needle to remain parallel to the injection site and minimize venous irritation.

d. Catheter tips are used for wound irrigation and administration of enteral feedings. They are not intended for injections.

X. INTRAVENOUS DRUG DELIVERY

A. Injection sites

1. Peripheral vein injection is preferred for drugs that do not irritate the veins, administration of isotonic solutions, and patients who require only short-term IV therapy. Generally, the dorsal forearm surface is chosen for venipuncture.
2. Central vein injection is preferred for administration of irritating drugs or hypertonic solutions, patients requiring long-term IV therapy, and situations in which a peripheral line cannot be maintained. Large veins in the thoracic cavity, such as the subclavian vein, are used.

B. Infusion methods
1. Continuous-drip infusion is the slow, primary-line infusion of an IV preparation to maintain a therapeutic drug level or provide fluid and electrolyte replacement.
a. Flow rates must be carefully monitored. Generally, these rates are expressed as volume per unit of time (e.g., mL/hr, drops/min) and sometimes as mg/min for certain drugs.
b. Administration. Drugs with a narrow therapeutic index such as oxytocin (Pitocin), heparin, and pressor agents such as norepinephrine (Levo-Phed) and phenylephrine (Neo-Synephrine) typically are administered by this method.
2. Intermittent infusion allows drug administration at specific intervals (e.g., every 4 hours) and is most often used for antibiotics.
a. Three different techniques may be used.
(1) Direct (bolus) injection rapidly delivers small volumes of an undiluted drug. This method is used to:
(a) Achieve an immediate effect (as in an emergency)
(b) Administer drugs that cannot be diluted
(c) Achieve a therapeutic serum drug level quickly
(2) Additive set infusion, using a volume-control device, is appropriate for the intermittent delivery of small amounts of IV solutions or diluted medications. The fluid chamber is attached to an independent fluid supply or placed directly under the established primary IV line.
(3) The **piggyback method** is used when a drug cannot be mixed with the primary solution. A special coupling for the primary IV tubing permits infusion of a supplementary secondary solution through the primary system.
(a) This method eliminates the need for a second venipuncture or further dilution of the supplementary preparation.
(b) Admixtures in which the vehicle is added to the drug are known as manufacturers' piggybacks. Admixtures in which a special drug vial is attached to a special IV bag are known as the ADD-Vantage system (see Figure 27-7).
b. In some cases, **intermittent infusion injection devices** are used. Also called scalp-vein, heparin-lock, or butterfly infusion sets, these devices permit intermittent delivery while eliminating the need for multiple venipunctures or prolonged venous access with a continuous infusion. To prevent clotting in the cannula, dilute heparin solution or NSS may be added. Benefits of intermittent infusion injection devices include the following:

(1) This method is especially suitable for patients who do not require, or would be jeopardized by, administration of large amounts of IV fluids (e.g., those with congestive heart failure).
(2) Because intermittent infusion injection devices do not require continuous attachment to an IV bottle or bag and pole, they permit greater patient ambulation.
C. Pumps and **controllers** are the electronic devices used to administer parenteral infusions when the use of gravity flow alone might lead to inaccurate dosing or risk patient safety. Pumps and controllers are used to administer parenteral nutrition, chemotherapy, cardiac medications, and blood products.
1. Pumps are used to deliver IV infusions with accuracy and safety.
a. Two **types of mechanisms** are used in infusion pumps.
(1) Piston-cylinder mechanisms use a piston in a cylinder or a syringe-like apparatus to pump the desired volume of fluid.
(2) Linear peristaltic mechanisms use external pressure to expel the fluid out of the pumping chamber.
b. Types of pumps
(1) Volumetric pumps are used for intermittent infusion of medications such as antibiotics. They are also used for continuous infusion of IV fluid, parenteral nutrition, anticoagulants, and anti-asthma medications.
(2) Syringe pumps are used to administer intermittent or continuous infusions of medications (e.g., antibiotics, opiates) in concentrated form.
(3) Mobile infusion pumps are small infusion devices designed for ambulatory and home patients and used for administering chemotherapy and opiate medications.
(4) Implantable pumps are infusion devices surgically placed under the skin to provide a continuous release of medication, typically an opiate. The reservoir in the pump is refilled by injecting the medication through a latex diaphragm in the pump.

(5) Patient-controlled analgesic pumps are used to administer narcotics intermittently or on demand by the patient within the patient-specific parameters, which are ordered by the physician and programmed into the pump.
c. **Benefits.** Despite their extra costs and the training required by personnel, pumps provide a number of important benefits. They maintain a constant, accurate flow rate and can detect infiltrations, occlusions, and air. Pumps also may decrease the amount of time a nurse spends dispensing medication. Newer devices are equipped with “drug libraries” that have prespecified high and low dose infusion limits which may facilitate medication administration and reduce errors.
2. Controllers, unlike pumps, exert no pumping pressure on the IV fluid. Rather, they rely on gravity and control the infusion by counting drops electronically, or they infuse the fluid mechanically and electronically (e.g., volumetric controllers). In **comparison to pumps,** the following are characteristics of controllers:
a. They are less complex and generally less expensive.
b. They achieve reasonable accuracy.

c. They are very useful for uncomplicated infusion therapy but cannot be used for arterial drug infusion or for infusion into small veins.

D. IV incompatibilities. When two or more drugs must be administered through a single IV line or given in a single solution, an undesirable reaction can occur. Although such incompatibilities are relatively rare, their consequences can be deadly. A patient who receives a preparation in which an incompatibility has occurred could experience toxicity or an incomplete therapeutic effect.

1. Types of incompatibilities

a. A **physical incompatibility** occurs when a drug combination produces a visible change in the appearance of a solution. The solution should never be administered to a patient.

(1) An **example** of physical incompatibility is the evolution of carbon dioxide when sodium bicarbonate and hydrochloric acid are admixed.

(2) Various **types** of physical incompatibilities may occur:

(a) Visible color change or darkening

(b) Formation of precipitate, which may result from the combination of phosphate and calcium.

b. A **chemical incompatibility** reflects the chemical degradation of one or more of the admixed drugs, resulting in toxicity or therapeutic inactivity.

(1) The degradation is not always visible. **Nonvisible chemical incompatibility** may be detected only by analytical methods.

(2) Chemical incompatibility occurs in several **varieties.**

(a) Complexation is a reaction between products that inactivates them. For example, the combination of calcium and tetracycline leads to formation of a complex that inactivates tetracycline.

(b) Oxidation occurs when one drug loses electrons to the other, resulting in a color change and therapeutic inactivity.

(c) Reduction takes place when one drug gains electrons from the other.

(d) Photolysis (chemical decomposition caused by light) can lead to hydrolysis or oxidation, with resulting discoloration.

c. A **therapeutic incompatibility** occurs when two or more drugs, IV fluids, or both are combined and the result is a response other than that intended. An example of a therapeutic incompatibility is the reduced bactericidal activity of penicillin G when given after tetracycline. Because tetracycline is a bacteriostatic agent, it slows bacterial growth; penicillin, on the other hand, is most effective against rapidly proliferating bacteria.

2. Factors affecting IV compatibility

a. pH. Incompatibility is more likely to occur when the components of an IV solution differ significantly in pH. This increased risk is explained by the chemical reaction between an acid and a base, which yields a salt and water; the salt may be an insoluble precipitate.

b. Temperature. Generally, increased storage temperature speeds drug degradation. To preserve drug stability, drugs should be stored in a refrigerator or freezer, as appropriate.

c. **Degree of dilution.** Generally, the more diluted the drugs are in a solution, the less chance there is for an ion interaction leading to incompatibility.
P.584

d. Length of time in solution. The chance for a reaction resulting in incompatibility increases with the length of time that drugs are in contact with each other.
e. Order of mixing. Drugs that are incompatible in combination, such as calcium and phosphate, should not be added consecutively when an IV admixture is being prepared. This keeps these substances from pooling, or forming a layer on the top of the IV fluid, and, therefore, decreases the chance of an incompatibility. Thorough mixing after each addition is also essential.
3. Preventing or minimizing incompatibilities. To reduce the chance for an incompatibility, the following steps should be taken:
a. Each drug should be mixed thoroughly after it is added to the preparation.
b. Solutions should be administered promptly after they are mixed to minimize the time available for a potential reaction to occur.
c. The number of drugs mixed together in an IV solution should be kept to a minimum.
d. If a prescription calls for unfamiliar drugs or IV fluids, compatibility references should be consulted.
E. Hazards of parenteral drug therapy. A wide range of problems can occur with parenteral drug administration.
1. Physical hazards
a. Phlebitis, which is generally a minor complication, may result from vein injury or irritation. Phlebitis can be minimized or prevented through proper IV insertion technique, dilution of irritating drugs, and a decreased infusion rate.
b. Thrombosis, the formation of a blood clot in a vein or artery.
c. **Extravasation** may occur with administration of drugs with vesicant properties (see VII.D.3.b).
d. Irritation at the injection site can be reduced by varying the injection site and applying a moisturizing lotion to the area.
e. Pain from infusion is most common with peripheral IV administration of a highly concentrated preparation. Switching to central vein infusion and/or diluting the drug might alleviate the problem.
f. Air embolism, potentially fatal, can result from entry of air into the IV tubing.
g. Infection, a particular danger with central IV lines, may stem from contamination during IV line insertion or tubing changes. Infection may be local or generalized (septicemia). The infection risk can be minimized by following established protocols for the care of central lines.
h. **Allergic reactions** can result from hypersensitivity to an IV solution or additive.
i. Central catheter misplacement may lead to air embolism or pneumothorax. To ensure that the catheter has passed into the subclavian vein and advanced to the level of the vena cava, the placement should always be verified radiologically.

j. Hypothermia, possibly resulting in shock and cardiac arrest, might stem from administration of a cold IV solution. This problem can be prevented by allowing parenteral products to reach room temperature.
k. Neurotoxicity may be a serious complication of intrathecal or intraspinal administration of drugs containing preservatives. Preservative-free drugs should be used in these circumstances.
2. Mechanical hazards
a. Infusion pump or **controller failure** can lead to runaway infusion, fluid overload, or incorrect dosages.
b. IV tubing can become kinked, split, or cracked. It also may produce particulates, allow contamination, or interfere with the infusion.
c. **Particulate matter** may be present in a parenteral product and can cause embolism.
d. Glass containers may break, causing injury.
e. Rubber vial closures may interact with the enclosed product.
3. Therapeutic hazards
a. Drug instability may lead to therapeutic ineffectiveness.
b. Incompatibility may result in toxicity or reduced therapeutic effectiveness.
c. **Labeling errors** can cause administration of an incorrect drug or improper dosage.
d. Drug overdose can be caused by runaway IV infusion, failure of an infusion pump or controller, or nursing or pharmacy errors.
P.585

e. Preservative and solubilizing agent toxicity can be a serious complication, especially in children. For example, premature infants receiving parenteral products containing benzyl alcohol can develop a fatal acidotic toxic syndrome, which is referred to as the gasping syndrome. Rapid administration of phenytoin (Dilantin) and diazepam (Valium) both utilize propylene glycol as a solubilizing agent, has been associated with cardiovascular collapse.
P.586

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.
1. Parenteral products with an osmotic pressure less than that of blood or 0.9% sodium chloride are referred to as
(A) Isotonic solutions
(B) Hypertonic solutions
(C) Hypotonic solutions
(D) Iso-osmotic solutions

(E) Neutral solutions

View Answer***1. The answer is C[VII.B.b,].*****2. Aseptic technique should be used in the preparation of all of the following medications with the exception of;**

(A) Neomycin irrigation solution

(B) Ganciclovir (Cytovene) intraocular injection

(C) Phytonadione (Aquamephyton) subcutaneous injection

(D) Ampicillin (Prinicipen) IV admixture piggyback

(E) Bacitracin ointment

View Answer***2. The answer is E[].*****3. Which needle has the smallest diameter?**

(A) 25 gauge, 3¾ inches

(B) 24 gauge, 3½ inches

(C) 22 gauge, 3 ½ inches

(D) 20 gauge, 33/8 inches

(E) 26 gauge, 35/8 inches

View Answer***3. The answer is E[].*****4. Intra-articular injection refers to injection into the**

(A) Muscle mass

(B) Subcutaneous tissue

(C) Spinal fluid

(D) Superficial skin layer

(E) Joint space

View Answer***4. The answer is E[IV.1].*****5. Advantages of the intravenous route include**

(A) Ease of removal of the dose

(B) A depot effect

(C) Low incidence of phlebitis

(D) Rapid onset of action

(E) A localized effect

View Answer***5. The answer is D[].*****6. A central vein, either subclavian or internal jugular, may be considered a suitable route for IV administration in which of the following situations?**

(A) When an irritating drug is given

(B) When hypertonic drugs are given

(C) For long-term therapy

(D) For administering dextrose 35% as parenteral nutrition

(E) All of the above

View Answer***6. The answer is E[].*****7. To prepare a total parenteral nutrition (TPN) that requires 10** mEq **of calcium gluconate and 15 mM of potassium phosphate, the appropriate action to take would be which of the following?**

(A) Add the calcium first, add the other additives, then add the phosphate last, thoroughly mixing the solution after addition.

(B) Add the calcium gluconate and potassium phosphate consecutively.

(C) Not combine the agents together but give them as a separate infusion.

(D) None of the above.

View Answer***7. The answer is A[].***8. **Which needle gauge would be most likely used as a subcutaneous injection of epoetin?**

(A) 25 gauge, 5/8 inch

(B) 16 gauge, 1 inch

(C) 18 gauge, 1½ inches

(D) 22 gauge, 1½ inches

(E) None of the above

View Answer***8. The answer is A[]***9. **Which of the following drugs should NOT be prepared in a horizontal laminar flow hood?**

(A) Ampicillin (Principen)

(B) Dopamine

(C) Cisplatin (Platinol)

(D) Nitroglycerin

(E) Bretylium tosylate (Bretylol)

View Answer***9. The answer is C[].***P.587

10. All of the following statements about d5w are true EXCEPT

(A) Its pH range is 3.5-6.5.

(B) It is hypertonic.

(C) It is a 5% solution of D-glucose.

(D) It should be used with caution in diabetic patients.

(E) It is often used in IV admixtures.

View Answer***10. The answer is B[].***11. **All of the following are potential hazards of parenteral therapy EXCEPT**

(A) Hypothermia

(B) Phlebitis

(C) Extravasation

(D) Allergic reactions

(E) Ileus

View Answer***11. The answer is E[].***12. **Procedures for the safe handling of antineoplastic agents include all of the following EXCEPT**

(A) Use of Luer-Lok syringe fittings.

(B) Wearing double-layered latex gloves.

(C) Use of negative-pressure technique when medication is being withdrawn from vials.

(D) Wearing closed-front, surgical-type gowns with cuffs.

(E) Use of horizontal laminar flow hood.

View Answer***12. The answer is E[].***13. **In preparing an intraspinal dose of bupivacaine, the best pore size filter for cold sterilization would be**

(A) 8-mm filter

(B) 5-µm filter

(C) 0.45-µm filter

(D) 0.22-µm filter
(E) None of the above

View Answer***13. The answer is D[].*****14. Process simulation**
(A) Is a method of quality assurance.
(B) Evaluates the adequacy of a practitioner's aseptic technique.
(C) Requires the use of a microbial growth medium.
(D) Is carried out in a manner identical to normal sterile admixture production under routine operating conditions.
(E) All of the above.

View Answer***14. The answer is E[].*****For questions 15-18:** The pharmacist receives a prescription for hydromorphone (Dilaudid) injection to be compounded to a solution of 15 mg per mL. Dilaudid is commercially available in an ampule but the concentration is 10 mg per mL. The physician would like a more concentrated solution prepared so that 50 mls can be instilled into the titanium resevoir of a Medtronic infusion pump. The hydromorphone solution will be continuously infused, intrathecally, over approximately 30 days, for a patient with chronic back pain, uncontrolled with oral narcotics. The pharmacist checks his inventory and finds a bottle of Hydromorphone powder, USP. He proceeds to weigh out enough powder for a 60 mL preparation. The weighing step is checked by a colleague pharmacist.
15. According to USP **Chapter 797 this sterile preparation would be considered a**
(A) High risk level CSP
(B) Medium risk level CSP
(C) Low risk level CSP
(D) None of these

View Answer***15. The answer is A[].*****16. What would be an appropriate environment for the aseptic manipulations required for this preparation.**
(A) Pharmacy workbench or counter in ambient room air
(B) Inside an Anteroom, with ISO Class 8 quality air
(C) Inside a Barrier Isolator with ISO Class 5 quality air
(D) A horizontal laminar flow workbench bench, newly installed, with no certification, but manufacturer guarenteed to be ISO 5 Class air quality.

View Answer***16. The answer is C[].***P.588

17. The pharmacist begins to gather his supplies for this preparation. These should include:
(A) Millipore 0.45 micron HV Filter with sterile water for injection
(B) Millipore 0.22 micron GS Filter with sodium chloride 0.9%
(C) Bectin-Dickinson 16 gauge, 5 micron filter needlwith sodium chloride 0.9%
(D) Millipore AA 0.8 micron Filter with dextrose 5% in water

View Answer***17. The answer is B[].*****18. After the solution was prepared the appropriate quality assurance or double check by another pharmacist would include:**

(A) Inspection of the powder and the label to ensure hydromorphone was the prepared ingredient and that the label contained a beyond use date and the 15 mg per mL concentration.
(B) Sending a solution sample or aliquot to a microbiology lab to test for the presence of bacteria and pyrogens prior to dispensing.
(C) Check to ensure a correct sterilizing filter was utilized.
(D) Visual inspection to ensure the final acqueous solution had no visible participates.
(E) All of the above.

View Answer***18. The answer is E[].***P.589

ANSWERS AND EXPLANATIONS

1. The answer is C *[VII.B.b,* X.A*].*
Hypotonic solutions have an osmotic pressure less than that of blood (or 0.9% saline), whereas hypertonic solutions have an osmotic pressure greater than that of blood, and isotonic or iso-osmotic solutions have an osmotic pressure equal to that of blood.

2. The answer is E *[*II.A.5*].*
Irrigation solutions, ophthalmic preparations and parenteral products, and subcutaneous and IV medications should be prepared using aseptic technique. Since Bacitracin ointment is applied to the skin and does not bypass the body's protective barriers, its preparation would not be held to the same requirements.

3. The answer is E *[*IX.A.1*].*
The gauge size refers to the outer diameter of the needle. The lower the gauge size number, the larger the needle.

4. The answer is E *[IV.1].*
Intra-articular injection refers to an injection into the joint space. This administration route generally is used for certain types of corticosteroids to reduce inflammation associated with injury or rheumatoid arthritis.

5. The answer is D *[*VI.C*].*
The IV route of drug administration allows for rapid onset of action and, therefore, immediate therapeutic effect. There can be no recall of the administered dose, and phlebitis, or inflammation of a vein, can occur. In addition, a depot effect (i.e., accumulation and storage of the drug for distribution) cannot be achieved by administering a drug intravenously. Delivering a drug intravenously results in a systemic rather than a localized effect.

6. The answer is E *[*X.A.2*].*
Irritating drugs, hypertonic drugs, long-term therapy, and dextrose 35% are best given by central IV administration. Peripheral vein injection is used for postoperative hydration, administration of nonirritating drugs, or isotonic solutions and for short-term IV therapy.

7. The answer is A *[*X.D.2.e*].*

Physical incompatibilities occur when two or more products are combined and produce a change in the appearance of the solution, such as the formation of a precipitate. Calcium and phosphate solutions when directly combined or added consecutively to a solution will form a white precipitate. By altering the order of mixing, they can be safely added to TPN solutions.

8. The answer is A *[*IX.A.3.b.*]*

Since subcutaneous injection does not require penetration through several skin layers or muscle tissue, a short needle with a narrow diameter is used. A 16- or 18-gauge needle is most commonly used in the pharmacy for preparing parenteral solutions. A 22-gauge needle would be used for intramuscular injection.

9. The answer is C *[*II.B.2.b.1*].*

CisPlatin is an antineoplastic agent and, consequently, should be prepared only in a vertical laminar flow hood because of the potential hazard of these toxic agents to the operator.

10. The answer is B *[*VII.B.1.a*].*

d5w (dextrose [D-glucose] 5% in water) is acidic, its pH ranges from 3.5-6.5, and it is isotonic. It is often used in IV admixtures and should be used with caution in diabetic patients.

11. The answer is E *[*VII.D.2., X.E*].*

Parenteral therapy is often a treatment for ileus. Hypothermia, phlebitis, extravasation, and allergic reactions can be hazards of parenteral therapy.

12. The answer is E *[*VII.D.2*].*

In order to prevent drug exposure, a vertical flow laminar hood (not horizontal) should be used when an antineoplastic agent is prepared. The other precautions mentioned in the question are important safety measures for handling parenteral antineoplastics. All pharmacy and nursing personnel who handle these toxic substances should receive special training.

13. The answer is D *[*IV.D.2.c.2*].*

Since intraspinal and epidural doses of bupivacaine are frequently prepared from nonsterile powders, cold sterilization, accomplished by filtration, is a simple method of ensuring complete microbial removal. The filters listed 8 mm to 0.45 µm will remove only particulate matter. A 0.22 µM filter ensures the removal of microorganisms.

14. The answer is E *[*III.F*].*

Process simulation is one part of an overall quality assurance program. It requires duplicating sterile product preparation using a growth medium in place of actual products. It serves to evaluate the aseptic technique of the individual performing all the necessary steps of sterile product preparation.

15. The answer is A *[*II.A.6.c*].*

The hydromorphone preparation is a high risk level CSP because it is made from non-sterile powder.

16. The answer is C *[*II.B.4*].*

USP Chapter 797 requires an ISO Class 5 air quality enviroment for this preparation. A Barrier Isolator within a cleanroom creates an ISO Class 5 environment. Ambient room air is unacceptable for any preparation. An Anteroom is generally an area of relatively high personnel and supply traffic. While air quality may be acceptable, it does not provide an acceptable critical site of aseptic manipulations. All new laminar flow work benched should be tested for air velocity and filter integrity prior to use.

17. The answer is B *[*IV.D.2.c(2)*].*

The hydromorphone requires sterilization prior to intrathecal administration. This is best achieved with a 0.22 micron filter. Sodium chloride 0.9% is the solution most similar to the CNS fluid and would be a better choice over sterile water of dextrose 5% injection.

18. The answer is E *[*III.B*].*

Each step in sterile compounding should have an associated quality assurance double check. Inspection of the initial ingredients, review of supplies, monitoring of aseptic technique, and examination of the final product creates multiple opportunities to intercept an error and make necessary corrections. High risk levels CSPs should be used within 24 hours in the absence of sterility testing. Given this product will be administered over 30 days, a sterility and pyrogen test would be appropriate.

28

Parapharmaceuticals, Diagnostic Aids, and Medical Devices

Jenny A. Van Amburgh

Todd A. Brown

I. AMBULATORY AIDS

A. Canes. These simple ambulatory aids provide balance and allow for the transfer of weight off a weakened leg.

1. Height. The height of the cane must be adjusted to the individual patient. A cane that is correctly fitted allows for maximum weight transfer without allowing the patient to lock the elbow. The correct height should provide a 25-degree angle at the elbow, or the top of the cane should come to the crease of the wrist while patient is standing erect.

2. Types of canes. Canes may be made of wood or metal.

a. Wooden canes come in varying thicknesses. The thicker ones are intended for males, and the thinner ones are for females. They may be cut to the correct height for the patient.

b. Metal canes are usually adjustable in height to fit the individual patient.

c. **Folding canes** will fold to allow for easy transport or storage when not in use.

d. A **quad cane** is a metal cane that has a quadrangular base with four legs. This allows for greater weight transfer. The base of the quad cane comes in two sizes. The larger base provides greater stability but is more difficult to manipulate because of the size and weight.

e. Seat canes contain an area that can be folded down and used to sit on. They are useful for individuals who cannot walk long distances without resting.

B. Crutches may be used by patients with temporary disabilities (e.g., sprains, fractures) or by those with chronic conditions.

1. Use. Crutches are used to take all the weight off an injured or weakened leg. The crutches are used in place of the leg. Crutch sizes range from toddler to adult. Accessories that are used with a crutch include a tip to prevent slipping, handgrip cushion, and arm pad (for axillary crutch).

2. Types of crutches

a. An **axillary crutch,** the **most commonly used** crutch, is typically used for temporary disabilities. The top of the crutch should be 2 inches below the axilla to prevent “crutch paralysis” (i.e., injury to the axillary nerves, blood vessels, and lymph nodes). The height of the handgrip should be set so that the elbow forms a 25-degree angle.

b. A **forearm crutch** (also called a **Canadian** or **Lofstrand** crutch) remains in position by attaching to the forearm by a collar or cuff. It is commonly used by patients who need crutches on a long-term basis.

c. A **quad crutch** is a forearm crutch with a quadrangular base that has four legs. The base is attached to the crutch with a flexible rubber mount. This allows for more stability and constant contact with the ground.

d. A **platform crutch** contains a rectangular area in which to place the forearm. The crutch may be held by a handgrip or secured by a belt that wraps around the forearm. It is commonly used by patients who do not have enough hand strength and control for a forearm crutch.

C. Seat lift chairs are electric-powered chairs that raise the patient from a sitting to a standing position.

P.592

D. Walkers are lightweight rectangular-shaped devices that are made of metal tubing and have four widely placed legs.

1. Use. Walkers are used by patients who need more **support** than a cane or crutch or who have trouble with balance during ambulation. The use requires reasonably good arm, hand, and wrist function. The patient holds on to the walker and takes a step, then moves the walker and takes another step.

2. Types of walkers. Walkers come in two sizes: **adult** and **child.** Walkers may be adjustable in height. Some walkers will fold to make storage or transporting easier. Walkers can have wheels on the front legs to allow the user to move the walker by raising the back legs and rolling it instead of having to pick it up. Patients with loss of arm, wrist, or hand function on one side might use a **hemiwalker** or a **side walker.**

a. A **hemiwalker** is similar to a standard walker except that it has one handle in the center of the walker for manipulation.

b. A **side walker** is placed to the side of the patient instead of in front of the patient.

c. A **reciprocal walker** contains two hinges, one on each side of the walker. This allows the user to swing each side alternately during ambulation.

d. A **rollator** is a walker with wheels on all four legs. The movement is controlled by hand brakes.

E. Wheelchairs. Many different types of wheelchairs are available. The patient's disabilities, size, weight, and activities are the main considerations in wheelchair selection. The following options should be considered when selecting a wheelchair.

1. Seat size. The standard chair is 18 inches wide and 16 inches deep. A narrow wheelchair is 16 inches wide. Wheelchairs are available in widths up to 48 inches. The chair should be 2 inches wider than the widest part of the patient's body (usually around the buttocks or thighs).

2. Arms can be fixed or detachable to allow the patient to transfer on and off the chair. Halflength arms (as opposed to full length) allow the use to get closer to a table or work surface. Various types of padding and adjustments in the arm position can assist the patient in obtaining a position that is comfortable and keeping the arms on the arm rests.

3. Tires can be hard rubber or pneumatic (i.e., air filled) which allows the chair to transverse rougher surfaces.

4. Wheels can be reinforced with spokes or can be composite based.

5. Leg rests can be of different sizes and are available with padding. Some have adjustable elevation to aid in healing an acute injury.
6. Footrests can be of different sizes and are available with or without heel loops to keep the foot on the footrest.
7. Casters (i.e., **front wheels**) can be hard rubber or pneumatic.
8. Calf rests can be of different sizes and are available with padding.
9. Seat upholstery holds the patient in the chair. Seats come in a variety of materials to accommodate patients' needs.
10. Back upholstery supports the patient's back while he or she is sitting in the chair. The material in the seat and back are usually the same.
11. Cross braces add stability and durability to the chair.
12. Weight. Standard wheelchairs weigh 35-50 lb. Lightweight wheelchairs (25-35 lb.) are available for those who are unable to manipulate a standard chair and for ease of transport.
F. Sports chairs are wheelchairs that are lightweight and durable. They are designed for people who are very active.
G. Powered wheelchairs are designed for people who cannot wheel themselves. This type of wheelchair is powered by an electric motor and battery.

II. BATHROOM EQUIPMENT.

This equipment is used for patients who cannot get to the bathroom or for patients who need assistance using the toilet or bathtub.
A. Elevated toilet seats are used to increase the height at which the patient sits over the toilet. This assists patients with limited mobility in getting on and off the toilet. Additional support can be provided with **toilet safety rails.** These rails allow the patient to transfer weight from the feet to the hands, and they help prevent the patient from falling when getting on or off the toilet.
B. Commodes are portable toilets that are used by patients who cannot get to the bathroom. Commodes contain a frame (with or without a backrest), a seat, and a bucket. Some are adjustable in height and have arms that drop to facilitate transfer to and from the commode. Folding commodes are available to make storage easier.
C. Three-in-one commodes function as combination commode, elevated toilet seat, and toilet safety rails. These are beneficial for patients requiring varying assistance during recuperation.
D. Bath benches are seats with or without a back that fit in the bathtub and allow the patient to sit while taking a shower.
E. Transfer benches are placed over the outside of the bathtub. They are available with or without a back. A transfer bench assists the patient in getting into the bathtub and serves as a bath bench while the patient takes a shower.
F. Grab bars are bars that either attach to the wall around the bathtub or to the bathtub itself to assist patients in getting on and out of the bathtub.

III. BLOOD PRESSURE MONITORS.

Patients with hypertension use this equipment to monitor blood pressure so that appropriate therapeutic decisions can be made. A patient's blood pressure measured at home is typically 5 mm Hg lower than when measured at the office.[1] The type of monitor that is recommended should be determined by the patient's ability to use the product correctly. Items to consider when assisting a patient in the selection of a blood pressure monitor: ease of use (e.g. automatic inflation), use of the monitor with one hand (has D-ring cuff), the size of the display monitor (visually impaired patients), blood pressure cuff size, and the capability to store readings. Types of monitors include the following:

A. Mercury sphygmomanometer. This type of monitor is the **most accurate** and does not need calibration. Mercury in a graduated column rises in response to pressure applied to the cuff. The blood pressure is determined by measuring the length of the mercury column while listening for the Korotkoff sounds in the stethoscope. Mercury monitors are usually not used as a home device because of their large size, the need for use of a stethoscope, and the potential for mercury spill. Owing to the risk of mercury exposure, this type of sphygmomanometer is being phased out of healthcare facilities.

B. Finger monitors. These detect blood pressure by compressing the finger and converting blood vessel movement into blood pressure by oscillometric technology. Many environmental conditions and medications can interfere with the results of these monitors. Finger blood pressure monitors are **least accurate** and not recommended for home monitoring.

C. Aneroid sphygmomanometer. This is similar to a mercury sphygmomanometer, except that instead of a column of mercury, it has a dial to be read. Aneroid models have the advantage of being **less expensive** than mercury models; however, they do require regular calibration in a healthcare provider's office with a mercury sphygmomanometer to ensure proper results. These types of monitors are portable and lightweight, however. Most require manual inflation of the cuff, but a separate stethoscope is not required.

D. Electronic or digital monitor. This type of monitor detects blood pressure by using a microphone or by oscillometric technology, which converts movement of vessels into blood pressure. This type is easier to use than a mercury or aneroid sphygmomanometer as most offer automatic inflation and deflation and there is not a need for a separate stethoscope. These models are more **expensive,** can provide inaccurate readings if the patient moves while the blood pressure is being performed, and requires frequent calibration against a mercury sphygmomanometer; but they represent an alternative for patients who cannot use a sphygmomanometer. Some of these monitors come with a wrist cuff which may be useful in overweight or obese patients for whom the regular size arm blood pressure cuff is too small. Patients with very large or very small upper arms may need to purchase a special cuff in order to obtain an accurate reading.

IV. HEAT AND COLD THERAPY.

For musculoskeletal disorders (e.g., sprains, strains, arthritis), treatment may include the application of heat or cold to specific areas of the body.

A. Heat can be applied in a dry or moist form. **Dry** heat is less effective than moist heat but is tolerated better; thus its clinical effectiveness is similar. **Moist** heat has an advantage of not causing as much perspiration and is often recommended. The application of heat produces vasodilation and muscle relaxation. This facilitates pain relief and healing. Products that can deliver heat include the following:

1. A **hot water bottle,** a rubber container, should be half filled with hot water. The remaining air is squeezed out of the container, which is then capped. This results in a flexible container that can be shaped to the area of the body for which it is being used to provide dry heat.

2. A **heating pad** is an electrically powered pad that can produce moist or dry heat. Moist heat is supplied by inserting a wet sponge in a pocket that is next to the pad. Patients should be instructed to place the pad on top of the body instead of lying on the pad to prevent burning.

3. A **moist-heat pack** (also called a hydrocollator) contains silica beads, which absorb heat when placed in boiling water. The heated pack is wrapped in a towel and applied to the body to provide moist heat. A moist-heat pack must be kept moist to retain its absorbent properties. The pack should be wrapped in plastic and stored in the refrigerator if use is anticipated or in the freezer if long-term storage is required.

4. A **gel pack** provides dry heat after it is heated in boiling water or in the microwave. It is reusable by repeating the heating process.

5. Chemical hot packs provide dry heat by mixing chemicals from two compartments. The chemicals undergo an exothermic reaction. Some packs are reusable by reheating in boiling water or in the microwave.

6. Paraffin baths provide moist heat by covering the body with heated paraffin. Once the wax cools and hardens, it is removed. This method is commonly used for patients with arthritis in the hands and fingers.

B. Cold application is indicated mainly as acute therapy to decrease circulation to a local area and to provide pain relief. Cold is contraindicated in patients with circulatory stasis or lacerated tissue. Products that can deliver cold include the following:

1. An **ice bag** is a flexible plastic container designed to hold ice. The bag is then applied to the body.

2. A **gel pack** can be used to apply cold by freezing and then applying to the body.

3. Chemical packs can be used to apply cold. Chemicals from two compartments are mixed together, resulting in a chemical reaction that produces cold. These packs are used once and then disposed of.

V. DIAGNOSTIC AIDS

A. Self-care tests or **kits** are used as screening tests or for monitoring. Many factors can affect the accuracy of the tests. The most common factors are patients not following directions and patients having poor technique. Pharmacists should be prepared to counsel patients on the selection of a test, on the proper use, and on interpretation of results. Pharmacists should refer patients to the appropriate healthcare provider if necessary.

B. Types of tests

1. Urine tests

a. The **urine glucose test** detects sugar in the urine. Patients with diabetes can use this to evaluate glucose control. Blood glucose monitoring is preferred, however, because it is more accurate and gives a better description of current glycemia.

b. The **ketone test** detects the presence of ketones in the urine. This is used by patients with diabetes as an indicator of severely uncontrolled diabetes.

c. **Ovulation prediction tests** predict when ovulation occurs to increase the chance of conception.

(1) These tests detect the presence of **luteinizing hormone (LH)** in the urine. Its presence means that ovulation should occur within 20-48 hr.

(2) The test is performed daily until a positive result is obtained. Many kits recommend not using the first morning urine as the LH surge typically starts in the morning and may not be detectable until later in the day. Therefore, it is recommended to test between 10 A.M. and 8 P.M.

(3) The day on which the patient begins testing depends on the length and regularity of her menstrual cycle. Patients with menstrual cycles of consistent length may need to test only for 4 days, whereas those with menstrual cycles that change in length may need to test for 8 or 9 days.

(4) False-positive results can occur if the patient is taking fertility medications (e.g., clomiphene), oral contraceptives, or hormone-replacement therapy or if the patient has polycystic ovary syndrome or impaired liver or kidney function.

d. Pregnancy tests detect pregnancy by the presence in the urine of **human chorionic gonadotropin (hCG),** which is secreted after fertilization. Many pregnancy test kits can detect hCG 1 day after missed menses.

(1) False-positive results can occur if the patient takes the test too early, is taking fertility medications (e.g., hCG), or has ovarian cysts.

(2) If a patient uses a household container or a waxed cup to collect urine, it may affect the test results.

(3) Patients should be referred to the appropriate healthcare provider if they receive a positive result or two negative results 7 days apart and have not had menses.

e. The **urinary bacteria test** detects the presence of nitrite in the urine. The presence of nitrite is used as an indicator of a **urinary tract infection (UTI)** because the most common bacteria associated with UTIs are gram-negative bacteria, which convert nitrate to nitrite.

(1) Because this test is not specific for bacteria, false results can occur.

(2) This test is used by patients who have recurrent or chronic UTIs or many risk factors. Risk factors include previous UTIs, diabetes, urinary tract abnormalities,

enlarged prostrate, and behavioral risk factors (e.g., frequent sexual activity, delayed urination, the use of spermicides or diaphragms).
(3) False positives can result from medications (e.g., phenazopyridine) the patient may be taking or from menstrual blood in the urine, depending on the test used. In addition, a false negative may be detected if the patient is taking high doses of vitamin C, adheres to a strict vegetarian diet, or has frequent urination.
f. There are a variety of FDA approved **urine drug tests** available for use at home. Substances that may be detected in the urine include: amphetamine, methamphetamine, ecstasy, marijuana, cocaine, phencyclidine, opiates, benzodiazepine, barbiturates, methadone, tricyclic antidepressants, and oxycodone. Most urine drug tests require two steps: screening (at home) and confirmation (laboratory).
(1) The first step requires the collection of urine in the provided collection cup and reviewing the results as color bands on the device at home. The color bands are similar to results obtained on a home pregnancy test. If no drug is detected, a negative result will appear.

(2) A preliminary positive result indicates the urine sample may contain the drug but a confirmation is needed. To obtain confirmation testing, it is necessary to send the urine sample that was used to perform the first step to the drug test manufacturer's contracted laboratory. The results are available from the laboratory 7 to 10 business days after the specimen is mailed and are anonymous as they are tracked by a personal identification number.
2. Blood tests
a. The **cholesterol test** determines a patient's total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL) and/or triglycerides.
(1) Some tests provide the patient only with a TC level, whereas others provide a full lipid profile (TC, LDL, HDL, and/or triglycerides).
(2) Some cholesterol kits are a single-use test in which patient applies a blood sample onto a collecting card, which is mailed to a laboratory for evaluation. Other singleuse tests can be performed and evaluated by the patient at home. The measurement of the amount of cholesterol is determined by a color chart, which is provided with the test.
(3) Regardless of the test used, the patient places a large drop of blood onto the test card or cassette. Some of the tests require the patient to fast—meaning nothing to eat or drink except water for 12-14 hr before collecting the blood.
(4) These tests can be useful for patients who want to monitor their therapy. They are also useful as screening tests. Patients who test borderline or higher for high cholesterol should be referred to the appropriate healthcare provider.
b. The **blood glucose test** measures the concentration of glucose in the blood. Patients with diabetes use this information, along with diet, exercise, and medication, to keep glucose levels within a target range.

(1) Other tests are designed to be used with **blood glucose meters,** which read the test and display the actual blood glucose value. Some blood glucose meters contain optical units that measure the color change caused by glucose; others measure the electric charge produced by glucose. The result is then calibrated to provide whole blood or plasma glucose concentration. Whole blood is approximately 15% lower than plasma glucose, which is what is measured in the standard laboratory tests. Many of the new glucometers provide results as the “plasma equivalent,” meaning they test whole blood but use an internal algorithm to calculate the plasma glucose.
(2) Patients using blood glucose tests must perform the tests properly and understand the appropriate actions to take when the resulting values are outside the desired range.

c. Other **home blood test kits** are available that provide results at the time of testing in the home or the collected specimen is sent to a laboratory for results. These home testing kits include HIV, hepatitis C virus (HCV), glycosylated hemoglobin A1c (A1c), anemia, prostrate specific antigen (PSA), and thyroid. If the specimen is mailed away for processing, the results can be obtained by calling a toll-free number.

d. There are a variety of **point-of-care testing (POCT)** devices that are available for use in pharmacies. Because a majority of them meets the Clinical Laboratory Improvements Amendments (CLIA)-waived requirements, pharmacies are able to offer these services to their patients. When selecting a POCT device for use make sure to research the device specifications, portability, testing procedure, and cost. Examples of point-of-care tests that are available in select pharmacies include: electronic peak flow meters, portable spirometry, HIV rapid test, rapid Strep testing, coagulation analyzers, osteoporosis screening with quantitative ultrasound or peripheral dual-energy absorptiometry, and blood tests that measure A1c, fructosamine, ketones, urinary microalbumin, alanine aminotransferases, and lipid profiles.

3. Fecal occult blood tests detect the presence of blood in the stool as a screening test for colorectal cancer. Patients drop a pad into the toilet after defecation. The pad will change color if blood is present. Patients should eat high-fiber foods during the testing period and are instructed to test three consecutive stool samples. Patients with a positive result should be referred to the appropriate healthcare provider. Certain conditions (gastrointestinal bleed, nosebleed, menstruation), foods (red meat), medications (nonsteroidal anti-inflammatory drugs [NSAIDs]), and toilet-bowl cleaners can produce false-positive results.

4. Fertility microscopes allow women to determine their most fertile time of the month. A woman places saliva on a viewing slide or plate, allows the saliva to dry for 5-7 min, and

then views it under a microscope. The appearance of a ferning pattern means ovulation has occurred. Estrogen levels rise and peak with ovulation, causing an increase in salt levels in the saliva, resulting in a fernlike pattern in dried saliva. Simple dots or a bubblelike appearance is found during a nonfertile period. A

woman should be advised to avoid smoking, eating, or drinking for 2 hr before testing. Polycystic ovary syndrome and perimenopause can cause false-positive results.

VI. HOSPITAL BEDS AND ACCESSORIES.

Hospital beds are used by patients who are confined to bed for long periods of time or who require elevation of the head or feet as part of their treatment. Hospital beds may be manually or electrically operated.

A. Types of hospital beds

1. A **manual** hospital bed has no electrically powered motors; the head, foot, and bed height are adjusted manually.

2. A **semielectric** hospital bed contains two electric motors that raise the head and foot of the bed. The patient can usually adjust the head and foot position with a handheld control. The height of the bed is adjusted manually. The semielectric bed can usually be adjusted manually in case of loss of electricity.

3. A **fully electric** hospital bed contains three motors that can change the height of the bed as well as raise the head and foot via electrically powered motors. The fully electric hospital bed can usually be adjusted manually in case of loss of electricity.

B. Accessories

1. Bed rails keep the patient in the bed and allow the patient to change positions.

2. A **trapeze** is a triangular-shaped object that hangs above the patient and is used to change the patient's position.

3. Alternating pressure pads are used by patients to prevent decubitus ulcers (i.e., bed sores). As a preventive measure, these pads inflate, thus changing the areas of the body that receive pressure.

VII. INCONTINENCE AND INCONTINENCE PRODUCTS

A. Urinary incontinence is a condition in which involuntary urine loss is a social or hygienic problem and is objectively demonstrable. Incontinence is a common problem in the elderly. Types of incontinence include

1. Urge incontinence, which is uncontrolled contractions of the bladder

2. Stress incontinence, a weakness of the sphincter that causes leakage when intra-abdominal pressure increases (e.g., while laughing, coughing, sneezing) and is common in pregnancy

3. Overflow incontinence, which is caused by obstruction of urine flow from the bladder and is common in elderly men as a result of prostate enlargement

4. Functional incontinence, which is related to physical or psychological problems that impair the patient's ability to get to the bathroom

5. Transient incontinence, which is caused by medications, urinary tract infections, or mental impairment

6. Mixed incontinence, which is a combination of more than one type of incontinence

B. Incontinence products

1. Shields are disposable, absorbent pads that are placed in the underwear and held with an adhesive strip on the back of the pad. These pads are used for light incontinence problems.

2. Undergarments are disposable absorbent garments that are worn under the underwear and held in place with elastic straps that go around the hips. They are designed for moderate incontinence problems.
P.598

3. Briefs look like adult-size diapers that are kept in place with adhesive strips. They are designed for heavy incontinence problems.
4. Pull-up pants are absorbant disposable garments that look like underwear and are used for heavy incontinence problems.
5. Underpads are absorbent pads to be placed on the bed underneath a patient with incontinence. These pads contain a barrier to protect the bedding.
6. Waterproof sheets are plastic or vinyl sheets that protect the mattress. They may be lined with a soft material to prevent friction against the skin.
7. Incontinence systems are garments that look like underwear but have a pouch or pocket designed for a disposable or reusable pad.

VIII. ORTHOPEDIC BRACES AND SURGICAL FITTINGS.

These products promote proper body alignment and support injured areas. Pharmacists should have additional training before attempting to fit an orthopedic device.
A. Abdominal supports are elastic and are used to support and hold surgical dressings in place. Abdominal supports come in different widths.
B. Arm slings are used to provide comfort and support during recuperation from fractures, sprains, and surgery. The elbow should form a 90-degree angle in an arm sling to allow for proper circulation.
C. Back supports are worn by patients to provide support or promote proper alignment. Such supports are named after the area of the spine on which it is worn.
1. A **sacral belt** (also called **sacral cinch** or **sacroiliac belt**) supports the lower back.
2. A **lumbosacral support** supports the lower and middle back.
3. A **thoracolumbar support** supports the middle and higher areas of the back.
D. Cervical collars support or limit the range of motion of the neck. Cervical collars should be of sufficient length so that the patient can adjust the degree of compression. The width of the cervical collar should equal the measurement from the chin to the sternum when the patient is standing straight, looking ahead.
1. Soft or **foam** cervical collars provide mild support and remind the wearer to keep the neck straight.
2. Hard or **rigid** cervical collars provide more support and limit movement to a greater degree.
3. A **Philadelphia** or **extrication** collar is used to immobilize the neck and is commonly used in emergency situations.
E. Clavicle supports are used as aids for the reduction and stabilization of the clavicle (i.e., collarbone). These supports are sometimes called **figure-eight straps** because of their appearance.

F. Knee braces (also called **knee cages**) are used to support the knee. Some braces have metal stays on the side to prevent the lateral movement of the knee. Those with metal stays may also have hinges to allow for movement of the knee. Some knee braces have a cut-out hole and padding around the patella (i.e., knee cap) to prevent its movement.

G. Knee immobilizers prevent any motion of the knee and are used for severe injuries and fractures. They are available in different lengths and are adjustable in size.

H. Nighttime ankle brace keeps the ankle at a 90-degree angle while sleeping. It can be used in the treatment of Achilles tendon injuries or plantar fasciitis.

I. Shoulder immobilizers prevent movement of the shoulder and arm. The elbow should be at a 90-degree angle to allow for healing without affecting circulation.

P.599

J. Tennis elbow supports apply pressure to the forearm to provide pain relief and decrease inflammation from tennis elbow (i.e., epicondylitis).

K. Wrist braces prevent movement of the wrist to allow healing. The brace may be shaped to have the wrist flexed so that the tendons in the hand remain stretched during the period of inactivity.

IX. OSTOMY APPLIANCES AND ACCESSORIES

A. Definitions. An **ostomy** is a surgical procedure in which an artificial opening is created in the abdominal wall for the purpose of eliminating urine or fecal waste. The opening is called a **stoma.** Ostomies can be temporary to allow for repair or healing of the digestive tract or can be permanent. Each procedure is named to describe the anatomical location involved.

1. In a **colostomy,** part of the colon is cut and attached to the abdominal wall. This procedure is done mainly in patients with colon or rectal cancer, lower-bowel obstruction, or diverticulitis. A colostomy may be temporary or permanent, the discharge may be liquid or semisolid (as with an **ascending** colostomy), or it may be solid (as with a **descending** or **sigmoid** colostomy). Patients with an ascending colostomy and some patients with a transverse colostomy have gastric enzymes present in the discharge. These patients must take extra care to ensure that the discharge does not come into contact with the skin.

2. In an **ileostomy,** the ileum is attached to the abdominal wall. This procedure is performed in patients with ulcerative colitis or Crohn disease.

3. A **urostomy** is performed in patients with bladder cancer. In this procedure, an **ileal conduit** is created by attaching the ureters to the ileum and the distal end of the ileum to the abdominal wall.

B. Ostomy appliances. The ostomy appliance contains a **skin barrier** that attaches to the skin around the stoma. The skin barrier protects the skin and allows for the collection device or **pouch** to be worn on the body. The selection of an ostomy appliance depends on the type of discharge produced. In addition to size, color, and

flexibility, appliances may have detachable pouches and be able to be drained by releasing a clip at the bottom of the appliance.

C. Ostomy accessories

1. Washers, powder paste, and **ointments** are designed to be used with a skin barrier and provide additional protection of the skin around a stoma.

2. Cement, elastic belts, and **tape** are used to hold the appliance in place.

3. Deodorizers help control fecal odor. **External** deodorizers can be placed into the appliance; systemic deodorizers (e.g., bismuth subgallate, chlorophyll, charcoal) can be ingested as **internal** deodorizers.

4. Moisturizers and **disinfectants** can be used to treat the skin and prevent complications.

5. Irrigation devices are used by patients who have control over the elimination of waste to facilitate removal of the accumulated waste. The devices are used to instill water into the intestine, which produces peristalsis.

D. Special considerations for ostomy patients. Drug therapy can present unique problems for ostomates. Absorption of enteric-coated or sustained-release products may not be possible. Antibiotics, sulfa drugs, laxatives, and diuretics are some of the common problem medications in these patients.

X. RESPIRATORY EQUIPMENT

A. Continuous positive airway pressure (CPAP) is used in patients with sleep apnea. The pressure supplied from this machine keeps the airway open. It is typically worn while sleeping to allow the patient to sleep without disturbance.

B. A **humidifier** puts moisture into the air by breaking water into small particles and blowing them into the air to be evaporated. Humidifiers are sometimes referred to as called “coolmist vaporizers.”

1. Vaporizers are similar to humidifiers in that they are used to deliver moisture to the air. However, a vaporizer produces a steam to increase humidity, whereas a humidifier produces a nonheated mist.

2. An **ultrasonic humidifier** contains a transducer, which produces a finer mist. It is commonly used to promote expectoration in patients with upper-respiratory infections.

3. Both types of humidifiers and vaporizers need to be cleaned regularly to prevent the growth of mold or bacteria.

C. A **nebulizer** is used to deliver medication to the mouth or throat. Patients with a sore throat may use a nebulizer to deliver a topical anesthetic to the throat. An **ultrasonic nebulizer** is used to deliver medication into the lungs. The medication is diluted with normal saline and then inhaled. An ultrasonic nebulizer is used by patients with respiratory infections, asthma, or chronic obstructive pulmonary disease (COPD).

D. Oxygen is administered for a variety of conditions. Oxygen can be stored as a gas or a liquid or can be extracted from the air via a **concentrator.** The amount of

oxygen required by the patient is measured in liters per minute (L/min). A **registered respiratory therapist** can be consulted for information on the correct procedures, cautions, and laws regarding oxygen use.

E. A **peak flow meter** is used by patients with asthma to detect constriction of the airways before symptoms appear. Early detection of an upcoming attack allows for therapy designed to stop or minimize the severity of the disease. Patients exhale as much as possible into a peak flow meter to obtain the expiratory flow rate. If this rate is below a predetermined baseline, patients might be instructed to change therapy.

F. Home spirometry is a noninvasive pulmonary function test. It allows for measurement of (a) the forced expiratory volume in one second (FEV1), and (b) the forced vital capacity (FVC) in the person's home. This device may be used for post lung transplant patients or patients with a history of asthma and/or chronic obstructive pulmonary disease (COPD).

XI. THERMOMETERS.

These instruments measure body temperature and are **most commonly used** to detect or evaluate the treatment of infections.

A. A glass **thermometer** has a sealed glass constriction chamber that contains liquid mercury, red- or blue-colored fluid, or Galinstan (a mixture of gallium, indium, and tin). Responding to temperature changes, the mercury, red- or blue-colored fluid, or Galinstan expands or contracts. It remains at the maximum temperature registered until shaken back into the reservoir at the bottom. Glass fever thermometers are graduated from 96°F to 106°F in two-tenths-of-a-degree increments. These types of thermometers should be cleaned and sterilized with alcohol after each use. The American Academy of Pediatrics recommends against the use of mercury-containing thermometers because of the risk of mercury exposure if it breaks. However, more research is needed to assess the accuracy of the newer glass thermometers (redor blue-colored fluid or Galinstan).[2]

1. The **oral** thermometer has a long slender reservoir. It is placed under the tongue, and the lips are sealed around the thermometer for 3-4 min. Invalid results may occur if the patient eats, drinks, or chews gum before the temperature is taken; incorrectly places the thermometer in the mouth; talks or breathes rapidly through mouth or nose while the temperature is being taken; or has oral abscess or dentures.

2. The **rectal** thermometer has a blunt, pear-shaped bulb to prevent breakage and aid in retention. It is inserted 1 inch into the rectum and left for at least 2 min. A lubricant should be used to aid insertion. Rectal temperature is 1°F higher than oral temperature. Rectal temperatures have been found to lag behind the core temperature. So if a patient has a rapid change in core temperature, the rectal temperature will not immediately reflect it.

3. The **stubby** thermometer has a short, stubby bulb to prevent it from breaking. It can be used as an oral or a rectal thermometer. Although a stubby thermometer can be used as either oral or rectal, it is recommended that one route of administration is selected and used.

4. Any of the three types of glass thermometers can be used to take the **axillary temperature** if an oral or rectal temperature cannot be taken. An axillary temperature is taken by holding the thermometer snugly under the arm for 3-4 min. Axillary temperature is 1°F lower than oral temperature. However, there is controversy about the accuracy of axillary temperature. Using this temperature location can be clinically useful as long as the site is recorded and used consistently.[3]

B. The basal thermometer is used to measure basal body temperature. Basal thermometers are available as a glass or digital thermometer. A digital thermometer may lower the potential for user error as it offers more accuracy. The basal body temperature is used to predict ovulation to increase or decrease the chance of conception. Basal body temperature can be taken orally, rectally, or vaginally, but the route should be consistent.

C. Digital thermometers register temperature quickly. Heat alters the current running through a resistor, and the temperature is displayed via a digital readout. The current is supplied by a battery, some of which are rechargeable. Digital thermometers can be used orally or rectally and generally require placing a plastic sheath over the tip of the thermometer before using. Digital thermometers have been integrated into pacifiers to assist in taking an infant's temperature.

D. Tympanic thermometers use infrared technology to detect the temperature of the tympanic membrane. The temperature is determined within seconds and is less invasive than other thermometers. These thermometers use disposable tips that are inserted into the ear. The American Academy of Pediatrics recommends that this type of thermometer be used in older babies and children because the probe needs to accurately fit into the ear. Inappropriate placement and too much earwax can cause inaccurate readings.[4]

E. Skin thermometers are placed directly on the skin (usually the forehead) to calculate body temperature. This type of thermometer is a liquid-crystal strip that changes colors based on temperature. Environment factors such as sweating and ambient temperature will affect the skin temperature. This method is not as accurate as the others and should be reserved for situations in which other methods are not possible.

XII. URINARY CATHETERS.

These devices allow for the **collection** and **removal of urine** from the bladder.

A. External catheters are used for **heavy incontinence** problems or complete loss of urine control. They are attached to a stationary collection device or a leg bag to allow for ambulation. Types of external catheters include the following:

1. The **male** external catheter is placed around the penis. Some have adhesive to assist in keeping the catheter secure.

2. The **female** external catheter, which is a contoured device that fits snugly in the vagina.
P.602

B. Internal catheters are used during **surgery** or when external catheters are inappropriate. Internal catheters can be used at home, but the patient must be taught proper insertion techniques to prevent infection. The catheter is inserted through the urethra into the bladder and is attached to a stationary collection device or leg bag. Catheters are sized by the **French scale:** the larger the number, the larger the diameter of the catheter. Types of catheters include the following:
1. The **straight** catheter is used for **intermittent catheterization** to drain the bladder. It consists of a rubber tube; urine drains from one end and the other end connects to the collection device.
2. The **Foley** catheter, an indwelling catheter, can be used for **up to 30 days before changing.** The end inserted into the bladder contains a balloon, which is inflated with sterile water or saline to hold the catheter in place. The balloon is deflated before removal.
P.603

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.
1. When a patient is fitted with an axillary crutch, how far below the underarm should the top of the crutch rest?
(A) 0.5 inch
(B) 1 inch
(C) 2 inches
(D) 3 inches
(E) 4 inches

View Answer***1. The answer is C[see].*****2. What angle should the elbow form when a cane is the correct height?**
(A) 10 degree
(B) 25 degree
(C) 45 degree
(D) 60 degree
(E) 90 degree

View Answer***2. The answer is B[see].*****3. A product that delivers moisture to the air by heating water to produce steam is called a**
(A) nebulizer.
(B) humidifier.
(C) ventilator.

(D) peak flow meter.

(E) vaporizer.

View Answer***3. The answer is E[see].*****4. An absorbent product designed for patients with light incontinence problems is a**

(A) brief.

(B) shield.

(C) undergarment.

(D) underpad.

(E) catheter.

View Answer***4. The answer is B[see].*****5. When an oral temperature is taken, the thermometer should be placed into the mouth for**

(A) 1-2 min.

(B) 3-4 min.

(C) 5-6 min.

(D) 7-8 min.

(E) > 9 min.

View Answer***5. The answer is B[see].*****6. The diameter of urinary catheters is measured by which of the following scales?**

(A) Leur

(B) English

(C) French

(D) gauge

(E) metric

View Answer***6. The answer is C[see].*****7. A cervical collar that immobilizes the neck is called a**

(A) soft cervical collar.

(B) hard cervical collar.

(C) foam cervical collar.

(D) extrication collar.

(E) rigid cervical collar.

View Answer***7. The answer is D[see].*****8. Incontinence that is caused by an obstruction of the bladder is called**

(A) overflow incontinence.

(B) urge incontinence.

(C) stress incontinence.

(D) functional incontinence.

(E) transient incontinence.

View Answer***8. The answer is A[see].*****9. A colostomy or ileostomy could be performed for all of the following conditions *except***

(A) lower bowel obstruction.

(B) malignancy of the colon or rectum.

(C) ulcerative colitis.

(D) duodenal ulcer.

(E) Crohn disease.

View Answer***9. The answer is D[seeand].*****10. Pregnancy test kits are designed to detect which substance?**

(A) luteinizing hormone (LH)

(B) progesterone

(C) human chorionic gonadotropin (hCG)

(D) estrogen

(E) follicle-stimulating hormone

View Answer***10. The answer is C[see].***P.604

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* I.B.2.a*].*

When a patient is fitted for an axillary crutch, the top of the crutch should be 2 inches below the axilla (underarm).

2. The answer is B *[see* I.A.1*].*

When a patient is properly fitted for a cane, the elbow should form a 25° angle. This allows for maximum weight transfer.

3. The answer is E *[see* X.B*].*

A vaporizer produces moisture by heating water to produce steam. A humidifier also produces moisture; however, it works by mechanically creating small water particles. A nebulizer is used to deliver liquid to the mouth and throat. A ventilator is used to assist in breathing. A peak flow meter is used to detect airway constriction.

4. The answer is B *[see* VII.B.1*].*

Shields are pads that are placed in the underwear and held with adhesive strips. They are used for patients with light incontinence problems.

5. The answer is B *[see* XI.A.1*].*

Oral temperature is taken by inserting the bulb of the thermometer under the tongue and sealing the lips around the thermometer for 3-4 min.

6. The answer is C *[see* XII.B*].*

The French scale is used to measure the diameter of a urinary catheter. The Leur scale is used to measure syringe tip size. The gauge scale is used to measure needle diameter. The metric scale is a general system of measurement.

7. The answer is D *[see* VIII.D.3*].*

An extrication collar (also known as a Philadelphia collar) is used to immobilize the neck. It is commonly used in emergency situations. Soft or foam cervical collars provide mild support and remind the patient to keep the neck straight. Hard or rigid cervical collars provide moderate support but allow some movement.

8. The answer is A *[see* VII.A.3*].*

Overflow incontinence is caused by obstruction of the bladder. Urge incontinence is caused by uncontrolled bladder contractions. Stress incontinence is caused by increases in intra-abdominal pressure. Functional incontinence is related to physical or psychological problems. Transient incontinence is caused by medications, urinary tract infections or mental impairments.

9. The answer is D *[see* IX.A.1 *and* 2*].*

Lower-bowel obstruction, malignancy of the colon or rectum, and diverticulitis may all require a colostomy. Ulcerative colitis and Crohn disease may require an ileostomy. The treatment of a duodenal ulcer would not include a colostomy or an ileostomy.

10. The answer is C *[see* V.B.1.d*].*

Pregnancy tests detect hCG in the urine. This is secreted after the embryo has implanted in the uterus. Ovulation-prediction tests detect LH. Progesterone, estrogen, and follicle-stimulating hormone are all involved in controlling the menstrual cycle.

OTC Otic, Dental, and Ophthalmic Agents

Jennifer D. Smith

Connie Lee Barnes

I. OTIC OVER-THE-COUNTER (OTC) PRODUCTS

A. The ear can be divided into three distinct parts: the external ear, the middle ear, and the inner ear.

1. The external ear is typically thought of as the part of the ear one can see. However, being made up of the auricle, the external auditory canal, and the outer surface of the tympanic membrane, the external ear extends much farther.

a. The **auricle,** also referred to as the **pinna,** functions to collect sound and channel it toward the middle ear.

b. The **external auditory canal,** also known as the **ear canal,** is about 1 inch in length, leading directly to the eardrum. The ear canal contains small glands that are responsible for secreting cerumen, better known as earwax.

c. The outer surface of the tympanic membrane is known as the **eardrum.** The eardrum separates the external auditory canal from the middle ear.

2. The **middle ear** is an air-filled chamber that provides direct access to the inner ear and indirect access to the nose and throat by way of the eustachian tube. The middle ear houses three small bones (malleus, incus, and stapes) known as the ossicles. When sound strikes the eardrum, it vibrates, transmitting the sound vibrations to the ossicles, which in turn transmit the sound to the inner ear.

3. The **inner ear** is a delicate structure composed of auditory and vestibular components.

a. The auditory component of the inner ear (the cochlea) is responsible for hearing. The cochlea, a snail-shaped structure filled with fluid, is attached to one of the ossicles (the stapes) in the middle ear. When the stapes moves, it creates waves within the cochlea. Depending on the wave produced, neural impulses are created and transmitted to the brain for interpretation.

b. The vestibular component of the inner ear (the semicircular canals and the vestibule) is responsible for maintaining balance and equilibrium.

B. Common ear disorders

1. Excessive/impacted cerumen (earwax). Contrary to current social beliefs, earwax does not need to be removed with objects such as fingers, towels, and cotton-tipped applicators because these objects typically cause impaction of the earwax, rather than its removal. Instead, the external ear has a unique self-cleansing mechanism. Ear canal skin is constantly shed and removed via lateral migration from the tympanic membrane (at a rate of 2-3 mm per day) to the external canal, where cerumen adheres to the shed skin and other debris. Movement such as chewing moves the cerumen outward where it is removed by drying, flaking, or simply falling out. The use of hearing aids or earplugs can block this outward migration, developing earwax impaction and leading to hearing loss.

a. The **functions** of cerumen include

(1) Lubrication of the lining of the ear canal

(2) Temporarily repelling water
(3) Resistance to infection owing to its acidic nature (pH = 4-5), which creates an unfavorable environment for organism survival
(2) Trapping dust, debris, and foreign objects
b. Epidemiology. Aside from impaction caused by manipulation, some patient populations are more prone to experience impacted cerumen, including patients with an overproduction

of cerumen, patients with narrowed ear canals, the elderly, and patients with mental retardation.
c. **Symptoms** of impacted cerumen include earache, itching of the ear, reflex cough, dizziness, vertigo, tinnitus, and compromised hearing.
d. Earwax-softening agents may be used alone or followed by the use of an otic syringe (see I.C).
(1) Carbamide peroxide 6.5% in anhydrous glycerin is the **only U.S. Food and Drug Administration (FDA) approved agent for cerumen removal.** When carbamide peroxide makes contact with tissue enzymes, oxygen is released, producing a foaming action. This **foaming action softens impacted cerumen.**
(a) Available agents. Murine, Debrox, Dent's Ear Wax
(b) Instructions for use. Patients **aged 12 and older** should tilt the head sideways and instill 5-10 drops into the ear. The applicator tip should not be inserted into the ear canal. Patients should keep the head tilted to the side (or insert cotton) for several minutes to increase contact time with the cerumen. Repeat the process **twice daily for up to 4 days.** For children < 12 with suspected cerumen impaction, a medical provider should be consulted.
(2) Olive oil (sweet oil) is used to soften earwax and alleviate itching.
(3) Mineral oil, recommended as 2 drops in the affected ear(s) once per week, has been used to liquefy the cerumen, thus aiding in its removal.
(4) Docusate sodium given 15 min before provider in-office irrigation has shown efficacy, but no data exist to support the superiority of docusate sodium over carbamide peroxide.
(5) Hydrogen peroxide is a component of carbamide peroxide and has weak antibacterial properties. As an otic solution, hydrogen peroxide may be diluted 1:1 with warm water and instilled in the ear to aid in cerumen softening and removal.
(6) Ear candles, also known as coning candles, are made of paraffin-coated fabric wound into a foot-long cone. Patients are instructed to place the cone in the ear canal and light the distal end with a match. Allegedly, the cerumen is liquefied and negative pressure draws out the wax. In one study of ear candles, more candle wax was deposited into the ears of patients than earwax was removed. However, no data support this dangerous process for efficacy. Furthermore, complications may include external otitis, temporary hearing loss, and burns.
e. Patients with perforated tympanic membrane, ear drainage, ear pain, or a rash in the ear should be referred to a healthcare provider. In the office, providers may use various devices or irrigating systems to remove impacted cerumen.

2. Vertigo is a loss of equilibrium, in which one might describe a room as spinning. As described in I.A.2.B, the vestibular compartment of the inner ear is responsible for maintaining balance and equilibrium. The autonomic system may become involved if the vertigo is severe, producing dizziness, pallor, sweating, and nausea. Patients expressing symptoms of vertigo (aside from motion sickness) should be referred to a medical provider.

3. Tinnitus may be described by patients as a ringing, buzzing, hissing, whistling, or humming noise lasting from seconds to minutes. Tinnitus has been linked to a variety of causes, including Ménière disease, head injuries, otitis media, syphilis, temporomandibular-joint (TMJ) dysfunction, and certain medications (salicylates, nonsteroidal anti-inflammatory drugs, aminoglycosides, loop diuretics, and chemotherapeutic agents). If tinnitus is constant or severe, a medical consult is advised. Currently, there are no FDA-approved treatments for tinnitus.

4. External otitis, also referred to as otitis externa, is **inflammation of the external auditory canal** secondary to a bacterial or fungal infection.

a. Cause. External otitis, frequently referred to as swimmer's ear, is thought to be most commonly the result of **local trauma** to the external canal (e.g. cotton-tipped applicators, fingers, sharp objects) or **prolonged exposure to moisture.** Prolonged exposure to moisture (e.g., humid environment, underwater swimming, diving) promotes maceration of the thin skin lining the ear canal, allowing bacteria to penetrate and grow. Trauma to the external canal lends itself to susceptibility to damage and thus easier infiltration of microorganisms. The predominant microorganisms isolated from patients with swimmer's ear are ***Pseudomonas aeruginosa*** and ***Staphylococcus aureus.***

b. Symptoms. Initial symptoms include **itching** and a sensation of **pressure/fullness in the ear,** followed by **pain,** an **otic discharge,** and a possible **decrease in hearing.** The pain may become quite intense, especially if the outer ear is touched or with movement of the jaw, such as chewing.

c. **Treatment** is with a **prescription otic antibiotic** and **corticosteroid** if bacterial in origin and otic antibiotic alone if fungal in origin, as well as discontinuation of mechanical trauma and/or swimming (until resolution of infection). Oral antibiotics are not necessary unless the infection is unresponsive to otic treatment, the patient is immunocompromised, or a middle ear infection coexists. **External otitis should not be self-treated.**

d. Prevention of external otitis is the key. Mechanical trauma to the ear, by way of cotton-tipped applicators, and fingers should cease immediately. Water should be removed as gently and effectively as possible after swimming or showering/bathing using a towel around the edges of the ear or a hair dryer set on low heat. It may also be beneficial to tilt the head to the side to help expel water. If reoccurrence is frequent, one might consider using molded ear plugs, but consideration should be given to the risk of impacted cerumen with the use of such devices.

5. Water-clogged ear may be a contributing factor to external otitis owing to tissue maceration from prolonged periods of exposure to water; however, water-clogged ear is a separate disorder. Therefore, labeling of products approved by the FDA for the treatment of water-clogged ear may not allude to its use for prevention of external otitis. The only agent FDA approved as safe and effective as an ear-drying agent is isopropyl alcohol 95% in anhydrous glycerin 5%, approved for use in patients 12 years of age and older. A home solution of 50/50 isopropyl alcohol and white vinegar may also be used to dry the ear. Caution must be taken not to recommend self-treatment for water-clogged ear for patients with signs of infection, discharge or bleeding from the ear, ear surgery within the previous 6 weeks, or tympanostomy tubes.

6. Furuncles, also known as boils, are small abscesses surrounding the base of a hair follicle in the outer portion of the external ear canal. *Staphylococcus aureus* is typically the offending organism. Furuncles are usually self-limiting and may be managed with warm compresses and a topical antibiotic.

7. Otitis media is a bacterial infection that is most prevalent between the ages of 3 months and 3 years, owing to the length, angle, and function of the eustachian tube in children. Symptoms include ear pain, fever, fluid discharge from the ear, and possible decreased hearing. All patients with suspected otitis media must be referred to a medical provider for evaluation and treatment.

C. Administration of otic agents

1. Instructions for use of otic drops

a. Warm the solution by holding the bottle in the hand for a few moments.

b. Tilt the head sideways with the affected ear upward.

c. Pull the earlobe up and back to straighten the canal for adults and down and back to straighten in children.

d. Use the other hand to squeeze the bottle of drops, carefully delivering the number of recommended drops into the ear canal. Caution should be taken not to insert the applicator into the ear canal.

e. Keep the head tilted sideways for several minutes or place cotton in the ear to prevent the medication from draining out. If cotton is used, it must be large enough, so as not to become lodged in the ear, and should not be left in the ear for longer than 1 hr.

f. Repeat the procedure on the opposite ear, if necessary.

2. Instructions for use of an otic syringe

a. Prepare a *warm* solution of plain water. Fill the otic syringe with the warm water solution.

b. Straighten the ear canal using the appropriate method, as noted above. Tilt the head over a sink or basin to catch the outflow solution.

c. Insert the tip of the otic syringe into ear, with the tip pointed slightly upward.

d. Gently squeeze the bulb of the otic syringe to allow the solution to enter the ear. Allow the solution to drain from the ear into the sink or basin. If pain or dizziness occurs, remove the syringe and consult a medical provider.

e. Repeat on opposite ear, if necessary.

II. DENTAL OTC PRODUCTS

A. Dental anatomy. Anatomically, the teeth are divided into two parts: the **crown** (above the gingival line) and the root (below the gingival line).

1. Enamel is the crystalline calcium salts (hydroxyapatite) that cover the crown to protect the underlying tooth structure.

2. Dentin is the largest part of the tooth structure, located beneath the enamel. It protects the dental pulp.

3. Cementum is a bone-like structure that covers the root and provides the attachment of the tooth with the periodontal ligaments.

4. Pulp consists of free nerve endings.

B. Common dental problems and OTC **products**

1. Dental caries (i.e., **cavities**) are formed by the growth and implantation of cariogenic microorganisms.

a. Causes

(1) Bacteria (primarily *Streptococcus mutans* and *Lactobacillaceae*) produce acids (e.g., lactic acid) that demineralize enamel. Initially, demineralized enamel appears as a white, chalky area and becomes bluish white and eventually brown or yellow.

(2) Diet is another factor in the development of dental caries. Foods with a high concentration of refined sugar (i.e., sucrose) increase the risk of dental caries. Sucrose is converted by bacterial plaque into volatile acids that destroy the hydroxyapatite.

(a) Fructose and **lactose** are less cariogenic than sucrose.

(b) Noncariogenic sugar substitutes are xylitol, sorbitol, and aspartame.

b. OTC **products** for dental caries include products that can alleviate the pain and sensitivity until the patient can get to the dentist. Examples of ingredients that are beneficial in this regard include lidocaine, benzocaine (e.g., Anbesol, Orajel), or an oral analgesic (e.g., aspirin, acetaminophen).

2. Plaque and calculus

a. Causes

(1) Plaque is a sticky substance formed by the attachment of bacteria to the pellicle, which is a thin, acellular, glycoprotein (a mucoprotein coating that adheres to the enamel within minutes after cleaning a tooth).

(2) Calculus (or **tartar**) is the substance formed when plaque is not removed within 24 hr. The plaque begins to calcify into calculus when calcium salt precipitates from the saliva. Calculus can be removed only by a professional dental cleaning.

b. OTC **products**

(1) Toothbrushes. Soft, rounded, nylon bristles are preferred by dentists because hard bristles can irritate the gingival margins and cause the gums to recede. Some toothbrushes have specially designed bristles that reach deep between teeth and along the gumline to remove stains and polish teeth and massage gums. Examples include Colgate Whitening and Colgate Massager toothbrushes. Electric toothbrushes can benefit patients who require someone to clean their teeth for them

or patients who have orthodontic appliances. Toothbrushes should be replaced when they begin to show wear or every 3 months, whichever comes first. Patients should replace their toothbrush after having an upper-respiratory infection.

(2) Irrigating devices direct a high-pressure stream of water through a nozzle to the hard-to-clean areas by gently lifting the free gingiva to rinse out crevices. Two types are available: **pulsating** (i.e., intermittent low- and high-pressure water streams) and **steady** (i.e., constant and consistent water pressure), neither of which has shown superior irrigating ability.

(a) Irrigating devices should serve as adjuncts in maintaining oral hygiene.

(b) Examples include Interplak Water Jet, Hydro-Pik, and the Waterpik oral irrigator.

c. **Dental floss** is available waxed, unwaxed, thick, thin, flavored, or unflavored. Some dental flosses are impregnated or coated with additives such as baking soda and fluoride. Also, several manufacturers are marketing floss made of materials with superior antishredding properties (e.g., Glide, Colgate Precision). There are no differences among

dental flosses in terms of plaque removal and prevention of gingivitis. There is no evidence of a residual wax film with the use of waxed dental floss.

(1) The selection of dental floss depends on the characteristics of the patient, such as tooth roughness or tightness of tooth contacts (e.g., waxed floss is recommended for tight-fitting teeth because it can pass easily between the teeth without shredding).

(2) The American Dental Association (ADA) recognizes the following brands as safe and effective: Butler, Johnson & Johnson, and Oral-B.

d. Dentifrices are products that enhance the removal of stains and dental plaque by the toothbrush. These include toothpastes, antiplaque and anticalculous mouthwashes, cosmetic whiteners, desensitizing agents, disclosing agents, and dental gums.

(1) Toothpastes are beneficial in decreasing the incidence of dental caries, reducing mouth odors, and enhancing personal appearance. Some toothpastes may contain the antioxidant coenzyme Q10 (CoQ10; e.g., Perfect Smile Q10).

Ingredients include the following:

(a) Abrasives are responsible for physically removing plaque and debris. Examples include silicates, sodium bicarbonate, dicalcium phosphate, sodium metaphosphate, calcium pyrophosphate, calcium carbonate, magnesium carbonate, and aluminum oxides. Mentadent contains sodium bicarbonate, whereas PeroxiCare and Colgate baking soda and peroxide whitening contain sodium bicarbonate and peroxide. High-abrasive formulations are not advised for long-term use or for use by patients with exposed root surfaces.

(b) Surfactants are foaming agents that are incorporated into most dentifrices because their detergent action aids in removing debris. The **most frequently used** surfactants are **sodium lauryl sulfate** and **sodium dodecyl benzene sulfonate.** Sodium lauryl sulfate-containing dentifrices have been associated with an increase

in the occurrence of canker sores. Dentifrices such as Rembrandt Natural, Sensodyne, and Biotene do not contain sodium lauryl sulfate.

(c) Humectants prevent the preparation from drying. Examples include sorbitol, glycerin, and propylene glycol.

(d) Suspending agents add thickness to the product. Examples include methylcellulose, tragacanth, and karaya gum.

(e) Flavoring agents include sorbitol or saccharin.

(f) Pyrophosphates are found in tartar-control toothpastes. These products retard tartar formation; however, they form an alkaline solution that may irritate the skin. Some patients might experience a rash around the outside of the mouth. These patients should use regular toothpaste and only occasionally brush with tartar-control toothpaste (e.g., Colgate Tartar Control Whitening). Tartar-control toothpastes do not penetrate below the gumline, where tartar does the most damage.

(g) Fluoride is anticariogenic because it replaces the hydroxyl ion in hydroxyapatite with the fluoride ion to form fluorapatite on the outer surface of the enamel. Fluorapatite hardens the enamel and makes it more acid resistant. Fluoride also has demonstrated antibacterial activity.

(i) Fluoride is **most beneficial** if used from birth through **age 12 or 13** because unerupted permanent teeth are mineralizing during that time. Whether or not a patient receives fluoride depends on the concentration in his or her local drinking water (Table 29-1).

Table 29-1. Daily Fluoride Supplement Requirements for Infants and Children, Based on Concentration of Fluoride in Drinking Water

Fluoride Concentration (ppm)	Age	Fluoride Supplement Required (mg/day)
> 0.6	6 months to 3 years	0
	3-6 years	0
0.3-0.6	6 months to 3 years	0
	3-6 years	0.25
	6-16 years	0.50
< 0.3	6 months to 3 years	0.25

	3-6 years	0.50
	6-16 years	1.00

(ii) Common fluoride compounds in toothpaste include 0.24% sodium fluoride and 0.76% or 0.80% sodium monofluorophosphate (e.g., Aim, Crest, Aquafresh, Colgate). Crest Gum Care contains a reformulated version of stannous fluoride (0.454%), which might reduce gingivitis and bleeding of the gums by an average of 20% and 33%. However, it can also stain the teeth brown.
(iii) A fluoride warning label, which recommends contacting a poison control center or seeking professional assistance if more than a brushful of fluoride toothpaste is ingested, is required by the FDA on fluoride-containing dentifrices because the federal agency lists fluoride as a toxic substance.
(iv) The estimated toxic dose of fluoride is 5-10 mg/kg.
(v) Acute fluoride toxicity causes nausea, vomiting, and diarrhea. The ADA limits the maximum amount of fluoride in ADA-accepted toothpaste to 260 mg per container.
(2) Agents with **antiplaque** potential for inclusion in dentifrices include plant extracts (sanguinarine), metal salts (zinc and stannous), phenolic compounds (triclosan), and essential oils (thymol and eucalyptol).
(a) Triclosan is an antimicrobial agent that has been demonstrated clinically to help prevent gingivitis, plaque, cavities, and tartar.
(i) Colgate Total contains 0.24% sodium fluoride and 0.30% triclosan and is formulated with the polymer **Gantrez,** which works to prolong the contact of triclosan with oral structures.
(ii) Therefore, Colgate Total continues to work in between brushings.
(b) Colgate Total has been accepted by the ADA as efficacious.
(3) Anticalculous dentifrices include the ingredients zinc chloride, zinc citrate, and 33% pyrophosphate to prevent calculus formation.
(a) The ADA does not evaluate anticalculous claims because it regards the inhibition of supragingival calculus as a nontherapeutic use.

(b) The ADA has directed that the following statement appear on all package and container labeling for accepted fluoride dentifrice products with calculus-control activity: "[*Product name*] has been shown to reduce the formation of tartar above the gumline, but has not been shown to have a therapeutic effect on periodontal diseases."

(4) Cosmetic whitening agents. The **most common ingredient** in these products that is responsible for whitening the teeth is **10% carbamide peroxide** (i.e., in Gly-Oxide, Simply White, or Proxigel) and hydrogen peroxide (i.e., in Crest Whitestrips).

(a) Carbamide peroxide is a white crystal that reacts with water to release hydrogen peroxide, which in turn liberates free oxides.

(b) Some cosmetic whiteners may contain hydrogen peroxide or perhydrol urea in gel or liquid form.

(c) Products specifically marketed to dentists include Colgate Platinum Professional Tooth Whitening System and Rembrandt Lighten Gel.

(i) Patients should perform tooth bleaching only with a dentist's supervision.

(ii) Crest Extra Whitening uses a patented soft-silica technology. Owing to this technology, the product contains 50% more silica, which greatly enhances the removal of extrinsic stains without increasing abrasiveness.

(iii) Colgate Luminous also contains a silica whitening technology and fluoride.

(d) Possible risks associated with using whitening products include alteration of normal flora, tissue damage, tooth sensitivity, gingivitis, and potentiation of carcinogenic effects of other agents.

(e) Antiseptics have been used as whiteners (e.g., Gly-Oxide, Proxigel).

(5) Desensitizing agents reduce the pain in sensitive teeth caused by cold, heat, acids, sweets, or touch. These products should be nonabrasive and should not be used on a permanent basis unless directed by a dentist.

(a) Examples of **5% potassium nitrate compounds** include Colgate Sensitive, Sensodyne, Aquafresh Sensitive, and Crest Sensitivity.

(b) Dibasic sodium citrate in Pluronic gel and 10% strontium chloride were classified as class III pending further evidence of effectiveness.

(6) Disclosing agents aid in visualizing where dental plaque has formed. These products are for occasional use only and should not be swallowed. The FDA-approved product is a vegetable dye, Food, Drug, and Cosmetic (FD&C) Red No 3. Following use, the consumer should rinse the mouth with water and then expectorate.

(7) Mouthwashes may contain astringents, demulcents, detergents, flavors, germicidal agents, and fluoride. They can be used for cosmetic purposes, reducing plaque, or supplementing fluoride consumption.

(a) Cosmetic mouthwashes freshen the breath. They are nontherapeutic and are not effective as an antiseptic agent. These mouthwashes are classified by their active ingredients, alcohol content, and appearance. The most popular products are

those that contain medicinal phenol and mint. The higher the percent of alcohol, the higher the effect of the flavor within the mouth.

(b) Antiplaque mouth rinses. Mouth rinses claiming anticalculous or tartar-control activity contain the same active ingredients as anticalculus dentifrices. Cool Mint Listerine has received the ADA seal of approval.

(i) Cetylpyridinium chloride (CPC), a mouthwash ingredient, has been approved for class I for plaque and gingivitis treatment. Examples of products in this class include Cepacol, Scope, Oral-B Anti-Plaque Rinse, and Crest Pro-Health Rinse.

(ii) Chlorhexidine is an active ingredient in some mouthwashes. An example is Colgate PerioGard.

(iii) Staining is associated with the overuse of CPC and chlorhexidine.

(iv) Fluoridated mouthwashes are used after cleaning the teeth and should be expectorated. Nothing should be put into the mouth for 30 min after using these mouthwashes. The ADA has approved the following products: ACT Anti-Cavity Dental Rinse, ACT for Kids, Fluorigard Anti-Cavity Dental Rinse, and Reach Fluoride Dental Rinse, Oral-B Rinse Therapy and Anti-Cavity Treatment, and Colgate Phos-Flur.

(8) Dental gums are promoted to reduce plaque, whiten teeth, possibly reduce the risk of tooth decay, and freshen breath. Chewing gum is associated with increased salivary flow, which apparently produces a beneficial buffering effect against acids in the oral cavity.

(a) Some contain baking soda as a mild abrasive cleaner and to neutralize acid.

(b) Calcium may be added to help remineralize the teeth and prevent cavities.

(c) These gums also contain xylitol, a sweetener that is less likely to cause cavities than sugar or sorbitol. Examples are Trident Advantage, Arm & Hammer Dental Care, BreathAsure, Dental Care, Advance Breath Care, Aquafresh Whitening, and Biotene. BreathAsure Dental Gum contains an ingredient called PXT-20, which is an emulsion of polydimethylsiloxane and poloxamer 407. It forms a thin coating on the tooth that is supposed to reduce plaque buildup.

(d) These gums are not a substitute for good oral hygiene, including brushing and flossing, but may be useful for people who are unable to brush after lunch.

(e) It is not known if these products have any advantage over regular sugarless gum.

3. Gingivitis is inflammation of the gingiva. The gingiva may appear larger in size with a bluish hue caused by engorged gingival capillaries and a slow venous return.

a. Cause. Gingivitis is caused by microorganisms that eventually damage cellular and intercellular tissues. **Chronic gingivitis** may be localized or generalized. The gums readily bleed when probed or brushed, and the patient should seek dental assistance.

b. OTC **products** include anesthetics containing eugenol or benzocaine (e.g., Orajel) to relieve the pain. Mouthwashes may freshen the breath; however, it is important to consider the potential of these products to disguise and delay treatment of pathological conditions (e.g., gingivitis) before use. Also, acetaminophen (Tylenol) can be recommended. The patient should seek the advice of a dentist.

4. Periodontal disease is the result of chronic gingivitis left untreated.
a. The periodontal ligament attachment and alveolar bone support of the tooth deteriorate.
b. Risk factors include gender (men affected more than women), age (> 35 years old), smoking, lack of oral care and regular dentist visits, diabetes, hypertension, rheumatoid arthritis, and loss of anterior teeth.
c. Periodontitis may be treated with prescription products:
(1) Periostat (doxycycline hyclate, 20-mg capsules)
(2) Atridox (doxycycline hyclate 10%) in the Atrigel Delivery System.
(a) Atridox provides local antibacterial effects.
(b) Low-dose doxycycline inhibits collagenase, an enzyme that destroys connective tissue in the gums, leading to tooth loss.

5. Acute necrotizing ulcerative gingivitis (ANUG) (also called **trench mouth**) is characterized by necrosis and ulceration of the gingival surface with underlying inflammation. This condition is usually seen in teens and young adults.
a. Signs and **symptoms** of ANUG include severe pain, halitosis, bleeding, foul taste, and increased salivation.
b. The **cause** of ANUG is unknown. It is postulated that it might be associated with the overgrowth of spirochete and fusiform organisms.
c. **Risk factors** include anxiety, stress, smoking, malnutrition, and poor oral hygiene.
d. Treatment consists of local débridement. Also, penicillin VK (penicillin V is a derivative of penicillin G; however, it is more stable in an acidic medium and, therefore, is better absorbed from the gastrointestinal tract; K stands for potassium) or metronidazole may be used in certain cases (e.g., widespread lesions).
e. OTC **products** include acetaminophen and products with benzocaine (not eugenol because it may cause soft tissue damage). The patient should be advised to see a dentist. The use of salicylates is not recommended if the patient is predisposed to bleeding. Also, adequate nutrition, high fluid intake, and rest are essential. Rinsing the mouth with warm normal saline or 1.5% peroxide solution might be helpful for the first few days.
6. Temporomandibular joint syndrome is caused by an improper working relationship between the chewing muscles and the TMJ.
a. Signs and **symptoms** include a dull, aching pain around the ear, headaches, neck aches, limited opening of the mouth, and a clicking or popping noise upon opening the mouth.
b. Risk factors include bruxism (i.e., grinding the teeth) and occlusal (i.e., bite) abnormalities.
c. **Treatment** consists of moist heat applied to the jaw, muscle relaxants, bite plates or occlusal splints, a diet of soft foods, correcting the occlusion, or surgery.
d. OTC **products** that can help relieve the pain include oral analgesics (e.g., acetaminophen, ibuprofen).

7. Teething pain. The ADA has not accepted any product for teething pain. A **frozen teething ring** can provide symptomatic relief. Persisting pain may be treated with a local anesthetic such as benzocaine (found in Anbesol Baby and Orajel Baby). If a teething child presents with a fever, a physician should be contacted.
8. Xerostomia (i.e., dry mouth) is caused by improper functioning of the salivary glands (as in Sjögren syndrome and diabetes mellitus). **Artificial saliva** is available as an OTC product. The ADA has approved the following artificial saliva products: Moi-Stir, Salivart, Xero-Lube, and OralBalance Gel.

C. Common oral lesions and OTC **products**

1. Canker sores (also called **recurrent aphthous ulcers or recurrent aphthous stomatitis**)

a. The **cause** of canker sores is unknown. Studies suggest that the sores may be caused by hypersensitivity to bacteria found in the mouth or dysfunction of the immune system initiated by minor trauma or stress. This is why physicians or dentists may use prednisone or a topical steroid to reduce allergic reaction or have the patient rinse with a tetracycline suspension. Peridex and Listerine appear to help decrease bacteria in the mouth.

b. Lesions can occur on any nonkeratinized mucosal surface in the mouth (i.e., tongue, lips) and usually appear gray to yellow with an erythematous halo of inflamed tissue surrounding the ulcer. Most lesions persist 7-14 days and heal without scarring.

c. OTC **products** can control the pain of canker sores, shorten the duration of current lesions, and prevent new lesions. Products include **protectants, local anesthetics,** and **débriding and wound-cleansing agents.**

(1) Protectants include Orabase, denture adhesives (see II.F.2), and benzoin tincture. Denture adhesives are not approved for this use by the FDA.

(2) Local anesthetics, such as benzocaine or butacaine, are the **most common anesthetics** found in these OTC products.

(a) The FDA has approved the following ingredients:

(i) Benzocaine (5%-20%)

(ii) Benzyl alcohol (0.05%-0.1%)

(iii) Dyclonine (0.05%-0.1%)

(iv) Hexylresorcinol (0.05%-0.1%)

(v) Menthol (0.04%-2%)

(vi) Phenol (0.5%-1.5%)

(vii) Phenolate sodium (0.5%-1.5%)

(viii) Salicyl alcohol (1%-6%)

(b) Examples of OTC local anesthetics for oral use include Anbesol, Blistex, Campho-Phenique, Orajel, Orajel CoverMed, Zilactin-B, Zilactin-L, Benzodent, and Rembrandt Canker Pain Relief Kit.

(c) The use of products containing substantial amounts of menthol, phenol, camphor, and eugenol should be discouraged owing to their ability to irritate tissue.

(d) Aspirin should not be retained in the mouth or placed on an oral lesion in an attempt to provide relief.

(e) Prescription products. Amlexanox (Aphthasol) has been approved for the treatment of canker sores.

(i) It is applied 4 times daily after meals and at bedtime.

(ii) Advise patients to start using the product as soon as they notice symptoms and to continue until the ulcer is healed, approximately 10 days.

(f) Gelclair is indicated for local management and relief of oral pain associated with aphthous ulcers. It provides oral pain relief by acting as a protective adherent barrier over the surface of the mouth and throat.

(i) Patient should use one packet at least 3 times a day or as needed.

(ii) Advise patients to mix 1 packet with 3 tablespoons of water, swish for a minute, then expectorate. Do not eat or drink for approximately 1 hr after treatment.

(g) Investigational **products. Thalidomide** is being studied for the treatment of AIDSassociated oral canker sores.

(3) Débriding and wound-cleansing agents include 10%-15% carbamide peroxide, 3% hydrogen peroxide, 1.2 g sodium perborate monohydrate, and sodium bicarbonate. The FDA considers these four active ingredients to be safe and effective for débriding or wound-cleansing agents for oral healthcare.

2. Cold sores/fever blisters (also called **herpes simplex labialis**) are caused primarily by the herpes simplex virus type 1 (HSV-1). HSV-1 is contagious and is thought to be transmitted by direct contact. An outbreak may be provoked by stress, minor infection, fever, or sunlight. Cold sores usually occur on the lips and are recurrent, often arising in the same location.

a. Presentation. An outbreak is preceded by burning, itching, or numbness. Red papules of fluid-containing vesicles then appear, and these eventually burst and form a crust. These sores are typically self-limited and heal in 10-14 days without scarring.

b. OTC **products** for cold sores include products that contain softening compounds (e.g., emollient creams, petrolatum, protectants), which keep the cold sore moist to prevent it from drying and fissuring. Local anesthetics in nondrying bases (e.g., Orabase, with benzocaine) decrease pain. Highly astringent bases should be avoided. The ADA contraindicates caustic agents (e.g., phenol, silver nitrate), camphor and other counterirritants, and hydrocortisone for the treatment of cold sores. Lesions should be kept clean by gently washing with mild soap.

(i) Docosanol 10% cream (**Abreva**) is indicated for the treatment of cold sores. It prevents the cold sore infection from entering healthy cells. It is approved by the FDA to shorten healing time and duration of symptoms. Patients should apply the cream at the first sign of an outbreak and continue to apply the cream five times a day until the lesion is healed.

(ii) Viractin gel (2% tetracaine) is used for the temporary relief of pain and itching associated with cold sores.

(1) If a **secondary infection** develops, bacitracin or Neosporin antibiotic ointments should be recommended. If necessary, the patient should consult a physician for a systemic antibiotic prescription.

(2) A lip **sunscreen** should be used for patients whose cold sores appear to be caused by sun exposure.
(3) The essential amino acid L-lysine has been used in oral doses of 300-1200 mg daily to accelerate recovery or suppress recurrence of cold sores. However, studies have produced conflicting data regarding L-lysine and its effect on the duration, severity, and recurrence rate of cold sores.
c. **Prescription products**
(1) Valacyclovir (Valtrex) is indicated for the treatment of herpes labialis.
(2) Acyclovir cream 5% (Zovirax) is indicated for the treatment of cold sores in adults and adolescents > 12 years of age. Therapy should be initiated at the onset of sign and symptoms and applied 5 times per day for 4 days.

(3) Penciclovir cream 1% (Denavir) is an antiviral medication for the treatment of cold sores in adults and children 12 years of age and older. Patients should apply the cream every 2 hr while awake for 4 days, beginning at the first sign of tingling or swelling.
D. Common oral infections and OTC **products**
1. Candidiasis (also called **thrush**) is caused by the fungus *Candida albicans,* which is the most common opportunistic pathogen associated with oral infections. Thrush has a milky curd appearance, and affected patients should contact a physician.
2. Oral cancer. The most common oral cancer is **squamous cell carcinoma,** which can appear as red or white lesions, ulcerations, or tumors.
a. Signs and **symptoms** include a color change in the tongue, a sore throat that does not heal, and persistent or unexplained bleeding. Patients with any of these signs should contact a physician or a dentist.
b. Risk factors include smoked and smokeless tobacco as well as alcohol.
c. **Treatment** consists of eliminating use of tobacco and alcohol in any form (e.g., alcoholic beverages, mouth rinses with alcohol). Also, treatment generally includes **wide local excision** for small lesions and **en bloc excisions** for larger lesions (in continuity with radical neck dissection if lymph nodes are involved). Radiation, alone or combined with surgery, may be appropriate. Chemotherapy may be used as palliation or as an adjunct to surgery and radiation.
d. OTC **medications** should not be administered until after checking with a physician. For example, OTC medications used for inflammation can increase the effects of methotrexate. Chemotherapeutic agents can produce many possible side effects that require immediate medical attention (e.g., chest pain, inflammation, unusual bleeding). Some examples of side effects that usually do not require medical attention include nausea, vomiting, loss of appetite or hair, and trouble sleeping. OTC medications can be useful in these cases; however, nausea and vomiting are treated by prescription medications such as ondansetron or metoclopramide. Nonpharmacological measures, such as avoiding disturbing

environmental odors and vestibular disturbances, might be helpful in minimizing nausea and vomiting.

E. Recommended standard prophylaxis for prevention of endocarditis

1. Amoxicillin 2.0 g orally 1 hr before the procedure for adults, and 50 mg/kg orally for children, is the recommended standard prophylactic regimen for all dental, oral, upper-respiratory tract, and esophageal procedures.

2. For patients who are **allergic to penicillin,** the recommended **alternative oral regimens** include the following:

a. Clindamycin, 600 mg for adults; 20 mg/kg for children

b. Cephalexin or **cefadroxil,** 2.0 g for adults; 50 mg/kg for children

c. **Azithromycin** or **clarithromycin,** 500 mg for adults; 15 mg/kg for children, 1 hr before the procedure

F. OTC **denture products**

1. Denture cleansers are either **chemical** or **abrasive** in respect to their cleansing ability.

a. Chemical denture cleansers include alkaline peroxide, alkaline hypochlorite, or dilute acids.

(1) Alkaline peroxide is the **most commonly used** chemical denture cleanser and is available as tablets or powders. It causes oxygen to be released, which creates a cleansing effect. Alkaline peroxide does not damage the surface of acrylic resins; however, it may bleach them.

(2) Alkaline hypochlorite (i.e., bleach) dissolves the matrix of plaque but has no effect on calculus. It is both bactericidal and fungicidal. A **disadvantage** of alkaline hypochlorite is that it **corrodes metal denture components.** It can also bleach acrylic resin. Therefore, it should not be used more than once a week.

b. Abrasive denture cleansers are available as gel, paste, or powder (e.g., silicates, sodium bicarbonate, dicalcium phosphate, calcium carbonate).

(1) Dentures should not be soaked in hot water because the heat could distort or warp the appliances.

(2) The ADA accepts the following denture cleansers as safe and effective: Denture-Brite, Efferdent, and Polident.

2. Denture adherents contain materials (e.g., karaya gum, pectin, methylcellulose) that swell, gel, and become viscous to promote adhesion, which increases the denture attachment to underlying soft tissues.

a. Disadvantages. As the use of denture adherents increases, the soft tissue deteriorates. Denture adherents can also provide a medium for bacterial and fungal growth. Daily use of denture adherents is not recommended.

b. The ADA accepts the following denture adherents as safe and effective: Fixodent, ORAfix, Sea-Bond, Super Poli-Grip, and Effergrip.

G. Pharmacist's responsibilities to the patient using OTC **oral products**

1. Refer a patient to a dentist if the oral complaint involves an abscess with fever, swelling, malaise, lymphadenopathy, or purulent exudate.

2. Remind patients that cold and canker sores, with appropriate treatment, are usually a self-limiting problem.
3. Patients should be informed about **how to use recommended products,** the duration of use, the expectations of using the product, and the procedure to follow if the product is ineffective.
4. If a nonprescription product does not improve a condition, or if the condition worsens, use of the product should be discontinued and a physician or dentist should be contacted.

III. OPHTHALMIC OTC PRODUCTS

A. Anatomy of the eye

1. The **sclera,** also known as the white of the eye, functions to protect intraocular contents and maintain the shape of the eye.
2. The **cornea** is the main refracting surface of the eye.
3. The anterior chamber of the eye houses a continuous supply of **aqueous humor,** which is produced in relation to the intraocular pressure. The aqueous humor is responsible for nourishing the cornea.
4. The **iris** is the colored part of the eye that regulates the entrance of light through the pupil.
5. The **pupil** is the contractile opening at the center of the iris that dilates and constricts in response to light.
6. The **lens** is found directly behind the iris and pupil and is responsible for enabling the eye to accommodate, focusing for near and distance vision. The lens continues to grow throughout life, gradually becoming thicker over time. The lens is, therefore, susceptible to the degenerative effects of aging, most noticeably evident in the 5th decade of life as the inability to focus and refocus for near and distance vision.
7. Approximately two thirds of the volume of the eye is occupied by the **vitreous humor.** As one ages, the gel-like characteristics of the vitreous humor is lost and shadows are cast by various cells, giving the illusion of “floaters.”
8. The **retina** is composed of the optic disc, the retinal vessels, and the macula. The optic nerve enters the retina through the optic disc. The macula is responsible for central vision and the remaining parts of the retina are responsible for peripheral and color vision.
9. The **optic nerve,** also known as the second cranial nerve (CN II), transmits impulses from the retina to the brain.

B. Ophthalmic Formulations

1. Vehicles provide increased viscosity, thereby enhancing contact time of the product. Vehicles commonly found in ophthalmic products include carboxymethylcellulose (CMC), povidone, polyvinyl alcohol (PVA), and hydroxypropyl methylcellulose (HPMC).

2. Preservatives provide antimicrobial activity for ophthalmic preparations and include benzalkonium chloride (BAK), chlorhexidine, methylparaben, propylparaben, ethylenediaminetetraacetic acid (EDTA), and sorbic acid.
3. Antioxidants prevent product deterioration. Common antioxidants found in ophthalmic preparations include edetic acid, sodium bisulfite, sodium metabisulfite, sodium thiosulfate, and thiourea.
4. Wetting agents reduce surface tension of the lens and include polysorbate 20, polysorbate 80, poloxamer 282, and tyloxapol.
5. Buffers are used in ophthalmic preparations to maintain a pH between 6.0 and 8.0. Buffers include acetic acid, boric acid, hydrochloric acid, phosphoric acid, potassium bicarbonate, potassium borate, potassium citrate, sodium acetate, sodium bicarbonate, sodium bisphosphate, sodium borate, sodium carbonate, sodium citrate, sodium hydroxide, and sodium phosphate.
6. Tonicity adjusters ensure an isotonic agent, equal to 0.9%-60.2% sodium chloride. These agents include dextrose, glycerin, potassium chloride, propylene glycol, and sodium chloride.

C. Nonprescription ophthalmic agents

1. Artificial tears are used to **hydrate and lubricate the eye** by stimulating tear production and decreasing tear evaporation. Initial dosing is recommended as 2 times daily, up to 4 times daily, as needed. However, solutions may be used hourly, if clinically indicated. To reduce ocular irritation, preservative-free artificial tears should be recommended to patients who will need to use the medication frequently.
2. Lubricating ointments include white petrolatum, mineral oil, and lanolin, which act to lubricate and hydrate the eye. As an ointment, these agents are able to **provide increased contact time with the ocular surface but may result in blurred vision.** If possible, blurred vision may be minimized (or less noticeable) by decreasing the amount of ointment instilled into the eye or by administering the ointment at bedtime. Initial dosing is recommended as 2 times daily, but may be used as often as every few hours, or only occasionally, depending on patient response. Preservative-free ophthalmic ointments may reduce ocular irritation in patients requiring frequent dosing. When using eye drops and ointment, **drops should be instilled into the eye before applying ointment.**
3. Vasoconstrictors (decongestants) work by producing a **temporary constriction of the conjunctival blood vessels,** thereby reducing eye redness. Available ophthalmic vasoconstrictors include naphazoline, phenylephrine, tetrahydrozoline, and oxymetazoline. These agents **may have a rebound effect (congestion) if used in excess** or for extended durations and should be avoided in patients with narrow-angle glaucoma.
4. Antihistamines may be used for the treatment of ophthalmic conditions associated with allergic rhinitis, though their use has been classified by the FDA as less than effective because of the lack of data demonstrating clinical effectiveness. Ketotifen, sold under the brand name Zaditor®, is the only available nonprescription ocular antihistamine and mast cell stabilizer indicated for the temporary prevention of itching of the eye due to allergic conjunctivitis. Pheniramine and antazoline are

also nonprescription ophthalmic antihistamines, but are only available in combination with the ophthalmic decongestant naphazoline.
a. Typical dosing of ophthalmic antihistamines is 1-2 drops in each eye 3-4 times daily.
b. Ophthalmic antihistamines should not be recommended in patients with glaucoma or patients at high risk of developing narrow-angle glaucoma, as pupil dilation associated with the use of these agents may cause this disorder.
c. Side effects of these agents may include burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation. Patients using ketotifen drops should also be advised of the possible adverse effect of blood shot eyes.

5. Astringents decrease ocular inflammation. The only FDA-recommended astringent is **zinc sulfate,** recommended as 1-2 drops four times daily.
6. Irrigant solutions work to **rinse and remove debris and contaminants** from the eye, while maintaining ocular moisture.
7. Hyperosmotic agents increase the tonicity of the tear film, eventually eliminating excess fluid from the cornea.
D. Eye disorders
1. Dry eye, also known as keratoconjunctivitis sicca, is a common condition in which patients complain of a foreign body sensation, ophthalmic itching, decreased tear production, redness, pain, and difficulty moving the eyelids. Symptoms are the result of a deficiency to produce aqueous, mucin, or lipid tear film components, which may be attributable to certain disease states (e.g., thyroid disease, Parkinson disease), infection, or medications (e.g., antihistamines, oral contraceptives). Nonprescription treatment for dry eye includes the use of **artificial tears during the day and ophthalmic ointment at** night.
2. Conjunctivitis is inflammation of the conjunctiva which may be caused by bacterial or viral infection, allergy, or environmental factors.
a. Allergic conjunctivitis symptoms affect both eyes and include redness, mild edema of the eyelid, excessive tearing, extreme itching, string-like mucoid discharge, and chemosis. Nonprescription treatment recommendations avoidance of the allergen if feasible, cold compresses, vasoconstrictors, and antihistamines. Nonprescription ophthalmic products containing a combination of a vasoconstrictor and an antihistamine are available (e.g., Naphcon A, Opcon A, Visine-A).
b. The causes of **bacterial conjunctivitis** depend on patient's age. Approximately one quarter of patients presenting with bacterial conjunctivitis will have **concomitant otitis media.** Therefore it is prudent for all children presenting with a purulent ocular discharge on waking in the morning and abrupt onset of redness to have their ears examined for otitis media. **Treatment for bacterial conjunctivitis is prescription only.**
c. **Viral conjunctivitis** is most often attributable to the **adenovirus** and is **highly contagious.** More commonly known as **"pink eye,"** individuals often experience an upper-respiratory infection or are exposed to another individual with viral

conjunctivitis before the onset of symptoms (e.g., pink eye, thick ocular discharge, extreme tearing, foreign body sensation). **Treatment is supportive** and may include cold compresses, artificial tears, and topical vasoconstrictors.

3. Chemical burns can result from medications, chlorinated swimming pools, or exposure to toxic fumes or irritants (e.g., hairsprays, battery acid, vinegar, oven cleaners, lye). **Treatment includes immediate and continued irrigation** of the eye(s) with saline or sterile water and emergency attention from a physician or eye care specialist.

4. Corneal edema is characterized by **halos or star bursts** around lights, which are the result of an underlying disorder (e.g. damage to the eye). Once diagnosed by a physician, **hyperosmotic agents** such as Muro solution or ointment may be used to **draw the fluid away from the cornea.** Dosing should begin with a 2% solution used 4 times daily with the addition of a 5% ointment used at nighttime if needed. If unresolved, the 2% solution may be changed to a 5% solution with continued use of the ointment.

5. A **hordeolum,** more commonly known as a **sty,** is an infection of the glands of the eyelids caused by ***Staphylococcus aureus.*** Sties present as painful, red, and edematous but may be relieved by the application of **warm compresses** for 10-15 min 3-4 times daily. Topical antibiotics may be required.

6. A **chalazion,** simply a **granuloma,** may involve the glands of the eyelids or the surrounding area but is **not infectious.** When in its early stages, the inflammation may be relieved by **warm compresses** applied for 10-15 min 3-4 times daily. If not resolved within 1 week, provider consultation is appropriate, and surgical excision may be necessary.

7. Blepharitis is a **bilateral inflammation of the eyelid margins,** attributable to *Staphylococcus,* seborrheic dermatitis, or a combination of the two. Blepharitis may be identified by red,

scaly, thickened eyelids with possible loss of the eyelashes. Staphylococcal blepharitis requires antibiotic treatment, but seborrheic blepharitis may respond to lid hygiene with warm compresses for 15-20 min 2-4 times daily, followed by lid scrubs with a mild detergent.

E. Antioxidants

1. The antioxidant vitamins include vitamin A (retinol and β-carotene), vitamin C, and vitamin E. **β-Carotene 50** mg every other day may prevent the development of cataracts, especially in smokers. However, the **use of antioxidants in patients who smoke increases the risk of lung cancer and should, therefore, not be recommended. Vitamin C** has been studied for the prevention of cataracts. However, insufficient data in published trials limits the recommendation of this supplement for this purpose.

2. Lutein, an antioxidant pigment that functions to filter and protect the visual apparatus and its vascular supply, may be beneficial for improvement in vision in patients with dry age-related macular degeneration and prevention of cataracts.

However, more data by way of large randomized controlled trials are necessary to assess safety and efficacy of this supplement.

3. Patients with moderate and advanced age-related macular degeneration (ARMD) have shown a reduction in the progression of the disease and its associated vision loss with antioxidants plus zinc, as well as a combination of the following supplements: vitamin C 500 mg, vitamin E 400 IU, β-carotene 15 mg, zinc oxide 80 mg, and copper 2 mg. Ocuvite PreserVision, a formulation of the above antioxidants, zinc, and copper, is a dietary supplement currently under patent based on the promising results of the National Eye Institute's (NEI's) landmark Age-Related Eye Disease Study (AREDS). Studies of patients with mild or borderline ARMD have not shown benefit from antioxidant plus zinc supplementation. Therefore, this formulation should be **recommended only to patients who are nonsmokers** (owing to an increased risk of lung cancer) **with a diagnosis of moderate or advanced ARMD.**

F. Contact Lenses

1. Types of contact lenses

(a) Hard contact lenses were the first “original” contact lens, which were made of polymethylmethacrylate (PMMA). Because of the hydrophobic nature of PMMA, the permeability of oxygen is limited, thus restricting the once-common use of hard contact lenses.

(1) A **spectacle blur,** the inability to see well with glasses after removal of the contact lens, may occur with the use of hard lenses. The small diameter of the lens may also contribute to loss of the lens from the eye.

(2) Care of hard contact lenses includes cleaning between the fingertips, soaking, and wetting with each removal of the lens from the eye. Furthermore, care must be taken to avoid scratching and chipping the surface of the contact lens.

b. Rigid gas-permeable (RGP) lenses infuse oxygen permeability of soft contact lenses with the features of the hard contact lenses. RGP lenses are generally thicker than soft lenses, but more oxygen is delivered to the cornea by these agents.

(1) The RGP lenses are available in daily- and extended-wear versions, approved for up to 7 days of wear.

(2) Care of the RGP lens includes cleaning the lens in the palm of the hand with a surface-active cleaning product and an enzymatic product. The lens should then be soaked for a minimum of 4 hr in a conditioning solution before reinsertion.

c. **Soft lenses** are more comfortable and easier to remove than other contact lenses, however, the visual improvement noted may not be as significant as that which is seen with RGP or hard lenses. **Soft lenses should not be worn when applying topical ophthalmic products,** except those products specifically formulated for such use (e.g., rewetting solution).

(1) Extended-wear soft contact lenses are approved for 7 days of continuous wear. However, a relatively new product, Focus Night and Day, is approved for continuous 30day use, though not all patients will be able to tolerate the lens placement for 30 days.

(2) Daily-wear soft contact lenses are designed to be worn for 1 day, up to 3 months, depending on the lens chosen. Because the lenses will be discarded within a short period of time, an enzymatic solution is generally not necessary for this type of lens, but general cleaning and disinfecting each time they are removed from the eyes is advisable. Sleeping in these lenses is not recommended.

2. Solution ingredients are generally specific to the type of contact lens chosen (e.g., soft, hard, or RPG). Therefore, the patient should ensure the product selected is in accordance with the type of lens worn.

a. Cleaning solutions act to remove residue (e.g., debris, oils) from the contact lens by nonionic or amphoteric surfactants. If not cleaned regularly, the residue will build and harden, creating an ocular irritant, and possibly an ophthalmic infection. A homemade cleaning solution of baking soda and distilled water may be used, but is not typically recommended owing to the increased risk of ocular infection and difficulty in removing the agent from the lens.

b. Soaking solutions are used to provide an aseptic environment for the lens once removed from the eye and may also aid in removal of residual contaminant on the lens not removed during cleaning. Soaking solutions generally have a higher concentration of preservative than wetting agents, but the lens should be thoroughly rinsed before insertion.

c. **Wetting solutions** are applied directly to the lens before insertion into the eye. The function of the wetting solution is to transition the lens surface from hydrophobic to hydrophilic, provide lubrication, and enhance fingertip adhesion to allow for easier insertion. Wetting solutions are not necessary for insertion if the patient has significant tearing immediately after insertion of the lens. Saliva should not be used in place of a wetting solution because of the potential for infection.

d. Multipurpose products are generally a solution composed of a cleaning solution, soaking solution, and wetting solution for ease of use with contact lenses. However, a multipurpose product may not be as efficacious in the removal of the residue or providing adequate lubrication as the use of the three individual agents.

e. Rewetting solutions may be used to clean and moisten the surface of the contact lens while the lens is still in the eye.

f. Conditioning solution is essentially an enhanced wetting solution, providing improved comfort and wettability of the lens.

G. Instillation of eye medication (Figure 29.1)

1. Wash hands.

2. Shake suspensions to evenly distribute ingredients.

3. Hold the lower eye lid down to form a pouch between the lid and the eyeball.

4. Always apply eye drops before applying eye ointment. Dispense the recommended number of drops into the pouch for eye drops. Keep the eyelids closed and apply gentle pressure to the inner canthus for 1-2 min. Wait 5-10 min before instilling another eye medication.

5. Ointments should be applied to the lower conjunctival sac as a 1/2-inch ribbon. To minimize blurred vision, a decreased amount of ointment may be applied to the

eye. Blurred vision will be less noticed by the patient if the ointment is administered at bedtime, if feasible.

STUDY QUESTIONS

Directions for questions 1-3: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

1. Which of the following nonprescription products is approved by the U.S. Food and Drug Administration (FDA) for treatment of impacted cerumen?

I. olive oil

II. carbamide peroxide

III. isopropyl alcohol 95% in anhydrous glycerin

A if **I and II** are correct

B if **I, II, and III** are correct

C if **II only** is correct

D if **III only** is correct
E if **I only** is correct

View Answer***1. The answer is C[see].*****2. Which of the following otic conditions can be treated with a nonprescription agent?**
I. vertigo
II. tinnitus
III. external otitis
IV. water-clogged ear
A if **I, II, and III** are correct
B if **III and IV** are correct
C if **I and IV** are correct
D if **I and II** are correct
E if **IV only** is correct

View Answer***2. The answer is E[seeand].*****3. Which of the following conditions is appropriate for the use of isopropyl alcohol 95% in anhydrous glycerin?**
I. treatment of impacted cerumen
II. treatment of water-clogged ears
III. prevention of external otitis
IV. treatment of external otitis
A if **I and II** are correct
B if **II and III** are correct
C if **III and IV** are correct
D if **II only** is correct
E if **III only** is correct

View Answer***3. The answer is D[see].*****Directions for questions 4-5:** Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.
4. All of the following are true regarding carbamide peroxide *except* which one?
(A) Carbamide peroxide softens earwax by the foaming action produced when oxygen is released.
(B) Carbamide peroxide is safe for pharmacist recommendation in patients age 6 years and older.
(C) Appropriate dosing for carbamide peroxide is 5-10 drops in the ear 2 times daily.
(D) Carbamide peroxide should be used for a maximum of 4 days unless otherwise directed.

View Answer***4. The answer is B[see].*****5. All of the following are true regarding external otitis *except* which one?**
(A) Initial treatment for external otitis is an oral antibiotic and corticosteroid.
(B) Symptoms of external otitis include otic itching, pressure and fullness in the ear, pain, and otic discharge.

(C) Mechanical trauma to the ear with cotton-tipped applicators can contribute to increased susceptibility to external otitis.
(D) External otitis is also referred to as swimmer's ear.

View Answer***5. The answer is A[seeand].***P.622

Directions for question 6: The question in this section can be correctly answered by **one or more** of the suggested answers. Choose the answer, **A-E.**

6. Which of the following is an appropriate counseling tip for administration of otic drops?

I. Pull the earlobe up and back to straighten the ear canal for children.
II. Pull the earlobe down and back to straighten the ear canal for adults.
III. Fill the otic syringe with hot water.
IV. If cotton is used to retain medication in the ear, it should not be left in the ear for longer than 1 hr.

A if **III only** is correct
B if **IV only** is correct
C if **I and II** are correct
D if **I, II, and IV** are correct
E if **III and IV** are correct

(D) rewetting solution

View Answer***11. The answer is D[see].*****12. Which of the following is true regarding ophthalmic antihistamines?**

(A) Pheniramine and tetrahydrozoline are the only two nonprescription ophthalmic antihistamines available.
(B) Ophthalmic antihistamines are available only in combination with naphazoline.
(C) Ophthalmic antihistamines may cause burning, stinging, dry eyes, or mydriasis.
(D) Ophthalmic antihistamines may produce rebound congestion if used in excess or for extended durations.

View Answer***12. The answer is C[see].*****13. Which of the following is the only astringent used in nonprescription ophthalmic agents that is recommended by the U.S. Food and Drug Administration (FDA)?**

(A) edetic acid
(B) benzalkonium chloride
(C) zinc sulfate
(D) povidone

View Answer***13. The answer is C[see].***P.623

14. The definition of a surfactant (an ingredient in toothpaste) can best be described by which of the following statements?

(A) It prevents drying of the preparation.
(B) It removes debris by its detergent action and causes foaming, which is usually desired by the patient.
(C) It physically removes plaque and debris.
(D) It determines the texture, dispersiveness, and appearance of the product.
(E) It adds flavor to the preparation, which makes it more appealing to the patient.

View Answer***14. The answer is B[see].*****15. A 16-year-old girl stops by a pharmacy on her way home from school. She says to the pharmacist, "I have been using Proxigel daily to bleach my teeth in preparation for my spring formal. However, my teeth are becoming very sensitive." Each of the following statements is advice that the pharmacist might suggest *except* which one?**

(A) There is a possibility that you may damage the gingival tissue and tooth pulp.
(B) Oxidizing agents may have the potential for mutating or enhancing the carcinogenic effects of other agents (e.g., tobacco).

(C) Bleaching teeth is best done under dental supervision.
(D) Proxigel is an antiseptic that contains zinc and should not be used for cosmetic whitening of the teeth.
(E) The most common ingredient in products responsible for teeth whitening is 10% carbamide peroxide, which can cause sensitivity.

View Answer***15. The answer is D[see].*****16. All of the following products may be recommended by a pharmacist for the treatment of canker sores *except***
(A) benzocaine.
(B) Zilactin-B.
(C) Bayer aspirin placed directly on the oral lesion.
(D) Anbesol.
(E) Orajel.

View Answer***16. The answer is C[see].*****17. The U.S. Food and Drug Administration (FDA) has approved which ingredient for protection against painful sensitivity of the teeth caused by cold, heat, acids, sweets, or contact?**
(A) dicalcium phosphate
(B) sodium lauryl sulfate
(C) 5% potassium nitrate
(D) zinc chloride
(E) calcium carbonate

View Answer***19. The answer is C[seeand].*****20. Pharmacists can recommend over-the-counter (**OTC**) drug treatment for which of the following ear conditions?**

I. treatment of accumulated earwax

II. prevention of blocked ears caused by altitude changes

III. treatment of water-clogged ears

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***20. The answer is E[see].***P.624

ANSWERS AND EXPLANATIONS

1. The answer is C (II) *[see* I.B.1.d.(1)*].*

Carbamide peroxide is the only FDA-approved agent for cerumen removal. Olive oil and mineral oil are used to remove cerumen, but are not FDA approved. Isopropyl alcohol 95% in anhydrous glycerin is FDA approved for water-clogged ears, but not cerumen removal.

2. The answer is E (IV) *[see* I.B.1.d; I.B.2, 3 *and* 4*].*

Patients exhibiting symptoms of vertigo, aside from motion sickness, should be referred to a medical provider. There is no FDA-approved treatment for tinnitus. External otitis (swimmer's ear) should be treated with a prescription otic antibiotic and corticosteroid. Only impacted cerumen and water-clogged ears may be treated with nonprescription products.

3. The answer is D (II) *[see* I.B.5*].*

Isopropyl alcohol 95% in anhydrous glycerin is FDA approved only for treatment of water-clogged ears. Labels on products of isopropyl alcohol 95% in anhydrous glycerin should not claim to be used for treatment or prevention of external otitis (swimmer's ear) because this is a separate disorder from water-clogged ears. Treatment for impacted cerumen is carbamide peroxide.

4. The answer is B *[see* I.B.1.d.(1)*].*

Carbamide peroxide softens earwax through its foaming action when oxygen is released. It is labeled for ages 12 and older. Therefore, for children < age 12 with suspected cerumen impaction should be seen by a medical provider. Patients should instill 5-10 drops of carbamide peroxide into the ear 2 times daily for up to 4 days.

5. The answer is A *[see* I.B.4.a, b *and* c*].*

External otitis is referred to as swimmer's ear. Though prolonged exposure to moisture is the typical cause of external otitis, mechanical trauma, such as the use of cotton-tipped applicators, fingers, or sharp objects in the ear, may cause the external ear canal to be more susceptible to damage and microorganism infiltration. Patients with external otitis may present with otic itching, a sensation of pressure or fullness in the ear, pain, or an otic discharge. Initial treatment is with an otic

antibiotic and corticosteroid, not an oral antibiotic. Oral antibiotics are indicated when the infection is unresponsive to otic treatment, the individual is immunocompromised, or a middle ear infection coexists.

6. The answer is B (IV) *[see* I.C*].*

The earlobe should be pulled up and back to straighten the canal for adults and down and back to straighten the canal in children. Only warm water should be used in the otic syringe, as cold or hot water may induce dizziness. If cotton is used in the ear to retain the medication, it must be large enough to remove easily and should not be left in the ear for longer than 1 hr.

7. The answer is D *[see* III.B*].*

Buffers are used in ophthalmic preparations to maintain a pH between 6.0 and 8.0. Tonicity adjusters ensure the product is isotonic, equal to 0.9%-60.2% sodium chloride.

8. The answer is A *[see* III.D*].*

Once diagnosed by a physician, corneal edema is treated with hyperosmotic agents such as Muro solution or ointment to draw the fluid away from the cornea.

9. The answer is C *[see* III.D.2*].*

Viral conjunctivitis is most often attributable to the adenovirus and is more commonly known as pink eye.

10. The answer is A *[see* III.E*].*

The antioxidant vitamins examined for the prevention and/or treatment of ophthalmic disorders include vitamin A (retinol and β-carotene), vitamin C, and vitamin E. Lutein is an antioxidant pigment that functions to filter and protect the visual apparatus and its vascular supply. Lutein, is therefore, thought to be beneficial for improvement in vision in patients with dry age-related macular degeneration and prevention of cataracts. Vitamin D is not an antioxidant vitamin.

11. The answer is D *[see* III.F.2*].*

Rewetting solutions are the only contact lens solutions that may be used while the lens is still in the eye.

12. The answer is C *[see* III.C.4*].*

Currently, there are three available ophthalmic antihistamines: ketotifen, pheniramine, and antazoline. Pheniramine and antazoline are only available in combination with the ophthalmic decongestant naphazoline. Ophthalmic antihistamines may cause burning, stinging, dry eyes, or mydriasis. Vasoconstrictors, not antihistamines, may produce rebound congestion when used in excess or for extended durations.

13. The answer is C *[see* III.B*].*

Edetic acid is an antioxidant and benzalkonium chloride (BAK) is a preservative used in ophthalmic formulations. Zinc sulfate is the only FDA-recommended astringent. Povidone is a vehicle used in ophthalmic formulations.

14. The answer is B *[see* II.B.2.d.(1)*].*

Sodium lauryl sulfate is used frequently as a surfactant in most dentifrices. Its detergent action aids in the removal of debris, and the foaming is usually desired by the patient. There is no evidence that surfactants possess anticaries activity or decrease periodontal disease. The FDA considers surfactants an inactive ingredient in dentifrices.

15. The answer is D *[see* II.B.2.d.(4)*].*

Teeth-whitening agents usually contain 10% carbamide peroxide, which is a white crystal that reacts with water to release hydrogen peroxide and, therefore, liberates free oxides. Cosmetic agents can alter the normal flora or cause tissue irritation, gingivitis, and teeth sensitivity. Antiseptics have been used as cosmetic whiteners (e.g., Gly-Oxide, Proxigel) along with calcium peroxide (e.g., Calprox in EpiSmile). EpiSmile also contains sodium monofluorophosphate.

16. The answer is C *[see* II.C.1.c.(2)*].*

Local anesthetics can provide relief of canker sore pain. The most common local anesthetics found in OTC products include benzocaine and butacaine. Some examples are Anbesol, Zilactin-B, and Orajel. Aspirin should not be retained in the mouth before swallowing or placed in the area of the oral lesions because of the high risk for chemical burn with necrosis.

17. The answer is C *[see* II.B.2.d.(5)*].*

Desensitizing agents should not be abrasive or used on a chronic basis unless directed by a dentist. The products approved by the ADA include the ingredients 5% potassium nitrate, 10% strontium chloride, and dibasic sodium citrate 2% in Pluronic gel.

18. The answer is D (II, III) *[see* II.B.2.d.(1).D*].*

Suspending agents are products that add thickness to the dentifrices. Examples are tragacanth, karaya gum, and methylcellulose. Dicalcium phosphate is categorized as an abrasive product.

19. The answer is C (I, II) *[see* II.C.2.a *and* b*].*

Cold-sore treatment involves keeping the lesion moist with emollient creams, petrolatum, or protectants. Local anesthetics (e.g., benzocaine, dyclonine, salicyl alcohol) may be used. In addition, docosanol 10% cream (Abreva) and tetracaine 2% gel (Viractin) are available without a prescription for the treatment of cold sores. Topical counterirritants (e.g., camphor) and caustics or escharotic agents (e.g., phenol, menthol, silver nitrate) are not recommended because they may further irritate the tissue. Cold sores are usually self-limiting and heal within 10-14 days without scarring.

20. The answer is E (I, II, III) *[see* I.B*].*

OTC drug treatment can be recommended for all of these ear conditions.

OTC Dermatological Agents

Larry N. Swanson

I. PEDICULOSIS AND PEDICULICIDES

A. Introduction. Pediculosis is a skin infestation produced by blood-sucking lice. Lice are small, flat, wingless insects with stubby antennae and three pairs of legs that end in sharp, curved claws. Three **types of lice infest humans.**

1. *Pediculus humanus capitis* (i.e., the head louse)

2. *Pediculus humanus corporis* (i.e., the body louse)

3. *Phthirus pubis* (i.e., the pubic, or crab, louse)

B. Life cycles. The lice that infest humans pass through similar life cycles.

1. Location. All lice need human warmth to survive.

a. Head and **pubic lice** spend their entire cycle on the skin of the human host.

b. Body lice live in clothing, coming to the skin surface only to feed.

2. Development

a. Each type of louse develops from **eggs (nits)** that incubate for about 1 week. When the small, gray-white, tear-shaped eggs hatch, the nymphs appear.

b. In about 3 weeks, the **nymphs** mature; then the females start to lay eggs.

c. Each type of louse survives about 1 month as a **mature adult.** During this time, the female head louse can produce 3-6 eggs a day.

3. Egg deposit

a. Body lice deposit their eggs on fibers of clothing, particularly in the seams. These lice can survive without food up to 10 days, and the eggs may remain viable for about 1 month. Daily clothing changes and boiling or ironing infested clothing can eradicate **body lice.**

b. Head and **pubic lice** deposit their eggs on hair strands, about 1/4 inch from the skin. Adult head lice can survive on inanimate objects for about 20 hr; head lice nits may survive up to 10 days off the body.

C. Incidence. The incidence of lice infestations increases each year.

1. More than 10 million cases of head lice occur each year in the United States.

2. The bulk of these cases occur between September and November, when students are back in school.

3. In outbreaks of head lice, 70% of cases occur in children younger than 12 years.

4. Infestations tend to be more common in girls, presumably because of their greater tendency to share grooming items.

5. Unlike the other two forms of lice, body lice are associated with improper hygiene and are often present in homeless people. This infestation is rare in the United States, especially when people follow proper hygiene routines.

D. Medical problems

1. Both adult and nymph lice are blood sucking; they feed on humans by piercing the skin and introducing a small amount of saliva (which contains an **anticoagulant**) into the feeding area. All lice types feed on blood for about 30-45 min every 3-6 hr.

a. The attachment of lice to the body causes an **erythematous papule,** which may **itch.**

b. The female louse produces a sticky **cement-like secretion** that holds the eggs in place on the hair shaft so securely that ordinary shampooing does not remove it.

P.627

2. Neither head nor crab lice transmit infections, but body lice transmit **typhus, relapsing fever,** and **trench fever.**

3. Lice and humans have a true **parasitic relationship;** lice depend on the human host for shelter, food, and reproductive success. Once hatched, nymphs must have access to the human host within the first 12- to 24-hr period, if they are to survive.

E. Methods of transmission

1. Head lice are most commonly **spread by head-to-head contact** with an infested person through hats, caps, scarves, pillowcases, communal combs and brushes, or clothing that is hung close together (e.g., on a coat rack).

2. Pubic lice are **transmitted primarily through sexual contact,** but also through shared undergarments, towels, or toilet seats.

a. The lice affect teens and young adults most often through sexual contact.

b. Lice frequently coexist with other sexually transmitted diseases.

c. Scratching in the genital areas may transmit pubic lice to other hairy regions, such as the eyelashes, eyebrows, sideburns, and mustaches.

F. Signs and symptoms

1. Head lice

a. Most patients have fewer than 10 lice.

b. The most common sign is **head scratching.**

c. **Skin redness around the nape (i.e., back) of the neck** and above the ears is usually seen.

d. The lice can be identified by direct examination using wooden applicator sticks or a comb to part the hair, then looking at the hair through a magnifying glass.

e. The lice appear as tiny brownish gray spots that are often difficult to see. The shiny, **whitish silver eggs,** which appear almost as grains of sugar, are more likely to be seen than the lice. The nits are initially **deposited** about **1/4 inch from the scalp** on the hair shaft, and they may be **confused with dandruff or hairspray droplets.** Usually, hair grows at a rate of about 1/2 inch per month, so the duration of infestation can be assessed based on this information.

2. Pubic lice. The primary symptom is scratching in the genital area.
3. Body lice. The most common symptoms are bites and itching, which are commonly seen as vertical excoriations on the trunk area.
G. Treatment
1. There are **three steps** in the treatment of **head and body lice.**
a. Treat the lice and nits with a pediculicide agent.
b. Control the symptoms of itching to prevent secondary infection.
c. Clean the environment of potential lice and nits.
2. Itching. Pharmacists should advise patients that even after the causative organism and nits have been killed, itching may persist for several days. This aspect is very important because patients may decide to use pediculicides excessively, thinking that they have been ineffective when the itching continues. **Excessive use of pediculicides may result in excessive drying, which can cause further itching.**
3. Home remedies. Because of the social stigma attached to lice infestation, some individuals may resort to harmful home remedies. Examples of such uncomfortable, ineffective, and potentially dangerous approaches that should not be used include
a. Shaving the head and pubic area
b. Applying heat to the infested area with a hair dryer
c. Soaking the head in hot water for several minutes
d. Soaking the area of infestation with gasoline or kerosene
4. Over-the-counter (OTC**) pediculicide products** are considered first-line treatments and include
a. Pyrethrins 0.17%-0.33% with piperonyl butoxide 2%-4%. This product is safe and effective for the treatment of **head** and **pubic lice.** The combination of ingredients is an example of **pharmacological synergism.**
P.628

(1) Pyrethrins kill by **disrupting ion-transport mechanisms at the nerve membranes.** These natural insecticides are derived from a mixture of substances obtained **from** the flowers of the **chrysanthemum** plant. Because not all eggs may be killed (it takes about 4 days for the nervous system of the louse to develop) with a single application of this agent or removed with a nit comb, it may be necessary to reapply the pyrethrin product within 7-10 days of the first application (because the usual hatching time of the eggs is 7-10 days).
(2) Piperonyl butoxide enhances the pediculicide effect of pyrethrins by **suppressing the oxidative degradation mechanisms of the lice.** Therefore, the length of time that the pyrethrins contact the lice is increased.
(3) Side effects from either agent are **uncommon.**
(a) Contact dermatitis (see IV) is the most frequently reported side effect.

(b) Allergic reactions. Because pyrethrins are derived from a plant (chrysanthemum), they may produce hay fever (i.e., allergic rhinitis) and asthma attacks in susceptible individuals. Thus patients who have known allergies to ragweed or chrysanthemum plants should use this product with caution.

(4) Common **trade names** for this product include RID maximum strength Shampoo, A-200 maximum strength Shampoo.

(5) Directions for use (shampoo)

(a) Apply the product, undiluted, to the dry hair until it is entirely wet.

(b) Allow the product to **remain on the head for 10 min.**

(c) Rinse thoroughly with warm water.

(d) Dry the area, preferably with a disposable cloth.

(e) Comb hair in the previously infested area **with a fine-toothed comb** to remove dead lice and eggs.

(f) Do not exceed two applications within 24 hr. It may be necessary to reapply the shampoo in 7-10 days [see I.G.4.a.(1)].

b. Permethrin (Nix) is a pyrethroid (i.e., a synthetic version of a pyrethrin). It is indicated for the treatment of **head lice only.**

(1) Mechanism of action. Permethrin has a **similar mechanism of action as the pyrethrins.**

(2) Application. Permethrin comes in the form of a 1% **creme rinse** and should be applied like a conventional hair conditioner after the hair has been shampooed (use a shampoo with no conditioner), rinsed, and towel dried. The hair should be thoroughly saturated with undiluted permethrin (25-30 mL), which should **remain on the hair for 10 min. then rinsed.**

(3) Effectiveness. A single application is generally effective in killing lice. Because the agent is retained on the hair shaft, the product provides **continuing activity for up to 14 days.** This residual effect persists regardless of normal shampooing.

(a) Even with the residual activity, there still may be the need for retreatment in 7-10 days.

(b) Comb hair in the previously infested area **with a fine-toothed comb** to remove dead lice and eggs.

(c) There is, at least theoretically, the speculation that because low-level residual amounts of this agent are retained on the hair, it may be possible that when suboptimal levels are present, some lice may survive and give rise to strains that are resistant.

c. OTC **pediculicide treatment failure.** Treatment failure with the use of the preceding agents has been reported. Speculations as to the cause of this treatment failure include failure to follow product instructions, noncompliance with nit removal, and head-lice drug resistance. Studies support the theory that there are now “super lice” that have survived exposure to pyrethrins and permethrin.

5. Prescription products are included here to put into perspective how the OTC agents fit into therapy.

a. Malathion (Ovide) is an organophosphate cholinesterase inhibitor that has been widely used as a lawn and garden insecticide. Resistance has also become an issue with this agent.

(1) Mechanism of action. Sulfur atoms in the malathion bind with sulfur groups on the hair, giving a residual protective effect against reinfestation.

(2) Application. Malathion is prepared as a lotion in 78% alcohol; therefore, caution should be used near an open flame or a hair dryer. The product should be sprinkled on dry hair and left for 8-12 hr before rinsing. A fine-toothed comb should be used to remove the dead lice and eggs.

(3) No systemic **adverse effects** have been reported with topical use of this medication.

(a) The alcoholic vehicle may produce stinging and possible flammability.

(b) Although this agent may be effective, its unpleasant odor (owing to sulfhydryl compounds), the required time of 8-12 hr on the scalp, and those points noted in I.G.5.a.(3).(a) represent the main drawbacks.

b. Lindane, or γ-benzene hexachloride has fallen into disfavor because of the potential for toxicity and the fact that its efficacy is less than the other agents available (both prescription and OTC products). Resistance to this agent is widespread.

(1) It has **neurotoxicity potential** because of percutaneous absorption; therefore, its use should be avoided in infants, pregnant and nursing women, and anyone with a neurological disorder. Severe **central nervous system (CNS) toxicity** has occurred in infants, with seizures and deaths reported, particularly when the lotion is used or when the agent is ingested. Toxicity has been minimal when the shampoo is used properly to treat head lice.

6. Adjunctive therapy

a. Nit removal

(1) The pediculicide products mentioned vary in their ability to kill the lice nits. To ensure successful therapy, after pediculicide application, the nits should be removed with a **fine-toothed comb.** A sturdy **metal comb** (like the LiceMeister) is recommended by the National Pediculosis Association (NPA). Many schools have a **"no nit" policy**—that is, a child's hair and scalp must be free of nits before he or she is allowed to return to the classroom.

(2) Although various substances have been used in an effort to dislodge the nits from the hair shafts, most, if not all, have been unsuccessful. A mixture of 50% vinegar and 50% water has been recommended, but its effectiveness has been questioned. A lice egg remover containing various enzymes comes as part of a kit, but challenges have been made to its effectiveness.

b. Treatment of other household members. Once a lice infestation has been identified in one member of the household, all other members should be examined carefully. Everyone who is infested should be treated at the same time.

c. **Adjunctive methods for controlling lice infestations**

(1) Washable material items such as linens, towels, hats, and clothing should be machine-washed in hot water and dried in a hot dryer to destroy lice and nits.

(2) Nonwashable material goods should be dry-cleaned or sealed in a plastic bag for 2 weeks.

(3) Personal items (e.g., comb, brushes) should be soaked in hot water (130°F) for at least 15 min.

(4) Furniture and household items (e.g., carpets, chairs, couches, pillows) should be vacuumed thoroughly. OTC spray products that contain pyrethrins are no more effective than vacuuming in terms of removing the risk of reinfestation.

d. Pediculicides should not be used around the eyes. For **eyelash pubic lice infestations, petrolatum** applied five times a day has been used to supposedly “asphyxiate” lice but this may only slow lice movement. Gentle removal with baby shampoo may be helpful.

H. Head lice myths are numerous. The following additional facts may reassure and inform patients and parents of patients.

1. No significant difference in incidence occurs among the various socioeconomic classes or races.

2. Hygiene and hair length are not contributing factors.

3. Head lice do not fly or jump from person to person.

4. Head lice do not carry other diseases.

5. Head lice cannot be contracted from animals, and pets are not susceptible to *Pediculus humanus capitis*.

6. The head does not have to be shaved to get rid of lice.

7. Washing hair with “brown” soap is not effective.

8. Head lice are unrelated to ticks.

9. Hair does not fall out as a consequence of infestation.

10. Head lice infestations can occur at any time of the year.

II. ACNE AND ITS TREATMENT

A. Overview

1. Definition. Acne vulgaris is a disorder of the pilosebaceous units, mainly of the face, chest, and back. The lesions usually start as open or closed comedones and evolve into inflammatory papules and pustules that either resolve as macules or become secondary pyoderma, which results in various sequelae.

2. Incidence

a. Acne vulgaris is the **most common** skin disease of adolescence; it affects about 85% of all people between the ages of 12 and 24.

b. It affects primarily adolescents in junior high and senior high, then decreases in adulthood.

3. Importance

a. Acne vulgaris is usually **self-limiting.**

b. However, the condition is significant to adolescents because of heightened self-consciousness about appearance.

c. A great majority of people do not consult a physician for treatment of acne; therefore, a pharmacist can play a significant role.

B. Origins and pathophysiology

1. The **pathogenesis** of acne vulgaris involves **three events.**

a. Increased sebum production

(1) Sebum secretion is regulated primarily by **androgens,** which are actively secreted in both sexes beginning at puberty.

(2) One of these androgens, testosterone, is converted to **dihydrotestosterone (DHT).**

(3) DHT levels induce the sebaceous glands to increase in size and activity, resulting in increased amounts of sebum.

b. Abnormal clumping of epithelial horny cells within the pilosebaceous unit

(1) Normally, keratinized horny cells are sloughed from the epithelial lining of the pilosebaceous duct in the hair follicles and are carried to the skin surface with a flow of sebum.

(2) In the patient with acne, the keratinization process is abnormal, characterized by increased adherence and production of follicular epithelial cells. This process is called **retention hyperkeratosis,** and it results in obstruction of the outflow of the pilosebaceous unit.

c. **Presence of *Propionibacterium acnes*** (a gram-positive anaerobe)

(1) People with acne have skin colony counts of *P. acnes* that are significantly higher than the counts of those without acne.

(2) *P. acnes* produces several enzymes, including lipases, that break down sebum triglycerides to short chain free fatty acids (FFAs), which are irritating, cause comedones, and result in inflammation.

2. Sequence of acne lesion development

a. Mechanical blockage of a pilosebaceous duct by clumped horny cells results in a **closed comedo (i.e., a whitehead).**

b. When a closed comedo develops, it can form either a papule or an **open comedo (i.e., a blackhead).** The **dark color** of the blackhead is attributed to a combination of melanin, oxidized lipid, and keratinocytes, **not** to **dirt.**

c. The lesion may enlarge and fill with pus, which is then termed a pustule.

d. In more severe cases of acne, papules may develop into nodules or cysts.

e. The term *pimple* nonspecifically refers to whiteheads, blackheads, papules, and pustules.

C. Clinical features

1. Location. Acne vulgaris lesions usually occur on the face, neck, chest, upper back, and shoulders. Any or all types of lesions may be seen on a single patient.

2. Symptoms. This condition is usually asymptomatic; however, some patients may have pruritus or pain if large, tender lesions are present.

3. Classification. It is important to differentiate **noninflammatory** from **inflammatory** acne to determine the best treatment approach. There have been many rating or grading scales for acne severity (Table 30-1). **Cystic acne** is present when the follicular wall ruptures occur deeper in the dermis and nodules and cysts are seen. Because of the potential for scarring, cystic acne patients should be referred to a physician for treatment. Scarring occurs with hypertrophic ridges, keloids, or atrophic “ice pick” pits.

D. Complicating factors. Other factors have been implicated in the exacerbation of acne.

1. Drugs and hormones

a. Many topical and systemic medications (e.g., bromides, iodides, topical coal tar products, androgens, phenytoin, progestins, lithium, corticosteroids) can be comedogenic and can make acne worse or can induce acne-like eruptions (i.e., acneiform lesions).

b. Acneiform eruptions differ from true acne lesions in that apparently no comedo forms, eruptions are usually acute, and the lesions usually are all in the same stage of development.

2. Stress does not cause acne but may exacerbate it.

3. Diet. There is very little evidence to support a relationship between diet and acne. Many different foods have been blamed for acne, from chocolates and sweets to shellfish to nuts and other fatty foods. Several studies have demonstrated that **chocolate does not affect acne.** The majority of dermatologists today make the following recommendations regarding diet.

a. The patient should be eating a well-balanced diet. As with most other diseases, and as a matter of good health, excess fats and simple carbohydrates should be avoided.

b. The patient who insists that certain foods cause exacerbation of acne should probably avoid those foods.

4. Physical trauma or **irritation** can promote the rupture of plugged follicles, which can produce more inflammatory reactions. Scrubbing the face, wearing headbands, cradling the chin with the hand, and picking at the pimples can contribute to the primary inflammation process. **Gentle** regular **washing** with soap and water can be beneficial.

Table 30-1. Assessment of Acne Severity

Grade of Acne	Qualitative Description	Quantitative Description
I	Comedonal acne	Comedones only, < 10 on face, none on trunk, no scars; noninflammatory lesions only
II	Papular acne	10-25 papules on face and trunk, mild scarring; inflammatory lesions < 5 mm in diameter
III[a]	Pustular acne	More than 25 pustules, moderate scarring; size similar to papules but with visible, purulent core
IV[a]	Severe/persistent pustulocystic acne	Nodules or cysts, extensive scarring, inflammatory lesions > 5 mm in diameter
—	Recalcitrant severe cystic acne	Extensive nodules/cysts

[a] Some overlap with previous grade of acne.

Reprinted with permission from Berardi RR. *Handbook of Nonprescription Drugs: An Interactive Approach to Self-Care,* 14th ed. Washington, DC, American Pharmaceutical Association, 2004:916.

5. Cosmetics. Some cosmetic bases and certain cosmetic ingredients are comedogenic (e.g., lanolins, petroleum bases, cocoa butter). Preparations such as cleansing creams, suntan oils, and heavy foundations should be avoided.

6. Menstrual cycle. Some women may notice flare-ups of acne during the premenstrual part of the cycle. Fluctuations in the level of progesterone are the probable cause.

7. Environmental factors. Very humid environments or heavy sweating lead to keratin hydration, swelling, and a decrease in the size of the pilosebaceous follicle orifice, which results in duct obstruction. The sun, as well as artificial ultraviolet (UV) light, can help acne by drying and peeling the skin, but both also can aggravate acne.

E. Treatment and care

1. General

a. Most patients can be treated successfully with either topically or systemically administered medications or both. Acne often improves when patients reach their early 20s.

b. Even the most effective treatment programs may take several weeks to produce any clinical improvement. This aspect must be emphasized.

c. People affected with acne should avoid anything that seems to worsen the condition (e.g., cosmetics, clothing, cradling the chin with the hand).

d. The number and type of lesions should be roughly determined to assess further therapeutic responses.

e. Self-treatment with OTC **agents** is appropriate only for patients with **noninflammatory grade I acne** of mild to moderate severity.

2. Cleansing recommendations

a. Because many acne patients have oily skin, **gentle cleansing** two to three times daily is recommended for removing excess oil.

b. Acne lesions cannot be scrubbed away. Compulsive scrubbing may actually worsen the acne by disrupting the follicular walls and thus setting the stage for inflammation.

c. Mild facial soaps, such as Dove, Neutrogena, and Purpose, should be used to cleanse the skin.

d. Medicated soaps containing sulfur, resorcinol, or salicylic acid are of little value because the medication rinses away rather than penetrates the follicle.

e. Patients with mild comedonal acne might find benefit from cleansers containing pumice, polyethylene, or aluminum oxide particles (e.g., Brasivol). However, patients with inflammatory acne or sensitive skin should avoid these products.

3. Approaches to treatment depend on the severity of the condition. Although acne cannot be cured, most cases can be managed successfully with topical treatment alone. Based on the pathogenesis of the condition, potential methods include

a. Unblocking the sebaceous duct so that the contents can be easily expelled

b. Decreasing the amount of sebum that is secreted

c. **Changing** the composition of the **sebum** to make it less irritating by decreasing the population of *P. acnes*

4. Nonprescription topical medications

a. Benzoyl peroxide (2.5%-10%)—for example, Clearasil Maximum Strength Acne Treatment Cream, PanOxyl Aqua Gel (U.S. Food and Drug Administration [FDA] category 3)—has traditionally been recognized as the most effective topical OTC agent for acne, and many OTC acne products contain it. However, the latest monograph from the FDA changed the status of benzoyl peroxide from category 1 (generally recognized as safe and effective) to category 3I, indicating that more data are needed to prove its safety in regard to long-term photocarcinogenic effects. Marketing of this agent is permitted pending final evaluation of its tumorigenic potential.

(1) Effects. Benzoyl peroxide has irritant, drying, peeling, comedolytic, and antibacterial effects. The clinical response shows only minimal differences among the 2.5%, 5%, and 10% concentrations.
(a) A **beneficial effect** should be noticed within about 2 weeks, but the usual length of a therapeutic trial is 6-8 weeks.
(b) As for **adverse effects,** benzoyl peroxide may cause a burning or stinging sensation, which gradually disappears. Most of the adverse effects from this agent relate to its therapeutic effect of irritating and drying the skin. For this reason,

the lowest concentration available should be chosen initially. About **2.5%** of patients will **develop a contact dermatitis** with its use.
(c) The vehicle for the benzoyl peroxide is also important in its overall activity. The alcohol gel vehicle tends to be more effective than the lotion or cream formulations.
(d) Benzoyl peroxide can discolor certain types of fabric or clothing material and can also bleach hair.
(2) Mechanism of action. Benzoyl peroxide has a dual mode of action, so it is effective against both inflammatory and noninflammatory acne.
(a) Benzoyl peroxide decomposes to release oxygen, which is lethal to the *P. acnes* anaerobe.
(b) As an irritant, it increases the turnover rate of epithelial cells, resulting in increased sloughing and promoting of resolution of comedones.
(3) Application
(a) The affected area should be washed with mild soap and water, then gently patted dry.
(b) The product should be massaged gently into the skin, avoiding the eyes, mouth, lips, and inside of the nose.
(c) The product can be applied at night, left on for 15 or 20 min to test sensitivity, then washed off.
(d) If no excessive irritation develops, apply once daily for the first few days.
(e) If drying, redness, or peeling does not occur in 3 days, increase application to twice daily.
(f) If patients have to use benzoyl peroxide during the day, advise them to use a sunscreen and avoid unnecessary sun exposure.
b. Salicylic acid (0.5%-2%), an irritant keratolytic agent, results in increased turnover of the epithelial lining (category 1). Through this effect, salicylic acid probably promotes the penetration of other acne products.
c. **Sulfur** (3%-8%), **sulfur** (3%-8%) **combined with resorcinol** (2%), **or resorcinol monoacetate** (3%)—for example, Clearasil Adult Care Acne Treatment Cream, Acnomel (category 1)
(1) Sulfur is a keratolytic agent and has antibacterial actions.
(2) Sulfur traditionally has been recognized as a less desirable product because it may be acnegenic with continued use, and it has an offensive color and odor.

d. Resorcinol (as a single agent-category 2) is a keratolytic agent that has been recognized as safe and effective (category 1) against acne **when the agent is combined with sulfur.**

F. Prescription medications, both topical and systemic, are included here for completeness and to put into perspective how OTC agents fit into acne therapy.

1. Topical prescription agents

a. Tretinoin (vitamin A acid, *trans*-retinoic acid, Retin-A) increases the turnover rate of nonadhering horny cells in the follicular canal, which results in comedo clearing and inhibits new comedo development.

(1) Effectiveness. Tretinoin is probably the most effective topical agent for acne, especially acne characterized by comedones. It is best used for **noninflammatory** acne. Tretinoin also may be used in combination with antibiotics or benzoyl peroxide for management of inflammatory acne.

(2) Side effects. Because of its irritant properties, tretinoin can cause **excessive irritation, erythema, peeling,** and increased risk for **severe sunburn.** There may be an initial exacerbation of the acne (pustular flare) at 2-4 weeks, but usually by 8 weeks, the patient will see marked improvement. Because this agent may cause photosensitivity, it should generally be applied at night.

(3) Application. The cream formulation of tretinoin, which is less irritating than the gel form should be used initially for patients with dryer skin. The patient with very oily skin may do well initially with the gel form. The retinoids should be applied 30 min after washing because moisture on the skin increases absorption and irritation. To minimize irritation, initially such a product can be applied every other day for 2 weeks, then daily. Other irritating substances, such as strong abrasive cleaners and astringents, should be avoided during treatment with tretinoin. Newer microsize reformulations of this agent (Retin-A Micro, Avita) are less irritating.

b. Adapalene (Differin) is a topical retinoid-like compound that is dosed once daily. It can be applied in the morning because of no photodegradation, and it has less potential for photosensitivity.

(1) Effectiveness. It appears to cause less irritation than tretinoin with equivalent efficacy. Therapeutic results should be noticed in 8-12 weeks. It can be used as an alternative to tretinoin in individuals with mild to moderate acne.

(2) Side effects. The same precautions that apply to tretinoin apply also for adapalene.

c. **Tazarotene gel and cream** (Tazorac) is a retinoid prodrug for mild to moderately severe facial acne that is applied once daily in the evening. It has similar efficacy and precautions as tretinoin, and the dose-related **adverse effects** include itching, burning, stinging, and erythema (redness). The gel form appears to be more irritating than tretinoin. A pustular flare may occur at about 10-14 days after this product is begun.

d. Topical antibiotics: erythromycin (Eryderm), **clindamycin** (Cleocin-T) and **tetracycline.** These topical antibiotics are most effective when used in combination

with benzoyl peroxide or topical retinoids. Combination products containing benzoyl peroxide and erythromycin (Benzamycin) and benzoyl peroxide and clindamycin (BenzaClin) are also available. When these antibiotics are used alone, bacterial resistance occurs rapidly. Benzoyl peroxide use in combination with these antibiotics protects against this resistance.

(1) Mechanism of action. The mechanism of action apparently involves suppression of the *P. acnes* organism, which in turn minimizes the inflammatory response due to the acne.

(2) Application. These antibiotics are applied directly to acne sites, thus minimizing serious side effects from oral administration.

(3) Side effects. There are **minimal** side effects to these topically applied antibiotics. **Mild burning** or **irritation** may occur. Although daily topical **Clindamycin** does not produce detectable levels in the urine after 8 weeks of administration, there is a potential risk of **pseudomembranous colitis.** **Tetracycline** can cause a **yellow staining of the skin.**

e. Azelaic acid (Azelex) and **sodium sulfacetamide and sulfur** are additional topical agents that are less effective than the other topical prescription agents. These agents might be used when others are not tolerated or as adjuncts to other therapies.

2. Systemic prescription agents

a. Oral antibiotics/anti-infectives are the most effective against inflammatory lesions because they suppress *P. acnes.* They may be used when topical combinations are not tolerated or have failed. Oral antibiotics have an onset of action of 3-4 weeks. They are prescribed for daily use over 4-6 months and then tapered and ultimately discontinued with acne improvement. Antibiotics do not affect existing lesions, but prevent future lesions through this effect. *P. acnes* resistance to antibiotic therapy has become an increasing problem; erythromycin resistance is the most commonly reported, and minocycline resistance is reported rarely. As noted previously, concomitant administration of benzoyl peroxide may decrease the incidence of resistance.

(1) Tetracycline is the **most frequently used** oral antibiotic for acne. It is preferred because of its effectiveness, low toxicity, and low cost. This agent should be taken on an empty stomach; food, antacids, iron, and dairy products decrease absorption. The tetracyclines also have direct anti-inflammatory effects in acne.

(a) Initial doses are 250 mg, 2-4 times daily, gradually reduced to a maintenance dose of about 250 mg per day.

(b) Side effects. The more common adverse effects include upset stomach, vaginal moniliasis, and photosensitivity.

(2) Erythromycin (E-Mycin) may be used as an alternative to tetracycline.

(a) Initial doses range from 500 to 2000 mg per day in divided doses. A maintenance dose ranges from 250 to 500 mg per day.

(b) Side effects. The primary side effect associated with erythromycin is gastrointestinal distress.

(3) Minocycline (Minocin) **or doxycycline** (Vibramycin). Either of these agents can be taken in doses of 50-200 mg per day. Because of greater lipid solubility and

enhanced penetration into sebaceous follicles, these agents may be useful for refractory cases. Either can be taken if bacterial resistance is suspected to erythromycin or if intolerable gastric irritation occurs after oral tetracycline. These two agents can be taken with food. Side effects to minocycline, including dizziness or vertigo and headache, discoloration

of skin and visceral tissue, and drug-induced lupus erythematosus, limit the use of this agent. Doxycycline may be photosensitizing and should be swallowed with adequate fluids to prevent esophageal ulcerations.

(4) Trimethoprim-sulfamethoxazole (Bactrim, Septra) has been used successfully in patients with acne resistant to erythromycin or tetracyclines. Minocycline and doxycycline are preferred over this drug combination because of its side-effect profile. **Oral clindamycin** (Cleocin) is used rarely because of the risk of pseudomembranous colitis.

b. Oral isotretinoin (Accutane) is a vitamin A derivative indicated for **severe nodulocystic acne.** A single course of therapy results in a long-term stable remission in > 80% of patients.

(1) Mechanism of action. Although the exact mechanism is unknown, isotretinoin decreases sebum production and keratinization, and it reduces the population of *P. acnes.*

(2) Dosage. Treatment is usually begun with a daily dose of 0.5 mg/kg and increased to 1 mg/kg given in two divided doses with food for the usual duration of 20 weeks. A micronized formulation allows for lower once daily dosing with no regard to food intake.

(3) Side effects include

(a) Mucocutaneous dryness. Cheilitis (i.e., inflammation of the lips), dryness of the nasal mucosa, and facial dermatitis may occur with isotretinoin use. These effects can be treated with topical lubricants. Dryness of the eyes can also occur, so people using isotretinoin should not wear contact lenses.

(b) Elevated serum levels. Isotretinoin may elevate serum triglycerides and cholesterol, as well as liver enzymes.

(c) Birth defects. Isotretinoin is a **potent teratogen** and should not be given to pregnant women. A strict risk management program for isotretinoin use requires physicians to register patients to document negative pregnancy tests before use. Physicians who prescribe this agent and pharmacies that dispense it must be registered in an electronic FDA system.

(d) Psychiatric effects. There have been reports of depression, suicidal behavior, and suicide. Data are inadequate to establish a causal relationship between isotretinoin administration and depression and suicide. This information must be taken in the context that teenagers with acne may often be depressed related to their appearance.

c. **Antiandrogens and hormones**

(1) Estrogens can decrease sebum production through an antiandrogenic effect.

(2) Some progestin agents in oral contraceptives (e.g., norethindrone, norgestrel) have androgenic activity that can stimulate sebum secretion resulting in acne. One of the progestins, **norgestimate,** is minimally androgenic, and when it is combined with **ethinyl estradiol** as a triphasic combination oral contraceptive agent (Ortho Tri-Cyclen), it is effective in the treatment of moderate acne in some women and is FDA approved for such. **Norethindrone acetate/ethinyl estradiol** (Estrostep) is also FDA approved for acne.
(3) Spironolactone (Aldactone) is an oral antiandrogen which acts to decrease sebum production and may be used on a limited basis.
(4) Corticosteroids. Although corticosteroids have been implicated as causing acne, they also can be used to treat severe acne. Intralesional injections of triamcinolone and systemic corticosteroids have been used for severe inflammatory acne and severe cystic acne, respectively. Prednisone (or its equivalent) in doses of 20 mg per day or higher may be used for a short period of time to quickly improve acne for important events like a wedding. Topical corticosteroids are not effective.

III. SUNLIGHT, SUNSCREENS, AND SUNTAN PRODUCTS

A. Introduction. Overexposure to sunlight damages skin. A suntan, which has traditionally been associated with health, is actually a response to injury. Of the three types of solar radiation, only the UV spectrum produces sunburn and suntan.
1. The **UV spectrum** ranges from 200 to 400 nanometers (nm). Natural and artificial UV light is further subdivided into three bands.

a. UVA (320-400 nm) can cause the skin to tan, and it tends to be weak in causing the skin to redden. UVA is about 1000 times less potent than a comparable dose of UVB in causing erythema, but it is only slightly blocked out by the ozone layer and reaches the earth's surface in 10-100 times the amount of UVB. Some have proposed that UVA be further subdivided into UVA I (340-400 nm) and UVA II (320-340 nm). UVA I is less erythrogenic and melanogenic than UVA II or UVB. UVA II is similar in effect to UVB.
(1) Uses. UVA is often used in tanning booths and in psoralen plus UVA (PUVA) treatment of psoriasis.
(2) Disadvantages. UVA is responsible for many **photosensitivity** reactions, **photoaging,** and **photodermatoses.** UVA rays can also **penetrate deeply into the dermis** and augment the cancerous effects of UVB rays.
b. UVB (290-320 nm) **causes the usual sunburn reaction** and stimulates tanning. It has long been associated with sunlight skin damage, including the various skin cancers. It is the **most erythrogenic** and **melanogenic** of the three UV radiation bands. Small amounts of this radiation are required for normal **vitamin D synthesis** in the skin.
c. **UVC** (200-290 nm) does not reach the earth's surface because most of it is absorbed by the ozone layer. Artificial UVC sources (e.g., germicidal and mercury arc lamps) can emit this radiation.

2. The **visible spectrum** (400-770 nm) produces the “brightness” of the sun.
3. The **infrared spectrum** (770-1800 nm) produces the “warmth” of the sun.

B. Sunburn and suntan

1. Sunburn is generally a **superficial burn involving the epidermis.** This layer is rapidly repaired while old cells are being sloughed off in a process called **peeling.** The newly formed skin is thicker and offers protection for the lower dermal layers.

a. Normal sequence after mild to moderate sunlight UV radiation (UVR) exposure

(1) Erythema occurs within 20-30 min as a result of oxidation of bleached melanin and dilation of dermal venules.

(2) The initial erythema rapidly fades, and true sunburn erythema begins 2-8 hr after initial exposure to the sun.

(3) Dilation of the arterioles results in increased vascular permeability, localized edema, and pain, which become maximal after 14-20 hr and last 24-72 hr.

b. Manifestations range from mild (a slight reddening of the skin) to severe (formation of blisters and desquamation). If the effect is severe, the patient may experience pain, swelling, and blistering. Fever, chills, and nausea may also develop, as well as prostration, which is related to excessive synthesis and diffusion of prostaglandins.

2. Suntan is the result of two processes:

a. Oxidation of melanin, which is already present in the epidermis

b. Stimulation of melanocytes to produce additional melanin, which is subsequently oxidized on further exposure to sunlight

(1) With increased melanin production, the melanocytes introduce the pigment into keratin-producing cells, which gradually become darkened keratin and a full suntan in 2-10 days.

(2) Tanning increases tolerance to additional sunlight and reduces the likelihood of subsequent burning. However, dark skin is not totally immune to sunburn.

C. Factors affecting exposure to UVR

1. Time of day and season. The greatest exposure to harmful UVB rays occurs between 10 A.M. and 4 P.M. in midsummer. UVA rays are fairly continuous throughout the day and season.

2. Altitude. Sunburn is more likely to occur at high altitudes. UVB intensity increases 4% with each 1000-ft. increase in altitude.

3. Environmental factors. Atmospheric conditions (e.g., smog, haze, smoke) may affect (i.e., decrease) the amount of UVR reaching the skin. Although direct sunlight greatly reduces the amount of UV exposure needed to produce a burn, sunburn can occur without it. For example, a sunburn can also develop on a cloudy day because there is some UVR penetration through cloud layers (60%-80%). However, the **reflection of light rays** (e.g., by snow, sand, water) greatly **increases** the amount of UV **exposure to sunlight.**

4. Predisposing factors. People with fair skin and light hair are at greater risk for developing sunburn and other UVR skin damage than their darker counterparts.

D. Other reactions to sunlight (UVR) exposure

1. Actinic keratosis is a precancerous condition and may occur after many years of excessive exposure to sunlight. Typically arising during middle age or later, this disorder manifests as a sharply demarcated, roughened, or hardened growth, which may be flat or raised, and it may progress to **squamous cell carcinoma.**

2. Skin cancer. Chronic overexposure to sunlight may lead to **squamous cell carcinoma, basal cell carcinoma,** or **malignant melanoma.**

a. Squamous cell carcinoma. Lesions usually appear as thickened, rough, scaly patches, which can bleed, and most commonly develops from actinic keratosis. It accounts for about 15% of skin cancers.

b. Basal cell carcinoma. This is the most common of all skin cancers and accounts for about 80% of skin cancers. It may appear as pearly or translucent bumps and originates in the basal cells.

c. **Malignant melanoma.** Malignant melanoma originates from melanocytes and is the deadliest form of skin cancer, and its incidence has been increasing. Moles should be watched for indications of malignancy—the **ABCD**s are

(1) Asymmetrical shape

(2) Border irregularity

(3) Color that is nonuniform

(4) Diameter > 6 mm.

d. Malignant melanoma formation may be associated with intense, intermittent overexposure to the sun (sunburning).

3. Drug-induced photosensitivity reactions

a. Types

(1) Photoallergy reactions occur when light makes a drug become antigenic or act as a hapten (i.e., a photoallergen). These reactions also require previous contact with the offending drug. Photoallergy reactions are relatively **rare** and are associated more frequently with topically applied agents than with oral medications.

(a) Occurrence of these reactions is not dose related. The patient is usually cross-sensitive with chemically related compounds.

(b) Rashes are most prominent on light-exposed sites (i.e., face, neck, forearms, back of hands), and they usually occur, after an incubation period of 24-48 hr of combined drug and sun exposure, as an intensely pruritic eczematous dermatitis (a severe rash).

(2) Phototoxic reactions occur when light alters a drug to a toxic form, which results in tissue damage that is independent of an allergic response.

(a) Occurrence. These reactions are usually dose related, and the patient usually has no cross-sensitivity to other agents.

(b) Rashes often appear as an exaggerated sunburn and are usually confined to areas of combined chemical and light exposure.

b. Implicated drugs. Many drugs have been implicated in causing photoallergy and phototoxic reactions: thiazides, tetracyclines, phenothiazines, sulfonamides, and even sunscreens. Some drugs may produce both types of reactions.

c. **Prevention.** Standard sunscreens do not always prevent photosensitivity reactions caused by drugs. UV light above 320 nm (i.e., UVA light) has been implicated in inducing photosensitivity reactions, so a chemical or physical sunscreen must cover this spectrum (see III.E.2).

4. Photodermatoses are skin conditions that are triggered or worsened by light within specific wavelengths. These conditions include polymorphous light eruption (PMLE), lupus erythematosus, and solar urticaria.

5. Photoaging is a skin condition that is not merely an acceleration of normal aging. UVA radiation is thought to be involved. The skin appears dry, scaly, yellow, and deeply wrinkled; it is also thinner and more fragile.

E. Sunscreen agents. People can protect their skin from harmful UVR by avoiding exposure to sunlight and other sources of UVR, wearing protective clothing, and applying sunscreen.

1. Application and general information. All exposed areas should be covered evenly and liberally (2 mg/cm^2, which requires about 1 ounce of sunscreen per one total body application

for an average-size adult in a swimsuit) with sunscreen, optimally 30 min (2 hr for PABA and PABA esters) before sun exposure to allow for penetration and binding to the skin.

a. Substantivity. Perspiration, swimming, sand, towels, and clothing tend to remove sunscreen and may increase the need for reapplication.

(1) Substantivity is the ability of a sunscreen formulation to adhere to the skin while swimming or perspiring.

(2) Water resistant labeling indicates that the formula retains its sun protection factor (SPF) after 40 min of activity in the water, sweating, or perspiring.

(3) Labeling a product as **very water resistant** indicates that the product retains SPF after 80 min of activity in the water, sweating, or perspiring.

b. Protection. Sunscreen products vary widely in their ability to protect against sunburn; the SPF and UVA/UVB ray protection should be noted to determine the level of protection. Moreover, baby oil, mineral oil, olive oil, and cocoa butter are not sunscreens (but are often used to attain a tan).

(1) SPF gives the consumer a guide for determining how the product will protect the skin from UV rays, principally UVB rays. An SPF of 30 blocks about 97% of the UVB rays. Scientific evidence shows a point of diminishing returns at levels > 30; any benefits that might be derived from using sunscreens with an SPF > 30 are negligible. The FDA's most recent monograph requires sunscreens with an SPF > 30 to use one collective term “SPF 30 Plus” or “30+.” An SPF of at least 15 for most individuals is recommended by the Skin Cancer Foundation.

(a) Definitions. A **minimal sun protection product** has an SPF of 2 to under 12; a **moderate sun protection product** has an SPF of 12 to under 30; a **high sun protection product** has an SPF of 30 or above.

(b) Derivation. SPF is defined as the **minimal erythema dose (MED)** of protected skin divided by the MED of unprotected skin. MED is the amount of solar radiation needed to produce minimal skin redness.
(c) Example. A person who usually gets red after 20 min in the sun and wants to stay in the sun for 2 hr (120 min) should apply a sunscreen with an SPF of 6 (120 min ÷ 20 min = SPF 6). An SPF 6 product should provide adequate coverage, provided it is not washed off (as from swimming) or dissolved by sweat. An SPF of 15 blocks approximately 93% of the UVB rays.
(d) Up until now, there has been **no generally accepted comparable term that measures UVA protection,** although a few have been proposed (see below). One major concern is that people may be staying out in the sun longer when they use sunscreen products that have high SPF values. If inadequate UVA protection is provided in that product, these individuals may be exposing themselves to very high amounts of UVA, with the potential for significant overexposure to this form of UV radiation.
(2) Proposed FDA UVA Protection Rating System. In August 2007, the FDA proposed a "consumer-friendly" rating system to rate sunscreen products regarding their level of UVA protection using a one to four stars rating. If the product does not provide at least a "one star" protection, then "no UVA protection" would need to be noted on the label.
(a) One star: low UVA protection
(b) Two stars: medium UVA protection
(c) Three stars: high UVA protection
(d) Four stars: highest UVA protection
If approved, an additional warning would be required on sunscreen products: "UV exposure from the sun increases the risk of skin cancer, premature skin aging, and other skin damage. It is important to decrease UV exposure by limiting time in the sun, wearing protective clothing, and using a sunscreen." SPF maximums, under this new proposed rule, would increase from SPF 30+ to SPF 50+.
(3) Skin cancer prevention. Sunscreen application has been shown to prevent squamous cell carcinoma, but it is not absolutely confirmed that their use prevents melanoma. In fact, some studies have found that individuals who regularly use sunscreen have a higher risk of this cancer (perhaps because they can stay out in the sun longer before burning and thus experience longer periods of sun exposure).
c. **Sensitivity.** Some people may be hypersensitive to sunscreen agents. Discontinue use if signs of irritation or a rash occur. Contact dermatitis may occur with some of these agents.

If sensitive to benzocaine, procaine, sulfonamides, or thiazides, avoid PABA or PABA esters.
d. Specific information
(1) Do not use these products on infants younger than 6 months of age (there is concern about absorption of these agents).

(2) Do not use a product with an SPF < 4 on children younger than 2 years of age (there is concern that an SPF < 4 will not provide adequate protection).
(3) Recommend sunscreen products that are broad-spectrum sunscreens (i.e., that block both UVB and UVA).
2. The two basic **types of sunscreen agents** are physical sun blocks and chemical sunscreens (Table 30-2).
a. Physical sun blocks are opaque formulations that reflect and scatter up to 99% of light in both the UV and visible spectrums (290-700 nm). Examples include **titanium dioxide** and **zinc oxide.** These sun blocks are less cosmetically acceptable than chemical sunscreens because they have a greasy appearance, but they may be useful for protecting small areas (e.g., the nose). These sun blocks are also useful for photosensitization protection. Newer, more dilute versions of titanium dioxide products and microfine, transparent forms of zinc oxide are more cosmetically appealing. Red petrolatum covers a lesser spectrum (290-365 nm).

Table 30-2. Sunscreen Ingredients

Type	Sunscreens	UV Spectrum (nm)	Concentrations (%)
Chemical	*Benzophenones*	UVA and UVB	
	Oxybenzone	270-350	2-6
	Dioxybenzone	260-380[a]	3
	PABA and PABA esters	UVB	
	P-aminobenzoic acid	260-313	5-15
	Ethyl dihydroxy propyl PABA	280-330	1-5
	Padimate O (octyl dimethyl PABA)	290-315	1.4-8

	Glyceryl PABA	264-315	2-3
Cinnamates		UVB[b]	
	Cinoxate	270-328	1-3
	Ethylhexyl-*p*-methoxycinnamate	290-320	2-7.5
	Octocrylene	250-360	7-10
	Octyl methoxycinnamate	290-320	—
Salicylates		UVB[c]	
	Ethylhexyl salicylate	280-320	3-5
	Homosalate	295-315	4-15
	Octyl salicylate	280-320	3-5
Miscellaneous		UVB	
	Menthyl anthranilate (meradimate)	260-380[d]	3.5-5
	Digalloyl trioleate	270-320	2-5
	Avobenzone (butyl	UVA	3

		methoxydibenzoylmethane; Parsol 1789)	320-400	
		Phenylbenzimidazole sulfonic acid	290-320	4
Physical	Titanium dioxide		290-700	2-25
	Red petrolatum		290-365[e]	30-100
	Zinc oxide		290-700	—

[a] Values available when used in combination with other screens.

[b] Some UVA spectrum.

[c] Primarily UVB, but has about one third the absorbency of PABA.

[d] Values are concentrations higher than normally found in nonprescription drugs.

[e] At 334 nm, 16% UV radiation is transmitted; at 365 nm, 58% is transmitted.

b. Chemical sunscreens act by absorbing a specific portion of the UV light spectrum to keep it from penetrating the skin. They can be categorized on the basis of their spectra of UVR blockage and basic chemical classification. Five main groups of chemical sunscreens are available.

(1) PABA and **PABA esters** primarily absorb UVB rays. Examples are *p*-aminobenzoic acid, padimate O, and glyceryl PABA.

(2) Cinnamates primarily absorb UVB rays. Examples are cinoxate and octyl methoxycinnamate.

(3) Salicylates primarily absorb UVB rays. Examples are ethylhexyl salicylate and homosalate.
(4) Benzophenones absorb UVB rays and sometimes extend into the UVA range. Examples are oxybenzone and dioxybenzone. Because of their extension into the UVA range, they are somewhat protective against photosensitivity reactions.
(5) Dibenzoylmethane derivatives. Avobenzone (Parsol 1789) or butyl methoxydibenzoylmethane, provides coverage over the entire UVA range although its absorbance decreases dramatically at 370 nm. Photosensitivity reactions from medications may not be completely prevented in the 370-400 nm range. In combination with other agents that cover the UVB range, reasonable protection for both the UVA and UVB ranges can be achieved. It is the only available agent that blocks UVA wavelengths up to 400 nm.
(6) Other chemical sunscreens. Phenylbenzimidazole sulfonic acid does not match up with any of the classes above. It covers just the UVB range 290-320 nm.
(7) A new agent **ecamsule,** incorporated into a combination product (Anthelios SX) with avobenzone and octocrylene was approved by the FDA in July, 2006. The combination protects against both UVA and UVB.
c. OTC **sunscreen products.** Most sunscreen products on the market contain combinations of two or more of the classes of chemical sunscreen agents described in preceding sections. To get adequate UVA protection, choose a product with avobenzone or a product with titanium dioxide or zinc oxide.

F. Special agents of interest

1. Dihydroxyacetone (DHA) is a chemical agent that darkens the skin by interacting with keratin in the stratum corneum to produce an **artificial suntan.** It provides **no protection against UV rays** and may not produce a natural-looking tan. This is known as an artificial tan extender. DHA must be applied evenly. If an artificial suntan is achieved with this chemical, it wears off in a few days. In addition, it can discolor hair and clothing.
2. Bronzers are artificial tan products that stain the skin. They are fully washable with soap and water and will not protect against solar radiation.
3. β-Carotene, a vitamin A precursor, may produce skin coloration when ingested orally. Although β-carotene is protective against some forms of abnormal photosensitivity (e.g., erythropoietic protoporphyria), it has not been shown to protect against sunburn in normal individuals.
4. Canthaxanthin is a carotenoid (provitamin A). It has been used as a food-coloring agent but has not been approved by the FDA for use as an oral tanning agent. It **does not produce a true suntan** but is deposited into fatty tissues under the skin. It probably does not protect the skin from sunburn.
5. Tyrosine has been promoted as a **tan accelerator** or **tan promoter.** Because melanin pigment is eventually synthesized from tyrosine, the theory is that topically applied tyrosine will enhance the formation of melanin. However, **studies have not confirmed an enhanced tanning effect from this agent.**

IV. CONTACT DERMATITIS AND ITS TREATMENT

A. Introduction

1. Types of contact dermatitis. Contact dermatitis is one of the **most common** dermatological conditions encountered in clinical practice. It has traditionally been divided into **irritant contact dermatitis** and **allergic contact dermatitis** on the basis of the origin and immunological mechanism.
P.641

a. Irritant contact dermatitis is caused by direct contact with a primary irritant. These irritants can be classified as absolute or relative primary irritants.
(1) Absolute primary irritants are intrinsically damaging substances that injure, on first contact, any person's skin. Examples include strong acids, alkalis, and other industrial chemicals.
(2) Relative primary irritants cause most cases of contact dermatitis seen in clinical practice. These irritants are less toxic than absolute primary irritants, and they require repeated or prolonged exposure to provoke a reaction. Examples of relative primary irritants include soaps, detergents, benzoyl peroxide, and certain plant and animal substances.
b. Allergic contact dermatitis. Many plants, and almost any chemical, can cause allergic contact dermatitis. Poison ivy is a classic example of allergic contact dermatitis, which is classified as a type IV hypersensitivity reaction. This type of allergic reaction is T cell-mediated, and the following **sequence of events** must occur to provoke it:
(1) The epidermis must come in **contact** with the hapten (i.e., the specific allergen).
(2) The **hapten-epidermal protein complex** (i.e., the complete antigen) must form.
(3) The antigen must **enter the lymphatic system.**
(4) Immunologically competent lymphoid cells, which are selective against the antigen, must form.
(5) On **reexposure** to the hapten, the typical, local delayed hypersensitivity reaction (i.e., contact dermatitis) occurs.
(6) The **induction period,** during which sensitivity develops, usually requires 14-21 days but may take as few as 4 days or more than several weeks. **Once sensitivity is fully developed:**
(a) Reexposure to even minute amounts of the same material elicits an eczematous response, typically with an onset of 12 hr and a peak of 48-72 hr after exposure.
(b) Sensitivity usually persists for life.
(i) Most contact allergens produce sensitization in only a small percentage of exposed persons.
(ii) Allergens or substances such as poison ivy, however, produce sensitization in > 70% of the population (50%-95% are sensitive to the poison ivy plant).
2. General phases of contact dermatitis
a. Acute stage. Wet lesions, such as blisters or denuded and weeping skin, are evident in well-outlined patches. Also evident are erythema, edema, vesicles, and oozing.

b. Subacute stage. In this phase, crusts or scabs form over the previously wet lesions. Allergic contact dermatitis and irritant contact dermatitis caused by absolute primary irritants produce both the acute and subacute stages.
c. **Chronic stage.** In this phase, the lesions become dry and thickened (i.e., lichenified). Initially, dryness and fissuring are the signs. Later, erythema, lichenification, and excoriations appear. The chronic phase of contact dermatitis usually occurs more often with irritant contact dermatitis caused by relative primary irritants.
B. Toxic plants. Poison ivy and poison oak are the **most common causes** of allergic contact dermatitis in North America. These plants were formerly known as the *Rhus* genus, but they are now properly referred to as the *Toxicodendron* genus.
1. Poison ivy (*Toxicodendron radicans* and *T. rydbergii*) grows as a vine or as a bush. It is found in most parts of the United States, but is especially prevalent in the northeastern part of the country. Poison ivy is often identified by its characteristic growth pattern, described by the saying “Leaves of three, let it be.”
2. Poison oak (*T. diversilobum*) is found in the western United States and Canada. It grows as an upright shrub or a woody vine. *T. toxicarium* is found in the eastern United States.
3. Poison sumac (*T. vernix*) grows in woody or swampy areas as a coarse shrub or tree and is prevalent in the eastern United States and southeastern Canada.
C. Toxicodendron dermatitis. For dermatitis to develop, previous sensitization (a 5- to 21-day incubation period) caused by direct contact with a sensitizing agent is required (see IV.A.1.b). An oleoresin, **urushiol oil,** which is a pentadecacatechol, is the active sensitizing agent in poison ivy, poison oak, and poison sumac. There are slight differences in the chemical structures of the sensitizing agent in each of these plants, but the three agents cross-react.

1. Release of the urushiol oil. The plants must be bruised or injured to release the oleoresin. It is **present in** the **roots, stems, leaves,** and **fruit.** The urushiol oil may remain active on tools, toys, clothes, pets, and under fingernails if those items have had contact with the broken plants.
a. Urushiol oil does not volatilize, so one cannot get dermatitis from just being near a poison ivy plant; direct contact is necessary. **Burning plants,** however, can cause droplets of oil carried by smoke to enter the respiratory system, which can cause significant respiratory distress.
b. A cut or damaged poison ivy, poison oak, or poison sumac plant initially yields a **clear fluid** containing the oleoresin, which **turns to a black inky lacquer** on exposure to air within a few minutes. This change can be a means for confirming identification of these plants.
c. Because the oleoresin can rapidly penetrate the skin, the affected **area must be washed with soap and water within 10 min** after exposure to prevent the dermatitis eruption. Washing up to 30 min after exposure is still useful in removing some of the oleoresin.

2. If an individual has been **previously sensitized,** the lesions usually occur within 6-48 hr after contact with the allergen.
3. Typically, the **initial eruption** exists as small patches of erythematous papules (usually streaks). **Pruritus (itching) is the primary symptom.**
a. Papules may progress to vesicles, which may then ooze and bleed when they are scratched. Secondary infection may then develop. Often, the inflammation is severe, and a significant amount of edema occurs over the exposed area.
b. The lesions may last from a few days to several weeks. Left untreated, the condition rarely persists longer than 2-3 weeks.
4. Poison ivy dermatitis does not spread. New lesions, however, may continue to appear for several days despite lack of further contact with the plant. This reaction may be owing to the following facts:
a. Skin that has been minimally exposed to the antigen begins to react only as the person's sensitivity heightens.
b. Antigen is absorbed at varying rates through the skin of different parts of the body.
c. The person inadvertently touches contaminated objects or may have residual oleoresin—for example, underneath the fingernails.
5. Poison ivy is not contagious. The serous fluid from the weeping vesicles are not antigenic. No one can “catch” poison ivy from another person.
D. Treatment. The treatment of irritant and allergic contact dermatitis focuses on therapy for the specific symptomatology.
1. A pharmacist should **refer a patient** with a poison ivy eruption to a physician if:
a. The eruption involves a large area of the body (about 25%).
b. The eruption involves the eyes, genital area, mouth, or respiratory tract (some patients may experience respiratory difficulties if they inhale the smoke of burning poison ivy plants).
2. The **severity of the eruption** depends on:
a. The quantity of allergen that the patient has been exposed to
b. The individual patient's sensitivity to the allergen
3. For severe eruptions, a patient should consult a physician, who may prescribe **systemic corticosteroids.**
a. Systemic corticosteroids are the cornerstone of therapy. One should use sufficiently high doses to suppress this inflammation. Generally, it is recommended that prednisone be given in a dose of 60 mg/day for 5 days, then reduced to 40 mg/day for 5 days, then 20 mg/day for 5 days, then discontinued. Prepacked dosage packs of corticosteroids used over 6 days provide too low of a dose over too short a period of time.
b. Some blisters may be drained at their base. The skin on top of the blister should be kept intact. Draining the blister allows more topical medication to penetrate for an antipruritic effect. Baths and soaks [see IV.D.4.b.(1).(b)] may be beneficial as well.
4. For a less severe eruption, the principal goals are to relieve the itching and inflammation and to protect the integrity of the skin.

a. Several therapeutic classes of agents can be used **to relieve itching.**
(1) The application of **local anesthetics**—for example, benzocaine (5%-20%)—may relieve itching. Relief may be of short duration (30-45 min), but application of benzocaine may be especially useful at bedtime, when pruritus is most bothersome. There is some question about the frequency of the sensitizing ability of benzocaine (0.17%-5%). Certainly, treatment should be discontinued if the rash worsens.
(2) Topical antihistamines—for example, diphenhydramine (Benadryl cream or spray)—may provide relief of mild itching principally through a topical anesthetic effect rather than any antihistamine effect. Many would not recommend their use because they may also have a significant sensitizing potential, and in children with varicella infections (where the integrity of the skin is compromised), systemic absorption has occurred with symptoms of anticholinergic toxicity produced. Topical and oral diphenhydramine should not be used concurrently.
(3) Counterirritants include camphor (0.1%-3%), phenol (0.5%-1.5%), and menthol (0.1%-1%). These agents have an analgesic effect as a result of depression of cutaneous receptors. The exact antipruritic mechanism is not fully known, but a placebo effect may result from the characteristic medicinal odors of these agents.
(4) Astringents are mild protein precipitants that result in contraction of tissue, which in turn decreases the local edema and inflammation.
(a) The principal agent used is **aluminum acetate** (Burow's solution).
(b) Calamine (zinc oxide with ferric oxide, which provides the pink color) is also used sometimes. Calamine contracts tissue and helps dry the area, but the formation of the thick dried paste may not be tolerated by some people.
(5) Topical hydrocortisone (e.g., Cortaid), which is available in concentrations up to 1%, is minimally useful for its antipruritic and anti-inflammatory effects.
b. Basic treatment
(1) Acute (weeping) lesions (see IV.A.2.a)
(a) Wet dressings work on the principle that water evaporating from the skin cools it and thus relieves itching. Wet dressings have an additional benefit of causing gentle débridement and cleansing of the skin.
(b) Burow's solution (Domeboro) in concentrations of 1:20-1:40 as a wet dressing or a cool bath of 15-30 min 3-6 times per day provides a significant antipruritic effect.
(c) Colloidal oatmeal baths (e.g., Aveeno) may also provide an antipruritic effect.
(d) Topical therapy that may hinder treatment
(i) Local anesthetics and topical antihistamines may sensitize.
(ii) Calamine may make a mess without doing much good!
(2) Subacute dermatitis (see IV.A.2.b). **A thin layer of hydrocortisone cream or lotion (0.5%-1%)** may be applied 3-4 times a day to treat subacute dermatitis. Supplemental agents, such as topical anesthetics, may be used as well.
(3) Chronic dermatitis (see IV.A.2.c) is best treated with hydrocortisone ointment. This stage is observed more frequently in forms of contact dermatitis that involve continuous exposure to the irritant or allergen.

E. Prevention

1. The best treatment for poison ivy contact dermatitis is to **prevent contact** with the offending cause. This approach involves avoiding the plant and wearing protective clothing.

2. Barrier preparations. Bentoquatam (quaternium-18 bentonite), Ivy Block, an organoclay, is the first poison ivy blocker proven safe and effective. It comes as a lotion that should be applied at least 15 min before contact with the plant and then every 4 hr for continued protection against urushiol. It should be applied to leave a smooth, wet, visible film on the skin. Ivy Block may be removed with soap and water. Because of its alcohol content, patients should be instructed to stay away from flame during application until the product has dried on the skin.

P.644

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A woman, who has not been in the sun for 4 months, develops redness on her chest after lying in the sun for 20 min. The next day, she applies a suntan lotion and develops the same degree of redness on her back in 2 hr and 20 min. What is the sun protection factor (SPF) of the lotion she is using?

(A) 14

(B) 10

(C) 12

(D) 9

(E) 7

View Answer***1. The answer is E[see].*****2. Which of the following cleansing products would a pharmacist recommend for a patient with inflammatory acne?**

(A) an abrasive facial sponge and soap used 4 times a day

(B) aluminum oxide particles used 2 times a day

(C) sulfur 5% soap used 2 times a day

(D) mild facial soap used 2 times a day

View Answer***2. The answer is D[see].*****3. If a patient needs a second application of an over-the-counter (**OTC**) pyrethrin pediculicide shampoo, how many days after the first application should this be done?**

(A) 4-5

(B) 6

(C) 7-10

(D) 14-21

(E) 15-17

View Answer***3. The answer is C[see].*****4. All of the following treatments for personal articles infested with head lice would be effective *except***

(A) placing woolen hats in a plastic bag for 2 weeks.

(B) using an aerosol of pyrethrins with piperonyl butoxide sprayed in the air of all bathrooms.
(C) machine-washing clothes in hot water and drying them using the hot setting on the dryer.
(D) dry-cleaning woolen scarves.
(E) soaking hair brushes in hot water for 15 min.

View Answer***4. The answer is B[see].*****5. All of the following sunscreen agents or combinations of agents would likely help prevent a drug-induced photosensitivity reaction *except***
(A) titanium dioxide.
(B) octyl methoxycinnamate plus homosalate.
(C) oxybenzone and padimate O.
(D) zinc oxide.
(E) padimate O plus avobenzone.

View Answer***5. The answer is B[see].*****6. All of the following would be appropriate recommendations for an adult patient in the acute stage (i.e., blistering, weeping) of poison ivy contact dermatitis *except***
(A) 60 mg per day of prednisone initially, then tapered over 15 days.
(B) Burow's solution; 1:20 wet dressing to area for 15-30 min, 4 times per day.
(C) two soaks per day in Aveeno Bath Treatment.
(D) two applications of Ivy Block.

View Answer***6. The answer is D[seeand].not*****7. All of the following nonprescription agents have been classified by the U.S. Food and Drug Administration (FDA) as safe and effective (category 1) for acne *except***
(A) sulfur.
(B) salicylic acid.
(C) sulfur-resorcinol combination.
(D) benzoic acid.

View Answer***7. The answer is D[see].*****8. Pharmacists educating patients about acne should mention all of the following *except***
(A) eliminating all chocolate and fried foods from the diet.
(B) cleansing skin gently 2-3 times daily.
(C) using water-based noncomedogenic cosmetics.
(D) not squeezing acne lesions.
(E) keeping in mind that acne usually resolves by one's early 20s.

View Answer***8. The answer is A[see].***P.645

9. A 15-year-old male patient has been using benzoyl peroxide 5% cream faithfully every day for the past 2 months with no apparent side effects. All of the following can be said about this patient *except*
(A) he has been using this product for a long enough time to determine if the dose and dosage form are going to have any benefit.
(B) he should use this product no more frequently than every other day because of its irritating properties.

(C) this starting dose and dosage form are useful, especially if he has dry skin or it is wintertime.
(D) his scalp hair may look bleached if the product comes in contact with it.
(E) the product would sting if it got into his eyes.

View Answer***9. The answer is B[see].*****10. All of the following descriptions match the therapeutic agent for poison ivy *except***
(A) calamine: phenolphthalein gives it the pink color.
(B) Ivy Block: useful in preventing poison ivy dermatitis.
(C) benzocaine: data regarding incidence of hypersensitivity are conflicting.
(D) hydrocortisone: useful for its antipruritic and anti-inflammatory effects.

View Answer***10. The answer is A[see].*****11. All of the following statements related to sun protection are true *except* which one?**
(A) The sun's intensity increases 20% when going from sea level to an altitude of 5000 ft.
(B) Water resistant labeling on a sunscreen product indicates that it will retain its SPF after 40 min of activity in water, sweating, or perspiring.
(C) Baby oil is not a sunscreen, but its application to the skin after tanning causes melanin to rise to the surface.
(D) Per the FDA, a product with an SPF of 50 must now be labeled “SPF 30 Plus.”
(E) The SPF is really only a measure of ultraviolet B (UVB) protection.

View Answer***11. The answer is C[seeand].*****12. All of the following statements about sunscreens are correct *except* which one?**
(A) Malignant melanoma formation may be associated with intense, intermittent overexposure to the sun (sunburning).
(B) Dihydroxyacetone (DHA) will not prevent sunburn.
(C) Sunscreens are best applied immediately before going out in the sun.
(D) Avobenzone provides sunscreen coverage for the UVA spectrum.
(E) Tyrosine has been marketed as a tan accelerator or tan magnifier.

View Answer***12. The answer is C[see].***P.646

ANSWERS AND EXPLANATIONS

1. The answer is E *[see* III.E.1*].*
The SPF is the minimal erythema dose (MED) of protected skin divided by the MED of unprotected skin. Thus 2 hr and 20 min (140 min) divided by 20 min equals an SPF of 7.

2. The answer is D *[see* II.E.2*].*
For patients with inflammatory acne, the best product is a mild facial soap used 2 times a day. The soap should be gently rubbed into the skin with only the fingertips. Cleansing products that irritate already inflamed skin should be avoided.

3. The answer is C *[see* I.G.4.a.(1)*].*
Reapplication of pyrethrins with piperonyl butoxide should be within 7-10 days of the first application. Any lice nits that were not killed on the first application would have time to hatch and then be killed with the second application.

4. The answer is B *[see* I.G.4 a; I.G.6.c*].*
Pyrethrins with piperonyl butoxide in an aerosol form can be sprayed directly on inanimate objects (e.g., chairs, headrests) to kill head lice, but the combination should not be sprayed in the air like an aerosol deodorizer. Moreover, vacuuming the furniture would probably be as effective as spraying it. The other selections are appropriate for personal articles infested with head lice.
5. The answer is B *[see* III.E.2; III.D.3.c*].*
Octyl methoxycinnamate and homosalate protect against only UVB exposure. Because photosensitivity reactions are often associated with UVA radiation exposure, people also need sunscreen protection for this portion of the UV radiation band. The other agents listed cover at least part of both UVA and UVB spectra.
6. The answer is D *[see* IV.D.3 *and* 4; IV.E.2*].*
Ivy Block is used as a barrier protectant for the prevention of poison ivy dermatitis, *not* for the treatment of an acute eruption. The other options are appropriate to recommend to someone suffering from the acute stage of poison ivy dermatitis.
7. The answer is D *[see* II.E.4*].*
Benzoic acid has not been shown to be effective for acne treatment. The other agents, sulfur, salicylic acid, and a sulfur-resorcinol combination, are all safe and effective products for treating acne.
8. The answer is A *[see* II.D.3*].*
Evidence does not show that acne worsens from any particular type of food, including chocolate or fried foods. The other choices are pieces of information that the pharmacist should convey to a patient with acne.
9. The answer is B *[see* II.E.4.a*].*
Although the irritating properties of benzoyl peroxide might dictate applying it only every other day on initiating treatment, this patient has tolerated the agent on a daily basis for 2 months. Thus there would be no need to decrease the application frequency. All of the other choices do apply to this patient's use of benzoyl peroxide.
10. The answer is A *[see* IV.D.4.a*].*
Ferric oxide provides the pink color of calamine. All of the other descriptions match their associated agents.
11. The answer is C *[see* III.C.2; III.E.1.b *and* c; III.E.2.b*].*
Baby oil is not a sunscreen, and it has no effect on melanin. SPF does measure UVB protection, and an SPF higher than 30 must be labeled SPF 30 Plus. Water resistant sunscreen products must retain their SPF value after 40 min of water activity. The intensity of the sun does increase by 4% with each 1000-ft. rise in elevation.
12. The answer is C *[see* III.D.2; III.E.1; III.E.2.b; III.F.1; IIIF.4*].*
Optimally, sunscreens should be applied 1-2 hr before exposure to the sun. This allows time for the product to bind to the stratum corneum, which provides better protection. The other responses are correct.

OTC Weight Control, Sleep, and Smoking-Cessation Aids

Jennifer D. Smith

I. WEIGHT CONTROL

A. Obesity is a growing epidemic in America, spanning all age groups from childhood to adulthood. Approximately 30.5% of adults were considered obese in the year 2000, and 15.5% of adolescents were considered overweight. This growing epidemic was responsible for 5.7% of total recent U.S. health expenditures.

1. The U.S. Preventive Services Task Force (USPSTF) determined that the body mass index (BMI) is reliable and valid identifier for **adults** at increased risk for morbidity and mortality owing to overweight and obesity. The BMI is calculated as either weight (in pounds) divided by height (in inches squared) multiplied by 703 or as weight (in kilograms) divided by height (in meters squared). The following guidelines relate BMI to overweight and obesity:

a. Morbid obesity is defined as a **BMI > 40 kg/**m2.

b. Obesity is defined as a **BMI > 30 kg/**m2.

c. **Overweight** is defined as a **BMI between 25 and 30 kg/**m2.

2. Trunkal fat accumulation, measured by **waist circumference,** is a **risk factor for cardiovascular disease and other diseases** (e.g., type 2 diabetes, sleep apnea, knee osteoarthritis) regardless if the individual is considered obese. Waist circumference is not a valid measurement in individuals with a BMI > 35 kg/m2. Individuals with the following waist circumferences are considered at increased risk for cardiovascular and other diseases:

a. A waist circumference in **men > 40 inches** (102 cm)

b. A waist circumference in **women > 35 inches** (88 cm)

B. Management. Diet and exercise (lifestyle modifications) are the recommended first approach to weight loss, as well as sustained weight control. Though it seems relatively simple to eat a well-balanced diet and exercise regularly, time constraints and ease of access to highly processed foods are hurdles that Americans face in the fight against the bulge.

1. Caloric restriction. To reduce weight (and thus BMI), energy intake should be less than the energy expended.

a. The approximate adult energy requirements, based on actual weight, may be roughly estimated as follows. A 120 lb. active woman would require approximately 1800 kcal/day to maintain her current weight.

(1) Bedridden or sedentary individuals: 10-12 kcal/lb.

(2) Moderately active individuals (walking at regular pace): 13 kcal/lb.

(3) Active individuals: 15 kcal/lb.

(4) Very active individuals: 20 kcal/lb.

b. To lose about 0.5 kg/week, a **deficit of 500-1000 calories (kcal) per day** must be met. A **safe rate of weight loss is considered to be 1-2** lb./**week.**

c. Several commercially available weight loss programs (e.g., Weight Watchers and Jenny Craig) exist today. When compared to self-help weight loss programs, some

commercially available programs have shown enhanced and sustained weight loss, which may be attributable to the social support provided.

2. Dietary Fat Absorption Inhibitor. Currently, the only available nonprescription agent that is FDA approved for weight loss is **orlistat,** a dietary fat absorption modifier. Dietary modifications in combination with orlistat can produce clinically modest weight loss (approximately 5% of baseline weight). Orlistat has been available in prescription form (Xenical®) since 1999, and gained FDA approval for nonprescription status in 2007 under the brand name Alli®.

a. Alli® is available for individuals 18 and older who are mildly to moderately overweight **(BMI between 25 and 28 kg/**m2).

b. Nonprescription dosing is **60** mg **TID** (as compared to 120 mg TID for Xenical®) during or within 1 hour of each fat-containing meal. Dose-related efficacy is observed with orlistat up to 300-400 mg daily, but effects plateau thereafter.

c. Onset of orlistat takes approximately 2 weeks and statistically significant weight loss has been observed in obese patients after 3 months. Thus individuals should be counseled that weight loss may not be significant with orlistat and may take several months for noticeable results.

d. The use of orlistat will result in **gastrointestinal adverse effects,** including soft or liquid stools which may be fatty or oily in appearance, increased defecation, fecal urgency, and abdominal pain. Adverse effects are directly related to the dose and inversely related to the fat content of the diet. Gastrointestinal adverse effects may lessen over time.

e. Prescription doses orlistat have been associated with decreased absorption of vitamins A, D, E, K, and beta-carotene. However, at doses ≤180 mg/day given for short periods of time (e.g., 2-3 months), reduced absorption of these vitamins has not been observed.

3. Exercise can decrease the appetite and increase body metabolism. Exercise adds only modestly to initial weight loss but is the key component of **sustained weight loss.**

C. Dietary supplements. In 2001, retail sales of weight loss supplements in the United States were estimated to be > **$1.3 billion.** Americans have begun to seek nonprescription weight loss products for a variety of reasons.

1. Some individuals may view dietary supplements as a quick resolution to the growing epidemic, because the obtainment of desired or reduced body weight with long-term lifestyle changes is perceived as difficult. Many advertisements of weight loss products give inflated claims, offering rapid results with little to no modification in lifestyle habits. Some people view dietary supplements as natural and, therefore, mistakenly believe they are safe to use.

2. With the implementation of the Dietary Supplement Health and Education Act of 1994, manufacturers are **not required to demonstrate product safety and efficacy before marketing** supplements. In addition, the **adherence to good manufacturing practices is not mandatory** for manufacturers of dietary supplements. The lack of

evidence for product safety and efficacy, coupled with potential deviation from good manufacturing practices raises concerns for healthcare providers who attempt to make appropriate recommendations to patients seeking nonprescription weight loss products.

3. The U.S. Food and Drug Administration (FDA) files action against manufacturers of supplements determined unsafe, falsely labeled, labeled with misleading claims, adulterated, or misbranded.

4. The Federal Trade Commission (FTC) takes action against manufacturers providing product advertising that is misleading or makes unsubstantiated claims.

5. Numerous single- and multiple-entity products are available on the market today, each under the scrutiny of the FDA and FTC. The most commonly seen ingredients in weight loss products currently marketed, organized by purported mechanisms of action, are the following:

a. Increase energy expenditure

(1) Ephedra. Contains supplements that were **banned by the FDA in April 2004** owing to unreasonable risks of illness or injury when used as labeled. Products formulated with ephedrine alkaloids (ephedra, ma huang, sida cordifolia, Pinellia) were removed immediately, though, unlike other dietary supplements currently available, ephedracontaining supplements did have convincing evidence for short-term weight loss.

(2) Bitter orange is an extract from the peel, flower, leaf, and fruit of the Seville orange. Typical dosage is about 1 g/day, standardized to 1.5%-6.0% synephrine, a stimulating agent that is chemically similar to ephedrine. Currently, there are no data to support its efficacy as an agent for weight loss. If combined with other stimulants such as caffeine, bitter orange may be cardiotoxic.

(3) Guarana seed contains 2.5%-7% caffeine and exerts a diuretic action. Effectiveness has been demonstrated only in combination with ephedrine. Tolerance and dependence can develop with chronic use.

(4) Caffeine is an FDA-approved product, efficacy of this agent for weight loss has been demonstrated only in combination with ephedrine, which has been removed from the market. Tolerance and dependence can develop with chronic use.

b. Modulate carbohydrate metabolism

(1) Chromium, an essential mineral, increases insulin sensitivity, lean body mass, and basal metabolic rate and decreases insulin blood levels and body fat. Chromium is used in weight loss products in the form of chromium picolinate, 200-400 µg/day, with no reported significant adverse effects. Rhabdomyolysis and renal failure have been reported with the use of chromium picolinate in doses exceeding 1000 µg/day. Though widely marketed, there have been no large, well-designed studies for the use of chromium in weight loss. Though its efficacy for weight loss remains uncertain, at least 115 products marketed for weight loss contain chromium.

(2) Ginseng, in the form of Panax ginseng, may improve glucose tolerance, according to preliminary data. Though ginseng is found in at least 20 commercially

available weight loss products, it has no demonstrated efficacy for weight loss in humans.

c. **Enhance satiety**

(1) Guar gum, a fiber derived from the Indian cluster bean, has been deemed relatively safe in doses of 7.5-30.0 g/day, however, it has not demonstrated efficacy for weight loss in at least 20 clinical trials. Adverse effects include abdominal pain, flatulence, and diarrhea.

(2) Glucomannan (*Amorphophallus konjac*) purportedly absorbs water in the gut, contributing to enhanced satiety and thus decreased caloric intake. Preliminary evidence has demonstrated that glucomannan (3-4 g/day) may be well tolerated and efficacious for weight loss. However, this agent can have a laxative effect.

(3) Psyllium forms a fibrous mass with a bulk laxative effect but has not demonstrated efficacy for weight loss. Potential adverse effects are significant, including esophageal obstruction and nephrotoxicity (if seeds are crushed, chewed, or ground, a pigment may be deposited in the renal tubules). If used, patients should be instructed to not crush, chew, or ground the seeds, and adequate fluids must be consumed.

d. Increase fat oxidation or reduce fat synthesis

(1) L-Carnitine is synthesized in the liver, kidney, and brain. It is fundamentally important for fatty acid transport for energy production. No trials demonstrate efficacy of L-carnitine for weight loss.

(2) Hydroxycitric acid (HCA) is derived from the rind of the brindle berry, a tropical fruit native to India. It is purported to inhibit mitochondrial citrate lyase, thereby suppressing acetyl coenzyme A and fatty acid synthesis. In doses of 300-3,000 mg/day, HCA has been well tolerated, with adverse effects of headache and gastrointestinal symptoms reported. Efficacy of HCA remains questionable.

(3) Green tea contains a polyphenol, epigallocatechin-3-gallate, better known as **EGCG.** Each cup (8 oz) of green tea provides 10-80 mg of caffeine, contributing to the tea's diuretic action and central nervous system (CNS) stimulation (e.g., increased heart rate, increased blood pressure, anxiety). Green tea has demonstrated increased fat oxidation and thermogenesis but lacks data regarding efficacy in weight loss.

(4) Vitamin B_5 has been postulated to induce weight loss; however, data are lacking to support this.

(5) Licorice safety and efficacy for weight loss remains unclear. Reported adverse effects of licorice include pseudoaldosteronism, hypertension, and hyperkalemia.

(6) Conjugated linoleic acid (CLA) is a group of *trans*-fatty acids, which is purported to alter body composition by increasing lean tissue deposition and decreasing triglyceride uptake in adipose tissue. In doses of 1.4-6.8 g/day, CLA may have efficacy in weight loss, especially in obese patients. Adverse effects include mild to moderate gastrointestinal symptoms. CLA may increase insulin levels and insulin resistance.

(7) Clinical trials of **pyruvate,** in doses of 6-44 g/day, have demonstrated weak evidence of its effectiveness for weight loss. Reported adverse effects include diarrhea and audible abdominal sounds.

(8) Calcium suppresses parathyroid hormone and 1,25-dihydroxyvitamin D to reduce fat synthesis and increase fat oxidation. Oral doses of calcium obtained through both diet (1.2-1.3 g/day) and supplementation (800 mg/day) have produced positive results in at least one randomized controlled trial (*n* = 32). A larger randomized controlled trial is needed to substantiate current advertising.

e. Block dietary fat absorption. Chitosan, a common ingredient in "fat-trapper" supplements, is derived from the exoskeleton of shellfish. In doses of 2.0-4.5 g/day, chitosan has not demonstrated clinically significant increases in fecal fat excretion or weight loss. Adverse effects include nausea, constipation, and flatulence. Furthermore, it is questionable if chitosan is safe in individuals with shellfish allergies.

f. Increase water elimination

(1) Dandelion (*Taraxacum officinale*) seems to have a diuretic effect, but has not been studied for weight loss in humans. At least 15 dietary supplements for weight loss contain dandelion.

(2) Cascara stimulates peristalsis and evacuation, allowing FDA to approve this agent for use as a stimulant laxative. However, cascara has not been studied in humans for weight loss.

g. Miscellaneous. Spirulina (blue-green algae) contains phenylalanine, an agent theorized to inhibit appetite. Spirulina was declared ineffective for weight loss in 1981 by the FDA, and no published studies have proven otherwise. At least 13 products for weight loss currently on the market contain spirulina.

II. SLEEP AIDS

A. Normal sleep and sleep requirements

1. Sleep requirements vary widely among individuals and change throughout the life cycle. The usual range of sleep time per night is 5-10 hr, with an average of about 7.5 hr. Newborns require a considerable amount of sleep time, up to 18 hr. Adolescents typically do not become sleepy until after midnight and awaken very late in the morning (if allowed), but require a total of 9.5 hr of sleep. The typical adult requires 7-8 hr of sleep to feel adequately restored, but this time may diminish with aging.

2. Polysomnography is the predominant tool for characterizing sleep physiology, though guidelines from the American Sleep Disorders Association do not indicate it as useful in the diagnosis and management of patients with insomnia. Using polysomnography, researchers have identified five stages of sleep, subdivided into rapid eye movement (REM) sleep and non-REM sleep.

a. Non-REM sleep consists of four stages. Each stage is a progression into a deeper sleep; and stages 3 and 4 are considered deep, restorative sleep. If time spent in stages 3 and 4 of sleep is diminished (as seen with aging), then sleep quality is compromised.

b. REM sleep is considered stage 5 of sleep. Most dreaming occurs during REM sleep. If awoken while in REM sleep, dreams may be described in vivid detail.

B. Insomnia

1. Definition. Insomnia is defined as one or more of the following sleep-related complaints: difficulty in sleep initiation (arbitrarily defined as a delay of > 30 min), difficulty in maintenance of sleep, shortened duration of sleep, or quality of sleep that results in adverse daytime consequences.

2. Epidemiology. Insomnia is the most common sleep disorder in the United States, affecting approximately 35% of the adult population. Those affected most include women, the less educated or unemployed, separated or divorced individuals, patients with chronic medical or psychiatric disorders, and substance abusers. Economic costs of insomnia are estimated to be > $46 billion annually in the United States. Direct costs include prescription and nonprescription medications, as well as visits to a healthcare provider. Indirect costs include absenteeism, diminished productivity, fatigue-related automobile crashes, and industrial accidents.

3. Classification of insomnia by duration.

a. Transient insomnia lasts < **1 week** and is typically the result of acute situational stress or circadian issues such as jet lag or shift work. This type of insomnia is often self-limiting.

b. Short-term insomnia lasts **1-4 weeks** and is attributable to situational stress (e.g., acute personal loss), often related to work and family life or to medical or psychological disorders. If short-term insomnia is not managed appropriately, it may progress to chronic insomnia because individuals become increasingly anxious and frustrated about the inability to sleep. There are no established predictors to determine if short-term insomnia will continue to become chronic insomnia.

c. **Chronic insomnia** lasts > **1 month.** People with chronic insomnia need further evaluation because the condition is often the result of a medical disorder (e.g., sleep apnea, restless

leg syndrome, primary insomnia), psychiatric disorder, or substance abuse. Up to 40% of chronic insomnia cases are correlated with psychiatric disorders, particularly depression.

4. Classification of insomnia based on cause

a. Primary insomnia is the main pathological condition in which a patient experiences continued insomnia in the absence of a related medical or psychiatric condition. Its pathogenesis is unknown, but the condition is treatable. Idiopathic insomnia is the inability to obtain adequate sleep, possibly stemming from a misaligned circadian rhythm. Psychophysiologic insomnia is increased wakefulness associated with the bed environment.

b. Secondary insomnia is more common than primary and can be attributed to the following:

(1) Adjustment insomnia is associated with situational stress.

(2) Inadequate sleep hygiene is associated with lifestyle habits that reduce the amount of quality sleep, such as noise in the bedroom or the use of caffeine.

(3) Insomnia owing to a psychiatric disorder
(4) Insomnia owing to a medical condition, which may include restless leg syndrome, chronic pain (arthritis), migraines, or cancer
(5) Insomnia owing to substance abuse
5. Treatment
a. Nonpharmacologic intervention is inexpensive and may be effective.
(1) Maintain a regular schedule and do not nap; avoid sleeping in late after a poor night's sleep.
(2) Use the bed only for sleep; avoid reading or watching television in bed.
(3) If unable to initiate sleep (or go back to sleep) within 20 min, engage in a relaxing activity (away from bed) until drowsy, and then return to bed.
(4) Avoid exercise within 3-4 hr of bedtime.
(5) Minimize or avoid caffeine after noon.
(6) Minimize or avoid alcohol, tobacco, or stimulants. Many people believe alcohol to be an agent for sleep induction; however, alcohol can act as a CNS stimulant, thereby increasing nocturnal awakenings.
b. Nonprescription drug therapy: It has been estimated that 40% of patients with insomnia self-medicate with either alcohol or nonprescription medications in an effort to correct the condition. The sales of single-entity nonprescription hypnotics (e.g., diphenhydramine, doxylamine) have increased since that estimate was made, but the sales of nighttime analgesics (nonprescription hypnotic plus an analgesic, typically acetaminophen) have surpassed the single-entity products. Currently, data supporting the safety and efficacy of complementary therapy as sleep aids are lacking.
(1) Diphenhydramine, an ethanolamine, blocks histamine$_1$ and muscarinic receptors, thus inducing sedation. Diphenhydramine is marketed as a nighttime sleep aid as Unisom SleepGels, Sleepinal, Compoz, and Simply Sleep.
(a) Diphenhydramine may be dosed for sleep induction as **25-50** mg**/night** in patients aged 13 and older. Doses > **50** mg **show no additional benefit,** but increased adverse effects. An initial dose of 25 mg may be recommended for patients over the age of 65 with no contraindications to the agent. A dose of 1 mg/kg/night (not to exceed 50 mg) may be recommended for patients aged 6-12. Diphenhydramine is not recommended for sleep induction in patients younger than age 6.
(b) Adverse effects of diphenhydramine are **anticholinergic,** including dry mouth, blurred vision, constipation, and urinary retention. Diphenhydramine use should be avoided in patients with glaucoma (narrow-angle), benign prostatic hypertrophy, dementia, or cardiovascular disease.
(c) The duration of sedation from diphenhydramine is 3-6 hr. However, this may be extended in elderly patients or those with delayed metabolism.
(d) The use of diphenhydramine for the alleviation of insomnia should be **limited to 7-10 consecutive nights.** If used longer than recommended, decreased efficacy may be noted and REM sleep may be suppressed.
(e) Diphenhydramine is available in combination with aspirin or acetaminophen as a **nighttime analgesic.** Data are available to support the use of these agents in

combination if pain is present. However, in the absence of pain, the addition of an analgesic simply provides increased opportunities for complications and drug-misadventures.
P.652

(2) Doxylamine, like diphenhydramine, is an ethanolamine antihistamine which induces sleep through the blockade of histamine and muscarinic receptors. Therefore, adverse effects and duration of sedation are similar to diphenhydramine. There are currently no studies demonstrating enhanced efficacy or safety of doxylamine compared to diphenhydramine.
(a) Doxylamine is dosed as **25** mg**/night.**
(b) Doxylamine is the active ingredient in Unisom Nighttime Sleep Aid Tablets. However, it should be noted that Unisom SleepGels contain diphenhydramine.
(3) Melatonin, a nocturnal neurohormone secreted by the pineal gland, has a **sleepphase-shifting effect on circadian rhythm.** Recent trials have observed effectiveness of melatonin for sleep onset in patients with misaligned circadian rhythms attributable to shift work or jet lag.
(a) Melatonin production decreases with age, possibly attributing to sleep disorders noted in elderly patients.
(b) Melatonin production can be decreased by tobacco, alcohol, and certain medications (nonsteroidal anti-inflammatory drugs, calcium channel blockers, steroids, benzodiazepines, and fluoxetine).
(c) When exogenous melatonin is **given in the early evening, the circadian phase will be advanced.** Although this may be beneficial for individuals who experience difficulty in initiating sleep, melatonin given in this manner may worsen the problem of individuals who complain of difficulty in reinitiating sleep after awakening too early.
(d) If melatonin is **given in the morning, the circadian phase is delayed,** offering the possibility that the patient may become sleepier earlier and awaken earlier. At present, it is unclear if continued administration of exogenous melatonin will suppress endogenous production.
(e) Melatonin may be dosed as **0.3-5** mg **during the day or at night,** depending on the desired effect. A physiologic dose of melatonin is 0.1 mg, an intermediate dose is 0.3 mg, and a pharmacologic dose is 3 mg. **Doses** > **1** mg may improve sleep efficiency but **have not demonstrated the ability to provide quality sleep restoration** as well as the intermediate dose.
(f) Attributable to its short half-life (30-50 min), melatonin should have **minimal, if any, residual effects the following morning.**
(4) Valerian root, derived from *Valeriana officinalis,* is classified as generally recognized as safe (GRAS) for food use in the United States. In doses of **600** mg**/day,** valerian root is purported to induce sedation through its blockade of γ-aminobutyric acid (GABA) breakdown. Adverse reactions of valerian root include vivid dreaming. Further research is necessary to determine the safety and efficacy of valerian root as a sleep aid.

(5) Kava, derived from *Piper methysticum,* is one of the most common dietary supplements used in the self-management of anxiety. It is theorized that if insomnia is caused by a state of hyperarousal, then management of anxiety and nervousness will help induce the desired sleep.

(a) A typical dose of kava is **120** mg**/day.**

(b) Reported adverse effects of kava are significant, including diarrhea, extrapyramidal side effects, and hepatotoxicity. A recent FDA advisory has **recommended against the use of kava because of the reports of hepatotoxicity,** including hepatitis, cirrhosis, and liver failure.

(6) L-Tryptophan was **banned in 1989** owing to its **association with eosinophilia-myalgia syndrome;** however, it remains available as a 500-mg capsule. The safety and efficacy of L-tryptophan as a sleep aid has not been studied and should not be recommended at this time.

III. SMOKING CESSATION

A. Introduction. More than 400,000 deaths annually are attributable to diseases directly linked to cigarette smoking, including atherosclerotic vascular disease, lung cancer, and chronic obstructive pulmonary disease. It is the most preventable contributor to morbidity and mortality in the United States and yet nearly one third of the adult population (approximately 48 million

adults) continues to smoke. The resulting economic burden is startling, estimated at $50 billion annually to treat smoking-related disorders and $47 billion for the loss of wages and productivity.

B. Physiologic effects of nicotine involve the CNS (e.g., enhanced relaxation, improved attention) and the cardiovascular system (e.g., elevated blood pressure, tachycardia). The manifestations of smoking become more pronounced as one ages and may include any or all of the following: deepening of the voice (an untoward effect in women); a constant, hacking cough; yellowed fingernails and surrounding skin from substances found in cigarette smoke; and premature aging of the skin, most noticeable on the face.

C. Benefits of smoking cessation are evident for both the patient and society.

1. Patient

a. Decreased carbon monoxide levels

b. Restoration of olfactory and gustatory senses within days

c. Increased self-respect, sense of accomplishment

d. Improved lung function (up to 30%) within 2-3 months

e. Reduction in the risk of coronary heart disease (50%) after 1 year. After 2 years, the risk is equivalent to individuals who never smoked.

f. Parallel risk of stroke to that of a nonsmoker within 5-15 years

g. Progressive decline in the risk of lung cancer as number of years of abstinence increases. However, the risk will never be equivalent to one who never smoked.

2. Society

a. Decreased healthcare costs for treatment of diseases directly linked to smoking

b. Decreased work absenteeism owing to smoking related disease
c. Cleaner environment from decreased secondhand smoke and cigarette remains (e.g., ashes or butts of cigarettes) in public places
D. Complications of smoking cessation. Smoking is an addiction and, therefore, not easy to give up. Nicotine withdrawal symptoms include tobacco cravings, depressed mood, insomnia, irritability, inability to concentrate, anxiety, decreased heart rate, and increased hunger. In a 1991 study in which individuals tried to stop smoking without aid, all symptoms of nicotine withdrawal resolved within 30 days, except increased hunger, which persisted past the 30-day cessation period.
E. Tailored interventions for smoking cessation should be offered to every patient who smokes. The U.S. Public Health Service endorses an approach known as the 5As, developed in 1996 by the Agency for Health Care Policy and Research:
1. Ask patients if they smoke.
2. Advise patients who smoke to quit.
3. Assess the patient's willingness to quit.
4. Assist the patient in efforts to quit through counseling and/or pharmacologic therapy. (The combination of counseling and pharmacologic therapy has proven to be the most successful method.)
5. Arrange follow-up within a short time frame.
6. To assess the patient's willingness to quit, the transtheoretical model of behavior change may be a useful tool. According to this model, patients are in one of five motivational stages to change their current behavior—that is, to stop smoking:
a. Pre-contemplation. Patient is not ready to change current behavior.
b. Contemplation. Patient is considering a change in current behavior in the future but not at the present time.
c. **Preparation.** Patient is actively considering a change in current behavior and is actively engaged in seeking more information.
d. Action. Patient is actively attempting to change behavior or has changed behavior within the last 6 months
e. Maintenance. Patient has sustained changed behavior for at least 6 months.

7. For patients in the precontemplation and contemplation stages, the healthcare professional should still advise the patient to quit smoking and repeat the assessment at future visits. For patients in the contemplation stage, the healthcare professional should assist the patient by offering a referral for smoking-cessation counseling and/or pharmacologic therapy. Behavior modification works best as a multidisciplinary approach, involving the healthcare provider, pharmacist, nurse, and dentist.
F. Nicotine-Replacement Therapy
1. Overview. Nicotine-replacement therapy (NRT) is a smoking-cessation aid used to ameliorate nicotine withdrawal symptoms by providing a **nontobacco, controlled-release amount of nicotine.**

a. Research has demonstrated that the use of NRT in individuals who smoke > 10 cigarettes a day **can double the chances of successful smoking cessation;** but it is most successful when combined with other nonpharmacologic measures, such as counseling.

b. Currently, three available dosage forms of NRT are approved by the FDA (gum, lozenges, and patches); however, **none is effective if the patient is not mentally ready to quit.** Furthermore, NRT is **not effective for the cessation of smokeless tobacco** (e.g., chewing tobacco, cigars, and pipes).

2. Safety. Though it is recommended by the U.S. Public Health Service that all people trying to abstain from smoking should receive pharmacotherapy support, not everyone is an ideal candidate.

a. For patients with **acute cardiovascular disease** (e.g., stroke, acute myocardial infarction, unstable angina) and **pregnant or breastfeeding women, absolute abstainment from nicotine should be recommended.** However, if the patient makes an informed decision, under the supervision of a provider, a rapidly reversible preparation is advisable (e.g., gum or lozenge).

b. In recent studies, NRT **appears to be safe in patients with stable cardiovascular disease.** Blood pressure should be monitored closely.

c. The sale of NRT is **restricted to those over age 18.** Therefore adolescents desiring smoking cessation, should consult a medical provider.

d. Patients with **asthma or depression** are instructed to consult their physician before the use of NRT. The levels of certain medications used for management of these disease states (e.g., theophylline, imipramine) may be altered by smoking cessation. The nicotine found in NRT does not alter these levels.

e. It is recommended that patients **do not smoke while using NRT** because the purpose of NRT is to alleviate symptoms while weaning from cigarettes. Although some studies have indicated that the combination may be safe, until further research is conducted, concomitant use of NRT and cigarettes should not be seen as permissible.

f. Patients are advised on the labeling of NRT products not to combine two forms of NRT. However, a few small studies have shown combinations of NRT to be superior to either agent alone. Therefore, some specialists in the field do recommend combination therapy. However, until further research is conducted in the form of well-developed, large trials, combination therapy with NRT should be discouraged unless prescribed by the supervising medical provider.

3. Available forms of NRT

a. Nicotine polacrilex gum received FDA approval for prescription sales in 1984 and nonprescription status in 1995.

(1) Dosing. Sold under the trade name Nicorette, the gum is available in a **2-**mg **dose** for people who smoke < 25 cigarettes daily and a **4-**mg **dose** for those who smoke > 25 cigarettes daily. The typical usage is **10 pieces daily,** with a maximum recommended usage of 60 mg/day for up to 3 months. The **strength of gum purchased does not change;** instead, the number of pieces used decreases over the course of treatment (Table 31-1).

(2) Chew-and-park method. The gum should be chewed slowly, releasing a peppery, tingling sensation, at which point the gum should be "parked" between the cheek and the gum to enhance buccal absorption of the nicotine.
(3) Adverse effects most commonly reported are sore jaw and mouth, mouth ulcers, and dyspepsia.

Table 31-1. Recommended Scheduling of Nicotine Gum and Lozenges[a]

Weeks	Dose
1-6	1 piece gum or 1 lozenge every 1-2 hr (at least 9/day)
7-9	1 piece gum or 1 lozenge every 2-4 hr
10-12	1 piece gum or 1 lozenge every 4-8 hr

[a]The recommended scheduling of nicotine polacrilex gum (Nicorette) and lozenges (Commit) is identical. If nicotine is needed past the 12-week schedule, a medical provider should be consulted.

(4) Counseling tips
(a) Slowly chew the gum until a peppery, tingling sensation is felt, then park the polacrilex gum between the cheek and the gum. Once the peppery, tingling sensation disappears, begin to slowly chew the gum again until the sensation returns. The gum should be parked in a different area than before. Once the gum looses the ability to produce the peppery, tingling sensation (approximately 30 min), discard the gum.
(b) Do not eat or drink for 15 min before using nicotine gum because it requires a basic pH for proper release and absorption of the nicotine.
(c) Do not use other forms of NRT or smoke while using the gum product, unless otherwise directed by a supervising provider.
(d) The gum may be chewed at the beginning of the first day or at least 30 min after the last cigarette was smoked.
b. Nicotine lozenges, currently sold only under the trade name Commit, delivers nicotine into the buccal mucosa when the individual sucks on the tablet, similar to a cough drop.
(1) Dosing. Commit has a unique **dosing strategy, based on the timing of the first cigarette.** If the first cigarette is craved within 30 min of waking, the **4-**mg lozenge may be recommended. If the first cigarette craving is after 30 min of waking, the **2-**mg lozenge may be recommended. The **strength chosen will not**

change throughout the course of cessation; instead fewer lozenges will be consumed each day during the **12-week proposed schedule** (Table 31-1).
(2) Adverse effects. If the lozenge is consumed too quickly or swallowed (rather than dissolved) dyspepsia may be experienced. Other reported adverse effects include insomnia, nausea, hiccups, coughing, headache, and flatulence.
(3) Counseling tips
(a) Avoid chewing or biting the lozenge. Rather suck on the lozenge slowly, moving it from side to side, until it is completely dissolved (20-30 min). If accidentally swallowed, wait at least 1 hr before using another lozenge.
(b) Do not use other forms of NRT and do not smoke cigarettes while using this product, unless otherwise directed by a supervising provider.
(c) The first lozenge may be taken at the beginning of the first day or at least 30 min after the last cigarette was smoked.
(d) Do not take more than 20 lozenges per day of either the 2-mg or 4-mg dose.
c. **Nicotine patches** were introduced in 1992 and acquired nonprescription status n 1996. Comparative studies of the available formulations of NRT have revealed that most individuals prefer the patch over the gum or a prescription nicotine inhaler. The patch must be **placed on a clean, dry, and hair-free area** (e.g., stomach, thigh, back), but not over joints (e.g., ankles, knees, elbows). The patch should never be placed over wounds or open areas and caution must be used in the patient with severe psoriasis and eczema. The most common adverse effect of the patches is **skin irritation,** but this may be reduced by rotating the patch site. Two trade name nonprescription nicotine patches are available: NicoDerm CQ and Nicotrol.
(1) NicoDerm CQ may be worn for **16-24 hr/day.** Patients with early-morning cigarette cravings may require 24-hr use. However, if insomnia or vivid dreaming occurs, the patch may be removed after 16 hr.
(a) Dosing: NicoDerm CQ is available in three strengths: **21-, 14-, and 7-**mg **patches.** The patch should be **tapered over 2-4 months,** depending on the starting dose.
(i) NicoDerm CQ 21-mg patch may be recommended to an individual who smokes > 10 cigarettes/day and then tapered as follows:

{**1**} Step 1: 21 mg/day for 6 weeks
{**2**} Step 2: 14 mg/day for 2 weeks
{**3**} Step 3: 7 mg/day for 2 weeks
(ii) Those who smoke < 10 cigarettes/day may begin with the NicoDerm CQ 14-mg patch and taper as follows:
{**1**} Step 1: 14 mg/day for 6 weeks
{**2**} Step 2: 7 mg/day for 2 weeks
(2) Nicotrol patches were formerly available only as a non-tapering single 15-mg dose to be used over a 6 week period. The new Nicotrol patches are available in a stepping pattern similar to Nicoderm CQ and are recommended to be worn for 16 hours and removed at bedtime.

Weeks 1-6: Step 1 (15 mg)
Weeks 7-8: Step 2 (10 mg)
Weeks 9-10: Step 3 (5 mg)
P.657

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. All of the following statements about dietary supplements are true *except* which one?

(A) Manufacturers are not required to demonstrate product safety and efficacy before marketing supplements.
(B) Adherence to good manufacturing practices is mandatory for manufacturers of dietary supplements.
(C) The U.S. Food and Drug Administration (FDA) files action against supplements determined unsafe.
(D) The Federal Trade Commission (FTC) takes action against manufacturers who present misleading product advertising.

View Answer***1. The answer is B[see].*****2. All of the following statements about chitosan are true *except* which one?**

(A) It is a common ingredient found in fat-trapper supplements.
(B) It is derived from the Indian cluster bean.
(C) Its safety is questionable for individuals with shellfish allergies.
(D) It is purported to inhibit dietary fat absorption.

View Answer***2. The answer is B[see].*****3. Jane is 36 years old and wants to lose weight. Her current body mass index (BMI) is 32 kg**/m2**, and her waist circumference is 40 inches. She has lost a minimal amount of weight in the past using fad diets and nonprescription weight loss products but has been unable to maintain the weight loss. Which of the following is true regarding Jane?**

(A) Based on her BMI, Jane is considered obese.
(B) Her waist circumference of 40 inches increases her risk for cardiovascular disease.
(C) A safe rate of weight loss for Jane would be 1-2 lb/week.
(D) Exercise will provide only a modest amount of weight loss but will help her maintain the weight loss.
(E) All of the above

View Answer***3. The answer is E[seeandand].*****4. Since the sudden death of his father 2 weeks ago, Bob has been unable to sleep at night. He has difficulty going to sleep and awakens early in the morning, unable to return to sleep. Which of the following would be the correct classification of Bob's current insomnia?**

(A) transient, primary insomnia
(B) short-term, primary insomnia
(C) transient, secondary insomnia
(D) short-term, secondary insomnia

View Answer***4. The answer is D[seeand].*****5. William works the swing shift at the local manufacturing plant. Based on a recommendation from a friend at work, William would like to try melatonin to help him get to sleep faster. Which of the following is true regarding William's use of melatonin?**
(A) An appropriate starting dose of melatonin is 5 mg/night.
(B) William may experience continued drowsiness the following morning owing to melatonin's long half-life.
(C) Recent trials have noted the effectiveness of melatonin in individuals participating in shift work.
(D) All of the above

View Answer***5. The answer is C[see].*****6. Which of the following complementary alternative medicines (CAM) has been banned because of its association with eosinophilia-myalgia syndrome?**
(A) melatonin
(B) kava
(C) L-tryptophan
(D) valerian root

View Answer***6. The answer is C[see].*****7. Sylvia is 33 years old and wishes to purchase a sleep aid for her recent bout of insomnia (duration 2 days). She has linked it to an overwhelming amount of stress she has been under lately at work, trying to meet deadlines, and her recent lack of sleep is not helping. She has no current medical conditions and takes a multivitamin daily. All of the following are true regarding Sylvia's taking diphenhydramine and doxylamine *except* which one?**
(A) Sylvia may benefit from diphenhydramine 50 mg used nightly.
(B) Sylvia should limit the use of diphenhydramine for insomnia to 10 consecutive nights.
(C) Sylvia may benefit from doxylamine 50 mg used nightly as needed.
(D) Sylvia may experience anticholinergic side effects with the use of doxylamine.

View Answer***7. The answer is C[seeand].***P.658

8. Jill, a 22-year-old college student, has been encouraged by her healthcare provider to stop smoking. She tells her doctor that she wants to quit but she does not want to gain weight right now or to sacrifice her grades as a result of an inability to concentrate during the day. According to the 5As and the transtheoretical model of change, what is the next step Jill's healthcare provider should take?
(A) Jill is in the precontemplation stage of change. Her provider should reassess her willingness to quit at the next visit.

(B) Jill is in the contemplation stage of change. Her provider should reassess her willingness to quit at the next visit.
(C) Jill is in the preparation stage of change. Her provider should reassess her willingness to quit at the next visit.
(D) Jill is in the preparation stage of change. Her provider should offer her counseling and/or pharmacologic therapy for smoking cessation.

View Answer***8. The answer is B[see].*****9. Zack is 55 years old and wishes to start taking nicotine lozenges to quit smoking. Which of the following is important in the recommendation and selection of nicotine lozenges?**
(A) number of cigarettes smoked daily
(B) timing of his first urge for a cigarette
(C) concomitant disease states and therapies
(D) both the number of cigarettes smoked daily and concomitant disease states and therapies
(E) both the timing of his first urge for a cigarette and concomitant disease states and therapies

View Answer***9. The answer is E[see].*****10. All of the following are important counseling tips for the use of nicotine replacement therapies *except* which one?**
(A) Do not eat or drink within 15 min of chewing nicotine gum.
(B) The initial start of nicotine replacement therapy may be 30 min after the last cigarette.
(C) Skin irritation associated with the use of a patch may be minimized by rotating the patch site.
(D) All nicotine patches should be removed and replaced every morning.

View Answer***10. The answer is D[seeand].*****11. Wendy, a 45 year old female, is seeking advice about the use of Alli® for weight loss. Her current weight is 228 lbs and her height is 5′6″. At her last provider visit, her provider suggested she set a weight loss goal of 2 pounds per week through diet and exercise. Wendy has type 2 diabetes and hypertension, both of which are well controlled. Which of the following would be appropriate information to provide Wendy?**
(A) Orlistat may assist in modest amounts of weight loss, but noticeable results may not be evident for several months.
(B) Orlistat is contraindicated in individuals with diabetes mellitus.
(C) Orlistat is taken as 1 capsule three times daily one hour after a fat-containing meal.
(D) Orlistat may reduce the absorption of fat-soluble vitamins, thus a multivitamin should be taken when nonprescription orlistat is initiated.

View Answer***11. The answer is A[seeand].***P.659

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* I.C*].*

Manufacturers of dietary supplements are not required to demonstrate product safety and efficacy before marketing, nor are they required to adhere to good manufacturing practices.

2. The answer is B *[see* I.C.5*].*

Derived from the exoskeleton of shellfish, chitosan is purported to block dietary fat absorption and thus is a common ingredient found in fat-trapper supplements. Because it is derived from the exoskeleton of shellfish, the safety of chitosan in individuals with shellfish allergies remains in question.

3. The answer is E *[see* I.A.1 *and* 2; I.B.1.b *and* c; I.B.2*].*

A BMI > 30 kg/m2 but < 40 kg/m2 is considered obese, but not morbidly obese. Women with a waist circumference > 35 inches are at increased risk of developing cardiovascular disease, as well as type 2 diabetes, sleep apnea, and osteoarthritis. If Jane's BMI had been > 35 kg/m2, her waist circumference measurement would not be valid for determining an increased cardiovascular risk. Diet and exercise are the best approach to weight loss. A reasonable weight loss is 1-2 lb./week. Although exercise is beneficial, it adds a only modest amount to the weight loss; it has greater effect in the maintenance of the weight loss.

4. The answer is D *[see* II.B.3 *and* 4*].*

Transient insomnia is insomnia lasting < 1 week, and short-term insomnia is insomnia lasting from 1 to 4 weeks. Primary insomnia is a pathological condition in which the patient experiences continued insomnia in the absence of a related medical or psychiatric condition. Secondary insomnia can be attributed to a variety of situations, especially situational stress, such as the death of a loved one.

5. The answer is C *[see* II.B.5.b.(3)*].*

Melatonin effectiveness for sleep onset has been observed in recent trials in individuals participating in shift work. However, melatonin is not FDA approved for this purpose. An initial starting dose of melatonin is 0.1-0.3 mg in the evening for patients desiring improved sleep onset. Doses > 1 mg daily have not been able to demonstrate the quality sleep restoration seen in 0.3-mg doses. Melatonin has minimal, if any, residual effects the following morning, owing to its short half-life of 30-50 min.

6. The answer is C *[see* II.B.5.b.(6)*].*

L-Tryptophan was banned in 1989 because of its association with eosinophilia-myalgia syndrome. However, it remains available for sale as a 500-mg capsule.

7. The answer is C *[see* II.B.5.b.(1) *and* (2)*].*

Diphenhydramine may be dosed as 25-50 mg nightly for a sleep aid used for up to 7-10 consecutive nights. The recommended dosage for doxylamine is 25 mg nightly. Both diphenhydramine and doxylamine are ethanolamine antihistamines. Therefore, anticholinergic effects may be experienced with the use of either agent.

8. The answer is B *[see* III.E*].*

Jill is in the contemplation stage, as she is considering a change in the future, but she does not feel that this is the right time to begin a smoking cessation program. Therefore, Jill's provider should reassess her willingness to quit at her next visit, when, it is hoped that Jill will be ready to quit.

9. The answer is E *[see* III.F.3.b*].*

The only currently available nicotine lozenge is Commit, which is unique in its dosing strategy. Dosing is based on the timing of the first urge for a cigarette, either within or after 30 min of waking up. Concomitant disease states should be considered as well. If the patient has hypertension, he will need to be monitored more closely while using nicotine replacement therapy. If he uses certain prescription medications for asthma or depression, his medication may need to be adjusted when he stops smoking.

10. The answer is D *[see* III.F.3.a, b *and* c*].*

Nicotrol nicotine patches are to be used only during the daytime for 16 hr and removed before bed. NicoDerm CQ patches may be worn for 24 hr if early-morning cravings for cigarettes are strong. If the patient develops insomnia or vivid dreams from NicoDerm CQ, he or she may benefit from removing the patch before bed, thus allowing only 16 hr of exposure to the nicotine.

11. The answer is A *[see* I.B.2.a, b *and* c*].*

Orlistat may alter metabolic control, necessitating a change in diabetes medication dosing regimen, however, orlistat is not contraindicated in patients with diabetes. Orlistat is dosed as 1 capsule three times daily with a fat-containing meal, but for optimal effects, it should be dosed during or within 1 hour of the meal not after the meal. It is advisable to recommend a multivitamin to individuals who will be using doses of orlistat greater than 180 mg/day or who will be using orlistat for greater than 2-3 months. However, at initiation of nonprescription strength orlistat (60 mg TID), a multivitamin has not been observed as necessary; however, it would be advisable if the individual does continue the medication past 2-3 months to recommend a MVI.

32

OTC Agents for Fever, Pain, Cough, Cold, and Allergic Rhinitis

Jennifer D. Smith

Gerald E. Schumacher

I. ANALGESIC, ANTI-INFLAMMATORY, AND ANTIPYRETIC AGENTS.

Over-the-counter (OTC) analgesics and antipyretics relieve mild to moderate pain and reduce inflammation and fever. These agents are effective for somatic pain (e.g., musculoskeletal pain in the joints; pain from headache, myalgia, and dysmenorrhea; discomfort resulting from generalized inflammation), but they are not effective in reducing discomfort from the visceral organs (e.g., stomach, lungs, heart). Salicylates and nonsteroidal anti-inflammatory drugs (NSAIDs) reduce pain, inflammation, and fever, but acetaminophen generally is effective for only pain and fever.

A. Pathogenesis of pain. Intense stimulus (e.g., tissue injury) releases substances that sensitize pain receptors to mechanical, thermal, and chemical stimulation. This triggers pain receptors to send pain impulses over afferent nerve fibers to the central nervous system (CNS).

1. Awareness of pain occurs in the thalamus.

2. Pain **recognition** and **localization** occur in the cortex.

3. Mechanism of analgesic, anti-inflammatory, and antipyretic action. These agents inhibit (centrally, peripherally, or both) the biosynthesis of various **prostaglandins,** substances involved in the development of pain and inflammation as well as in the regulation of body temperature.

B. Salicylates

1. Therapeutic uses.

a. Salicylates are used to relieve mild to moderate pain and reduce inflammation and fever.

b. Aspirin (acetylsalicylic acid), specifically, is also used to reduce the incidence of some forms of cardiovascular disease. Current evidence supports a modest reduction in the risk of strokes in women but notes less effect in men. On the other hand, evidence supports a significant reduction in the risk of myocardial infarction in men and women > 65 years but shows little effect on younger women.

c. Men and women who have had a previous myocardial infarction, stable and unstable angina pectoris, or coronary artery bypass surgery, are candidates for aspirin use.

d. No consensus has emerged on the prophylactic use of aspirin in healthy adults. The risks associated with aspirin use (see I.B.e.d) may outweigh the benefits of its widespread use.

2. Mechanism of action

a. Analgesic and anti-inflammatory actions. The action of aspirin results from both the acetyl and the salicylate portions of the drug. Actions of other salicylates

(e.g., sodium salicylate, salicylsalicylic acid, choline salicylate) result only from the salicylate portion of the agents.

(1) These drugs **inhibit cyclooxygenase,** the enzyme that is responsible for the formation of precursors of prostaglandins (PGs) and thromboxanes from arachidonic acid (Figure 32-1).

P.662

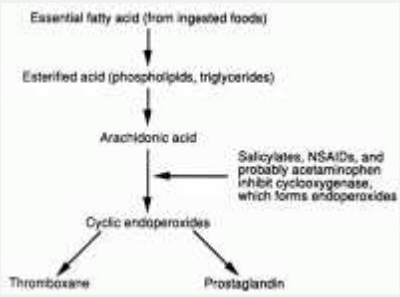

Figure 32-1. Inhibition of prostaglandin formation by aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), and acetaminophen.

(2) Analgesia is produced mainly by **blocking the peripheral generation of pain impulses** mediated by prostaglandins and other chemicals. Analgesia probably secondarily involves a reduction in the awareness of pain in the CNS.

b. Antipyretic action. The principal antipyretic action occurs in the CNS. Salicylates act on the hypothalamic heat-regulating center to produce peripheral vasodilation, which results from the inhibition of prostaglandin synthesis.

c. **Antiplatelet and antithrombotic actions**

(1) Antiplatelet. Aspirin (but not other salicylates, acetaminophen, or NSAIDs) **irreversibly inhibits cyclooxygenase in platelets,** which prevents the formation of the aggregating agent thromboxane A_2.

(2) Antithrombotic. At low doses, aspirin inhibits thromboxane A_2 formation but has a relatively small effect on prostacyclin. This results in blocking the platelet aggregating agent thromboxane A_2 while preserving the action of the aggregation inhibitor prostacyclin (prostaglandin I_2; PGI_2).

3. Administration and dosage

a. For **analgesia** or **antipyresis in adults,** 325-650 mg every 4 hr or 650-1000 mg every 6 hr should be administered as needed. The maximum daily dose is 4000 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician.

b. Child dosage depends on age. The dosages are 160 mg every 4 hr for children 2-4 years of age and 400-480 mg every 4 hr for children 9-12 years of age. Salicylates should be given for no longer than 5 days for pain, 3 days for fever, and 2 days for sore throat without consulting a physician.

c. The **antirheumatic dosage for adults** is 3600-4500 mg daily in divided doses.
d. For patients with **ischemic heart disease,** a 325-mg dose is given daily. Every other day is recommended for individuals with stable or unstable angina and evolving myocardial infarction. For patients without clinically apparent ischemic heart disease, the hemorrhagic complications associated with routine aspirin use may outweigh its benefit, unless individuals have established risk factors for atherosclerotic disease.
e. For patients at risk of stroke, an 81-mg dose is given daily or every other day. As described earlier (see I.B.3.d), the risks may outweigh the benefits.
f. Anti-inflammatory dosages. Although antipyretic and analgesic effects should appear within the first few doses, the anti-inflammatory effect may take 2 weeks or more to appear, even at high doses. The usual anti-inflammatory dosage of aspirin is 4000-6000 mg/day. The usual anti-inflammatory dosage of ibuprofen is 1200-3200 mg/day.

4. Precautions
a. Hypersensitivity to aspirin occurs in up to 0.5% of the population.
(1) Allergic reactions resulting in bronchoconstriction occur most frequently in people with **nasal polyps.**
(2) Cross-reactivity with other NSAIDs occurs in > 90% of people. Cross-reactivity with acetaminophen occurs in 5% of people.
b. Contraindications. Aspirin is contraindicated in patients with bleeding disorders or peptic ulcers. Also, aspirin should not be given to children or teenagers who have a viral illness, because Reye syndrome (i.e., fatty liver degeneration accompanied by encephalopathy) may occur.
c. **Pregnancy.** Salicylates in chronic high doses are recommended with extreme caution during the last trimester of pregnancy because of:
(1) Potential bleeding problems in the mother, fetus, or neonate
(2) Prolonging or complicating delivery
d. Gastrointestinal (GI**) disturbances** resulting from the inhibition of the gastric prostaglandins occur in 10%-20% of people at analgesic and antipyretic dosages. Anti-inflammatory regimens affect up to 40% of people. These effects decrease by using enteric-coated dosage forms and by taking salicylates with food or large doses of antacids. Buffered aspirin products contain insufficient buffers to counteract the adverse GI effects of aspirin.
e. CNS disturbances such as tinnitus, dizziness, or headache may occur at anti-inflammatory doses in some patients.
f. Salicylism (salicylate toxicity) may occur at anti-inflammatory doses. In addition to the CNS disturbances (see I.B.4.e), respiratory alkalosis, nausea, hyperthermia, confusion, and convulsions may occur.
5. Significant interactions
a. Salicylates potentiate the effect of **anticoagulants** and **thrombolytic agents.**
b. Salicylates potentiate (at anti-inflammatory doses) the effect of **hypoglycemics.**

c. Salicylates potentiate the adverse gastrointestinal reaction resulting from chronic **alcohol** or **NSAID** use.

d. Aspirin may competitively inhibit the metabolism of **zidovudine,** resulting in potentiation of zidovudine or aspirin toxicity.

e. Caffeine taken in conjunction with salicylates appears to enhance the analgesic effect.

C. Acetaminophen

1. Therapeutic uses. Acetaminophen is used to relieve mild to moderate pain and to reduce fever. Guidelines from the American College of Rheumatology now recommend it as first-line therapy for osteoarthritis of the knee and hip. Because it has minimal anti-inflammatory activity, it cannot be used to treat the swelling or stiffness resulting from rheumatoid arthritis.

2. Mechanism of action. The analgesic and antipyretic actions of acetaminophen are the same as those for aspirin (see I.B.2.a and b).

3. Administration and dosage. Available dosage forms are 325 mg and 500 mg. A prolonged-dosage-form caplet of 650 mg is also available.

a. For **analgesia** or **antipyresis in adults,** the dosage is 500-1000 mg three times daily as needed. The maximum daily dose is 4000 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician. For osteoarthritis, 1000 mg four times daily is recommended.

b. For **children age 6 years or older,** 325 mg is administered every 4-6 hr as needed. The maximum daily dose is 1600 mg for no longer than 5 days for pain, 3 days for fever, or 2 days for sore throat without consulting a physician.

c. **Routine use.** Acetaminophen is routinely used in patients who are

(1) Sensitive to the GI disturbances caused by salicylates and NSAIDs

(2) Prone to bleeding disorders

(3) Hypersensitive to salicylates

4. Precautions.

a. Patients with active alcoholism, hepatic disease, or viral hepatitis are at risk from chronic administration of acetaminophen. Toxicity is rare, but chronic daily ingestion of 5 g or more for longer than 1 month is likely to result in liver damage. Acute doses of 10 g or more are hepatotoxic.

b. Many OTC products contain acetaminophen in addition to other ingredients. It is important to counsel patients that the daily dosage limits cited in I.C.3.a and b apply to the total acetaminophen consumed from all products daily.

5. Significant interactions. Acetaminophen may competitively inhibit the metabolism of **zidovudine,** resulting in potentiation of zidovudine or acetaminophen toxicity.

D. NSAIDs. Currently, **ibuprofen, naproxen,** and **ketoprofen** are the only NSAIDs available without a prescription.

1. Therapeutic uses. NSAIDs are used to relieve mild to moderate pain and to reduce inflammation and fever. OTC drug use largely focuses on the analgesic and

antipyretic indications of these agents. Maximum OTC drug dosage is generally recommended for osteoarthritis.

2. Mechanism of action

a. Analgesic and anti-inflammatory actions. NSAIDs inhibit prostaglandin synthesis both peripherally and centrally. Like salicylates, these drugs inhibit cyclooxygenase (Figure 32-1). NSAIDs produce analgesia mainly by blocking the peripheral generation of pain impulses that are mediated by prostaglandins and other chemicals. Secondarily, analgesia probably involves a reduction in the awareness of pain in the CNS.

b. Antipyretic action. The principal antipyretic action is central. NSAIDs act on the hypothalamic heat-regulating center to produce peripheral vasodilation, which results from the inhibition of prostaglandin synthesis.

3. Administration and dosage. The available OTC dosage forms of ibuprofen are a 200-mg tablet and a 100-mg per 5-mL oral suspension. Naproxen sodium OTC is available as a 220-mg (200 mg of naproxen) tablet. Ketoprofen OTC is sold in a 12.5-mg tablet.

a. For **analgesia** or **antipyresis in adults,** the dosage of **ibuprofen** is 200-400 mg every 4-6 hr as needed. The maximum daily dose is 1200 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician. For **naproxen sodium,** the recommended dose is 220 mg every 8-12 hr as needed. The maximum daily dose is 660 mg. **Ketoprofen** is recommended as 12.5 mg every 4-6 hr as needed, with a maximum daily dose of 75 mg. The limitations on the duration of treatment without consulting a physician recommended for ibuprofen also apply to naproxen and ketoprofen.

b. For **rheumatoid arthritis dosage in adults, ibuprofen** is recommended to a maximum daily dosage of 3200 mg (administered on a 4- to 6-hr basis), **naproxen sodium** to a daily maximum of 1100 mg (divided doses every 8-12 hr), and **ketoprofen** to a maximum of 300 mg per day (administered every 4-6 hr).

c. **Naproxen sodium** and **ketoprofen** are not recommended for children < 12 years of age. **Ibuprofen** is available as a suspension for children 2-11 years of age.

4. Precautions

a. NSAIDs are contraindicated in patients with **bleeding disorders** or **peptic ulcers.**

b. NSAIDs are recommended with extreme caution during the last trimester of **pregnancy** because of:

(1) Potential adverse effects on fetal blood flow

(2) The possibility of prolonging pregnancy

c. GI **disturbances** resulting from the inhibition of the gastric prostaglandins occur in 5%-10% of people at analgesic and antipyretic doses. Anti-inflammatory regimens (i.e., higher doses) affect up to 20% of people. These effects decrease when NSAIDs are taken with food or large doses of antacids. Ibuprofen is often preferred to aspirin by patients because ibuprofen causes fewer GI disturbances and bleeding events.

d. Renal toxicity during chronic administration is a significant concern and may occur in the form of nephrotic syndrome, hyperkalemia, or interstitial nephritis.

5. Significant interactions

a. NSAIDs potentiate the effect of **anticoagulants** and **thrombolytic agents.**

b. NSAIDs potentiate (at anti-inflammatory doses) the effect of **hypoglycemics.**

c. NSAIDs potentiate the adverse GI reactions resulting from chronic **alcohol** or **salicylate** use.

d. Caffeine taken in conjunction with ibuprofen appears to enhance the analgesic effect.

e. Hypersensitivity to **aspirin** can occur with NSAID use.

f. OTC labeling for these agents cautions against use of combining NSAIDs.

P.665

II. THE COMMON COLD

A. General

1. The common cold is generally a mild and self-limiting viral infection of the upper respiratory tract, though its economic burden of lost productivity and expenditures in symptom relief has a significant impact in the United States.

2. Rather than typical epidemiologic measures, the prevalence of the common cold is expressed as the number of incidences per individual, per year. Adults typically experience 2-3 colds per year; preschool children typically experience 5-7 colds per year. Children < 5 years old who attend daycare or have frequent interactions with a number of other children may experience as many as 12 colds per year.

3. Approximately $2 billion is spent each year in the United States on OTC cough and cold medications by patients seeking symptom relief.

4. The common cold accounts for approximately 26 million days of school (people aged 5-17 years) and 23 million days of work missed annually.

B. Etiology

1. The coronaviruses, respiratory syncytial virus (RSV), and rhinoviruses are the most contributing pathogens of the common cold, and the rhinovirus is the most frequently associated pathogen. Other pathogens involved include influenza, parainfluenza, and adenoviruses.

2. Three accepted general modes of transmission of the common cold exist: small-particle aerosols, large-particle aerosols, and direct contact. Direct contact between the virus and the nasal mucosa is the most prevalent mechanism of transmission of the rhinovirus.

3. Colds occur year-round, but peak incidences of the common cold are September, October, and early spring (March and April).

C. Pathogenesis. Pathogenic events of the common cold caused by the rhinovirus begin when a small dose of virus is deposited into the nose or the eye either by direct contact or by aerosol transmission (Figure 32.2).

1. Mucociliary action transports the virus to the adenoid where the virus is able to attach to the intracellular adhesion molecule (ICAM) receptors on lymphoepithelial cells. There, the virus begins to replicate, triggering the release of inflammatory

mediators, including histamines, kinins, certain prostaglandins, and several interleukins (e.g., interleukin 1 [IL-1], IL-6, and IL-8).

2. Within 8-12 hr of viral entry into the nose or eye, the inflammatory mediators and parasympathetic nervous system reflex mechanisms lead to nasal congestion, rhinorrhea, sore throat, headache, and stimulation of cough and sneezing reflexes.

3. Cold symptoms decline and the risk of transmission of the virus is minimized after 3 days of infection.

D. Symptoms

1. Once viral contact has been made, individuals may begin to notice a scratchy throat 1-2 days after contact.

2. A sore throat is followed by a thin, watery discharge, known as rhinorrhea, and sneezing. Within 1-2 days, the thin, watery discharge may become thick and purulent.

3. A dry, nonproductive cough may develop between days 3 and 5, often evolving into a productive cough.

4. The general peak of cold symptoms is 2-4 days, and the median duration of the common cold is 7-13 days.

5. The pharmacist may recommend self-treatment for the following conditions: rhinorrhea, congestion, cough, headache, and sore throat.

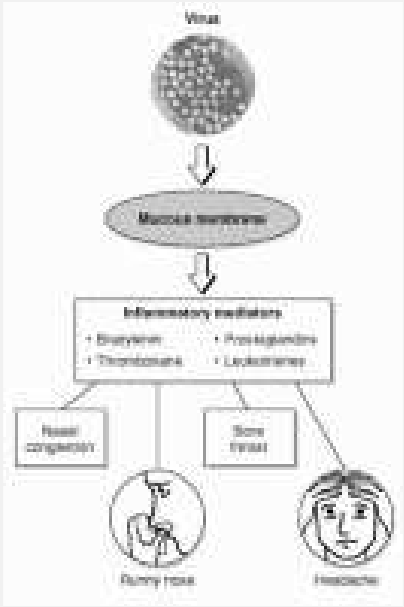

Figure 32-2. Pathogenesis of the common cold.

E. Nonpharmacologic treatment

1. Adequate fluid intake

2. Adequate rest

3. Increased humidification

4. Nasal irrigation

F. Pharmacologic treatment

1. Decongestants, also known as sympathomimetics, are the primary treatment for nasal congestion.

a. Both oral and topical decongestants produce vasoconstriction by stimulating α-adrenergic receptors, thereby reducing the volume of blood circulated to the nasal mucosa and decreasing mucosal edema.

b. Only **under the advice of a medical provider,** and **with extreme caution** should decongestants be **recommended to patients with disease states that are sensitive to adrenergic stimulation,** including coronary heart disease, hypertension, thyroid disease, diabetes, narrow-angle glaucoma, and difficulty in urination owing to an enlarged prostate gland.

c. **Patients currently taking** monoamine oxidase inhibitors (MAOIs) **or who are within 2 weeks of discontinuation should avoid the use of oral and topical decongestants** owing to an increased effect on blood pressure (Table 32-1).

d. Intranasal decongestants cause localized vasoconstriction by binding directly to adrenergic receptors. If the medication is used appropriately, systemic side effects should be minimal. However, given the difficulty of administration, systemic side effects are often seen with topical decongestants. Table 32-2 provides advice for patient counseling on device selected.
