Oxymetazoline	Afrin; Neo-Synephrine 12 hr; Vicks Sinex 12 hr; Mucinex Full Force; and Mucinex Moisture Smart	2-3 sprays q10-12h	Questionable use in hypertension or receiving MAOI *May* exacerbate: hyperthyroidism, intraocular pressure, coronary heart disease, prostatic hypertrophy	Use for only 3-5 days owing to potential for rebound congestion (rhinitis medicamentosa) Oxymetazoline is long acting *Adverse effects:* cardiovascular and CNS stimulation; burning;

				stinging; sneezing
Phenylephrine	Neo-Synephrine; Vicks Sinex	2-3 gtt q4h		Xylometazoline discontinued, but generics available Naphazoline (previously sold as Otrivin) has been removed from market, but generics may still be available
Levmetamfetamine	Vicks Vapor Inhaler	*6-12 years:* 1 inhalation, no more than every 2 hr *12+ years:* 2 inhalations, no more than every 2 hr		Does not cause rhinitis medicamentosa within a 7-day period; thus approved for up to 7-day use Lacks vasopressor effect; thus not contraindicated in patients with hypertension, thyroid disease, diabetes, narrow-angle glaucoma, or difficulty in urination owing to enlarged

				prostate
Oral decongestants				
Pseudoephedrine	Sudafed; Drixoral	*2-6 years:* 15 mg q4-6h *6-12 years:* 30 mg q4-6h *12+ years:* 60 mg q4-6h	Hypertension *May* exacerbate: hyperthyroidism, intraocular pressure, coronary heart disease, prostatic hypertrophy	Pseudoephedrine is absorbed well orally; however, phenylephrine has low oral bioavailability *Adverse effects:* cardiovascular (↑ BP, arrhythmias, tachycardia) and CNS stimulation (restlessness, insomnia, anxiety, hallucinations)
Phenylephrine	Sudafed PE	2-6y: 2.5 mg q4h 6-12y: 5 mg q4h 12 + y: 10 mg q4h		Concomitant use with TCA may affect BP (↑ or↓), depending on specific decongestant

BP, blood pressure; *CNS,* central nervous system; *MAOI,* monoamine oxidase inhibitor; *TCA,* tricyclic antidepressant.

Table 32-2. Patient Counseling Information for Nasal Decongestants

Drops	Spray (Atomizer)	Inhalers	Metered-Dose Pump (Spray)
• Blow nose • Squeeze rubber bulb on dropper and withdraw medication from bottle • Recline on bed and hang head over side (preferred) or tilt head back while standing or sitting • Place drops into each nostril and gently tilt head from side to side to	• Blow nose • Remove cap from spray container • For best results, do not shake squeeze bottle • Administer one spray with head in upright position • Sniff deeply while squeezing bottle • Wait 3-5 min, then blow nose • Administer another spray if necessary • Rinse spray tip with hot water, taking care not to allow water to	• Blow nose • Warm inhaler in hand to increase volatility of medication • Remove protective cap • Inhale medicated vapor in one nostril while closing off other nostril; repeat in other nostril • Wipe inhaler clean after each use • Replace cap immediately	• Blow nose. • Remove protective cap • Prime metered pump by depressing several times (for first use), pointing away from face • Hold bottle with thumb at base and nozzle between first and second fingers • Insert pump gently into nose with head upright • Depress pump completely, and sniff deeply • Wait 3-5 min, then

distribute drug • Keep head tilted back for several minutes after instilling drops • Rinse dropper with hot water	enter bottle • Replace cap	• *Note:* Inhaler loses its potency after 2-3 months even though aroma may linger	blow nose • Administer another spray if necessary • Rinse spray tip with hot water, taking care not to allow water to enter bottle • Replace cap

(1) Intranasal decongestants available in sprays and drops include phenylephrine and the imidazolines (oxymetazoline, naphazoline, and xylometazoline). Xylometazoline and naphazoline, previously sold under the trade names of Otrivin and Privine, respectively, have been removed from the market, but some generic formulations may be available.

(2) Intranasal decongestants approved by the U.S. Food and Drug Administration (FDA) are as follows:

(a) Ephedrine (topical): 0.5%, every 4-6 hr; not less than (NLT) age 6 years

(b) Naphazoline (topical): 0.025%-0.05%, every 4-6 hr; NLT age 12 years

(c) Phenylephrine (topical; Neo-Synephrine, Nostril)

(i) 0.25%-1%, every 4-6 hr; NLT age 6 years

(ii) 0.125%, every 4-6 hr; NLT age 2 years

(d) Xylometazoline (topical)

(i) 0.05%, every 8-10 hr; NLT age 2 years

(ii) 0.1%, every 8-10 hr; NLT age 12 years

(e) Oxymetazoline (topical; Afrin, Neo-Synephrine 12 Hour, Nostrilla, Mucinex)

(i) 0.05%, every 10-12 hr; NLT age 6 years

(ii) 0.025%, every 10-12 hr; NLT age 2 years

(3) Side effects. Topical nasal decongestants may cause a temporary burning or stinging sensation when used and may also increase nasal discharge.

(4) Counseling tips

(a) Patients using topical nasal decongestants should be cautioned to **limit use of the product to 3-5 days** to avoid rhinitis medicamentosa, a worsening of symptoms

directly related to extended use and then discontinuation of the product. Treatment of this condition is to slowly withdraw the topical decongestant and begin oral decongestants. Topical normal saline may also be used to relieve irritated nasal passages.

(b) To avoid spread of infection, patients should be counseled not to share topical nasal decongestants with others.

(5) Levmetamfetamine is an inhaler ingredient that has been deemed by the FDA as safe and effective as a nasal decongestant. It is currently found in Vick's Vapor inhalers.

(a) Dosing

(i) Ages 12 years and older: 2 inhalations in each nostril no more than every 2 hr

(ii) Ages 6-12 years: 1 inhalation in each nostril no more than every 2 hr

(b) Side effects. Levmetamfetamine lacks a vasopressor effect and, therefore, does not need to carry the warning for patients with cardiac conditions, hypertension, hyperthyroidism, diabetes, or difficulty in urination owing to an enlarged prostate gland.

(c) Counseling tips

(i) Unlike the imidazolines, levmetamfetamine has not demonstrated rebound congestion within a 7-day period; thus its use is approved for 7 days rather than carrying the 3- to 5-day limit. However, the manufacturers of the product voluntarily packaged the product with instructions to seek consultation with a provider if symptoms have not improved within 3 days.

(ii) Once opened, nasal inhalers should be discarded after 2-3 months because the active ingredient dissipates, even when the product is tightly capped.

(iii) Efficacy of this product may be diminished in the patient who has severely obstructed nasal passages because its use requires the ability of the medication to be delivered to the nasal mucosa.

e. Oral decongestants available in the United States include pseudoephedrine and phenylephrine.

(1) Phenylpropanolamine, a common ingredient found in weight-loss and cold products, was withdrawn from the market in recent years owing to an increased occurrence of stroke in certain populations (especially women).

(2) Pseudoephedrine has quickly become known in all states and communities as the key ingredient in the illegal manufacturing of methamphetamine because of the simplicity of the diversion. The sale of pseudoephedrine has been restricted, placing it behind pharmacy counters in all states.

(3) Phenylephrine is not as easily converted into methamphetamine and thus is more readily available to consumers who are seeking relief from congestion.

(4) Pseudoephedrine acts directly on both α- and β-adrenergic receptors, producing vasoconstriction of respiratory mucosa, relaxation of the bronchioles, and increased heart rate and contractility. Pseudoephedrine also enters the CNS readily.

(a) Dose

(i) Patients 2-5 years of age: 15 mg every 4-6 hr; maximum dose 60 mg/24 hr

(ii) Patients 6-12 years of age: 30 mg every 4-6 hr; maximum dose 120 mg/24 hr
(iii) Patients > 12 years of age: 30-60 mg every 4-6 hr *or* for sustained release 120 mg every 12 hr; maximum dose 240 mg/24 hr
(b) Side effects include central nervous stimulation (restlessness, insomnia, anxiety, or hallucinations), hypertension, and palpitations.
(c) Drug interactions include MAOIs (see II.F.1.c) and tricyclic antidepressants owing to an increased pressor response.
(d) Counseling tips
(i) Notify a healthcare provider if symptoms worsen or do not improve within 7 days.
(ii) Take the last dose no later than 4-6 hr before bedtime owing to the potential for insomnia.
(5) Oral **phenylephrine** is a more direct acting sympathomimetic agent than pseudoephedrine because it acts on α-adrenergic receptors and has weak action at β-adrenergic receptors. This specificity of action allows for minimized cardiovascular side

effects compared to pseudoephedrine, but such effects are still of concern when recommending its use in patients with coronary heart disease. Though data is available supporting the efficacy of topical phenylephrine, little is available to support the efficacy of oral phenylephrine. When administered orally, phenylephrine is metabolized by gut hormones, allowing only 38% of a 10 mg dose of phenylephrine to reach the nasal passages. Pseudoephedrine, when administered orally, is able to bypass these gut hormones, allowing approximately 90% of a pseudoephedrine dose to reach nasal passages. Thus, oral phenylephrine may have a cleaner cardiovascular profile than oral pseudoephedrine, but its bioavailability reduces its efficacy significantly. Phenylephrine is also an ingredient found in products for the treatment of hemorrhoids and ophthalmic preparations for relief from redness of the eye.
(a) Dose may be given every 4 hr, not to exceed six doses within 24 hr.
(i) Patients 2-5 years of age: 2.5 mg every 4 hr
(ii) Patients 6-12 years of age: 5 mg every 4 hr
(iii) Patients > 12 years of age: 10 mg every 4 hr
(b) Side effects may include increased heart rate and insomnia, though the occurrence of these effects are less than that noted with oral pseudoephedrine.
(c) Drug interactions include MAOIs (see II.F.1.c) and tricyclic antidepressants owing to an increased pressor response.
(d) Counseling tip. Notify a healthcare provider if symptoms worsen or do not improve within 7 days.
f. Nasal strips (Breathe Right) are **ideal in pregnancy, children,** and **in the elderly who take numerous medications.**
(1) Bandage like in appearance, nasal strips function to physically open the nasal passages.
(2) Some strips are available with menthol.
(3) The strip should be placed between the bridge and the tip of the nose.

(4) As the strip attempts to resume a flattened shape, the nares are pulled into a more opened state.

g. Decongestion alternatives (e.g., Coricidin HBP and its related line of products) are marketed for patients who are unable to take oral or topical nasal decongestants.

(1) Chlorpheniramine, an antihistamine, is typically the ingredient found in these products.

(2) Antihistamines are advantageous since patients may only experience minimal side effects; however, antihistamines fail to target the primary problem, which is obstruction of the nasal passages.

2. Antihistamines

a. Overview.

(1) First-generation antihistamines have been widely used in cough and cold preparations for relief from rhinorrhea and sneezing, but have no effect on nasal congestion.

(a) These agents are not FDA approved for use in children aged 2-5 years who are not under the supervision of a medical provider for such treatment. Many providers advise against treating children for rhinorrhea and sneezing with the common cold owing to the increased risk of adverse effects.

(b) The best advice to a caregiver seeking treatment of a runny nose for a child < 6 years of age is to simply let it run its course because the cold is a self-limiting viral infection.

(2) Second-generation antihistamines have not demonstrated efficacy in the common cold, attributable to the lack of substantial anticholinergic activity of these products and should, therefore, not be recommended in the patient seeking relief from the common cold (Table 32-6).

b. Common nonprescription first-generation antihistamines

(1) Brompheniramine (Dimetapp)

(a) Patients 6-12 years of age: 2 mg every 4-6 hr; maximum dose 12 mg/24 hr

(b) Patients > 12 years of age: 4 mg every 4-6 hr; maximum dose i24 mg/24 hr

(2) Chlorpheniramine (Chlor-Trimeton, Actifed) is the least sedating of the first-generation antihistamines and is considered a drug of choice in pregnancy for rhinorrhea and sneezing.

(a) Patients 6-12 years of age: 2 mg every 4-6 hr; maximum dose 12 mg/24 hr

(b) Patients > 12 years of age: 4 mg every 4-6 hr; maximum dose 24 mg/24 hr

(3) Diphenhydramine (Benadryl)

(a) Patients 6-12 years of age: 12.5-25 mg every 4-6 hr; maximum dose 150 mg/24 hr

(b) Patients > 12 years of age: 25-50 mg every 4-6 hr; maximum dose 300 mg/24 hr

(4) Dexbrompheniramine (Drixoral)

(a) Patients 6-12 years of age: 1 mg every 4-6 hr; maximum dose 6 mg/24 hr

(b) Patients > 12 years of age: 2 mg every 4-6 hours; maximum dose 12 mg/24 hr

c. **Side effects**

(1) Owing to anticholinergic properties, first-generation antihistamines may cause dry mouth (cotton mouth), blurred vision, difficulty in urination, constipation, irritability, and dizziness.

(2) Patients with narrow-angle glaucoma and benign prostatic hypertrophy should avoid first-generation antihistamines because the anticholinergic activities may exacerbate their condition.

(3) Patients taking first-generation antihistamines typically experience sedation, so caution should be taken driving or operating heavy machinery until one can identify how he or she will react to the ingredients.

(4) Though first-generation antihistamines cause sedation in the adult patient, children may experience paradoxical CNS stimulation.

3. Expectorants, also known as mucolytic agents, work to loosen sputum and thin bronchial secretions by irritating the gastric mucosa and stimulating secretions of the respiratory tract. This increases the volume of the respiratory fluid and thins mucus. Therefore, it is logical to use expectorants only to treat a productive cough. The only available expectorant is guaifenesin, approved for patients aged 2 years and older. Clinical efficacy of guaifenesin as an expectorant lacks demonstrated data. Thus some name brands, such as Robitussin, have removed guaifenesin as the active ingredient.

a. Dosing

(1) Adults

(a) Syrup: 200-400 mg every 4 hr; maximum dose 2.4 g/day

(b) Extended-release tablet: 600-1200 mg every 12 hr; maximum dose 2.4 g/day

(2) Pediatric

(a) Patients 2-5 years of age: 50-100 mg every 4 hr; maximum dose 300 mg/day

(b) Patients 6-12 years of age: 100-200 mg every 4 hr; maximum dose 1.2 g/day

b. Side effects. Guaifenesin is generally well tolerated, but side effects may include nausea and vomiting, dizziness, headache, rash, or diarrhea.

c. **Counseling tips**

(1) For enhanced efficacy in the loosening of mucus or phlegm in the lungs, patients should drink an ample amount of water when taking guaifenesin.

(2) If symptoms worsen (development of fever, rash, or unremitting headache) or no improvement is noted in 7 days, consult a medical provider.

4. Antitussives are recommended for a nonproductive cough.

a. Dextromethorphan, though a relative of morphine, is a nonnarcotic, having no analgesic or addictive properties, except in overdose. It is considered equipotent to codeine as a cough suppressant, however, data demonstrating its efficacy as a cough suppressant is lacking. Based on this lack of data, clinicians are recommending against the use of dextromethorphan as a cough suppressant, and many manufacturers are responding by either changing the active ingredient to a first generation antihistamine, which has efficacy data as a cough suppressant, or by adding the first generation antihistamine to the dextromethorphan-containing product.

(1) Dextromethorphan works centrally in the medulla to increase the cough threshold.
(2) Dosing
(a) Patients 2-5 years of age: 2.5-5 mg every 4 hr or 7.5 mg every 6-8 hr (one quarter of adult dose); maximum dose 30 mg/day
(b) Patients 6-12 years of age: 5-10 mg every 4 hr or 15 mg every 6-8 hr,; extended-release form 30 mg twice daily (half of adult dose); maximum 60 mg/day
(c) Patients > 12 years of age: 10-20 mg every 4 hr or 30 mg every 6-8 hr, extended-release form is 60 mg twice daily; maximum dose 120 mg/day

(3) Adverse effects are not generally seen at typical doses, but constipation, GI upset, abdominal discomfort, and dizziness may occur.
(4) Dextromethorphan should not be recommended for patients taking an MAOI (Nardil or Parnate) or who are within 2 weeks of discontinuation of these agents because the combination may cause serotonergic syndrome.
(5) Reports of abuse of dextromethorphan in powder form (capsules) for a euphoric effect have recently increased in the adolescent population in the United States. Though adverse effects of dextromethorphan are generally benign in recommended doses, brain damage, seizures, loss of consciousness, irregular heart beat, and death have been reported with abuse of the drug.
b. Codeine is a schedule C-V drug in a cough syrup, thus its sale may be restricted in some states.
(1) Codeine, like dextromethorphan, works centrally in the medulla to increase the cough threshold.
(2) Dosing of codeine is not recommended for children < the age of 6 years.
(a) Patients 6-12 years of age: 5-10 mg every 4-6 hr; maximum dose 60 mg/day
(b) Patients > 12 years of age: 10-20 mg every 4-6 hr; maximum dose 120 mg/day
(3) Adverse effects include drowsiness, nausea and vomiting, excitement, abdominal discomfort, or worsening/aggravation of constipation. An overdose of codeine may cause death from respiratory depression and cardiovascular collapse. Caution should be used in recommending this product for patients with pulmonary disease or shortness of breath.
c. First generation antihistamines are one of the few agents used for cough suppression that have demonstrated efficacy. For this reason, many cough formulations now contain a first generation antihistamine.
(1) As with dextromethorphan and codeine, first generation antihistamines exhibit an antitussive effect by acting centrally in the medulla to suppress the cough threshold.
(2) First generation antihistamines are not recommended in children < 6 years of age as an antitussive.
(3) Adverse effects include somnolence; sedation; and anticholinergic effects, such as dry mouth, blurred vision, difficulty in urination, and constipation.
d. Camphor and menthol are the only FDA-approved topical antitussives.

(1) Topical ointments containing 4.7%-5.3% camphor or 2.6%-2.8% menthol are FDA approved for alleviation of cough. Likewise, steam inhalants containing 6.2% camphor or 3.2% menthol are approved for use in steam vaporizers.
(2) Menthol or camphor ointment may be applied as a thick layer rubbed into the throat and chest. A warm, dry cloth may be used to cover the area. Application may be repeated up to three times daily or as directed by supervising physician.
(3) A menthol and camphor patch may be applied to the throat or chest of patients > 2 years of age. If the patient has sensitive skin, the patch may be applied to clothing covering the throat or chest, but the patch may not adhere to some types of polyester clothing. Clothing should be left loose so that vapors reach the nose and mouth. The patch should be removed and a new patch applied, if needed, up to three times daily.
(4) Menthol or camphor steam inhalants may be added directly to the water (1 tablespoon per 1 quart of water) in a hot steam vaporizer, bowl, or basin. Vapors should be breathed in. This process may be repeated up to three times daily or as directed by supervising provider.
(5) In 2002, the FDA ruled that all topical or inhalant products containing camphor or menthol must warn patients that their use near a flame, in hot water, or in a microwave oven may cause the products to splatter and cause serious burns to the user.
(6) Menthol (5-10 mg) is also effective as an antitussive available in oral lozenges or compressed tablets. Menthol stimulates cold sensory receptors, producing a sensation of coolness and a local anesthetic effect on the respiratory passageways, thus engendering a soothing, antitussive effect.
5. Intranasal normal saline, available in drops and sprays, may be used to moisten nasal membranes and assist in the removal of encrusted secretions.
a. Typical use of most intranasal normal saline products is 2-3 sprays in each nostril as needed.

b. Some products may be used as a spray when held upright, or as drops when held upside down.
c. Intranasal normal saline may be recommended for use in all patients, including infants and pregnant women, unless directed otherwise by a physician.
6. Local anesthetics in the form of lozenges and sprays may be useful in the alleviation of a sore throat. Mouthwashes have been recommended for use in the past; however, owing to localized action in the oral cavity, the pharyngeal wall may not be affected by these products.
a. Because a sore throat is the initial symptom of many other illnesses, care should be taken to recommend products for sore throat alleviation only to patients who have concurrent symptoms of the common cold. If the throat is red and inflamed, unusually painful, or has persisted for several days, the patient should be referred to a primary-care provider for further evaluation.

b. Throat sprays containing phenol (Chloraseptic) are approved down to age 2 and those containing benzocaine (Cepacol) are approved down to age 3.
c. Throat lozenges, approved for patients older than 2 years, may be used every 2 hr. Counsel caregivers that lozenges are potential choking hazards in young children.
7. Analgesics are occasionally indicated in the treatment of common cold symptoms when sore throat, myalgia, and/or headache exist. Aspirin, acetaminophen, ibuprofen, or naproxen sodium may be recommended, with consideration given to patient allergies, concurrent medications and disease states, and age.
8. Combination products
a. Numerous products are available that contain various combinations of antihistamines, decongestants, analgesics, expectorants, and antitussives. Certain product name designations help identify the ingredients.
(1) *Nighttime* and *P.M.* usually signify that the product contains diphenhydramine, chlorpheniramine, or doxylamine.
(2) *Sinus* usually signifies a decongestant (e.g., pseudoephedrine, phenylephrine) and/or an analgesic (e.g., acetaminophen).
(3) *Cough* usually signifies that the product contains dextromethorphan, but some also contain guaifenesin in combination with dextromethorphan.
(4) *Nondrowsy, A.M.,* and *daytime* usually indicate that the product contains a decongestant (e.g., pseudoephedrine, phenylephrine) and typically does not contain an antihistamine.
(5) *Allergy* signifies that the product contains an antihistamine.
(6) *Cold* and *flu* indicate that the product may contain any combination of ingredients, including a decongestant, antihistamine, cough suppressant, and/or antipyretic.
b. Combination products may be useful for simplicity of dosing and adherence if patients are experiencing a variety of symptoms that can be alleviated by one product. For example, if a patient has a dry, hacking, nonproductive cough, headache, and nasal congestion, he or she may benefit from a combination product of dextromethorphan, acetaminophen, and pseudoephedrine. However, it would be a shotgun approach to recommend a product containing an antihistamine and expectorant in combination with other ingredients for this patient.
c. Disadvantages to combination products occur when previously treated symptoms resolve, but the patient continues to treat other symptoms with the same product. This adds unnecessary medication(s) to the regimen, increasing the risk of adverse events. Combination products can also be difficult to recommend when selecting the appropriate product for patients with coexisting medical conditions.
9. Complementary therapy
a. Zinc gluconate's effects on the duration or severity of the common cold have been studied. Results have been mixed, lending to what remains a controversial subject.
(1) Current literature describes several possible mechanisms by which zinc may exert its effect, but such means remain unclear.

(2) Despite its controversial use, a number of zinc products have been formulated, including tablets, capsules, chewing gums, lozenges, nasal gels, nasal sprays, and nasal swabs.
P.674

(3) In studies showing the efficacy of zinc, formulations were begun within 24-48 hr of the onset of symptoms. Lozenges are recommended every 2 hr for the duration of the cold, and the nasal spray is recommended four times daily.
(4) Side effects reported with products containing zinc include nausea, GI upset, and unpleasant taste.
b. Vitamin C. Only a small number of studies have demonstrated the ability of vitamin C (dose > 1 g per day) to reduce the frequency or severity of the common cold. The clinical significance of the results of these studies remains questionable.
c. Echinacea has been used as a popular remedy for the common cold since the late 1800s. Unfortunately, current literature does not give definitive supportive evidence for the efficacy of Echinacea in the prevention and/or treatment of the common cold.
(1) Obstacles in studying echinacea lie in the fact that three different species of *Echinacea* exist, each with a different phytochemical composition. The composition may further be altered, depending on the part of the plant used and the time of year the plant is harvested.
(2) Current literature suggests that for echinacea to retain an immunostimulant effect, it should not be taken for longer than 2-3 weeks at a time.
G. Exclusions to self-treatment of the common cold
1. Fever > 101.5°F
2. Chest pain
3. Shortness of breath
4. Worsening of symptoms or development of additional symptoms
5. Concurrent underlying chronic cardiopulmonary diseases
6. AIDS or chronic immunosuppressant therapy
7. Frail patients of advanced age

III. ALLERGIC RHINITIS

A. Introduction. Rhinitis is an inflammation of nasal membranes, characterized by the four cardinal symptoms: nasal congestion, rhinorrhea, sneezing, and nasal itching.
1. Between 20 and 40 million people in the United States are affected by allergic rhinitis: 10-30% of the adult population and 40% of children. Allergic rhinitis typically develops before age 20, but its frequency increases with age until adulthood.
2. Treatment expenditures for allergic rhinitis and loss of productivity owing to absence from work or school are reported to be slightly over $5 billion.
3. Risk factors for allergic rhinitis include the following:
a. Family history of atopy
b. Higher socioeconomic class

c. Exposure to indoor allergens (animals and dust mites)

d. Positive allergy skin prick test

4. Allergic rhinitis may be classified as seasonal, perennial, episodic, or occupational. Seasonal and perennial, or a combination of the two, are the most frequent classifications.

a. Seasonal allergic rhinitis. Symptoms may occur with repetitive and predictable seasonal symptoms.

b. Perennial allergic rhinitis. Symptoms persist throughout the year without regard to changes in seasons.

c. Combination seasonal and perennial allergic rhinitis. Symptoms persist throughout the year with seasonal exacerbations.

B. Etiology. There are five main triggers for allergic rhinitis: pollens, molds, dust mites, animal allergens, and insect allergens. These allergens trigger an immunoglobulin E (IgE) mediated immunological reaction.

1. Seasonal allergic rhinitis is typically caused by pollens and molds.

2. Perennial allergic rhinitis is typically caused by dust mites, molds, and animal allergens.

C. Pathogenesis. Patients become sensitized to allergens; on subsequent exposure, the allergens trigger a genetically predetermined immune response that results in the symptoms of allergic rhinitis. Allergic rhinitis may then be characterized by early- or late-phase responses.

1. Early-phase response

a. Reexposure to the allergen triggers mast cells and eosinophils to generate inflammatory mediators (e.g., PGD_2 and leukotrienes) and release preformed mediators (e.g., histamine, tryptase, chymase, and kininogenase).

b. Generation and release of the inflammatory mediators results in increased vascular permeability, mucosal edema, and watery rhinorrhea. Dilated blood vessels cause sinusoidal filling and the subsequent nasal congestion.

c. Sensory nerves are stimulated, engendering a sensation of nasal itch, and thus sneezing.

2. Late-phase response

(a) Mast-cell-derived mediators lead to a migration and activation of eosinophils, neutrophils, and basophils, T lymphocytes, and macrophages within the nasal mucosa.

b. During the 4-8 hr after allergen exposure, these cells become activated and release inflammatory mediators, providing reoccurrence of initial symptoms, with the predominant symptom of congestion.

D. Signs and symptoms. The four classic symptoms of allergic rhinitis include rhinorrhea, nasal congestion, sneezing, and nasal pruritus. Nasal pruritus is typically not a symptom of the common cold. Because children often cannot verbalize the symptoms of allergic rhinitis, it is important to recognize the signs.

1. Repercussions of nasal pruritus include the following:

a. Gothic arch, a steady upward movement of the upper lip and teeth which may result in an overbite, as a result of the “allergic salute,” characterized by the constant upward rubbing of the nose with the palm of the hand.
b. Allergic crease: a visible transverse line appearing between the tip and the bridge of the nose, caused by constant rubbing.
2. Ophthalmic conditions present in the individual with allergic rhinitis include allergic shiners, a darkening of the lower eyelid attributable to chronic nasal obstruction, and Morgan lines (also known as the Dennie sign), which are seen as pleats under the eyes, running parallel to the lower eyelid margins.
3. Individuals with allergic rhinitis may also experience fatigue, irritability, and malaise. Owing to these symptoms, allergic rhinitis may be a contributing factor to poor schoolwork in children afflicted by this condition.
E. Treatment. The primary goal in the treatment of allergic rhinitis is to control the symptoms without altering the patient's ability to function. Treatment options include environmental control, nonprescription pharmacologic treatment, and prescription treatment. This section focuses on environmental control and nonprescription treatment (Tables 32-3 and 32-4).
1. The best treatment remains avoidance of the allergen(s), once determined, though this is sometimes impractical. Environmental controls directed toward particular allergens can be the first initiative toward resolution of symptoms.
2. Antihistamines, both first and second generation, are the mainstay of treatment for allergic rhinitis.
a. First-generation antihistamines are limited in continuous treatment of allergic rhinitis owing to their frequent dosing and related sedation. These agents remain the least expensive treatment option at this time; however, this aspect must be weighed against the ability to remain alert for work and school activities.
(1) Owing to their lipophilicity, first-generation antihistamines easily cross the blood-brain barrier, causing significant sedation. Though patients may not notice sedation, studies have clearly demonstrated a reduction in intellectual and motor function in patients taking first-generation antihistamines.

Table 32-3. Environmental Control Measures for Indoor and Outdoor Allergens

Allergen	Environmental Control Measure
	Indoor
Dust Mites	Encase bedding *or* wash at least weekly in hot (130°F) water
	Remove carpets (especially in bedrooms)
	Remove upholstered furniture
	Remove stuffed animals from home that cannot be laundered
Animal Dander	Avoid pets with fur if established allergen
	Some patients are allergic to long-haired dogs but are not affected by shorthaired breeds
Cockroaches	Use of pesticides or professional extermination
Mold	Check houseplants often for mold growth; move outdoors if source of problem
	Use of HEPA filter
	Lower household humidity
	Vent food preparation areas and bathrooms
	Repair damp basements and crawl spaces
	Apply fungicide to obvious molded areas
	Outdoor
Pollen	Avoid outdoor activities when pollen counts are high

	Close house and car windows
	HEPA filters

HEPA, high-efficiency particulate air.

(2) Children and the elderly are most susceptible to the adverse effects of antihistamines; thus they are at increased risk of experiencing nightmares, anxiety, restlessness, unusual excitement, or irritability.

b. Second-generation antihistamines are advantageous because of their preferential peripheral H_1-receptor binding. This allows for minimal CNS effects, minimal sedative effects, and minimal anticholinergic activity.

3. Oral decongestants are effective in relieving symptoms of nasal congestion but have no effect on other symptoms of allergic rhinitis, such as rhinorrhea, pruritus, or sneezing.

a. Because treatment of allergic rhinitis is for extended periods of time, oral decongestants should be used for nasal congestion rather than topical decongestants owing to the potential for rhinitis medicamentosa.

b. The combination of a decongestant and an antihistamine has proven to be an optimal treatment regimen for allergic rhinitis.

c. Consideration must be taken into account when recommending products containing pseudoephedrine to adolescents and adults participating in sports programs, because of the “doping” effect of these agents.

4. Ocular antihistamines may be used for the treatment of ophthalmic conditions associated with allergic rhinitis, though their use has been classified by the FDA as less than effective owing to a lack of data demonstrating clinical effectiveness.

a. Currently there are three ocular antihistamines available on the market: pheniramine, antazoline, and ketotifen. Pheniramine and antazoline are only available in combination with naphazoline (a decongestant). Ketotifen (Zaditor) became available as a nonprescription product in 2007 and is the only available ocular antihistamine that does not contain a decongestant.

b. Avoid the use of ocular antihistamines in glaucoma, as pupil dilation may cause angle-closure glaucoma.

c. Side effects may include burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation.

5. Cromolyn sodium (e.g., Nasalcrom) is best used as a preventive measure for the symptoms of allergic rhinitis but may also be used as treatment for all symptoms

except nasal congestion. However, maximum benefit, when used as treatment, will not be seen for 1-2 weeks. When used for prevention, cromolyn sodium should be initiated approximately 1 week before allergen contact.

Table 32-4. OTC **Treatment of Allergic Rhinitis**

Agent	Product(s)	Dosing	Avoid Use In …	Comments/Counseling Points
Nonsedating (second-generation) antihistamine				
Loratadine	Claritin Alavert Tavist ND Triaminic AllerChews	*2-6 years:* 5 mg q24h *6+ years:* 10 mg q24h		No anticholinergic activity Penetrates poorly into CNS; free of sedating effects at usual doses Liver/kidney disease may need lower dosage
Cetirizine	Zyrtec	*2-5 years:* 2.5-5 mg qd *5+ years:* 5-10 mg qd		No anticholinergic activity May cause CNS depression Liver/kidney disease may need lower dosage
Sedating (first-generation) antihistamines				
Chlorpheniramine	Chlor-Trimeton	*2-6 year*	Narrow-angle	Largest side effect is

	, Actifed	*s:* 1mg q4-6h *6-12 years:* 2 mg q4-6h *12+ years:* 4 mg q4-6h	glaucoma MAOI use Prostatic hypertrophy Use caution in emphysema and chronic bronchitis	drowsiness, followed by typical anticholinergic side effects Phenindamine may cause nervousness and insomnia Children and elderly may experience paradoxical stimulation Older adults are likely to have CNS depressive side effects, including confusion and hypotension *Photosensitizing:* Advise patients to wear sunscreen and protective clothing Chlorpheniramine is least sedating and is antihistamine of choice during pregnancy
Diphenhydramine	Benadryl	*2-6 years:* 12.5-25 mg q4-6h *12+ year*		

		s: 25-50 mg q4-6h		
Brompheniramine	Dimetapp	*6-12 years:* 2 mg q4-6h *12+ years:* 4 mg q4-6h		
Phenindamine	Nolahist	*6-12 years:* 12.5 mg q4-6h *12+ years:* 25mg q4-6h		
Dexbrompheniramine	Drixoral	*6-12 years:* 1 mg q4-6h *12+ years:* 2		

		mg q4-6h		
Ocular antihistamines (in combination with naphazoline)				
Pheniramine	Naphcon A Opcon-A Visine-A	1-2 gtt TID-QID	Narrow-angle glaucoma: pupil dilation can cause angle-closure glaucoma	*Side effects:* burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation
Antazoline	Vasocon A	1-2 gtt TID-QID		
Ocular Antihistamines				
Ketotifen	Zaditor	1-2 gtts BID	Narrow-angle glaucoma: pupil dilation can cause angle-closure glaucoma	*Side effects:* burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation
Mast cell stabilizer				
Cromolyn sodium	Nasalcrom	*6+ years:* 1 spray in each nostril 3-6 times		Most efficacious if started before seasonal symptoms May take 3-7 days for initial response and 2-4 weeks for maximal response

		daily		*Side effects:* sneezing, nasal stinging, burning Drug of choice in pregnancy for sneezing and rhinorrhea

CNS, central nervous system; *MAOI,* monoamine oxidase inhibitor.

P.679

a. Cromolyn sodium has a short duration of action and, therefore, must be dosed three to four times daily. This frequency in dosing may result in diminished adherence.

b. Cromolyn sodium is approved for use in patients 2 years of age and older and should be dosed as one spray in each nostril three to four times daily. It should not be used more than six times daily. A provider should be consulted if symptoms worsen or no improvement is seen within 2 weeks.

c. Adverse effects may include a brief stinging or sneezing directly after administration.

d. Cromolyn sodium is considered a preferred initial drug of choice during pregnancy for rhinorrhea and sneezing.

F. Exclusions to self-treatment of allergic rhinitis

1. Symptoms of otitis media or sinusitis

2. Symptoms that suggest lower-respiratory tract problems

3. History of nonallergic rhinitis

P.680

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which statement concerning the use of over-the-counter (OTC**) analgesic agents is true?**

(A) Aspirin is indicated for mild to moderate analgesia, inflammatory diseases, antipyresis, and prophylaxis for patients with ischemic heart disease.

(B) Ibuprofen is indicated for mild to moderate analgesia, reduction of fever, and prophylaxis for patients with ischemic heart disease but not for inflammatory disorders.
(C) Acetaminophen is indicated for mild to moderate analgesia but not for reduction of fever and arthritis.
(D) Naproxen sodium is indicated for mild to moderate analgesia, antipyresis, and prophylaxis for patients with ischemic heart disease.

View Answer***1. The answer is A[see].*****2. Which statement concerning drug interactions with over-the-counter (**OTC**) analgesic agents is true?**
(A) Aspirin potentiates the effects of antihypertensives, cardiac glycosides, and anticoagulants.
(B) Ibuprofen potentiates the effect of zidovudine, hypoglycemics, and aminoglycosides.
(C) Acetaminophen potentiates the effect of zidovudine.
(D) For naproxen sodium, the OTC dosage recommendations are similar to the prescription dosage.

View Answer***2. The answer is C[see].*****3. All of the following statements concerning contraindications with *chronic* use of over-the-counter (**OTC**) analgesic agents are correct *except* which one?**
(A) Aspirin, ibuprofen, naproxen sodium, and ketoprofen are contraindicated in patients with bleeding disorders, peptic ulcer, and the third trimester of pregnancy.
(B) Aspirin, acetaminophen, and ibuprofen are implicated in Reye syndrome.
(C) Acetaminophen is contraindicated in patients with active alcoholism, hepatic disease, or viral hepatitis.

View Answer***3. The answer is B[see].*****4. Which statement concerning dosage recommendations for over-the-counter (**OTC**) analgesic agents is true?**
(A) Aspirin for analgesia or antipyresis in adults is 325-650 mg every 4 hr or 650-1000 mg every 6 hr, with a maximum daily dose of 4000 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician; the antirheumatic dosage for adults is 3600-4500 mg daily in divided doses; and patients with ischemic heart disease should take 325 mg daily or every other day.
(B) Ibuprofen for analgesia or antipyresis in adults is 300-600 mg every 6-8 hr, with a maximum daily dose of 1800 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician; the anti-inflammatory dosage for adults is 1800-3600 mg daily in divided doses.
(C) Acetaminophen for analgesia or antipyresis in adults is 325 mg every 8-12 hr, with a maximum daily dose of 2000 mg for no longer than 10 days for pain and 3 days for fever without consulting a physician; patients with ischemic heart disease take 325 mg daily or every other day.

View Answer***4. The answer is A[see].*****5. Which of the following is an inhaler ingredient deemed safe and effective as a nasal decongestant?**
(A) oxymetazoline
(B) phenylephrine
(C) levmetamfetamine
(D) ephedrine

View Answer***5. The answer is C[see II.F.1.a.(2)].*****6. Alice is 27 years old and in the first trimester of her pregnancy. She needs a recommendation for sneezing, rhinorrhea, and nasal itching, which started 2 days ago. She feels miserable with her symptoms, which worsen when she cleans the house. Her current medications include calcium carbonate and docusate sodium. Which of the following would be the *best* recommendation for Alice's symptoms?**

(A) chlorpheniramine

(B) pseudoephedrine

(C) Breathe Right Nasal Strips

(D) intranasal cromolyn

View Answer***6. The answer is A[see].***P.681

7. John is a 48 year old male interstate truck driver with a chief complaint of a dry, hacking cough. He states the cough started yesterday, but he has not had any fever, chills, sore throat, or congestion. His only medical condition is hypertension, which is controlled with hydrochlorothiazide (HCTZ). What would be the *best* recommendation for John's cough?

(A) dextromethorphan

(B) codeine

(C) diphenhydramine

(D) guaifenesin

View Answer***7. The answer is A[seeand].*****8. The appropriate dose of pseudoephedrine for a 3-year-old child is**

(A) 2.5 mg q4-6h.

(B) 5 mg q4-6h.

(C) 15 mg q4-6h.

(D) 30 mg q4-6h.

View Answer***8. The answer is C[see II.F.1.b.(1).(a)].*****For questions 9-10:**

JB, a 42-year-old white male, complains of a scratchy throat, nasal congestion, and a cough that started 2 days ago. When he coughs, he brings up yellow-white phlegm. He has hypertension and dyslipidemia.

9. Which of the following would be the *best* recommendation for JB's cough?

(A) codeine

(B) dextromethorphan

(C) diphenhydramine

(D) guaifenesin

View Answer***9. The answer is D[see].*****10. Which of the following would be the *most* appropriate over-the-counter (OTC) product for JB's nasal congestion?**

(A) pseudoephedrine

(B) phenylephrine

(C) oxymetazoline

(D) levmetamfetamine

View Answer***10. The answer is D[seeand].*****11. SO, a 22-year-old female, asks for a recommendation for sneezing, watery and itchy eyes, and a runny nose. She has no significant medical history. She is in the midst of final exams and must remain alert. What would be the *best* recommendation for SO?**

(A) Alavert

(B) Benadryl

(C) Dimetapp

(D) Drixoral

View Answer***11. The answer is A[seeand].***P.682

ANSWERS AND EXPLANATIONS

1. The answer is A *[see* I.B*].*

Aspirin is the only analgesic agent with an approved labeling for analgesia, antipyresis, inflammation, and prophylaxis for ischemic heart disease.

2. The answer is C *[see* I.C*].*

Acetaminophen may competitively inhibit the metabolism of zidovudine, resulting in potentiation of zidovudine or acetaminophen toxicity. As for the other choices, OTC dosage levels are generally one half the prescription dosage; aspirin is not commonly recognized to interact with antihypertensives or cardiac glycosides; nor is acetaminophen expected to interact with aminoglycosides.

3. The answer is B *[see* I.B.4.b*].*

Aspirin is the only analgesic agent associated with the development of Reye syndrome.

4. The answer is A *[see* I.B.3; I.C.3; I.D.3*].*

The aspirin dosage OTC recommendations are correct; the levels for acetaminophen are too low, and for ibuprofen, too high. In addition, acetaminophen does not carry an ischemic heart disease prophylaxis recommendation.

5. The answer is C *[see II.F.1.a.(2)].*

Levmetamfetamine is an inhaler ingredient that has been deemed by the FDA as safe and effective as a nasal decongestant. It is currently found in Vicks Vapor Inhaler. Oxymetazoline, ephedrine, and phenylephrine are topical nasal decongestants found in pumps and drops, but not in inhalers.

6. The answer is A *[see* II.F.2.b.(2); III.E.5.d*].*

Rhinorrhea, sneezing, and nasal itching are symptoms of allergic rhinitis, differentiated from the common cold by the nasal itching. Pseudoephedrine and Breathe Right Nasal Strips are indicated for nasal congestion, which she does not have. Both chlorpheniramine and intranasal cromolyn sodium are recommended treatments for the relief of sneezing and rhinorrhea in pregnancy. However, this patient needs relief from symptoms now. Cromolyn sodium may be used for treatment, but will take 1-2 weeks for noticeable symptom improvement. Chlorpheniramine will produce symptom improvement within hours.

7. The answer is A *[see* II.F.3 *and* 4*].*

The complaint is a dry, hacking cough, warranting the use of an antitussive rather than an expectorant (e.g., guaifenesin). Dextromethorphan, diphenhydramine, and codeine are all antitussives used for relief of a dry, hacking cough. However, the patient in question is an interstate truck driver and codeine and diphenhydramine will both cause sedation. In addition, codeine may be a limited option due to its restricted sale in some states and the potential for allergic reactions. Dextromethorphan has minimal adverse effects when used at recommended doses and may provide some relief. It is also prudent to advise this patient that symptoms of the common cold will resolve in time without treatment.

8. The answer is C *[see II.F.1.b.(1).(a)].*

Pseudoephedrine should be dosed as 15 mg every 4-6 hr up to a maximum of 60 mg in 24 hr for patients 2-5 years of age. Patients aged 6-12 years may be safely recommended 30 mg every 4-6 hr, with a maximum recommended dose of 120 mg in 24 hr. Pseudoephedrine is not recommended for children < 2 years of age, unless under medical advice.

9. The answer is D *[see* II.F.3*].*

The patient is experiencing a productive cough, as noted by the yellow-white phlegm. An expectorant is the best agent for relief of a productive cough. The only available expectorant is guaifenesin, which works to loosen sputum and to thin bronchial secretions by irritating the gastric mucosa and stimulates secretions of the respiratory tract.

10. The answer is D *[see* II.F.1.a *and* b*].*

Pseudoephedrine is an oral decongestant, whereas phenylephrine can be found as an active ingredient in oral and topical products for nasal congestion. Oxymetazoline and levmetamfetamine are topical decongestants. Pseudoephedrine, phenylephrine, and oxymetazoline should be used cautiously in the patient with hypertension or diabetes, despite adequate control, owing to stimulation of adrenergic receptors. Levmetamfetamine lacks a vasopressor effect and, therefore, does not need to carry the warning for patients with cardiac conditions, hypertension, or diabetes.

11. The answer is A *[see* II.F.2.b *and* c; III.E.2*].*

The active ingredient in Alavert is loratadine, a second-generation antihistamine. Benadryl, Dimetapp, and Drixoral all contain first-generation antihistamines as the active ingredient. Though the least expensive treatment option, the use of first-generation antihistamines is limited owing to significant sedation. Studies have clearly demonstrated a reduction in intellectual and motor function in patients taking first-generation antihistamines. Second-generation antihistamines are advantageous because their preference for peripheral H_1-receptor binding. This allows for minimal CNS effects, sedative effects, and anticholinergic activity.

OTC Agents for Constipation, Diarrhea, Hemorrhoids, and Heartburn

Laura K. Williford Owens

I. CONSTIPATION

A. General information

1. Definition. Constipation is defined as a decrease in the frequency of fecal elimination and is characterized by the passage of hard, dry, and sometimes painful stools. Normal stool frequency ranges from three times daily to three times per week. Patients may experience abdominal bloating, headaches, low back pain, and/or a sense of rectal fullness from incomplete evacuation of feces.

2. Epidemiology

a. Age. Constipation is common in all age groups, however; there is a higher prevalence in people > 65 years of age.

b. Gender. Women suffer from constipation more often than men.

3. Causes. Constipation can be caused by many factors, including the following:

a. Diet

(1) Insufficient dietary fiber

(2) Inadequate fluid intake

b. Lack of exercise

c. **Poor bowel habits,** such as failure to respond to the defecatory urge or hurried bowels (i.e., incomplete evacuation)

d. Medications, such as narcotic analgesics, diuretics, or anticholinergics (e.g., antidepressants, antihypertensives, antihistamines, phenothiazines, antispasmodics). In addition, nonprescription medications such as iron supplements, calcium- or aluminum-containing antacids, nonprescription NSAIDs, and histamine-2 receptor antagonists (H_2RAs) (i.e., ranitidine) may contribute to constipation.

e. Pregnancy is a common contributor to constipation. The increased size of the uterus, hormonal changes, intake of calcium- and iron-containing prenatal vitamins, and a reduction in physical activity are all considered contributing factors.

f. Organic problems, such as intestinal obstruction, tumor, inflammatory bowel disease, diverticulitis, hypothyroidism, hyperglycemia, irritable bowel syndrome, cerebrovascular disease, or Parkinson disease

4. Practitioners should question the patient about the following:

a. Normal stool frequency

b. Duration of the constipation

c. Frequency of constipation episodes

d. Exercise routine

e. Amount of dietary fiber consumed and fluid intake

f. Presence of other symptoms

g. Current medications

h. Medications used to relieve constipation and their effectiveness

B. Treatment

1. Nonpharmacological

a. Increase intake of fluids (at least eight 8-oz. servings of noncaffeinated fluids daily) and fiber (e.g., whole-grain breads and cereals, beans, prunes, raisins, peas, carrots, corn).

b. Increase exercise to increase and maintain bowel tone.

c. Bowel training to increase regularity (i.e. allowing regular and adequate time for defecation).

2. Pharmacological. Therapeutic agents are classified according to their mechanism of action. Refer patients taking prescription medications that might cause constipation to their provider. Laxatives should not be taken if symptoms of appendicitis are present (i.e. nausea, vomiting, or abdominal pain).

a. Bulk-forming laxatives. These medications are natural or synthetic polysaccharide derivatives that adsorb water to soften the stool and increase bulk, which stimulates peristalsis. Bulk-forming laxatives work in both the small and the large intestines. The onset of action of these agents is slow (12-24 hr and up to 72 hr), which is why they are best used to prevent constipation rather than to treat severe acute constipation.

(1) Administration guidelines. All bulk-forming agents must be given with at least 8 oz. of water to minimize the possible esophagus, stomach, small intestine, and colon obstruction experienced by some patients. Some bulk-forming laxatives may contain sugar, so patients with diabetes should use sugar-free products.

(2) Adverse effects. Abdominal cramping and flatulence are the most common adverse effects experienced by patients.

(3) Warnings

(a) Bulk-forming agents should not be used if patients have an obstructing bowel lesion, intestinal strictures, or Crohn's disease because they can make this situation worse and possibly result in bowel perforation.

(b) Do not recommend sugar-free bulk-forming agents to patients with phenylketonuria.

(c) Patients should be advised not to use bulk-forming laxatives for more than 1 week to treat constipation; however, they can be used on a long-term basis for prevention.

(4) Natural bulk-forming laxatives

(a) Psyllium (e.g., Metamucil, Konsyl-D, Fiberall, Perdiem Fiber Granules). Adults: 3.5 g (1 rounded teaspoon) in 8 oz. of water one to three times per day; children: half the adult dosage one to three times per day

(b) Malt soup extract (e.g., Maltsupex). Adults: 8-16 g (1-2 scoops) two to four times per day; children: 16 g one to two times per day

(5) Synthetic bulk-forming laxatives

(a) Methylcellulose (e.g., Citrucel). Adults: 1-2 g (1 tablespoon) one to three times per day; children: 0.5 g one to three times per day

(b) Polycarbophil (e.g., Konsyl Fiber, Fiber Con, FiberCon Mitrolan). Adults: 1 g (2 tablets) one to four times per day; children: 0.5 g one to three times per day. Calcium polycarbophil may impair the absorption of tetracyclines if the drugs are taken concurrently.

b. Saline and **osmotic laxatives** work by creating an osmotic gradient to pull water into the small and large intestines. This increased volume results in distention of the intestinal lumen, causing increased peristalsis and bowel motility. These laxatives also increase the activity of cholecystokinin-pancreozymin, which is an enzyme that increases the secretion of fluids into the gastrointestinal (GI) tract. The **onset of action** depends on the ingredient and dosage form. Rectal formulations (e.g., enemas, suppositories) have an onset of action of 5-30 min, whereas oral preparations work within 3-6 hr.

(1) Administration guidelines. Patients should be advised to consume 8 oz. of water with each dose to prevent possible dehydration.

(2) Adverse effects. Diarrhea and abdominal cramping are common adverse effects. Less common adverse effects include excessive diuresis, nausea, vomiting, and dehydration.

(3) Warnings

(a) Patients with hypertension or congestive heart failure should not receive saline laxatives on a prolonged basis owing to fluid retention from sodium absorption.

(b) Patients with severe kidney disease should not use products containing magnesium unless advised by a physician.

(4) Saline laxatives include sodium and magnesium salts. As much as 20% of magnesium may be absorbed from these products, which may lead to hypermagnesemia in patients with preexisting renal impairment. Products include the following:

(a) Magnesium citrate (e.g., Magnesia Citrate). Adults: one full bottle; children 6-12 years of age: one third to one half bottle. Advise patients to refrigerate to increase palatability and help prevent crystallization.

(b) Magnesium hydroxide (e.g., Phillips' Milk of Magnesia, Phillips Caplets, and Freelax Caplets). Adults: 30-60 mL or 2-4 caplets daily; children 6-12 years of age: 15-30 mL; children 2-5 years of age: 5-15 mL

(c) Magnesium sulfate (e.g., Epsom salt). Adults: 10-30 g in 8 oz. of water; children 6-12 years of age: 5-10 g

(d) Sodium phosphate (e.g., Fleet Phospho-Soda). Adults: 20-45 mL; children 6-12 years of age: 5-20 mL

(5) Osmotic laxatives

(a) Glycerin is available in rectal products in suppository or enema form (e.g., Fleet Babylax).

(i) The only safe and effective use of glycerin is rectal. Rectal burning may occur with glycerin products. In addition to the osmotic effect, sodium stearate in these products can produce a local irritant effect.

(ii) Adults: 3 g in suppository form or 5-15 mL as an enema; children ≥ 6 years of age: 1-1.5 g in suppository form or 2-5 mL as an enema

(b) Lactulose (e.g., Chronulac, Enulose) is available only by prescription and is used to decrease blood ammonia levels in hepatic encephalopathy.

(i) It may cause flatulence and cramping and should be taken with fruit juice, water, or milk to increase the palatability. Onset of action is 24-48 hr.

(ii) Adults: 15-30 mL one to two times daily; children: 7.5 mL once daily, usually given after breakfast

(c) Sorbitol, a nonabsorbable sugar, is similar in efficacy to lactulose, which can be administered orally (70% solution) or rectally (25% solution).

(i) The **adverse effects** are the same as for lactulose and include flatulence, cramping, and abdominal pain over the first few days.

(ii) Adults: 30-150 mL orally (70% solution) or 120 mL rectally (25% solution); children 2-11 years of age: 15 mL orally (70% solution) or 30-60 mL of a rectal solution (25%)

(d) Polyethylene glycol 3350 (Miralax). In October 2006, the FDA switched Miralax to OTC status for the relief of occasional constipation. It can be used as an alternative to other osmotic laxatives and it is approved for patients 17 years of age or older.

(i) It has been shown to be more effective than lactulose in short-term trials with less abdominal cramping. Miralax typically produces a bowel movement in 1 to 3 days.

(ii) Adult dosage: 17 g (fill to top in white section of cap) dissolved in any 4-8 oz. of beverage (water, juice, cola, or tea) and drink once daily for up to 7 days. The beverage can be cold, hot, or room temperature.

(iii) Adverse effects: High doses of Miralax can cause diarrhea, excessive stool frequency, nausea, bloating, cramping, and flatulence.

(iv) Warnings: Do not recommend use in patients with kidney disease, during pregnancy or while breastfeeding, or in patients with irritable bowel syndrome.

c. **Stimulant laxatives.** These medications work in the small and large intestines to stimulate bowel motility (i.e., propulsive peristaltic activity) and increase the secretion of fluids into the bowel. The oral preparations usually have an onset of action within 6-12 hr; rectal preparations usually have an onset of action within 15-60 min. Stimulant laxatives are effective as initial drug therapy to treat constipation but should not be used for more than 1 week.

(1) Administration guidelines. Patients with undiagnosed rectal bleeding or signs of intestinal obstruction should not use stimulant laxatives.
(2) Adverse effects. All stimulant laxatives can cause abdominal cramping. Electrolyte and fluid deficiencies, enteric loss of protein, malabsorption, and hypokalemia are additional possible adverse effects. The suppository form may cause rectal burning.
(3) Warnings
(a) Chronic use of stimulant laxatives can lead to **cathartic colon,** which results in a poorly functioning colon and resembles the symptoms of ulcerative colitis. However, most cases of cathartic colon were published before 1960, when more toxic ingredients (e.g., podophyllin) were used in laxative products.

(b) Another issue surrounds the possible carcinogenicity of stimulant laxatives. Phenolphthalein was removed from the market as suggested by the U.S. Food and Drug Administration (FDA) when data of carcinogenic tumors and genetic damage in rats were reported. Subsequently, senna and the structurally similar products aloe and cascara sagrada are now considered category 3 drugs; more data are needed to assess their safety.
(4) Anthraquinone laxatives include senna (sennosides)
(a) Melanosis coli, which is a dark pigmentation of the colonic mucosa, can result with long-term use of anthraquinone laxatives. This usually disappears 6-12 months after discontinuing the medication. It was previously thought that melanosis did not result in adverse consequences; however, patients with melanosis have a threefold higher risk of cancer.
(b) Discoloration (pink/red, yellow, or brown) of the urine may occur.
(c) Additional anthraquinone laxatives (cascara, casanthranol, and aloe) were removed from the U.S. market because of carcinogenicity concerns.
(d) Anthraquinone products include the **sennosides** (e.g., Senokot, Ex-Lax, Fletcher's Castoria, Perdiem), which are considered to be potent and cause abdominal cramping.
(i) Sennosides can also be combined with docusate (stool softener) for relief of constipation (Peri-Colace, Senokot-S).
(ii) Adults: 12-50 mg twice daily; children: 6-25 mg twice daily
(5) Bisacodyl (e.g., Dulcolax, Doxidan, Correctol) is a **diphenylmethane derivative.**
(a) The tablet formulations of bisacodyl are enteric coated, so they should not be crushed or chewed. Also, bisacodyl-containing products should not be taken within 1 hr of ingesting antacids or milk.
(b) Adults (oral): is 5-15 mg daily; children ≥ 6 years of age (oral): 5 mg daily; adults (rectal): 10 mg (1 suppository); children > 2 years of age (rectal): 5 mg (1/2 suppository).
(6) Castor oil (e.g., Purge) has an onset of action within 2-6 hr.

(a) Castor oil works primarily at the small intestine, which can result in strong cathartic effects (e.g., excessive fluid and electrolyte loss). These cathartic effects can lead to dehydration.
(b) Castor oil should not be used in pregnant patients because it may induce premature labor.
(c) Adults: 15-60 mL; children 2-12 years of age: 5-15 mL
d. Emollient laxatives act as surfactants by allowing absorption of water into the stool, which makes the softened stool easier to pass. Emollient laxatives have a **slow onset of action** (24-72 hr), which is why they are not considered the drug of choice for severe acute constipation, and they are more useful for preventing constipation.
(1) Administration guidelines. These medications are particularly useful in patients who must avoid straining to pass hard stools, such as those who recently had a myocardial infarction or rectal surgery. However, clinical trials evaluating emollient stool-softening laxatives show that these products, when compared to placebo, do not affect the weight or water content of the stool or the frequency of stool passing.
(2) Adverse effects. Diarrhea and mild abdominal cramping are potential adverse effects.
(3) Warnings. Use should be avoided if nausea and vomiting, symptoms of appendicitis, or undetermined abdominal pain exist. Docusate products may facilitate the systemic absorption of mineral oil, so these agents should not be used concurrently.
(4) Products. Emollient laxatives are salts of the surfactant **docusate.** These products contain insignificant amounts of calcium, sodium, or potassium, and there are no specific guidelines for the selection of any one product. The products include
(a) Docusate sodium (Colace)
(b) Docusate calcium (Kaopectate)
(5) Dosage information
(a) Adults: 50-300 mg per day; children ≥ 2 years of age: 50-150 mg per day
(b) Each dose must be taken with at least 8 oz. of water. Liquid preparations should be taken in fruit juice or infant formula to increase palatability.
e. Lubricant laxative (mineral oil). Mineral oil works at the colon to increase water retention in the stool to soften the stool. It has an **onset of action** of 6-8 hr with oral administration and 5-15 min after rectal administration.

(1) Administration guidelines

(a) Mineral oil should be taken on an empty stomach. Because of possible aspiration of mineral oil into the lungs, patients should not take mineral oil at bedtime or recline after administration.
(b) Adults: 15-45 mL per day; children: 5-15 mL per day
(2) Adverse effects. Mineral oil products may cause anal seepage, which results in itching (i.e. pruritus ani) and perianal discomfort.
(3) Warnings
(a) Mineral oil can **decrease absorption of fat-soluble vitamins** (i.e., vitamins A, D, E, and K), so it should not be used on a chronic basis.
(b) Elderly, young, debilitated, and dysphagic patients are at the greatest risk of **lipid pneumonitis** from mineral oil aspiration.
(c) Emollients (e.g., docusate) may increase the systemic absorption of mineral oil, which can lead to **hepatotoxicity.**
(d) Mineral oil should not be given to patients with rectal bleeding or appendicitis.
(e) Mineral oil should not be given to children < 6 years of age.
C. Special patient issues
1. Pediatric patients. The bowel patterns of pediatric patients vary. During the first weeks of life, infants pass approximately four stools per day. As children get older, approximately one to three stools are passed per day. Constipation should be expected if there is a drastic change from a child's baseline bowel function.
a. Nonpharmacological methods, such as increasing the amount of fluid or sugar in a child's formula in younger children or increasing the bulk content of the child's diet (fruit, fiber cereals, vegetables), should be tried before medications are used.
b. If nonpharmacological methods do not work, rectal stimulation may be useful. Pharmacological agents that can be used for acute relief include glycerin suppositories and magnesium laxatives. Stimulant laxatives should be administered as a last resort, but enemas should not be used in children < 2 years of age and with extreme caution in children 2-5 years of age (see I.C.4). Bulk-forming agents and stool softeners can be used if the constipation does not need immediate relief.
2. Pregnant patients. Constipation in pregnancy is common and can be the result of compression of the colon by the enlarged uterus, ingestion of prenatal vitamins containing iron and calcium, and the influence of progesterone can cause bowel hypomotility. Pregnant patients should avoid any preparation that may be absorbed systemically (e.g., stimulant laxatives), any preparation that can interfere with vitamin absorption (e.g., mineral oil), or any preparation that can induce premature labor (e.g., castor oil). Pregnant patients should use bulkforming agents or stool softeners.
3. Geriatric patients tend to be at risk for constipation because of insufficient dietary (fiber) and fluid ingestion, failure to establish a regular bowel time habit, and abuse of stimulant laxatives resulting in a loss of

smooth muscle tone in the bowel, which promotes constipation (see I.C.5). These causes should be investigated in addition to primary disease states (e.g., hypothyroidism) and medications (e.g., opiates, anticholinergics) that may lead to constipation in elderly patients. A **major concern** with geriatric patients is the possible loss of fluid that can be induced by aggressive laxative treatment (e.g., enemas, high-dose saline laxatives). Geriatric patients should not use stimulant laxatives on a chronic basis, and patients with renal impairment should not use magnesium products. Glycerin suppositories or orally administered lactulose may be useful for initial treatment of constipation and bulk-forming agents used to prevent constipation.

4. Use of enemas. Enemas are useful for evacuation of the bowel before surgery, childbirth, and for the treatment of acute constipation that has not responded to other medications (e.g., bisacodyl suppositories).

a. An enema is instilled into the rectum, works locally, and the enema fluid determines the mechanism of evacuation (e.g., stimulant, osmotic). When administered correctly, an enema evacuates only the distal colon, similar to a normal bowel movement. This is accomplished by having the patient lie on his or her side with the knees tucked toward the chest. While in this position, 1 pint (500 mL) of enema solution should be slowly squeezed into the rectum. This should be retained up to 1 hr or until definite lower abdominal cramping is felt. At this point, the bowel movement is ready for expulsion.

b. Although all enemas cause abdominal cramping, some may have more serious **adverse effects** than others. Soap suds enemas can cause much rectal irritation and have been reported to cause anaphylaxis and rectal gangrene.

c. The popular sodium phosphate enemas (e.g., Fleet) are very effective but have resulted in hyperphosphatasemia, hypocalcemia (tetany), hypokalemia, metabolic acidosis, and cardiac death, usually owing to conduction abnormalities in very small children. This has mainly occurred in children < 2 years of age or from 2 to 5 years of age with predisposing factors.

(1) The factors include chronic renal disease, anorectal malformations, and/or Hirschsprung disease, which allow phosphate blood concentrations to become abnormally high and potassium and calcium to become low, predisposing these patients to cardiac arrhythmias and potentially death.

(2) Therefore, the use of enemas is highly discouraged in children < 5 years of age.

5. Laxative abuse is a term to describe the routine, chronic use of laxatives on a daily basis (e.g., elderly patients) to the administration of high doses several times daily by patients with anorexia nervosa or bulimia

for weight control. Excessive use of laxatives can lead to excessive diarrhea and vomiting, resulting in fluid and electrolyte abnormalities. In addition to the risks to patients from hypokalemia (e.g., metabolic alkalosis, cardiac conduction problems), patients can also develop osteomalacia, liver disease, and cathartic colon. Cathartic colon results from superficial ulcerations in the colon as well as damage to the muscularis mucosa and submucosa. This results in a loss of tone of the smooth and striated muscle and causes poor bowel function.

II. DIARRHEA

A. General Information

1. Definition. Diarrhea is defined as an increase in the frequency and looseness of stools compared to one's normal bowel pattern. The overall weight and volume of the stool is increased (> 200 g or mL/day), and the water content is increased to 60%-90%. In general, diarrhea results when some factor impairs the ability of the intestine to absorb water from the stool, which causes excess water in the stool.

2. Classification. Diarrhea can be classified based on mechanisms or origin.

a. Classification by mechanism

(1) Osmotic diarrhea occurs when a nonabsorbable solute pulls excess water into the intestinal tract. Osmotic diarrhea ceases when the patient converts to a fasting state.

(a) Ingestion of large meals or certain osmotic substances (e.g., sorbitol, glycerin) can lead to diarrhea.

(b) Disaccharidase deficiency which is a lack of enzymes needed to break down disaccharides in the gut for absorption (e.g., lactase deficiency), results in an increase in osmotic sugars (i.e., lactose, sucrose) in the intestinal tract.

(c) Medications that can induce osmotic diarrhea include lactulose and magnesium-containing antacids and laxatives.

(2) Secretory diarrhea occurs when the intestinal wall is damaged, resulting in an increased secretion rather than absorption of electrolytes into the intestinal tract. Common sources include

(a) Bacterial endotoxins (e.g., *Escherichia coli, Vibrio cholerae, Shigella, Staphylococcus aureus*)

(b) Bacterial infections (e.g., *Shigella, Salmonella*)

(c) Viral infections (e.g., rotavirus, Norwalk virus)

(d) Protozoal infections (e.g., *Giardia lamblia, Entamoeba histolytica*)

(e) Miscellaneous causes. Inflammatory bowel disease and medications (e.g., prostaglandins, antibiotics, colchicine, chemotherapeutic agents)

(3) Motility disorders. Diarrhea induced by motility disorders results from decreased contact time of the fecal mass with the intestinal wall, so less water is absorbed from the feces.

(a) Motility disorders include irritable bowel syndrome, scleroderma, diabetic neuropathy, gastric/intestinal resection, and vagotomy.
P.690

(b) Medications that can induce motility disorders include parasympathomimetic agents that enhance the effects of acetylcholine (e.g., metoclopramide, bethanechol), digitalis, quinidine, and antibiotics.
(i) Antibiotics cause diarrhea by causing intestinal irritation, increased bowel motility, and altered bowel microbial flora.
(ii) Most antibiotic-induced diarrhea can be minimized by taking the agent with food.
b. Classification by origin
(1) Acute diarrhea (usually self-limiting for 2-3 days but may last up to 2 weeks)
(a) Infection. Most common sources include viral and bacterial, but protozoal diarrhea also occurs. Organisms include the following:
(i) Viruses that commonly cause diarrhea are rotaviruses and the Norwalk virus.
{**a**} **Rotaviruses** usually affect children < 2 years of age. The virus has an onset of 1-2 days and lasts 5-8 days. Patients usually have vomiting and a mild fever, and may experience severe dehydration. There is usually no blood or pus in the stool.
{**b**} The **Norwalk virus** affects older children and adults. It has an onset of 1-2 days and lasts 24-48 hr (the “24-hr bug”). As with rotaviruses, there is mild fever but no blood or pus in the stool.
(ii) Bacteria. Most bacterial diarrhea results from consumption of contaminated water or food, with an onset of diarrhea in 8 hr to several days. Diarrhea caused by the consumption of contaminated food or water that occurs in a foreign country (e.g., Mexico, third-world countries) is referred to as “traveler's diarrhea.”
{**a**} **Toxigenic bacteria.** Diarrhea caused by toxigenic *E. coli, Staphylococcus aureus, V. cholerae,* and *Shigella* results from the secretory effects of enterotoxins released by these organisms in the small intestine. Patients usually experience large-volume stools that are watery or greasy.
{**b**} **Invasive bacteria.** Diarrhea caused by invasive *E. coli, Shigella, Salmonella, Campylobacter,* and *Clostridium difficile* results from mucosal invasion of the colon. This results in a dysentery-like diarrhea, which is characterized by an extreme urgency to defecate, abdominal cramping, tenesmus, fever, chills, and small-volume stools that contain blood or pus.
(iii) Protozoa. *G. lamblia, Entamoeba histolytica,* and *Cryptosporidium* cause explosive, foul-smelling, large-volume, watery stools. This is thought to be caused by invasion of the small intestine, which causes damage to the microvilli and, therefore, decreases absorption of fluids. This type of diarrhea can result in large fluid losses, and patients are at risk for

dehydration. Although protozoan-induced diarrhea is self-limiting, it may persist for several months, so therapy should be considered to eradicate the organism.

(b) Diet-induced diarrhea. Diarrhea induced by foods results from food allergies, high-fiber diets, fatty or spicy foods, large amounts of caffeine, or milk intolerance. The best treatment is prevention, by avoiding troublesome foods.

(c) Drug-induced diarrhea (see II.A.2.a)

(2) Chronic diarrhea (lasts longer than 2 weeks). If a patient suffers from diarrhea for long periods of time, or from recurrent episodes of diarrhea, the following causes must be considered: protozoal organisms, food-induced diarrhea (e.g., lactose intolerance), irritable bowel syndrome, malabsorption syndromes (e.g., celiac sprue, diverticulosis, short bowel syndrome), inflammatory bowel disease, pancreatic disease, and hyperthyroidism.

B. Patient evaluation

1. Pharmacists who are consulted by patients should ask the patient for the following information before recommending a therapy:

a. Age of the patient

b. Onset and duration of the diarrhea

c. Description of stool (i.e., frequency, volume, blood, pus, watery)

d. Other symptoms (e.g., abdominal cramping, fever, nausea, vomiting, weight loss)

e. Medications recently started or medications used to relieve the diarrhea

f. Recent travel (where and how long ago)

g. Medical history (history of GI disorders)

2. Referrals to a physician should be made by the pharmacist who encounters a patient with diarrhea that meets the following criteria:

a. Younger than 3 years of age or **older than 60 years** of age (with multiple medical problems), pregnant or breast-feeding patients, and patients with HIV.

b. Blood or mucus in the stools

c. **High fever** (> 101°F or 38°C)

d. Dehydration or weight loss > 5% of total body weight; signs of dehydration—dry mouth, sunken eyes, crying without tears, dry skin that is not elastic like normal skin

e. Duration of diarrhea > **2 days**

f. Vomiting

C. Treatment

1. Nonpharmacological

a. Food/breast-feeding. In the past, there was much controversy regarding the decision to feed or not to feed children during acute episodes of

diarrhea. Originally, parents were told that children should not receive food, milk products, or breast-feed for 6-48 hr after the onset of diarrhea. Parents were also told that if children did receive food, they should receive the BRAT diet, which consists of bananas, rice, applesauce, and toast. This diet does not work and is deficient in calories, protein, and fat. All patients should receive their normal diet or breast-feeding during bouts of diarrhea because these do not make the diarrhea worse and may actually improve the condition. Fatty foods, foods rich in simple sugars (can cause osmotic diarrhea), and spicy foods (may cause GI upset) should be avoided. Caffeine-containing beverages, which may worsen the diarrhea, should also be avoided.

b. Fluids. The most important part of treating acute diarrhea is the replacement of lost fluids and electrolytes. If patients experience mild to moderate fluid loss, fluid replacement can be achieved with oral-rehydration solutions (ORS). If fluid loss is severe (> 10% loss of body weight) and/or severe vomiting persists, then patients may need intravenous rehydration before oral maintenance fluids can be administered. ORSs can be easily made at home (Table 33-1) or purchased ready-to-use (e.g., Pedialyte, Rehydra-lyte). All of these solutions are considered equally safe and effective but have no effect on the duration of the diarrhea. The secretory and absorptive mechanisms of the bowel function separately, and this allows these ORS to be absorbed during acute episodes of diarrhea, preventing severe dehydration and complications. Not every patient needs ORS. For a child without evidence of dehydration (see II.B.2.d), administer 10 mL/kg or 1/2-1 cup of ORS for each loose stool. If a child is vomiting, administer smaller amounts (1-2 teaspoonsful) every 2-5 min as tolerated.

(1) Fluid and electrolyte replacement. Fluid and electrolyte therapy is aimed at replacing what the body has lost. During this situation, the patient's fluid input and output as well as weight should be monitored. The World Health Organization (WHO) has established guidelines for oral-replacement therapy (Table 33-1). Recommended doses are given in Table 33-2.

(2) Fluids to be avoided include hypertonic fruit juices and drinks (e.g., apple juice, powdered drink mixes, gelatin water), carbonated beverages, and caffeine-containing beverages, which can make diarrhea worse and do not contain needed electrolytes (i.e., Na^+, K^+). Gatorade diluted in water (1:1) is adequate and provides the necessary combination of glucose, sodium, and potassium.

2. Pharmacologic. Antidiarrheals may serve to prevent an attack of diarrhea or to relieve existing symptoms. Based on the FDA review of antidiarrheal products, three agents have been

identified as category 1 (i.e., safe and effective) ingredients: **kaolin, bismuth subsalicylate,** and **loperamide.** In April 2003, the FDA

reclassified attapulgite and polycarbophil products from category 1 to category 3 because of insufficient effectiveness data. Antidiarrheal agents are classified in different categories on the basis of their chemical class or pharmacologic mechanism of action.

Table 33-1. Guidelines for Oral-Replacement Therapy Established by the World Health Organization (WHO)

Ingredients	Dose
Sodium chloride (table salt)	90 mEq (1/2 teaspoon)
Potassium chloride (potassium salt)	20 mEq (1/4 teaspoon)
Sodium bicarbonate (baking soda)	30 mEq (1/2 teaspoon)
Glucose (sugar)	20 g (2 teaspoons)
Water	Enough to make 1 L of solution

Table 33-2. Guidelines for Fluid- and Electrolyte-Replacement Therapy

	Dose	
Age Group	Mild (2-3 stools/day)	Moderate (4-5 stools/day)
> 5 years of age	2 L/first 4 hr, then replace ongoing losses	2-4 L/first 4 hr, then replace ongoing losses
< 5 years of age	50 mL/kg/first 4 hr, then 10 mL/kg or 1/2-1 cup per stool	100 mL/kg/4 hr, then 10 mL/kg or 1/2-1 cup per stool

a. Antiperistaltic drugs

(1) Mechanism of action. Antiperistaltic drugs act by stimulating μ opioid receptors on the circular and longitudinal musculature of the small and large intestines to normalize peristaltic intestinal movements. They slow intestinal motility and affect water and electrolyte movement through the bowel. Loperamide is considered two to three times more potent than diphenoxylate and 50 times more potent than morphine in its ability to slow GI motility. Loperamide does not appreciably penetrate the central nervous system (CNS) and thus has a low risk for CNS side effects. Loperamide is

effective in acute, nonspecific diarrhea, traveler's diarrhea, and chronic diarrhea associated with inflammatory bowel disease. The frequency of bowel movements is decreased, and the consistency of stools is increased. However, replacement of fluids (through ORS) and dietary management are still the main focus of therapy for diarrhea.

(2) Contraindication. Antiperistaltic medications have always been restricted in patients with acute bacterial diarrhea associated with fecal leukocytes, high fever, or blood or mucus in the stool because of the potential for these drugs to decrease clearance of the organism and enhance systemic invasion of the organism. Most information shows that this is not significant and probably will cause no harm. However, these medications should not be used in patients with colitis (potential for the development of toxic megacolon) or in children < 6 years of age.

(3) Prescription agents in this class include the opiate-related agent diphenoxylate/atropine (e.g., Lomotil).

(4) Nonprescription agents. Loperamide (e.g., Imodium A-D) provides effective control of diarrhea as quickly as 1 hr after administration. Antiperistaltic drugs should not be used for more than 48 hr in acute diarrhea.

(a) Administration guidelines. Adults: 4 mg followed by 2 mg after each loose stool, not to exceed 16 mg/day; children: 1-2 mg up to three times per day, depending on weight and age.

(b) Adverse effects. At recommended doses, loperamide is generally well tolerated. Side effects are infrequent and consist primarily of abdominal pain, distention, or discomfort; drowsiness; dizziness; and dry mouth.

b. Adsorbents. These medications are not selective and adsorb toxins, bacteria, gases, and fluids. In addition, adsorbents may adsorb drugs in the GI tract. They are not absorbed systemically, so they produce **few adverse effects.** These products are given for symptomatic relief and are usually administered in large doses immediately following a loose stool. They are generally not effective for severe acute diarrhea.

(1) Kaolin

(a) Administration guidelines

(i) Adults and children 12 years of age and older (oral): 26.2 g after each loose stool.

(ii) Continue to take every 6 hr until stool is firm but not for more than 2 days.

(iii) Do not exceed 262 g in 24 hr.

(b) Adverse effects. Because activated kaolin is inert and is not absorbed systemically, adverse effects are minor with few patients experiencing constipation, bloating, and fullness.

(c) Warnings. It is recommended that this product not be given within 3 hr of other medications because it may decrease the absorption of other orally administered medications.

c. **Miscellaneous agents**

(1) Bismuth subsalicylate (e.g., Pepto-Bismol and Maalox Total Stomach Relief). Bismuth salts work as adsorbents but also are believed to decrease secretion of water into the bowel. It is effective and can reduce the number of stools by 50%. Bismuth preparations have moderate effectiveness against the prevention and treatment of traveler's diarrhea and nonspecific diarrhea, but doses required for relief are large and must be administered frequently, so these preparations may be inconvenient.

(a) Administration guidelines

(i) Adults: 2 tablets or 30-60 mL (524 mg) every hour as needed to a maximum of 8 doses in a 24-hr period; children > 2 years of age: one third to one half of adult dose.

(ii) Bismuth subsalicylate can prevent traveler's diarrhea when 2 tablets are taken four times per day.

(iii) Shake the suspension well before use.

(b) Adverse effects may include harmless grayish charcoal coloring of stools or tongue. Ringing in the ears (i.e. tinnitus) can occur with high doses, especially if the patient is simultaneously taking other salicylate products.

(c) Warnings/Contrandications

(i) Patients with black or bloody stools should not use this product.

(ii) Bismuth subsalicylate should not be given to children or teenagers during or after recovery from chickenpox or flu because of the possible association of salicylates with Reye's syndrome.

(iii) Patients with documented allergies to salicylates should not take this product.

(iv) Patients on anticoagulants should be monitored closely if taking these products.

(v) Pregnant or breast-feeding patients should not take these products.

(2) Lactobacillus (e.g., Bacid, Lactinex) products are intended to replace the normal bacterial flora that is lost during the administration of oral antibiotics. However, there is little information to show that these products are useful for antibiotic-induced diarrhea; with the increase in bowel organisms, patients can experience flatulence. Most clinicians do not recommend their use.

(3) Lactase (e.g., LactAid, Lactrase, Dairy Ease) is indicated for individuals who have insufficient amounts of lactase in the small intestine. Lactose (a disaccharide present in dairy products) must be broken down to glucose and galactose to be fully digested. If it is not, lactose draws water into the GI tract, and diarrhea results. Lactase is the enzyme responsible for digesting lactose. The dose is 1-2 capsules taken with milk or dairy

products or added to milk before drinking. Titration of doses to higher levels may be required in some patients.

(4) Anti-infectives. Depending on the suspected origin of the infectious diarrhea, prescription antibiotics and antiprotozoal medications can be used to eradicate the organisms and decrease the duration of symptoms (Table 33-3). If antibiotics are used to prevent traveler's diarrhea, therapy should be started 1 day before arrival in high-incidence regions and continued until 2 days after departure. If diarrhea has occurred, antibiotic treatment should last for 3 days.

(5) Anticholinergics (e.g., atropine, hyoscyamine) decrease bowel motility, which results in an increase of fluid absorption from the intestinal tract and a decrease in abdominal cramping. These products are found in combination with adsorbents or opiates. However, the amount of anticholinergic found in most products is not considered to be enough to alter the course of severe acute diarrhea. **Adverse effects** include dry mouth, blurred vision, and tachycardia. These products should not be used in patients with narrow-angle glaucoma.

III. HEMORRHOIDS

A. General Information

1. Definition. Hemorrhoids (also known as piles) are defined as abnormally large, bulging, symptomatic clusters of dilated blood vessels, supporting tissues, and overlying mucosus

membranes. Hemorrhoids can present in the lower rectum (internal hemorrhoids) or anus (external hemorrhoids). Simply, hemorrhoids represent downward displacement of anal cushions that contain arteriovenous anastomoses.

Table 33-3. Antibacterials Used For the Prophylaxis and Treatment of Traveler's Diarrhea

Antibacterials[a]	Prophylaxis dose[b]	Treatment dose[c]
Azithromycin	n/a	1000 mg po 1 × dose
Ciprofloxacin[d]	500 mg once daily	500 mg twice daily
Levofloxacin[d]	n/a	500 mg once daily
Norfloxacin[d]	400 mg once daily	400 mg twice daily
Ofloxacin[d]	n/a	200 mg twice daily

Rifaximin	200 mg once or twice daily	200 mg three times daily

[a] Sulfonamides, neomycin, ampicillin, doxycycline, tetracycline, and TMP-SMX are no longer recommended due to world-wide drug resistance.

[b] Prophylaxis should only be used for 2-3 weeks.

[c] Antibiotics are used for a 3-day course.

[d] *Campylobacter* species exhibit resistance to fluoroquinolones and should be considered in treatment.

n/a, not applicable; po, by mouth.

2. Epidemiology. Hemorrhoids are common, with approximately 10%-25% of the U.S. population afflicted. The risk of developing hemorrhoids increases with advancing age and peaks in individuals 45-65 years of age. The incidence of hemorrhoids in pregnant women is higher than that of nonpregnant women of similar age. Although they are considered a minor medical problem, they may cause considerable discomfort and anxiety.

B. Types of hemorrhoids are determined by their anatomical position and vascular origin.

1. An **internal** hemorrhoid is an exaggerated vascular cushion with an engorged internal hemorrhoidal plexus located above the dentate line and covered with a mucous membrane.

2. An **external** hemorrhoid is a dilated vein of the inferior hemorrhoidal plexus located below the dentate line and covered with squamous epithelium.

3. A **mixed** hemorrhoid appears as a baggy swelling and exhibits simultaneous characteristics of internal and external hemorrhoids.

C. Origin. Although heredity may predispose a person to hemorrhoids, the exact cause is probably related to acquired factors.

1. Situations that result in **increased venous pressure** in the hemorrhoidal plexus (e.g., chronic straining during defecation; small, hard stools; prolonged sitting on the toilet; occupations that routinely require heavy lifting; pelvic tumors; pregnancy) can transform an asymptomatic hemorrhoid into a problem. Pregnancy is the most frequent cause of hemorrhoids in women of childbearing age.

2. The hemorrhoidal veins are pushed downward during defecation or straining; with increased venous pressure, they **dilate** and **become engorged.** Over time, the **fibers** that anchor the hemorrhoidal veins to their underlying muscular coats **stretch,** which results in **prolapse.**

D. Signs/symptoms

1. The **most common** sign/symptom of hemorrhoids is **painless bleeding** occurring during a bowel movement. The blood is usually bright red and may be visible on the stool, on the toilet tissue, or coloring the water in the toilet.
2. Prolapse is the **second most common** sign/symptom of hemorrhoids. A temporary protrusion may occur during defecation, and it may need to be replaced manually. A permanently prolapsed hemorrhoid may give rise to chronic, moist soiling of the underwear. These patients may complain of a dull, aching feeling.
P.695

3. Pain is unusual unless **thrombosis** involving external tissue is present, and then the pain can be excruciating.
4. Discomfort, soreness, pruritus, swelling, burning, and **seepage** may also occur with hemorrhoids.
E. A proper diagnosis is important, because there are a number of conditions that may produce symptoms that mimic those of hemorrhoids. **Other conditions** that may **mimic** hemorrhoids include the following, which usually require a physician's intervention:
1. An **anal abscess,** usually a *Staphylococcus* infection
2. Cryptitis, which is inflammation of the crypts (small indentations at the mucocutaneous junction)
3. An **anal fissure,** which is a small tear in the lining of the anus
4. An **anal fistula,** which is an abnormal communication between the mucosa of the rectum and the skin adjacent to the anus
5. Inflammatory bowel diseases
6. A **polyp,** which is a tumor of the large intestine
7. Colorectal cancer
F. Internal hemorrhoids are graded and classified into one of four groups.
1. A **first-degree** hemorrhoid (grade 1) does not descend or prolapse during straining on defecation. Painless bleeding is present.
2. A **second-degree** hemorrhoid (grade 2) descends with defecation but returns spontaneously with relaxation. Mild discomfort and bleeding are present.
3. A **third-degree** hemorrhoid (grade 3) requires manual replacement into the rectum after prolapse (which occurs during defecation or exertion related to work). Pain, bleeding, and discharge of mucus are present.
4. A **fourth-degree** hemorrhoid (grade 4) is permanently prolapsed and cannot be manipulated manually. Thrombosis often occurs.
G. Treatment. The symptoms of hemorrhoids are produced by a cycle of events: the protrusion of the vascular submucosal cushion through a tight anal canal, which becomes further congested and hypertrophic, which causes the cushion to protrude farther. All treatments of hemorrhoids aim to break this cycle, and they fall into a number of broad groups.
1. For **first-** and **second-degree internal** hemorrhoids that bleed minimally, a conservative approach can usually be taken.

a. To **reduce straining** and **downward pressure** on the hemorrhoids, patients should avoid straining when defecating and avoid sitting on the toilet longer than necessary (suggest removing all reading materials from the bathroom).
b. Correction of constipation is of paramount importance. This can be accomplished by eating a high-fiber diet and increasing water intake and physical activity. Bulk-forming laxatives, such as psyllium, and stool softeners, such as docusate, may be helpful.
c. **Sitz baths** for 15 min, three to four times a day, can soothe the anal mucosa. Tepid water should be used, and prolonged bathing should be avoided. Epsom salts (magnesium sulfate) added to the bath or the application of an ice pack can help reduce the swelling of an edematous or clotted hemorrhoid.
d. OTC **hemorrhoidal ointments, creams, foams,** and **suppositories** may also help relieve symptoms (see III.H).
2. Higher-grade internal hemorrhoids usually require physician expertise and specialized procedures for treatment.
a. Symptomatic grades 2 or 3 hemorrhoids are often best treated with **hemorrhoid banding** (rubber band ligation). This procedure is performed through an anoscope; a rubber band ligature is placed on the rectal mucosa above the hemorrhoid, well above the dentate line to avoid excessive discomfort. The ligated area sloughs off in a few days.
P.696

Table 33-4. Guide to Hemorrhoidal Therapy Based on Approved Indication for OTC Anorectal Drug Products

Therapy	Burning	Discomfort	Irritation	Itching	Pain	Soreness	Swelling
Analgesic, anesthetic, antipruritic	Yes	Yes		Yes	Yes	Yes	
Astringent	Yes	Yes	Yes	Yes			
Keratolytic		Yes		Yes			
Local anesthetic	Yes	Yes		Yes	Yes	Yes	

Protectant	Yes	Yes	Yes	Yes			
Vasoconstrictor		Yes	Yes	Yes			Yes
Hydrocortisone		Yes		Yes			Yes

b. Infrared photocoagulation can be used for grade 2 hemorrhoids; it is less effective than banding with large hemorrhoids. Infrared light is focused at the base of the hemorrhoid, thereby destroying the varicosity secondary to the formation of a white coagulum.

c. **Sclerotherapy** (injection of a sclerosing agent into the hemorrhoid) or cryotherapy ("freezing" the hemorrhoid) are older therapies that have been used.

d. Surgical hemorrhoidectomy should be undertaken only for grades 3 or 4 hemorrhoids. Whether the procedure is done traditionally or with a laser, most patients have significant discomfort and a period of postoperative disability.

3. An **external, thrombosed hemorrhoid** can be completely excised in an office setting, clinic, or operating room.

H. Nonprescription medication for hemorrhoidal and other anorectal diseases (Table 33-4). The FDA has identified several ingredients as safe and effective to alleviate burning, discomfort, inflammation, irritation, itching, pain, and swelling. These products are simply palliative; they are not meant to cure hemorrhoids or other anorectal disease. If these products do not improve symptoms within 7 days, a physician should be consulted. A physician should also be consulted if bleeding, prolapse, seepage of feces or mucus, thrombosis, or severe pain occurs. Patients < 12 years of age should not rely on self-treatment but should seek medical attention immediately.

1. Ointments or creams versus suppositories. Generally, the ointment or cream dosage form is believed to be superior to a suppository, which may bypass the affected area. Patients should wash the anorectal area with mild soap and warm water and pat (not wipe) the area dry before applying a product. Alternatively, patients can use an OTC anal-cleansing pad (e.g., Tucks). Some ointments come with rectal pipes (pile pipes) that allow the patient to insert and apply the medication directly in the rectum. The openings in the rectal pipe allow the ointment to cover large areas of the rectal mucosa unreachable with the finger. The rectal pipe should be lubricated by spreading ointment around the tip of the pipe before insertion. Some clinicians advise against the use of the rectal pipe because the anal canal could be traumatized if the pipe is not inserted properly.

2. Local anesthetics work by blocking nerve-impulse transmission. **Agents** deemed safe and effective include benzocaine 5%-20% (e.g., Lanacane), pramoxine 1% (e.g., ProctoFoam), benzyl alcohol 1%-4% (e.g., Tucks Clear Gel), dibucaine 0.25%-1% (e.g., Nupercainal), dyclonine 0.5%-1% (e.g., Dyclone), lidocaine 2%-5% (e.g., Xylocaine), and tetracaine 0.5%-1% (e.g., Pontocaine).

a. Administration guidelines. Local anesthetics should be used for symptoms of pain, itching, burning, discomfort, and irritation in the perianal region or lower anal canal (not in the rectum). The rectum contains no sensory pain receptors. The products should not be applied to abraded skin as this will increase absorption systemically.

b. Adverse effects. These agents may produce a hypersensitivity reaction with burning and itching similar to that of anorectal disease. Systemic absorption is minimal unless the perianal skin is abraded. As a result of its unique chemical structure, pramoxine exhibits little cross-sensitivity compared to the other local anesthetics.

c. **Warnings**

(1) Allergic reactions may occur in some patients.

(2) Advise patients not to use preparations longer than 7 days.

3. Vasoconstrictors decrease mucosal perfusion by causing arteriole constriction in the anorectal area after topical application. However, because bleeding in this area may be a sign of more serious disease, vasoconstrictors are not approved for control of minor bleeding. For temporary relief of itching, discomfort, and irritation, these agents have a local anesthetic effect of unknown mechanism.

a. Agents deemed safe and effective include ephedrine sulfate 0.1%-1.25% in aqueous solution, epinephrine HCl 0.005%-0.01% in aqueous solution, and phenylephrine HCl 0.25% in aqueous solution. These agents are present in various ointments (e.g., Pazo) and suppositories (e.g., Preparation H).

b. Adverse effects. Topical vasoconstrictors, at recommended doses, may cause nervousness, tremor, sleeplessness, nausea, and loss of appetite. Cardiac arrhythmias, irregular heart rate, and elevation of blood pressure are potentially serious adverse effects, but less likely at recommended doses.

c. **Warnings/contraindications** apply to people with cardiovascular disease, high blood pressure, hyperthyroidism, diabetes, and prostate enlargement because of the possibility of systemic absorption.

4. Protectants provide a **physical barrier,** forming a protective coating over skin or mucous membranes, for temporary relief of itching, irritation, discomfort, and burning. They prevent irritation of anorectal tissue and prevent water loss from the stratum corneum. Protectants are often the bases or vehicles for other agents used for anorectal disease. Products include aluminum hydroxide gel, cocoa butter, kaolin, lanolin, hard fat, mineral oil, white petrolatum, petrolatum, glycerin (external use only), topical starch, cod liver oil, shark liver oil, and zinc oxide. When protectants are incorporated into the formulation of an OTC product, they should

make up at least 50% of the dosage unit. If two to four protectants are used, their total concentration should represent at least 50% of the whole product. Lanolin, a derivative of wool alcohol, may be allergenic to susceptible individuals.

a. Absorbents take up fluids that are on or secreted by skin or mucous membranes.

b. Adsorbents attach to substances secreted by skin or mucous membranes.

c. **Demulcents** combine with water to form a colloidal solution, which protects the skin in a way similar to mucus.

d. Emollients, which are derived from animal or vegetable fats or petroleum products, soften or protect internal or external body surfaces.

5. Astringents lessen mucus and other secretions and protect underlying tissue through a local and limited protein coagulant effect. Action is limited to surface cells, but astringents provide temporary relief of itching, discomfort, irritation, and burning. Products considered to be safe and effective include calamine 5%-25%, witch hazel 10%-50% (external use only), and zinc oxide 5%-25%.

6. Keratolytics cause desquamation and débridement of the surface cells of the epidermis and provide temporary relief of discomfort and itching. Theoretically, keratolytics expose underlying tissue to other therapeutic agents. Products considered to be safe and effective include aluminum chlorhydroxyallantoinate (alcloxa) 0.2%-2.0% and resorcinol 1%-3%. Resorcinol should not be used on an open wound owing to the potential for a serious hypersensitivity reaction. Keratolytics are reserved for external use only.

7. Analgesics, anesthetics, and **antipruritics** provide temporary relief of burning, discomfort, itching, pain, and soreness. The FDA has redesignated several ingredients into this category that were formerly classified as **counterirritants.** Ingredients considered to be safe and effective for external use in the anorectal area include menthol (0.1%-1%), juniper tar (1%-5%), and camphor (0.1%-3%). These agents should not be used to treat internal hemorrhoids.

8. Wound-healing agents. Live yeast cell derivative (LYCD; skin-respiratory factor), which is a water-soluble extract of brewer's yeast, was present in Preparation H in the past. LYCD was removed from the list of **safe and effective** active ingredients by the FDA, which determined that studies have not proven this agent effective. Preparation H products have been reformulated

without LYCD. Preparation H Ointment now contains protectants (petrolatum, mineral oil, shark liver oil, lanolin, and glycerin) and the vasoconstrictor phenylephrine.

9. Hydrocortisone (0.25%-1%) causes vasoconstriction, stabilization of lysosomal membranes, and antimitotic activity. These agents have the potential to reduce itching, inflammation, and discomfort in the anorectal area. Until recently, hydrocortisone-containing hemorrhoidal products were available by prescription only. As with any steroid cogener, hydrocortisone may mask the symptoms of bacterial or fungal infections. Hydrocortisone concentrations > 1% are available by prescription only.

IV. GASTROESOPHAGEAL REFLUX DISEASE (HEARTBURN)

A. General information

1. Definition. Gastroesophageal reflux disease (GERD) is defined as the retrograde movement of gastric contents into the esophagus (i.e., gastroesophageal reflux). Gastroesophageal reflux is generally a benign physiological process that occurs in normal individuals multiple times throughout the day. However, patients with GERD may experience esophageal tissue damage (reflux esophagitis) and/or symptoms of heartburn when the acidic gastric contents stay in prolonged contact with the esophagus.

2. Epidemiology. Between 30% and 50% of the population has experienced occasional episodes of heartburn. The following are predisposing factors for this condition:

a. Age. Patients of any age can experience heartburn; however, this condition is most common in people > 50 years of age.

b. Gender, males are more likely to experience GERD.

c. **Pregnancy.** Between 30% and 50% of pregnant patients experience heartburn during the course of pregnancy; 25% experiencing daily symptoms. It has been suggested that hormonal changes as well as the increase in intra-abdominal pressure contribute to the high incidence of heartburn during pregnancy.

d. Obesity may correlate to heartburn owing to the increase in intra-abdominal pressure or lower esophageal sphincter (LES) pressure. This predisposing factor can be voluntarily modified (i.e., weight loss) to reduce the patients risk of heartburn.

3. Symptoms. Heartburn (pyrosis) typically is described as a burning sensation or pain located in the lower chest. The pain may radiate higher in the chest, into the back, and into the throat or neck. Because the pain may radiate up into the chest, heartburn may be confused with pain associated with myocardial infarction (sweating associated with severe, crushing chest pain suggests a myocardial infarction and medical attention must be sought immediately). Symptoms usually occur soon after meals and when lying down at bedtime; patients may be awakened during the night with the pain. Pain on swallowing (odynophagia) may suggest severe mucosal damage in the esophagus.

4. Complications. Patients with severe, uncontrolled GERD may suffer bleeding from esophageal ulcers and pulmonary complications resulting from the aspiration of refluxed material into the upper airways and lungs. Patients who describe difficulty swallowing (i.e., dysphagia) may have an esophageal stricture, cancer, or a motility disorder.

5. Causes. There is an imbalance of aggressive forces (promote the development of GERD) and protective forces (prevent the development of GERD). Aggressive forces include acid and pepsin. The most important protective force is probably the LES. Many patients with GERD have a weak LES. As a result, the high pressure in the stomach creates enough force to overcome the weak squeeze of the LES and allows

reflux to occur. Other protective forces include esophageal clearance, gastric-emptying rate, saliva, and esophageal mucosal defense.

a. Drugs that reduce LES tone include calcium channel antagonists (e.g., nifedipine, verapamil, diltiazem), nitrates, anticholinergic agents (e.g., tricyclic antidepressants, antihistamines), and oral contraceptives and estrogen.

b. Foods that reduce LES tone include chocolate, fatty foods, onions, peppermint, and garlic.

c. Smoking (nicotine) reduces LES tone.

P.699

6. Pharmacists who are consulted by patients should ask for the following information before recommending a therapy:

a. Duration and frequency of symptoms

b. Severity of the pain and symptoms

c. Timing of the symptoms (especially in relation to meals and at bedtime)

d. Presence of other symptoms (nausea, vomiting, bloody stools, weight loss)

e. Use of alcohol or tobacco

f. Amount of high-fat foods, caffeine-containing products, chocolate, and tomato-based foods consumed

g. Medications used currently, including nonprescription medications

h. Medications used to relieve heartburn and their effectiveness

7. Patients with the following symptoms or conditions should be referred to a physician for evaluation rather than treated with nonprescription agents:

a. Severe abdominal or back pain

b. Unexplained weight loss

c. Chest pain that is indistinguishable from ischemic pain

d. Difficulty or pain on swallowing

e. Presence or history of vomiting blood

f. Black tarry bowel movements (if not taking iron or bismuth subsalicylate)

g. Children < 12 years of age

h. Possibility of being pregnant

i. Symptoms not responding to antacids or nonprescription H_2RAs within 2 weeks or recurring soon after stopping

B. Treatment

1. Nonpharmacological interventions for GERD attempt to reduce or eliminate dietary and lifestyle factors that promote reflux. Specific recommendations include the following:

a. Elevate the head of the bed 6-10 inches with blocks. This position improves esophageal clearance and reduces the duration of reflux. Try to avoid just propping a patient's head up with pillows because this may worsen symptoms by increasing abdominal pressure.

b. Eat evening meals at least 3-5 hr before going to bed to allow adequate time for gastric emptying.

c. Avoid foods that reduce LES tone.

d. Avoid foods that irritate the esophagus such as tomato-based products, coffee, citrus juices, and carbonated beverages (with or without caffeine).
e. Reduce the size of meals.
f. Avoid lying down for at least 2 hr after meals.
g. Stop use of tobacco products.
h. Limit alcohol intake.
i. Limit caffeine-containing beverages.
j. Lose weight if appropriate.
k. Avoid wearing tight-fitting clothing.
2. Pharmacological. The management of GERD may be viewed as a stepped-care approach, with antacids, nonprescription H_2RAs, and nondrug measures forming the basis for the first step (Figure 33-1). These measures may help alleviate symptoms in patients with mild to moderate GERD but cannot be expected to heal damaged esophageal mucosa or prevent complications. Steps 2 and higher use prescription-strength H_2RAs and other prescription medications as well as interventions such as surgery.
a. Antacids. Antacids are basic compounds that neutralize gastric acid, which increases the pH of refluxed gastric contents. As a result, the refluxed contents are not as damaging to the esophageal mucosa and alkalinization of gastric contents increase LES tone.
(1) Antacids generally relieve heartburn within 5-15 min of administration. Antacid suspensions generally dissolve more easily in gastric acid and thereby work quicker. In addition, sodium bicarbonate and magnesium hydroxide dissolve quickly at gastric pH and provide rapid relief; however, calcium carbonate and aluminum hydroxide dissolve slowly in stomach acid with a longer time frame for symptom relief (10-30 min).
(2) The duration of relief ranges from 1 to 3 hr if taken 1 hr after meals (duration of neutralization lasts only 20-40 min if taken without food). Because of their short duration, patients may need to take 4-5 doses throughout the day for adequate symptom relief. Antacids will not provide sustained neutralization of acid throughout the night.

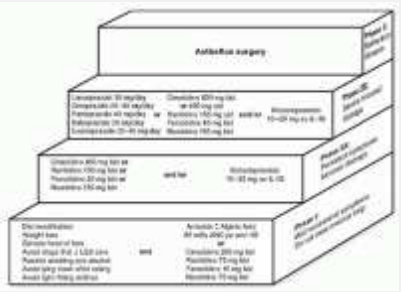

Figure 33-1. Step-wise progression of therapy for gastroesophageal reflux disease (GERD.) *ac,* before meals; *ANC,* acid-neutralizing capacity; *bid,* twice daily; *HS,* bedtime; *pc,* after meals; *qid,* four times daily.

(3) Adults: 40-80 mEq acid-neutralizing capacity (ANC) taken as needed for symptoms. If necessary, these doses may be titrated to a scheduled regimen, such as 40-80 mEq after meals and at bedtime.

(4) Sodium bicarbonate (e.g., Alka-Seltzer, Bromo-Seltzer) should be used for only short-term relief of symptoms. Because each gram of sodium bicarbonate contains 12 mEq of sodium, it is contraindicated in patients with edema, congestive heart failure, renal failure, cirrhosis, and patients on low-salt diets. It is the only systemic antacid available and can thus alter systemic pH.

(5) Calcium carbonate (e.g., Tums) is the most potent antacid ingredient but may cause constipation or, less likely, diarrhea. It is a good source of elemental calcium.

(6) Aluminum hydroxide (e.g., Amphojel, ALternaGEL) often causes constipation and should be avoided in patients with hemorrhoids or constipation, which is common in the elderly. Aluminum hydroxide has the lowest neutralizing capacity of all the antacids. Aluminum accumulation can be a problem in patients with chronic renal insufficiency.

(7) Magnesium hydroxide (e.g., Milk of Magnesia) rarely is used alone for heartburn because it frequently causes diarrhea. If used in renal failure patients, hypermagnesemia can occur rapidly.

(8) Magnesium-aluminum combination antacids (e.g., Maalox, Mylanta) provide the highest ANC per volume of antacid and are used most frequently. The predominant adverse effect of these combinations is diarrhea.

(9) Patient information

(a) Patients with renal failure should avoid the use of all antacids. Potassium and magnesium content of antacids should be considered for patients with cardiac disease.

(b) Patients should not take > 500-600 mEq ANC of antacid per day.

(c) Palatability with antacid liquids may be increased with refrigeration (do not freeze).

(d) Tablets must be chewed thoroughly to achieve optimal effect.
(e) Antacids can interfere with the absorption of many drugs. In general, antacids should be spaced at least 2 hr apart from the administration of interacting drugs. This is often quite difficult to accomplish. Important clinical interactions with antacids may occur with the following drugs:
(i) Tetracycline antibiotics
(ii) Quinolone antibiotics (e.g., ciprofloxacin, levofloxacin)
(iii) Iron supplements
(iv) Digoxin

b. Alginic acid

(1) Mechanism of action. Alginic acid works by reacting with sodium bicarbonate and saliva to form a viscous solution of **sodium alginate.** This viscous solution floats on the surface of gastric contents so that, when reflux occurs, sodium alginate rather than acid is refluxed, and irritation is minimized.

(2) Patient information

(a) Alginic-acid tablets must be chewed to be effective and should be followed by a full glass of water so that the viscous foam can float on it in the stomach.
(b) Alginic-acid products work best when patients are in the upright position. Thus these products should not be taken at bedtime or just before lying down.

c. **Nonprescription H_2RAs.** These medications inhibit gastric acid secretion by competitively blocking H_2-receptors on the parietal cell. By decreasing gastric acid secretion, the refluxed material is less damaging to the esophagus. The onset of symptom relief with H_2RAs is 1-2 hr, which is considerably longer than antacids; however, the duration of action can last up to 10 hr. All H_2RAs are contraindicated in children < 12 years of age. Nonprescription H_2RAs can be used for relief or prevention of heartburn.

(1) Cimetidine (Tagamet-HB)

(a) Adults (nonprescription): 200 mg as needed for symptoms, up to twice daily. Cimetidine 200 mg suppresses gastric acid for approximately 6 hr.
(b) Nonprescription doses of cimetidine may **impair** the **hepatic metabolism** and thus increase serum concentrations and the pharmacological effects of the following drugs:
(i) Warfarin
(ii) Phenytoin
(iii) Theophylline

(2) Famotidine (Pepcid-AC, Pepcid Complete, Maximum Strength Pepcid-AC). Unlike cimetidine, famotidine rarely impairs hepatic metabolism of other drugs
(a) Adults (nonprescription): 10-20 mg as needed for symptoms, up to twice daily; maximum dose 40 mg/day. Patients who anticipate heartburn or indigestion may take 10-20 mg (1 tablet) 1 hr before eating; maximum of 2 tablets within a 24-hr period. Famotidine 10 mg suppresses acid secretion for 8-10 hr.
(b) Famotidine, calcium carbonate, magnesium hydroxide (Pepcid Complete). A chewable combination of an H_2RA and an antacid.

(3) Ranitidine (Zantac 75, Zantac 150 Maximum Strength).

(a) Adults (nonprescription): 75-150 mg as needed for symptoms, up to twice daily; maximum 150 mg/day

(b) Ranitidine inhibits hepatic metabolism 5-10 times less than cimetidine; therefore, the potential for drug interactions is very small.

(4) Nizatidine (Axid-AR). Adults: 75 mg as needed for symptoms, up to twice daily. Nizatidine rarely impairs hepatic metabolism of other drugs.

(5) Adverse effects. These agents are extremely well tolerated. The **most common** adverse effects reported with nonprescription doses are headache, diarrhea, dizziness, and nausea.

d. Prescription H_2RAs. Patients with moderate to severe symptoms and/or esophageal mucosal lesions require higher doses of H_2RAs than are available over the counter. Unlike patients with peptic ulcer disease, patients with GERD respond best to multiple daily doses of H_2RAs rather than to single bedtime doses.

e. Prokinetic agents. Patients with moderate to severe GERD may benefit from the addition of these medications, which stimulate esophageal motility and increase LES tone. Prokinetic agents are available only by prescription.

(1) Metoclopramide (Reglan, generic). Adverse effects, such as sedation, depression, and extrapyramidal effects, limit the usefulness of this agent for many patients.

(2) Cisapride (Propulsid). The numerous drug interactions with this product have caused the manufacturer to voluntarily remove it from the market. Propulsid may still be obtained through an investigational limited-access program.

f. Proton pump inhibitors. These prescription-only agents (except omeprazole) provide complete acid suppression by inhibiting the hydrogen-potassium ATPase pump on the surface of the parietal cell. The duration of acid suppression with these agents is about 3 days. Proton pump inhibitors are the most potent and effective agents available for relieving severe GERD symptoms and healing esophageal lesions. In June 2003, the FDA switched omeprazole to OTC status for the prevention of symptoms of frequent (occurring 2 or more days per week) heartburn. These OTC drugs should be used for no more than 14 days every 4 months, unless directed by a physician.

(1) Omeprazole (Prilosec and Prilosec OTC**)**

(a) This drug may inhibit hepatic metabolism and thus increase serum concentration/pharmacologic effects of the following drugs: phenytoin, warfarin, and diazepam.

(b) Adverse effects. Although rare, these may include headache, diarrhea, constipation, or dizziness.

(2) Lansoprazole (Prevacid) has no clinically significant drug interactions.

(3) Pantoprazole (Protonix) is the only proton pump inhibitor with an oral and intravenous formulation.

(4) Rabeprazole (Aciphex)

(5) Esomeprazole (Nexium)

C. Special patient populations

1. Pediatric patients. Gastroesophageal reflux occurs commonly in infants and children. Signs and symptoms in pediatric patients include vomiting, chest pain, irritability, feeding refusal, belching, and apnea. Serious complications (e.g., failure to thrive, esophageal strictures) can occur in infants and children.

a. Antacids, with or without alginic acid, have been widely used in infants and children, but their safety has not been clearly established.

b. H_2RAs have been used safely in children under the supervision of healthcare providers. However, the nonprescription H_2RAs are not approved for use in children < 12 years of age unless directed by a physician.

2. Pregnant patients. Heartburn occurs commonly during pregnancy because of increased abdominal pressure owing to the expanding uterus, as well as reduced LES pressure resulting from high concentrations of estrogen and progesterone. Nearly half of pregnant women experience GERD, especially during the third trimester.

a. Antacids are generally considered safe in pregnancy as long as chronic high doses are avoided. It is best to avoid sodium bicarbonate because of the risks of systemic alkalosis and the sodium load leading to edema and weight gain.

b. Data regarding the **safety** of **alginic acid** during pregnancy are not available.

c. **Controlled data regarding the** safety of **H_2RAs** in pregnancy are limited. Pregnant women seeking a nonprescription H_2RA for GERD should be directed to use antacids, unless a physician has instructed her otherwise.

3. Elderly patients. Antacids and nonprescription H_2RAs may be safely used in elderly patients without any dosage adjustments.

a. Dosage reduction of prescription H_2RAs may be necessary in elderly patients with reduced renal function.

b. Elderly patients are more likely to be taking drugs that interact with antacids, H_2RAs, omeprazole, and/or cisapride.

c. Elderly patients are also more likely to have symptoms or conditions that require referral to a physician before beginning nonprescription therapy.

STUDY QUESTIONS

Directions for questions 1-20: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which laxative should *not* be used to treat acute constipation because of its slow onset of action?

(A) glycerin

(B) bisacodyl suppository

(C) psyllium

(D) milk of magnesia

View Answer***1. The answer is C[see].*****2. Which is *not* a risk factor for hyperphosphatemia and death from sodium phosphate enemas when used in children?**

(A) renal insufficiency

(B) Hirschsprung disease

(C) anorectal malformations

(D) children 6-12 years of age

View Answer***2. The answer is D[see].*****3. All of the following statements about emollient stool softener laxatives are true *except* which one?**

(A) They are not good for acute constipation.

(B) They are good for patients who should not strain by passing a hard stool (e.g., postsurgical patients).

(C) They never have been found to be better than placebo for long-term use.

(D) They are more effective than placebo for long-term use.

View Answer***3. The answer is D[see].*****4. Which of the following statements adequately describes bulk-forming laxatives?**

(A) can cause diarrhea if not taken with water

(B) are derived from polysaccharides and resemble fiber (bran) in mechanism of action

(C) onset of action in 4-8 hr

(D) produce much more complete evacuation of constipation than stimulant products

View Answer***4. The answer is B[see].*****5. Which of the following statements about nondrug therapies for acute diarrhea is *not* correct?**

(A) Breast-feeding should be continued as normal.

(B) Even if the patient is not vomiting, food should be withheld for 6-12 hr.

(C) Fluids can be given to patients who experience vomiting, but small amounts of fluid should be used.

(D) Replacement fluids mainly consist of water, sugar, potassium, sodium, and bicarbonate.

View Answer***5. The answer is B[see].*****6. Which of the following products should *not* be used to replenish lost fluids from acute diarrhea?**

(A) pedialyte solution

(B) Kool-Aid

(C) Gatorade (half-strength diluted with water)

(D) The World Health Organization (WHO) solution

View Answer***6. The answer is B[see].*****7. Which of the following statements about adsorbent drugs used for diarrhea is true?**

(A) useful for treatment of severe diarrhea

(B) very unsafe because not absorbed systemically

(C) in general, small doses needed to relieve diarrhea

(D) kaolin now generally recognized as a safe and effective OTC antidiarrheal agent

View Answer***7. The answer is D[see].*****8. Which of the following statements concerning traveler's diarrhea is true?**

(A) It can usually be avoided by not eating raw vegetables, seafood, or eggs when traveling to third world countries.

(B) It can be prevented by taking one dose of antibiotic 1 day before a trip.
(C) *Helicobacter pylori* is the primary pathogen responsible.
(D) Phillips' Milk of Magnesia is used to prevent and treat the condition.

View Answer***8. The answer is A[see].Escherichia coliHelicobacter pylori*****9. All of the following agents are considered close to ideal laxatives *except***
(A) emollient laxatives.
(B) bulk-forming laxatives.
(C) fiber.
(D) stimulant laxatives.

View Answer***9. The answer is D[see].*****10. A patient suffering from acute infectious diarrhea caused by *Shigella* can be managed in all of the following ways *except* which one?**
(A) No treatment necessary because signs and symptoms usually resolve in 48 hr.
(B) Use glucose solutions (e.g., soda, apple juice) to settle the stomach and decrease the number of stools.
(C) Avoid food for at least 6 hr, then slowly increase fluid intake.
(D) Use antibiotics (e.g., Bactrim, doxycycline) for 7 days.

View Answer***10. The answer is B[see].***P.704

11. Which local anesthetic should be used to treat symptoms of pain, itching, burning, and discomfort in patients with an established lidocaine allergy?
(A) tetracaine
(B) dibucaine
(C) pramoxine
(D) benzocaine

View Answer***11. The answer is C[see].*****12. All of the following items are part of a standard conservative approach to the treatment of first- or second-degree hemorrhoids *except***
(A) topical anesthetic (hemorrhoidal ointment).
(B) stool softener.
(C) sitz baths.
(D) rubber band ligation.

View Answer***12. The answer is D[see].*****13. What is the most common sign/symptom of hemorrhoids?**
(A) bleeding
(B) pain
(C) seepage
(D) pruritus

View Answer***13. The answer is A[see].*****14. Which of the following agents is designated as a safe and effective analgesic, anesthetic, and antipruritic by the Food and Drug Administration?**
(A) witch hazel
(B) juniper tar

(C) hydrocortisone

(D) phenylephrine

View Answer***14. The answer is B[see].*****15. All of the following vasoconstrictors are deemed safe and effective for the temporary relief of itching and swelling *except***

(A) ephedrine 0.1%-1.25%.

(B) epinephrine 0.005%-0.01%.

(C) phenylpropanolamine 1%-10%.

(D) phenylephrine 0.25%.

View Answer***15. The answer is C[see].*****16. All of the following symptoms associated with gastroesophageal reflux disease (GERD) may be treated with nonprescription agents *except***

(A) burning sensation located in the lower chest.

(B) pain that is worse after meals.

(C) pain or difficulty when swallowing.

(D) pain that is worse on lying down at bedtime.

View Answer***16. The answer is C[seeand].*****17. Which of the following is an appropriate nonpharmacological recommendation for patients with gastroesophageal reflux disease (GERD)?**

(A) Eat larger but fewer meals.

(B) Avoid meals high in protein.

(C) Eat evening meals at least 3 hr before bed.

(D) Prop a patient's head up with two pillows at night.

View Answer***17. The answer is C[seeand].*****18. All of the following statements regarding antacid use in gastroesophageal reflux disease (GERD) are correct *except* which one?**

(A) The onset of symptom relief with antacids is 1-2 hr.

(B) Antacids will relieve symptoms for 1-3 hr.

(C) Sodium bicarbonate should not be used in patients with edema, congestive heart failure, or those on low-salt diets

(D) The most frequent side effect of aluminummagnesium combination antacids is diarrhea.

View Answer***18. The answer is A[see].*****19. All of the following statements regarding use of nonprescription H_2RAs in gastroesophageal reflux disease (GERD) are correct *except* which one?**

(A) The most common adverse effects of nonprescription H_2RAs are headache, diarrhea, dizziness, and nausea.

(B) Cimetidine may increase serum concentrations of warfarin, theophylline, and phenytoin.

(C) The onset of symptom relief with these agents is 1-2 hr.

(D) Nonprescription H_2RAs will heal severely damaged esophageal mucosa.

View Answer***19. The answer is D[seeand].*****20. All of the following statements regarding use of nonprescription products for gastroesophageal reflux disease (GERD) in special populations are correct *except* which one?**

(A) Nonprescription H_2RAs are not approved for use in children < 12 years of age.

(B) Antacids may be safely used in pregnant patients as long as chronic high doses are avoided.
(C) Sodium bicarbonate is the preferred antacid in pregnant patients.
(D) Doses of nonprescription H_2RAs do not need to be reduced in elderly patients.

View Answer***20. The answer is C[see].***P.705

Directions for questions 21-23: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

21. Which of the following drugs most commonly causes constipation?
I. ampicillin
II. narcotic analgesics
III. drugs possessing anticholinergic properties
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***21. The answer is D[see].*****22. Which of the following statements about stimulant laxatives is correct?**
I. They produce a stool more quickly than any other type of laxative.
II. They are associated with more adverse effects than any other type of laxative.
III. They work by irritating the lining of the colon wall to increase peristalsis and produce a stool.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***22. The answer is D[see].*****23. When should a patient experiencing diarrhea be referred to a physician by a pharmacist?**
I. If the patient has pus or blood in the stool.
II. If the patient also suffers from vomiting.
III. If the patient has a fever.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***23. The answer is E[see].***P.706

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* I.B.2.a*].*

Glycerin and the bisacodyl suppository all produce stools in 30 min to a few hours, whereas psyllium, a bulk-forming laxative, produces stool in 24-72 hr in the same manner as a normal bolus of food or fiber.

2. The answer is D *[see* I.C.4*].*

The popular sodium phosphate enemas (e.g., Fleet) are very effective but have resulted in hyperphosphatemia, hypocalcemia (tetany), hypokalemia, metabolic acidosis, and cardiac death usually owing to conduction abnormalities in very small children. This has mainly occurred in children < 2 years of age or between 2 and 5 years of age with predisposing factors, such as chronic renal disease, anorectal malformations, and/or Hirschsprung disease. The use of enemas is highly discouraged in children < 5 years of age.

3. The answer is D *[see* I.B.2.d*].*

These agents have a long onset of action (24-48 hr); thus they should never be used for acute constipation but should be used mainly for patients who should not strain to pass hard stools (e.g., pregnant patients, postsurgical patients, post-myocardial infarction). However, they have never been found to be more effective than placebo in long-term use.

4. The answer is B *[see* I.B.2.a; I.B.2.c*].*

Stimulant products result in a quicker, more complete, and often more violent evacuation of the bowel than do the bulk-forming agents. Bulk-forming agents are developed from complex sugars, similar to fiber, that provide bulk to increase gastrointestinal motility and water absorption into the bowel. However, patients must drink plenty of water to facilitate the absorption of water into the bowel, or they may become more constipated.

5. The answer is B *[see* II.C.1*].*

The most important part of treating acute diarrhea is the replacement of lost fluids. If patients experience mild to moderate fluid loss, replacement can be done with oral-rehydration solutions. If fluid loss is severe (> 10% loss of body weight) and/or severe vomiting, then patients may need intravenous rehydration before oral-maintenance fluids can be administered. There has been much controversy regarding the decision to feed or not feed children during acute episodes of diarrhea. Recent information shows that children should remain on their normal diet or breast-feeding during episodes of diarrhea; these do not make the diarrhea worse and may actually improve the condition.

6. The answer is B *[see* II.C.1.b*].*

Replacement fluids for diarrhea should contain the appropriate amount of electrolytes (K^+, Na^+, Cl^-, citrate) and glucose per specified amount of water, as found in commercially available oral-rehydration solutions such as Pedialyte and Rehydralyte. The World Health Organization (WHO) solution, which can easily be made at home, and half-strength Gatorade provide the necessary electrolytes and glucose to replenish lost fluids. Kool-Aid does not contain potassium. Carbonated beverages are low in potassium, and some are too high in glucose.

7. The answer is D *[see* II.C.2.b*].*
Adsorbents are not effective for severe diarrhea because they simply cannot adsorb enough water and do not reverse the cause of the diarrhea. Large doses may decrease symptoms. Of all the adsorbents, kaolin is the most effective and is now recognized by the FDA as safe and effective. All adsorbents are safe because they are not adsorbed systemically.
8. The answer is A *[see* II.A.2.b; II.C.2*].*
Traveler's diarrhea is primarily caused by bacteria (mainly enterotoxin *Escherichia coli*). Prophylaxis and treatment regimens include oral antibiotics (fluoroquinolones, sulfonamides, doxycycline) and bismuth subsalicylate (Pepto-Bismol). *Helicobacter pylori* is the organism shown to contribute to refractory peptic ulcer disease.

9. The answer is D *[see* I.B.2*].*
The ideal laxative is natural (i.e., similar to food) and produces stool on a regular basis. The product produces stool quickly (i.e., in several hours) without adverse effects. such as abdominal cramping or the formation of a hard stool, which may be difficult to pass. Products such as fiber or bulk-forming agents produce a stool similar to a bolus of food, without adverse effects. Emollient laxatives (i.e., stool softeners) produce soft stools without difficult defecation. Stimulants produce a stool quickly, but patients often experience severe abdominal cramping and hard stools.
10. The answer is B *[see* II.C; Table 33-3*].*
Giving highly osmotic solutions of glucose (e.g., soda, fruit juice) can result in more water absorbed into the intestinal tract and thus further diarrhea. Many cases of diarrhea resolve within 48 hr without treatment. People with diarrhea can avoid food for at least 6 hr, then increase their fluid intake slowly. Severe cases of infectious diarrhea can be treated with antibiotics or antiprotozoals, depending on the organism that caused the episode.
11. The answer is C *[see* III.H.2.b*].*
Because of its chemically distinct structure, pramoxine exhibits less cross-sensitivity compared to the other anesthetics and should be used in patients with a lidocaine allergy.
12. The answer is D *[see* III.G.1*].*
A conservative approach to treatment includes sitz baths, the use of stool softeners to prevent straining when passing a stool, and the use of an anesthetic hemorrhoidal preparation. If improvement is not seen, more aggressive therapy may be pursued (e.g., rubber band ligation).
13. The answer is A *[see* III.D.1*].*
The most common sign/symptom of hemorrhoids is painless bleeding occurring during a bowel movement.
14. The answer is B *[see* III.H.7*].*

Juniper tar, menthol, and camphor are the only three agents deemed safe and effective as analgesics, anesthetics, and antipruritics by the FDA. These agents were formerly classified as counterirritants.

15. The answer is C *[see* III.H.3.a*].*

Vasoconstrictors deemed safe and effective by the FDA are ephedrine HCl, epinephrine, and phenylephrine.

16. The answer is C *[see* IV.A.2 *and* 3; IV.A.6*].*

Pain on swallowing often suggests severe esophageal mucosal damage, which would require prescription medications for healing. Difficulty on swallowing may indicate an esophageal stricture, cancer, or motor disorder. All of these conditions require diagnosis and treatment by a healthcare provider.

17. The answer is C *[see* IV.B.1.a, b, c, d, e, f, g, h, i, j *and* k*].*

Patients should be instructed to eat evening meals at least 3 hr before going to bed. This allows sufficient time for gastric emptying, so that the volume of refluxed material will be smaller and less irritating to the esophagus.

18. The answer is A *[see* IV.B.2.a*].*

One of the major advantages of antacid use in heartburn is its quick onset of action. Most patients with mild GERD will experience relief from antacids within 5-15 min of administration.

19. The answer is D *[see* IV.B.2.c *and* d*].*

Nonprescription doses of H_2RAs are too low to heal esophageal damage. Esophageal mucosal damage is difficult to heal and requires high doses of H_2Ras, which are available only by prescription. Alternatively, proton pump inhibitors, which completely suppress acid secretion, may be used to heal esophageal mucosal damage.

20. The answer is C *[see* IV.C.2*].*

Sodium bicarbonate should be avoided in pregnant patients because the high sodium load may cause systemic alkalosis, edema, and/or weight gain.

21. The answer is D (II, III) *[see* I.A.3.d*].*

Opiate analgesics (e.g., narcotics) and drugs with anticholinergic properties decrease bowel motility, which results in increased water absorption from the intestinal tract. This can cause a harder, drier stool, which results in constipation. Ampicillin is often poorly absorbed from the intestinal tract and can alter the flora of the intestinal bowel. This destruction of bowel organisms causes increased secretions into the bowel, which results in diarrhea.

22. The answer is D (II, III) *[see* I.B.2.c*].*

Stimulant laxatives do have a quick onset of action but not any quicker than the saline laxatives, which usually work in 4-6 hr. The mechanism of action for stimulant laxatives is that they irritate the lining of the colon wall, which increases peristalsis and produces a stool. These laxatives are associated with more adverse effects than other laxatives.

23. The answer is E (I, II, III) *[see* II.B.2*].*

Patients with pus or blood in the stool, vomiting, or fever may be suffering from severe bacterial diarrhea and may lose large amounts of fluid, which could result in severe dehydration.

OTC Menstrual, Vaginal, and Contraceptive Agents

Laura K. Williford Owens

I. MENSTRUATION AND MENSTRUAL PRODUCTS

A. Introduction. Menstruation is a physiological discharge of blood, endometrial cellular debris, and mucus through the vagina of a nonpregnant woman and is a result of the monthly cycling of female reproductive hormones. The menstrual cycle eliminates a mature, unfertilized egg and prepares the endometrium for the possible implantation of a fertilized egg the following month.

1. Onset. The average age at which the initial menstrual cycle occurs in U.S. women is 12 years. Normal menarche (initial menstrual cycle) can occur between the ages of 9 and 16 years. Factors such as race, genetics, nutritional status, and body mass determine the onset.

2. Duration. The **average** duration of the menstrual cycle is 28 days (the time between the onset of one menstrual flow and the beginning of the next) and the normal range is 21-35 days. Day 1 is the first day of menstrual flow, which can last for 3-7 days (average duration of flow is 5 days).

3. Physiology. The menstrual cycle results from a complex interplay of hormones produced by the hypothalamus, pituitary gland, and the ovaries (hypothalamic-pituitary-ovarian axis).

B. Menstrual abnormalities

1. Dysmenorrhea is painful menstruation. It is the most common gynecologic problem in the United States.

a. Types

(1) Primary dysmenorrhea is pain associated with menstruation in the absence of identifiable pelvic disease. It is prompted by increased levels of prostaglandins in the menstrual fluids.

(2) Secondary dysmenorrhea is associated with an underlying pelvic disorder. Possible causes include endometriosis, pelvic inflammatory disease (PID), and ovarian cysts.

b. Symptoms of dysmenorrhea are primarily lower abdominal cramping and can often include nausea, vomiting, diarrhea, headache, and dizziness. Abdominal cramping usually begins at onset of menstrual flow or a few hours before onset.

c. Practitioners should **question the patient** about the following:

(1) Current medications (including over the counter and herbals)

(2) Age

(3) Duration of dysmenorrhea

(4) A description of the dysmenorrhea symptoms

(5) History of pelvic disease (endometriosis, PID, ovarian cysts, infertility)

(6) Allergy to aspirin or nonsteroidal anti-inflammatory drug (NSAID)

(7) Bleeding disorder

(8) Exercise routine

d. Treatment

(1) Recommendation of therapy should be based on the patient's assessment of the degree of pain. Pain associated with dysmenorrhea generally tapers within 2 days. Prolonged pain may be associated with an underlying problem, and patients should be referred to a physician.

(2) Nonpharmacological recommendations include rest, heat, wearing loose-fitting clothing, and exercise.

(3) Agents for the relief of dysmenorrhea include

(a) Analgesics are used as primary treatment of dysmenorrhea and for relief of cramping associated with premenstrual syndrome (PMS; see I.B.4]. Analgesic

treatment provides relief for mild to moderate symptoms but will probably not help patients with severe symptoms.

(i) Nonsteroidal anti-inflammatory drugs (NSAIDs) inhibit the synthesis and action of prostaglandins. Because prostaglandins are responsible for the cramping of dysmenorrhea it makes logical sense to recommend NSAIDs to a patient.

For women who do not receive relief from over-the-counter (OTC) analgesics, prescription NSAIDs may prove more useful.

{**a**} **Administration guidelines.** Begin therapy at the onset of pain; there is no proven value in beginning therapy in anticipation of dysmenorrhea.

- Ibuprofen (e.g., Advil, Midol Cramp & Body Aches, Motrin IB): 200 mg every 4-6 hr; maximum 1200 mg/day
- Naproxen (e.g., Aleve, Pamprin All Day): 200 mg every 8-12 hr; maximum 600 mg/day

{**b**} **Adverse effects.** From a few days of use, adverse effects are limited. Common adverse effects associated with NSAIDs include upset stomach, vomiting, heartburn, abdominal pain, diarrhea, constipation, and dizziness. NSAIDs should be taken with food to decrease adverse gastrointestinal (GI) effects or bleeding.

{**c**} **Warnings.** Patients should be advised to use the lowest effective dose for the shortest duration needed to lessen the potential risk for cardiovascular events. Patients with an allergy to NSAIDs or active GI disease should not take any NSAIDs.

(ii) Treatment with **aspirin** or **acetaminophen** can prove of benefit for the symptoms associated with primary dysmenorrhea, however; aspirin is not as potent as the other NSAIDs and acetaminophen is not thought to prevent prostaglandin production to a great extent, although it can be helpful for treating the headache and backache that may occur with menstrual cramping.

(b) Diuretics are **recommended** by the U.S. Food and Drug Administration (FDA) for use in eliminating water during premenstrual and menstrual periods. When administered approximately 5 days before menses, diuretics help relieve bloating, excess water, cramps, and tension. Included in this category are ammonium chloride, caffeine, and pamabrom.

(i) Ammonium chloride (Aqua-Ban) is an acid-forming salt often used in combination with caffeine.

{**a**} Up to 3 g of ammonium chloride (NH_4Cl) per day can be administered in three divided doses for no longer than 6 days.

{**b**} Larger doses are often associated with GI symptoms.

{**c**} Aqua-Ban Plus contains both ammonium chloride and caffeine.

(ii) Caffeine (e.g., Midol Menstrual Complete and Menstrual Headache, No Doz, Vivarin), a xanthine derivative, promotes diuresis by inhibiting tubular reabsorption of sodium and chloride.

{**a**} The **recommended dosage** is 100-200 mg every 3-4 hr.

{**b**} **Side effects** associated with caffeine use are GI disturbances and central nervous system (CNS) stimulation.

{**c**} Patients should be counseled to limit the consumption of caffeine-containing foods or beverages while taking this product.

(iii) Pamabrom (e.g., Midol PMS, Midol Teen Formula, Pamprin) is a theophylline derivative often used in combination with analgesics and antihistamines. The recommended dosage is 50 mg four times daily, not to exceed 200 mg/day.

2. Amenorrhea is the absence of menstruation. The development of primary or secondary amenorrhea requires physician evaluation.

3. Intermenstrual pain and **bleeding** generally occur at midcycle and may last from several hours to days. Pain is often associated with ovulation (mittelschmerz). Therapy consists of nonprescription analgesics. Patients with pain lasting longer than 2 days should be referred to a physician.

4. PMS

a. Symptoms (e.g., marked mood swings, fatigue, appetite changes, bloating, breast tenderness, irritability, feelings of depression) begin 1-7 days before the onset of menses.

b. Nonpharmacological therapy includes regular exercise, dietary modifications, and reduction of stress factors. Dietary modifications include avoiding alcohol and caffeine, which can increase irritability, and consuming a balanced diet of fruits, vegetables, and complex carbohydrates while avoiding salty foods and simple sugars (can exacerbate fluid retention). Patients experiencing symptoms abnormal to their cycle should be referred to a physician.

c. **Pharmacological treatment.** The efficacy and safety of pharmacological treatment of PMS are aimed at the proposed causes (e.g., a drop in

progesterone concentrations, high levels of prolactin, elevated estrogen concentrations, deficiencies of vitamins A or B_6, or an underlying disorder) and are not well studied. Although clinical trials do not support the efficacy of vitamins A or B6, both have been used for the treatment of PMS.

(1) Prescription drug products that have been studied in the management of PMS include benzodiazepines, monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants (TCAs), and selective serotonin reuptake inhibitors (SSRIs). Fluoxetine (under the brand name Sarafem) has been approved for the treatment of premenstrual dysphoric disorder.

(2) Combination products are marketed for women with PMS symptoms. These products contain acetaminophen, pamabrom, and pyrilamine (Midol and Pamprin). Nonprescription diuretics such as pamabrom are commonly used to reduce fluid accumulation associated with PMS. Pain is an uncommon symptom of PMS, and the sedative effect of an antihistamine (pyrilamine) is unlikely to provide relief of the emotional symptoms associated with PMS. Combination products should be recommended only with caution.

(3) Daily **calcium supplementation** (equivalent to the recommended daily calcium intake for women of reproductive age) has been shown to reduce the emotional and physical symptoms of PMS.

5. Menorrhagia is excessive menstrual blood loss. (The development of menorrhagia requires physician evaluation.) Low hematocrit, low hemoglobin, and low serum iron levels may occur. Treatment for menorrhagia is usually an estrogen-progestin combination (i.e., oral contraceptive).

C. Toxic shock syndrome (TSS) is a rare but sometimes fatal illness often associated with menstruation.

1. TSS can be categorized either as menstrual or nonmenstrual, with approximately two thirds of cases associated with menstruation. TSS is known to occur in both men and women.

2. The condition usually affects women < 30 years of age who use tampons. Women between the ages of 15 and 19 years are at the highest risk.

3. TSS is characterized by an abrupt onset (8-12 hr) of flu-like symptoms (e.g., high fever, myalgia, vomiting, diarrhea). Neurologic symptoms such as headache, agitation, lethargy, seizures, and confusion can also occur.

4. TSS results from an exotoxin produced by *Staphylococcus aureus.*

5. The **primary risk factor** for TSS is the **use of tampons.** Additional risk factors include barrier contraceptives (e.g., diaphragms, cervical sponges).

6. When TSS is suspected, patients should be hospitalized immediately. To lower the risk of TSS, women should use lower-absorbency tampons and alternate the use of tampons with feminine hygiene pads; however, to lower the risk to nearly zero, women should use sanitary pads instead of tampons.

D. Menstrual products like feminine hygiene pads and tampons are used to absorb menstrual and other vaginal discharges.

1. Feminine hygiene pads are available in a wide variety of sizes and absorbencies. Super or maxi pads may be used for the heaviest menstrual flow (usually occurring on day 2 of the cycle). Mini or light pads and junior or teen pads are designed for women with smaller anatomy and/or lighter flow. Frequent changing of sanitary pads minimizes the occurrence of unpleasant odors and helps minimize irritation and chafing.
2. Tampons are intravaginal inserts designed to absorb vaginal discharge. Many women prefer tampons because they are worn internally, which lessens chafing, odor, bulkiness, and

irritation. Super tampons are designed for heavier flow. Junior or regular tampons are designed for moderate to light menstrual flow. Frequent changing of tampons will minimize the risks associated with TSS.

II. VAGINAL PRODUCTS

A. Vulvovaginal candidiasis

1. General considerations

a. Occurrence. Approximately 75% of all women will experience vulvovaginal candidiasis (yeast infection) at least once, and 50% will have a second episode. Only 5% of women experience recurrent infections (four or more infections within a 1-year period).
b. Cause. *Candida albicans* is responsible for up to 92% of infections. Infections owing to *C. glabrata* are increasing.
c. **Predisposing factors.** Antibiotics, oral contraceptives containing high-dose estrogen, pregnancy, diabetes, poor post-bowel movement hygiene, and immunosuppression increase the risk for infection.
d. Symptoms. Can include a thick, white, “cottage cheese-like,” nonmalodorous vaginal discharge; dysuria; vaginal burning; and pruritus.

2. Patient assessment

a. Patients should be questioned about presence of symptoms, medication use, medical conditions, and history of vaginal yeast infections.
b. The following patients should be referred to a primary-care provider for diagnosis and treatment:
(1) First episode of symptoms
(2) Pregnant
(3) Younger than 12 years of age
(4) Systemic symptoms such as fever
(5) History of recurrent vaginal yeast infections
(6) Discharge with a fishy odor (indicates bacterial vaginosis, most often caused by anaerobic bacteria) or a thin, malodorous purulent discharge (indicates of *Trichomonas* infection)

3. Pharmacological treatment

a. Nonprescription agents are recommended only for patients who have had a prior yeast infection and who can potentially recognize the infection and self-medicate.

b. The choice of nonprescription therapy is based on patient preference.

c. Available formulations include intravaginal creams, suppositories, and ointments.

d. External vaginal creams can be used in combination with intravaginal products to treat vulvar symptoms of pruritus.

e. Intravaginal products are used at bedtime, whereas the external creams can be used any time of day.

f. Available nonprescription therapies include the antifungal agents Gyne-Lotrimin and Mycelex-T (clotrimazole), Monistat 3 and Monistat 7 (miconazole), Femstat 3 (butoconazole), and Monistat 1 and Vagistat 1 (tioconazole).

(1) Gyne-Lotrimin and Monistat 7 are used for 7 consecutive days; Monistat 3 and Femstat 3 are used for 3 consecutive days; Monistat 1 and Vagistat 1 are used for 1 day.

(2) Efficacy rates approach 80%-90%.

(3) Many products are available as a "combination pack" including an internal cream or suppository and cream for external use.

4. Patient counseling

a. Nonpharmacological

(1) Dry vaginal area well after bathing with a towel.

(2) Avoid tight or damp clothing.

(3) Wear cotton underwear.

(4) Use unscented soap to avoid irritation.

(5) Avoid douching.

(6) Decrease consumption of sucrose and simple sugars.

b. Pharmacological

(1) Complete the course of therapy even if symptoms improve.

(2) Wash vaginal area with mild soap before application.

(3) Reusable applicators should be washed with soap and water.

(4) Avoid sexual intercourse during therapy.

(5) Avoid condoms and diaphragm use for 72 hr after therapy is completed.

(6) Continue use during menstrual period.

(7) Avoid tampons during use.

(8) Sanitary pads can be used for leakage of intravaginal products.

(9) Side effects can include burning or irritation.

B. Feminine hygiene products. There are a variety of feminine hygiene products available for cleansing and controlling odor associated with normal vaginal discharge. These products are not used to treat vaginal infections.

1. Vaginal douches (Summer's Eve) irrigate the vagina and can be used for cleansing, for soothing, as an astringent, or to produce a mucolytic effect.
2. Vaginal suppositories (Betadine-medicated suppositories) are used for soothing, to relieve minor irritations, and to reduce the number of pathogenic microorganisms.

III. OTC CONTRACEPTIVES

A. Introduction. The **efficacy** and **pregnancy rates** for various means of contraception depend greatly on the **degree of compliance.** Table 34-1 lists ranges of pregnancy rates reported for a variety of contraceptives.

Table 34-1. Pregnancy Rates for Various Means of Contraception (%)[a]

Method of Contraception		Typical[b]	Lowest[c]
Oral contraceptives			
Combination (estrogen-progestin)		0.1-0.34	0.1
Progestin only		0.5-1.5	0.5
Mechanical/chemical			
Cervical cap[d]			
	Multiparous	40	26
	Nulliparous	20	9
Male condom without spermicide		12-14	3
Male condom with spermicide		4-6	1.8
Diaphragm[d]		20	6
Female condom		21	5
Intrauterine device		≤ 1-2	≤ 1-1.5

Levonorgestrel implants	≤ 1	≤ 1
Medroxyprogesterone injection	≤ 1	≤ 1
Spermicide alone	20-22	6
Other		
Rhythm (all types)	25	1-9
Vasectomy/tubal ligation	≤ 1	≤ 1
Withdrawal	40-50	30
No contraception	85	85

[a] During first year of continuous use.

[b] A typical couple who initiated a method that either was not always used correctly or was not used with every act of sexual intercourse, and who experienced an accidental pregnancy.

[c] The method of birth control was always used correctly with every act of sexual intercourse but the couple still experienced an accidental pregnancy.

[d] Used with spermicide.

Adapted with permission from Nonprescription Drug Therapy Guiding Patient Self-Care, 4th ed. St. Louis, MO, Wolters Kluwer Health, 2005.

B. Methods of contraception that may make use of nonprescription products or devices include the following:

1. Fertility awareness methods make use of information concerning the menstrual cycle to determine the days when intercourse is most likely to result in a pregnancy. **Periodic abstinence** is also referred to as the **rhythm method, natural family planning,** or **ovulation detection method.** The various natural family planning methods allow the patient to monitor the

natural physiological signs that can, in many women, predict the fertile period (periovulatory phase of the menstrual cycle), enabling the couple to avoid coital exposure at that time. These methods are based on reproductive anatomy and physiology and are applied according to the signs and symptoms naturally occurring in the menstrual cycle.

a. Calculations of the period of fertility take into account the **sperm viability** in the female reproductive tract, which is estimated to average **2-3 days** (up to 5 days), and the **fertile period of the ovum,** which is estimated to be **24** hr. Recent studies indicate that conception is most likely to occur when couples have intercourse during a 6-day period ending on the day of ovulation. **Conception is highly unlikely if sexual intercourse occurs 6 or more days before ovulation or the day after ovulation.**

b. Disadvantages to the rhythm method (but necessary to ensure efficacy) include both the **long periods of abstinence** and the **charting of menses.** Methods of natural family planning and periodic abstinence include the temperature method, calendar method, Billings method, and symptothermal method.

c. **Temperature method. Basal body temperature** (BBT) determination makes use of a **basal thermometer,** which can be purchased without a prescription. The thermometer covers the range of temperature from 96°F to 100°F in 0.1° gradations.

(1) The significance of basal temperature determination lies in the fact that within 24 hr preceding ovulation, there is a **moderate drop in the basal temperature** followed by a **noticeable rise in the body temperature,** usually about 24 hr after ovulation. This rise is usually maintained for the remainder of the cycle and is thought to be the result of the thermogenic properties of **progesterone,** the hormone indicating the transition from the ovulatory phase to the luteal phase. Therefore, ovulation is marked by the transition of the falling temperature to the rising temperature.

(2) For many women, **abstinence** should be practiced from approximately **5 days after the onset of menses until 3 days after the transition in temperature.**

(3) Because the basal temperature reflects the amount of heat radiation when the body is at its metabolic low, the temperature should be taken first thing in the morning (i.e., before any activity). The thermometer may be placed under the tongue, in the rectum, or in the vagina (the temperature should always be taken from the same place) and should be left undisturbed for at least 5 min (mercury thermometer). Electronic digital thermometers are also available that have shorter recording times (45-90 sec). Infection, tension, a restless night, or any type of excessive movement can cause variations in temperature readings that do not reflect the BBT.

d. The **calendar method** estimates the possible day of ovulation. **Abstinence** should be practiced during the period around ovulation when there may be a fertilizable egg present. Whereas the calendar rhythm method was used for several decades, it has not been promoted as a

method of natural family planning for many years. Although women who have regular menstrual cycles are able to use the calendar rhythm method successfully, women with irregular cycles, women who are breast-feeding, or women with postponed ovulation cannot depend on the calendar rhythm method.

(1) For a span of **approximately 1 year,** the patient records her menstruation dates on a calendar.

(2) Calendar charting allows the patient to calculate the onset and duration of her fertile period—the time during which a viable egg is available for fertilization by sperm. Calculation of the fertile period rests on three assumptions:

(a) Ovulation occurs on day **14 (± 2 days) before the onset of the next menses.**

(b) Sperm remain viable for 2-3 days.

(c) The ovum survives for 24 hr.

(3) The calendar is then reviewed to determine the length of her shortest and longest cycle.

(a) The patient then subtracts 18 days from the number of days of her shortest cycle. This number should correspond to the first possible fertile day in any given cycle—14 + 2 = 16 days; 16 + 2 = 18 days (viability of sperm); see III.B.1.b.

(b) Next, the patient subtracts 11 days from the number of days of the longest cycle. This number should correspond to the last possible fertile day in any given cycle—14 - 2 = 12 days; 12 - 1 = 11 days (viability of ova); see III.B.1.b.

(4) Abstinence should be practiced from the first possible fertile day through the last possible fertile day.

(5) Example. Assume the shortest number of days between two consecutive menses is 25 and the longest number of days between two consecutive menses is 32. Then, 25 days (the shortest cycle) - 18 days = 7 (or day 7), and 32 days (the longest cycle) - 11 days = 21 (or day 21). Therefore, abstinence should be practiced from day 7 through and including day 21 of each cycle.

e. The **cervical mucus (Billings or cervical secretions)** method of rhythm is based on the principle that the normal, thick, creamy white vaginal mucus becomes clear and tenacious around the time of ovulation (much like a raw egg white).

(1) The woman should watch for this change in mucus consistency and practice abstinence around the time of ovulation.

(2) The woman should consider herself fertile for 3-4 days after the peak change.

f. The **symptothermal** method, rather than relying on a single physiological index, uses several indices to determine the fertile period.
(1) The **most common** calendar calculations and **changes in the cervical mucus** are used to estimate the **onset of the fertile period.**
(2) Changes in the mucus or basal temperature are used to estimate the end of the fertile period.
(3) Because several indices need to be monitored, this method is more difficult to learn than the single-index method, but it is more effective than the cervical mucus method (i.e., Billings method) alone.
2. Spermicidal agents are composed of an **active spermicidal chemical,** which immobilizes or kills sperm, and an **inert base** (e.g., foam, cream, jelly, gel, tablet, or suppository), which localizes the spermicidal chemical in proximity to the cervical os. These agents work by disrupting the sperm membrane and by decreasing the ability of sperm to metabolize fructose. Two forms of inert bases (gels and foams) act as a physical barrier against sperm.
a. The active ingredient includes **nonoxynol-9.** which is considered safe and effective by the FDA.
(1) Administration guidelines. Applicators may be prefilled before use.
(2) Side effects—for example, sensation of warmth, rare allergic reactions (**contact dermatitis** with rash, stinging, itching, and swelling)—are minimal. If a suspected reaction occurs, one should be instructed to use another product because the issue might be the concentration of the spermicide or an additive specific to a given brand. There are no significant differences in birth-defect rates between users and nonusers.
b. Effects against sexually transmitted diseases (STDs). Nonoxynol-9 is lethal to selected microbes in the laboratory setting and may help inhibit a variety of sexually transmissible organisms, including those responsible for gonorrhea, chlamydial infection, candidiasis, genital herpes, syphilis, trichomoniasis, and HIV/AIDS. There have been inconsistent results in human studies, however. One concern relates to the fact that frequent use of spermicides can cause vulvovaginal epithelial disruption, which may increase susceptibility to HIV. In addition, **spermicides** may alter the vaginal flora and, therefore, **should not be relied on alone for STD prevention.**
c. **Dosage forms. Contraceptive spermicides,** which are available in several forms, offer the greatest variety within one specific method of contraception (Table 34-2).
(1) Creams, jellies, and gels are used with a diaphragm. The concentration of spermicide is less than the necessary 8% to be employed as a single contraceptive method.
(2) Foams disperse better into the vagina and over the cervical opening but provide less lubrication than creams, jellies, and gels. They usually contain a higher concentration of spermicide (i.e., **the optimal concentration of 8% or higher**). Because of volume differences among brands, the dosage amounts vary. If vaginal or penile irritation develops, another brand should be tried.
(a) The can should be shaken vigorously 20 times before use.

(b) The foam should be inserted intravaginally about two thirds the length of the applicator, and the contents should be discharged.

(c) Foam should be reapplied during prolonged intercourse (i.e., lasting > 1 hr) and before every subsequent act of intercourse.

Table 34-2. Spermicides[a]

Type (Product)	Comments
Film (VCF)	Inserted by the female directly over the cervix; insert not less than 15 min and not more than 3 hr before intercourse; contraceptive protection begins 5-15 min after insertion and remains effective no more than 3 hr
Foam (Ortho Options Delfen foam, VCF Vaginal Contraceptive foam)	Contraceptive protection is immediate; remains effective no more than 1 hr, additional dose is needed before any subsequent intercourse
Jellies, creams, gels (KY Plus Lubricating, Ortho Options Gynol II jelly, Ortho Options Conceptrol gel, Advantage-S)	Contraceptive protection is immediate; used alone remains effective no more than 1 hr; when used with diaphragm or cap, keep diaphragm or cap in place for at least 6 hr after last intercourse
Suppositories and tablets (Encare Insert)	Contraceptive protection begins 10-15 min after insertion; remains effective no more than 1 hr

[a]The spermicidal agent in all listed products is nonoxynol-9.

Reprinted with permission from Hatcher RA. Contraceptive Technology 1994-1996, 16th ed. New York, Irvington, 1994:180.

(d) To ensure efficacy, the patient should wait at least 8 hr before douching to avoid diluting the spermicide effect or “forcing” sperm into the cervix.

(3) Suppositories and foaming tablets. These agents are both small and convenient. Although solid at room temperature, suppositories melt at body temperature, whereas foaming tablets effervesce.

(a) The tablets should be wetted before insertion, which may create a sensation of warmth.

(b) The tablet or suppository should be inserted high into the vagina, 10-15 min before intercourse.
(c) Intercourse must occur within 1 hr or the dose must be repeated.
(d) Another tablet or suppository should be inserted before each repeated act of intercourse.
(e) To ensure efficacy, the patient should wait 6-8 hr after the last act of intercourse before douching.
(4) Film comes as small paper-thin sheets (e.g., VCF). It is inserted on the tip of the finger into the vagina and placed at the cervical opening 5-15 min before intercourse.
(5) Sponge. This fairly popular product was removed from the market in the mid-1990s because of cost issues related to its manufacture. The new owner of the Today sponge (Allendale Pharmaceuticals) is currently remarketing this product. It is a doughnutshaped polyurethane device containing the spermicide nonoxynol-9; it is inserted into the vagina before sexual intercourse. Efficacy is approximately comparable to that of a cervical cap. It is believed to act as a contraceptive in three ways: (1) mechanically blocking the cervical entrance, (2) absorbing semen, and (3) providing a spermicide. It can remain in place for 24 hr. Concerns are a higher risk for TSS and a higher pregnancy rate for women who have never given birth (nulliparous women).
3. Condoms are used to prevent transmission of sperm into the vagina.
a. Types. They are made of latex rubber, processed collagenous lamb caecum sheaths (lambskin), or polyurethane.
(1) Latex condoms may help prevent the transmission of many STDs. They are usually packaged with the following label “when used properly, the latex condom may prevent the transmission of many STDs such as syphilis, gonorrhea, chlamydia infections, genital herpes, and AIDS.”
(a) Latex affords greater elasticity than lambskin, and latex condoms are more likely to remain in place on the penis.
(b) A variety of types are available (e.g., lubricated, ribbed, colored), including some with spermicide (concentration much less than that of a vaginal spermicide product).

It is doubtful that spermicide-lubricated condoms offer any better protection than plain latex condoms, and they have a shorter shelf life. There is a standard size, but smaller and larger versions are available.
(i) Latex condoms are available with a plain end or with a reservoir tip (sometimes designated as “enz”). The reservoir tip provides room for the ejaculate; however, a space may be left when using the plain-end condom, which accommodates the fluid just as effectively.
(ii) The **prelubricated condom** helps prevent dyspareunia in a couple with insufficient natural lubrication. Prelubrication decreases the risk of tearing the condom. However, the extra lubrication may be excessive, lessening sexual

fulfillment for a couple who have adequate natural lubrication or when contraceptive foam is also used.

(iii) Latex rubber may cause an allergic reaction. An estimated 1%-2% of the population is sensitized to natural rubber latex, and higher percentages are likely for those frequently exposed to latex (e.g., healthcare workers). The most common symptoms are genital inflammation with redness, itching, and burning. Sometimes, antioxidants or accelerators used during the manufacturing process may be the cause of the allergy.

(2) Lambskin condoms are **not** considered as effective as latex condoms (and cannot be labeled as such) in preventing the transmission of STDs, including AIDS. The lambskin condoms are structured to consist of membranes that reveal layers of fibers crisscrossing in various patterns. This gives the lambskin strength, but also allows for an occasional pore. Therefore, lambskin may allow HIV and hepatitis B virus, which are smaller than sperm, to pass through.

(a) Lambskin has less elasticity than latex, and lambskin condoms may slip off the penis.

(b) Lambskin affords **greater sensitivity** than latex.

(c) Lambskin condoms are more expensive than latex condoms.

(3) A **polyurethane condom** (e.g., Avanti, Trojan Supra) is available for men and is marketed for individuals who are allergic to latex. Some evidence exists that slippage and breakage rates may be higher than for latex condoms. In contrast to the latex condom, petroleum-based products will not degrade the polyurethane.

b. Advantages and disadvantages. The relative accessibility, ease of transport, and low cost make condoms an attractive method of contraception. However, the coital act must be interrupted to apply the condom, and often one or both partners complain of a partial or complete decrease in sensation.

c. **Use**

(1) The female external genitalia should not be touched with the exposed penis, and the vagina should not be penetrated, until the condom is unrolled onto the erect penis.

(2) The condom should be unrolled onto the penis as far as it will go. With the plain-end condom, a space between the tip of the penis and the tip of the condom should be left to catch the ejaculate.

(3) With either reservoir-tip or plain-end condoms, the tip of the condom must be held between the thumb and index finger to avoid trapping air while unrolling the condom onto the penis. (The space will decrease the likelihood of both rupture secondary to pressure and regurgitation of the ejaculate onto the external genitalia.)

(4) Proper lubrication to minimize the possibility of tearing can be ensured by using either a lubricated condom or by applying KY jelly or spermicidal cream or jelly to either the condom or the woman's genitalia. (*Note:* Petroleum jelly [Vaseline] should never be used because it causes deterioration of the rubber [latex] and is a poor lubricant.) Spermicidal foam, cream, or jelly is an excellent adjunctive contraceptive.

(5) Before the penis becomes flaccid, it must be withdrawn from the vagina and the condom eased off. The **condom** should be handled with special care so as not to lose it into the vagina or spill any of the ejaculatory fluid onto the external genitalia.
(6) A condom should never be reused.
(7) Condoms should not be stored near excessive heat.
(8) If the condom should break or leak, spermicide foam should be immediately inserted vaginally.
P.718

(9) Do not buy or use condoms that have passed their expiration date.
(10) Be sure to store condoms in a cool, dry place, out of direct sunlight. The glove compartment of a car is not a good place to store condoms. Do not store condoms in pockets, purses, or wallets for more than a few hours.
4. The **female condom** (Reality) is a **disposable polyurethane sheath** that fits into the vagina and **provides protection from pregnancy and STDs.**
a. The sheath resembles a plastic vaginal pouch and consists of an **inner ring,** which is inserted into the vagina near the cervix much like a diaphragm, whereas the **outer ring** remains outside the vagina, covering the labia. The condom is prelubricated, and additional lubricant is provided for use if needed. The polyurethane sheath is **stronger** and probably **less likely to tear or break** than the latex sheath of male condoms. It should be removed immediately after intercourse (before the woman stands up). It may be inserted up to 8 hr before intercourse.
b. If it is used properly, it provides the woman with a method of preventing the transmission of STDs. However, with the noted pregnancy failure rate (Table 34-1), it is certainly not that reliable for disease transmission. It has not been very popular; some women complain that it interferes with sensation and that it makes unpleasant noises during use.
5. The **diaphragm** is a contraceptive device that is self-inserted into the vagina to block access of sperm to the cervix. It requires a prescription and must be used in conjunction with a nonprescription spermicide to seal off crevices between the vaginal wall and the device.
a. The diaphragm is held in place by the spring tension of a wire rim encased by rubber. When positioned properly, the diaphragm forms a flexible dome to cover the cervix, the sides pressing against the vaginal muscle wall and the pubic bone.
b. There are **four types** of diaphragms: the **coil spring,** the **flat spring,** the **arcing spring,** and a **wide-seal rim.** The tone of vaginal muscles as well as the position of the uterus and adjacent organs usually determine the type of diaphragm necessary.
c. Sizes of the diaphragm range from 50 to 95 mm in diameter, in 5-mm gradations.
d. Use
(1) The diaphragm plus spermicide can be inserted as long as 6 hr before coitus. The device should be left in place for 6-8 hr after intercourse, but no longer than 24 hr. Additional spermicide is required for repeated intercourse.

(2) Before inserting the diaphragm, 1 teaspoonful (a 2- to 3-inch ribbon) of spermicidal cream or jelly should be spread over the inside of the rubber dome.
(3) Also, spermicide should be spread around the rim to permit a good seal between the diaphragm and the vaginal wall. (For added protection, it can be applied outside the dome.)
e. Proper care
(1) The diaphragm should be washed with soap and water, rinsed thoroughly, and dried with a towel.
(2) It should be dusted with cornstarch and kept in its original container (away from heat).
6. The **cervical cap** is a prescription rubber device smaller than a diaphragm that fits over the cervix like a thimble. It is more difficult to fit than the diaphragm.
a. It remains effective for more than one episode of intercourse, without adding more spermicide.
b. The cap should be filled one third full of spermicide cream or jelly; the spermicide is then applied to the rim.
c. The cervical cap may be left in place for a maximum of 48 hr and should be left in place for at least 8 hr after intercourse.

STUDY QUESTIONS

Directions for questions 1-8: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The most common cause of vaginal yeast infections is

(A) *Candida albicans.*
(B) *Candida glabrata.*
(C) *Trichomonas.*
(D) anaerobic bacteria.

View Answer***1. The answer is A[see].andida albicansC.*** ***glabrataTrichomonas*****2. The efficacy rate for nonprescription antifungal agents for vaginal yeast infections is**

(A) 50%.
(B) 60%.
(C) 70%.
(D) 80%.

View Answer***2. The answer is D[see].*****3. Which of the following statements about nonprescription antifungal agents for vaginal yeast infections is incorrect?**

(A) Femstat 3 should be applied intravaginally for 3 consecutive nights.
(B) Antifungal agents should be continued during menstruation.
(C) Monistat 1 contains miconazole.
(D) The choice of formulation is based on patient preference.

View Answer***3. The answer is C[see].*****4. The best product to treat vulvar pruritus in a woman with a vaginal yeast infection is**

(A) external miconazole (Monistat).

(B) external miconazole and intravaginal miconazole (Monistat 7 combination pack).

(C) intravaginal tioconazole (Vagistat 1)

(D) intravaginal butoconazole (Femstat 3).

View Answer***4. The answer is B[see].*****5. A patient complains of vaginal yeast infection symptoms. Under which of the following circumstances should she be referred to a physician?**

(A) There is a history of recurrent vaginal yeast infections.

(B) She is pregnant.

(C) She is < 12 years of age.

(D) All of the above

View Answer***5. The answer is D[see].*****6. All of the following statements regarding contraceptives are correct *except* which one?**

(A) Using the basal temperature method, intercourse should be avoided for a full 6 days after the noted temperature transition.

(B) If a condom should break or leak, one could recommend immediate insertion of a vaginal spermicide foam.

(C) Vaginal spermicides may kill many of the causative agents of sexually transmitted diseases (STDs), but they should not be relied on alone for STD prevention.

(D) Latex condoms can be labeled for the prevention of HIV transmission.

(E) Nonoxynol-9 is a safe and effective vaginal spermicide.

View Answer***6. The answer is A[see].*****7. All of the following statements concerning the vaginal spermicides are correct *except* which one?**

(A) Used without a condom or diaphragm, it is recommended that the nonoxynol-9 concentration should be at least 8%.

(B) Foams probably disperse the spermicide throughout the vaginal canal better than cream or jelly forms.

(C) Douching should not occur for 6-8 hr after the last intercourse because it may dilute the spermicide effect or even force sperm into the cervix.

(D) Evidence to date shows no definite link between these agents and birth defects.

(E) None; all of the statements are correct.

View Answer***7. The answer is E[see].*****8. All of the following statements concerning contraception or contraceptive agents are correct *except* which one?**

(A) Progesterone is apparently responsible for the increase in basal temperature after ovulation.

(B) Vaseline should not be used as a lubricant with latex condoms.

(C) Using a condom alone is more effective as a contraceptive than taking a combination oral contraceptive.

(D) According to the Billings method, vaginal mucus has an appearance similar to raw egg whites at around the time of ovulation.

(E) Sperm may be viable for up to 5 days in the female reproductive tract under the right conditions.

View Answer***8. The answer is C[see].***P.720

Directions for questions 9-10: Each statement in this section is most closely related to **one** of the following drug types. The drug types may be used more than once or not at all. Choose the **best** answer, **A-E.**

9. The primary nonprescription pharmacological treatment for pain associated with dysmenorrhea

A Diuretics

B Salicylates

C Nonsteroidal anti-inflammatory drugs (NSAIDs)

D Narcotic analgesics

View Answer***9. The answer is C[see].*****10. Recommended by the Food and Drug Administration (FDA) for elimination of water before and during menstruation**

A Diuretics

B Salicylates

C Nonsteroidal anti-inflammatory drugs (NSAIDs)

D Narcotic analgesics

View Answer***10. The answer is A[see].***P.721

ANSWERS AND EXPLANATIONS

1. The answer is A *[see* II.A.1.b*].*

C*andida albicans* remains the most common cause. Infections caused by *C. glabrata* are increasing. *Trichomonas* and anaerobic bacteria cause other types of vaginal infections.

2. The answer is D *[see* II.A.3.f.(2)*].*

Nonprescription antifungal agents' efficacy rates approach 80%-90%.

3. The answer is C *[see* II.A.3.f*].*

Monistat 1 contains tioconazole, a long-acting ointment.

4. The answer is B *[see* II.A.3.d*].*

External creams can be helpful for treating external itching. The vaginal yeast infection still must be treated with an intravaginal cream.

5. The answer is D *[see* II.A.2.b*].*

All of these patients should be referred for diagnosis and treatment.

6. The answer is A *[see* III.B.1.c.(2)*].*

Intercourse should be avoided for a full 3 days after the noted temperature transition. All of the other statements are correct.

7. The answer is E *[see* III.B.2*].*

All the statements are correct.

8. The answer is C *[see* Table 34-1*].*

The most effective contraceptive product available today is the combination oral contraceptive. All of the other statements are correct.

9. The answer is C *[see* I.B.1.d.(3).(a)*].*

10. The answer is A *[see* I.B.1.d.(3).(b)*].*

NSAIDs are approved by the FDA for the treatment of primary dysmenorrhea. For premenstrual and menstrual relief of water retention, bloating, and tension, the FDA has approved OTC diuretics.

35

Herbal Medicines and Nutritional Supplements

Teresa Klepser

I. INTRODUCTION.

Many of the drugs available on the market are derived from plants. Some of those include aspirin, atropine, belladonna, capsaicin, cascara, colchicine, digoxin (Lanoxin), ephedrine, ergotamine, ipecac, opium, physostigmine, pilocarpine, podophyllum, psyllium, quinidine, reserpine, scopolamine, senna, Taxol, tubocurarine, vinblastine, and vincristine. Herb products are also derived from plants; however, these products are not considered drugs by the U.S. Food and Drug Administration (FDA).

A. Regulations

1. The **Federal Food, Drug, and Cosmetic Act of 1938** mandated pharmaceutical companies to test drugs for safety before marketing.

2. The **Kefauver-Harris Drug Amendments of 1962** mandated pharmaceutical companies to test drugs for efficacy before marketing.

3. The **Dietary Supplement Health and Education Act of 1994** mandated the following:

a. Dietary supplements are not drugs or food. They are intended to supplement the diet.

b. Herbs are considered dietary supplements.

c. Dietary supplements do not have to be standardized.

d. The secretary of Health and Human Services may remove a supplement from the market only when it has been shown to be hazardous to health.

e. Dietary supplements may make claims only regarding the effects on structure or function of the body. No claims regarding a particular disease or condition may be made.

f. The following statement is required on the product label: “This product has not been evaluated by the FDA. It is not intended to diagnose, treat, cure, or prevent.”

4. German Federal Health Agency

a. In 1978, the German Federal Health Agency established Commission E.

b. Commission E evaluates the safety and efficacy of herbs through clinical trials and cases published in scientific literature.

c. There are > 380 published monographs on herbs.

B. Herbs considered unsafe for human consumption

1. Carcinogenic herbs include borage, calamus, coltsfoot, comfrey, life root, and sassafras.

2. Hepatotoxic herbs include chaparral, germander, kava, and life root.

3. High doses of licorice for long periods may cause pseudoaldosteronism, a condition that may include headache, lethargy, sodium and water retention, hypokalemia, high blood pressure, heart failure, and cardiac arrest.

4. Ma huang may cause myocardial infarction, strokes or seizures.

5. Pokeroot may be fatal in children.

6. Unsafe herbs according to the FDA. In the 1990s, the FDA's Center for Food Safety and Applied Nutrition created the Special Nutritional Adverse Event Monitoring System Web site for dietary supplements. Unfortunately, by 1999 the site was no longer being updated and thus was eventually deleted. According to the last update from that Web site, the following dietary supplements were considered unsafe by the FDA:

a. Arnica: muscle paralysis, death

b. American and European mistletoe: seizures, coma

c. Bittersweet and deadly nightshade: cardiac toxicity

d. Bloodroot: hypotension, coma

e. Broom: dehydration

f. Comfrey: cancer

g. Dutch and English tonka bean: hepatotoxicity

h. Heliotrope: hepatotoxicity

i. Horse chestnut: bleeding

j. Jimson weed: anticholinergic, hallucinations

k. Kava: hepatotoxicity

l. Lily of the valley: cardiac toxicity

m. Lobelia (nicotine): coma, death

n. Mandrake/mayapple: severe gastrointestinal symptoms

o. Morning glory: psychosis

p. Periwinkle: renal and hepatotoxicity

q. Snakeroot: reserpine derivative

r. Spindle tree: seizures

s. St. John's wort: drug interactions

t. Sweet flag: hallucinations, liver cancer

u. True jalap: purgative cathartic

v. Wahoo: seizures

w. Wormwood: seizures, paralysis

x. Yohimbe: renal failure, hypertension

II. COMMONLY USED HERBS

A. Black cohosh (*Cimicifuga racemosa*)

1. Commission E indications. Premenstrual symptoms, painful or difficult menstruation, and neurovegetative symptoms (hot flashes) caused by menopause

2. Mechanism of action

a. Black cohosh has estrogen-like effects that are exerted by an unknown mechanism, different from an estrogenic mechanism.

b. It does not appear to bind to estrogen receptors. Nor does it appear to up-regulate estrogen-dependent genes.

c. It does not affect the growth of estrogen-dependent tumors in experimental animals.

3. Efficacy

a. Uncontrolled as well as double-blind, randomized, placebo-controlled clinical trials compared black cohosh to hormone therapy in perimenopausal and postmenopausal women with neurovegetative menopausal symptoms of different degrees of severity. The Kupperman menopausal index and psychiatric clinical and self-evaluation scales were significantly reduced after 3 months of treatment with black cohosh. Vaginal-cytological parameters also improved in regard to estrogen stimulation. Black cohosh was shown to be superior to placebo and comparable to estriol, conjugated estrogens, and estrogen-progesterone therapy (Mahady).

b. Black cohosh may not be effective in premenopausal breast cancer survivors with tamoxifen-induced hot flashes (Jacobsen).

4. Contraindications/precautions

a. Pregnancy

b. Unknown if suitable for patients for whom hormone-replacement therapy is contraindicated, such as estrogen-receptor-positive breast cancer

c. Commission E recommends that length of use should not exceed 6 months.

d. Use caution in liver disease, such as hepatitis and fulminant liver failure.

5. Drug interactions

a. Cisplatin (Platinol) efficacy may be reduced.

b. Theoretically, black cohosh may interact with hepatotoxic drugs, such as acetaminophen (Tylenol), carbamazepine (Tegretol), and isoniazid (Nydrazid) because it is an inhibitor of cytochrome P450 3A4 (CYP34A) and CYP2D6 isoenzymes.

6. Side effects

a. Occasional intestinal problems may occur, such as nausea and vomiting; weight gain is possible.

b. Liver toxicity may occur; liver function tests should be monitored periodically.

c. Large doses of black cohosh may cause dizziness, nausea, severe headaches, stiffness, and trembling limbs.

d. Does not seem to increase risk of endometrial hyperplasia.

7. Dosage. Remifemin is a standardized product that contains 20 mg black cohosh and is taken twice daily. It is standardized to 1 mg of 27-deoxyactein per tablet.

B. Chaste tree berry (*Vitex agnus-castus*)

1. Commission E indications. Disorders of the menstrual cycle, breast swelling, and premenstrual symptoms

2. Mechanism of action

a. Chaste tree berry binds to dopamine receptors and inhibits prolactin secretion.

b. One of its ingredients, linoleic acid, binds to estrogen receptors.

c. It increases the pituitary gland's production of luteinizing hormone and inhibits follicle-stimulating hormone (FSH).

3. Efficacy. One randomized, double-blind, placebo-controlled, parallel group study included 170 women with premenstrual syndrome (Schellenberg). *Vitex* was given 20

mg daily for 3 cycles. Self-assessment and clinical global impression significantly improved.

4. Contraindications/precautions

a. Pregnancy and lactation

b. Women receiving hormone-replacement therapy

5. Drug interactions

a. Theoretically, chaste tree berry may interact with medications that increase dopaminergic activity, such as bromocriptine (Parlodel) and levodopa.

b. Theoretically, it may interact with medications that decrease dopaminergic activity, such as the antipsychotics.

c. Theoretically, it may interact with hormone-replacement therapy and oral contraceptives.

6. Side effects

a. Mild gastrointestinal upset

b. Skin rash

c. Increased menstrual flow

7. Dosage. Doses depend on the formulation. Typical dose range of chaste tree berry is 20-240 mg per day.

C. Cranberry (*Vaccinium macrocarpon*)

1. Commission E indications. Recurrent urinary tract infections

2. Mechanism of action

a. Urinary acidification

b. Benzoic and quinic acids break down and form hippuric acid (bacteriostatic).

c. Inhibition of *Escherichia coli* adherence to epithelial cells of urinary tract

d. Cranberry juice may suppress *Helicobacter pylori* infection.

3. Efficacy

a. A quasi-randomized, double-blind, placebo-controlled study included 153 women who received 300 mL of cranberry juice daily for 6 months (Avorn et al.). Bacteriuria with pyuria occurred less often in the cranberry group (15%) versus placebo (28%).

4. Contraindications

a. Benign prostatic hyperplasia

b. Urinary obstruction

c. Nephrolithiasis

d. Cranberry juice contains high amounts of salicylic acid and may trigger an allergic reaction in patients with an aspirin allergy or asthma.

e. Discontinue 2 weeks before surgery.

f. Ulcers, GERD

5. Drug interactions

a. Increased vitamin B_{12} absorption

b. Potential to enhance elimination of renally excreted drugs by changing urine pH

c. Cranberry juice may interact with warfarin, increasing the international normalized ratio (INR).

d. May inhibit cytochrome P450 2C9. Drugs that are metabolized by CYP2C9 include amitriptyline (Elavil) and diazepam (Valium).

6. Side effects

a. Nausea, vomiting, diarrhea

b. Nephrolithiasis

7. Dosage. Recommended dose of cranberry is 300-400 mg twice daily using a standardized product to include 11%-12% quinic acid per dose. Patients may also take 8-16 oz. 100% cranberry juice daily. Drinking lots of fluids is recommended.

D. Dong quai (*Angelica senensis*)

1. Traditional Chinese Medicine indications. Menstrual disorders, anemia, constipation, insomnia, rheumatism, neuralgia, and hypertension

2. Mechanism of action

a. Dong quai is only 1:400 as active as estrogen. However, it does not appear to produce any changes to the ovaries or vaginal tissue (Murray).

b. It contains seven different coumarin derivatives: oxypeucedanin, osthole, psoralen, angelol, angelicone, bergapten, and 7-desmethylsuberosin. Many coumarins have been shown to have vasodilatory and antispasmodic effects. One of the coumarins (osthole) is a central nervous system (CNS) stimulant.

c. It inhibits experimentally induced immunoglobulin E (IgE) titers, suggesting that components of the plant may have immunosuppressive activity.

d. It inhibits prostaglandin E_2 (PGE_2) release and, therefore, possesses analgesic, antipyretic, and anti-inflammatory actions.

e. It has a quinidine-type effect, so it may control tachycardia.

f. It normalizes uterine contractions.

g. It has antibiotic activity against gram-negative bacteria (*Bacillus dysenteriae, B. typhi, B. comma, B. paratyphi,* and *Escherichia coli*) and against gram-positive bacteria (hemolytic *Streptococcus* type A and B, *Corynebacterium diphtheriae*).

3. Efficacy. A randomized, double-blind, placebo-controlled trial included 71 postmenopausal women (mean age, 52.4 years) who had FSH < 30 mIU/mL with hot flashes (Hirata et al.). Women received 3 capsules of dong quai three times daily (equivalent to 4.5 g of dong quai root daily) or placebo for 24 weeks. Dong quai did not produce estrogen-like responses in endometrial thickness or in vaginal maturation or relieve menopausal symptoms. The study is criticized for using dong quai alone, because in Traditional Chinese Medicine, dong quai is used in combination with four or more other herbs.

4. Contraindications/precautions

a. Pregnancy (uterine stimulant) and lactation

b. Diarrhea

c. Hemorrhagic disease; discontinue 2 weeks before surgery

d. Hypermenorrhea

e. Hypotension

f. During colds or flus

g. Allergy to parsley

5. Drug interactions

a. Dong quai interacts with anticoagulants, such as warfarin (Coumadin)

b. Antihypertensives (hypotension)
c. Theoretically, may interact with hormone-replacement therapy.
d. Unknown if it interacts with other cardiovascular drugs such as procainamide (Pronestyl)
6. Side effects
a. Photodermatitis may occur in people collecting the plant.
b. Burping, flatulence, and headache

c. Safrole, found in the oil of dong quai, is carcinogenic and not recommended for ingestion.
d. May stimulate breast cancer cells.
7. Dosage. A variety of doses are suggested. No standardized product is available. According to traditional Chinese medicine, dong quai alone may not be effective.
E. Echinacea (*Echinacea purpurea, E. angustifolia*)
1. Commission E indications
a. Internal use: supportive therapy for infections of the upper respiratory tract (colds) and lower urinary tract
b. External use: local application for the treatment of hard-to-heal superficial wounds and ulcers
2. Mechanism of action. Echinacea increases the body's resistance to bacteria by:
a. Caffeic acid derivatives, which include cichoric acid, chlorogenic acid, and cynarin, increase phagocytosis and stimulate the production of immune-potentiating substances such as interferon, interleukins, and tumor necrosis factor.
b. Polysaccharides, such as inulin, stimulate macrophages and inhibit hyaluronidase activity to decrease inflammation.
c. Alkylamides, such as echinacein, have a local anesthetic effect and inhibit hyaluronidase activity to decrease inflammation.
d. Echinacea has little or no direct bacteriocidal or bacteriostatic properties.
3. Efficacy. In a review of 26 controlled clinical trials evaluating echinacea's ability to strengthen the body's own defense mechanisms, it was found that 30 of 34 echinacea therapies were more effective compared to controls (Melchart et al.).
4. Contraindications/precautions
a. Echinacea is contraindicated in infectious and autoimmune diseases such as tuberculosis, leukosis, collagenosis, multiple sclerosis, AIDS, HIV, and lupus.
b. Caution should be used in patients who are allergic to members of the ragweed family.
c. The effects of echinacea in pregnancy, lactation, and children are unknown. Comparison with a control group suggested no increased risk of major malformations in 206 pregnant women (Gallo et al.).
d. Therapy should not exceed 8 weeks. Theoretically, prolonged use of echinacea may depress the immune system, possibly through overstimulation.
5. Drug interactions
a. Unknown if echinacea interacts with immunosuppressants

b. Echinacea inhibits cytochrome P450 1A2. Some drugs metabolized by CYP1A2 are caffeine (Cafcit) and theophylline.
c. Echinacea induces and inhibits CYP3A4. Some drugs metabolized by CYP3A4 are midazolam (Versed), itraconazole (Sporanox) and fexofenadine (Allegra).
6. Side effects
a. Nausea, vomiting, dizziness, tiredness, allergic reactions, and anaphylaxis.
b. May interfere with male fertility.
7. Dosage. There are a variety of doses recommended. The most common dose is as the dried powder, 1 g or two 500-mg capsules orally three times daily. Recommended to use for 2 weeks only during a cold.
F. Feverfew (*Tanacetum parthenium*)
1. Commission E indication. Prophylaxis of migraine headaches
2. Mechanism of action
a. Feverfew inhibits the release of 5-hydroxytryptamine (serotonin) from platelets, which may be the same mechanism as methysergide maleate (Sansert).
b. It irreversibly inhibits prostaglandin synthesis through a different mechanism from that of the salicylates. It inhibits phospholipase A_2 by α-methylene butyrolactones (parthenolide and epoxyartemorin).
c. There is an antithrombotic potential owing to a phospholipase inhibition that prevents the release of arachidonic acid.

d. It inhibits polymorphonuclear leukocyte (PMN) degranulation, which reduces PMN-induced damage to the rheumatoid synovium.
e. It inhibits phagocytosis of human neutrophils, which may reduce tissue damage from oxygen radicals.
f. It inhibits mast cell release of histamine.
g. It may have cytotoxic activity against human tumor cells.
h. It may possess antimicrobial activity.
3. Efficacy. An evaluation of five trials for the efficacy of feverfew in the prevention of migraines compared to placebo was conducted (Cochrane Database of Systematic Reviews). A variety of doses and durations were used. Some trials showed the number and severity of migraine attacks and the degree of vomiting were reduced with feverfew. The duration of attacks was unaltered. Other trials showed no benefit.
4. Contraindications/precautions
a. Feverfew should be avoided in pregnancy, lactation, and children < 2 years of age.
b. Contraindicated in individuals with allergies to chrysanthemums.
c. Contraindicated in patients with bleeding disorders. Discontinue 2 weeks before surgery.
5. Drug interactions
a. Feverfew may interact with anticoagulants, increasing the risk of bleeding.

b. Feverfew may inhibit the following cytochrome P450 isoenzymes: 1A2, 2C19, 2C9, and 3A4.

6. Side effects

a. Gastric discomfort on oral consumption

b. Contact dermatitis

c. Minor ulcerations of oral mucosa, irritation of tongue, and swelling of lips may occur when fresh leaves are chewed.

d. Palpitations.

e. Post-feverfew syndrome: discontinuation of feverfew may produce muscle and joint stiffness and a cluster of nervous system reactions (rebound of migraines, anxiety, and insomnia).

7. Dosage. The usual dose of feverfew is 125 mg daily. A product containing at least 0.2% parthenolide is recommended.

G. Garlic (*Allium sativum*)

1. Commission E indications. Support dietary measures for the treatment of hyperlipoproteinemia and to prevent age-related changes in the blood vessels (arteriosclerosis)

2. Mechanism of action

a. Garlic inhibits platelet function by interfering with thromboxane synthesis.

b. It increases the levels of two antioxidant enzymes in the blood: catalase and glutathione peroxidase.

c. Organic disulfides found in garlic oil inactivate the thiol enzymes such as coenzyme A (CoA) and hydroxymethyl glutaryl (HMG) CoA reductase.

3. Efficacy

a. In a meta-analysis of eight studies evaluating the effect on blood pressure, the overall pooled difference in change of systolic blood pressure was 7.7 mm Hg lower with garlic than with placebo; diastolic blood pressure was 5.0 mm Hg lower with garlic (Silagy et al.).

b. In a meta-analysis of five studies evaluating the effect on total serum cholesterol, patients were excluded if they were receiving lipid-lowering drugs (Warshafsky et al.). The overall pooled total cholesterol difference between garlic and placebo was -23 mg/dL (-29 to -17).

4. Contraindications/precautions

a. Caution in diabetes. Garlic may increase the release of insulin or enhance the response to insulin.

b. Caution in pregnancy (emmenagogue and abortifacient) and lactation

c. Caution in peptic ulcer disease and gastroesophageal reflux

d. Discontinue 2 weeks before surgery

5. Drug interactions

a. Anticoagulants (increased bleeding)

b. Protease inhibitors (decreased efficacy)

c. Nonnucleoside reverse transcriptase inhibitors, such as nevirapine, efavirenz

d. Increases amphotericin B (Fungizone) activity against *Cryptococcus neoformans*
e. Antihypertensives (hypotension)
f. Antidiabetic agents (hypoglycemia)
g. May inhibit the following cytochrome P450 isoenzymes: 2C9, 2C19, 3A4, 2D6, and 2E1.
h. Caution should be used with contraceptive medications, cyclosporine, diltiazem, and verapamil.
6. Side effects. Gastrointestinal discomfort (heartburn, flatulence), sweating, light-headedness, allergic reactions, and menorrhagia
7. Dosage. Between 0.6 and 1.2 g dried powder (2-5 mg of allicin) daily or 2-4 g fresh garlic
8. Comments
a. Alliinase (the enzyme that converts alliin to allicin) is inactivated by acids. Enteric-coated tablets or capsules allow more absorption because they pass through the stomach and release their contents in the alkaline medium of the small intestine.
b. Odorless garlic preparations may not contain the active compounds.
H. Ginger (*Zingiber officinale*)
1. Commission E indications. Dyspepsia and prophylaxis of symptoms of travel sickness
2. Mechanism of action
a. Ginger promotes saliva and gastric juice secretion, which increases peristalsis and the tone of the intestinal muscle.
b. It acts on 5-hydroxytryptamine 3 ($5\text{-}HT_3$) receptors in the ileum, similar to ondansetron.
c. It has positive inotropic activity.
d. It inhibits thromboxane synthesis as a prostacyclin agonist.
3. Efficacy. A double-blind study included 36 blindfolded subjects with high susceptibility to motion sickness who were given ginger 940 mg, dimenhydrinate 100 mg, or placebo for the prevention of motion sickness induced by a tilted rotating chair. Ginger subjects remained in the chair an average of 5.5 min, dimenhydrinate 3.5 min, and placebo 1.5 min. The ginger group took longer to feel sick, but once sick, the sensations of nausea and vomiting progressed at the same rate in all groups (Mowrey et al.).
4. Contraindications/precautions
a. Bleeding disorders. Discontinue 2 weeks before surgery
b. It is contraindicated for gallstone pain.
c. It is recommended by the American College of Obstetricians and Gynecologists (ACOG) for use in pregnancy < 17 weeks of gestation with the following cautions: ginger is a uterine relaxant in low doses and a uterine stimulant in high doses.
d. Diabetes (hypoglycemia)
e. Heart conditions
5. Drug interactions
a. Antiplatelets and anticoagulants (increased bleeding)
a. Diabetic agents (hypoglycemia)
a. Calcium channel blockers (hypotension)

6. Side effects are dermatitis, heartburn, and diarrhea.
7. Dosage (for travel sickness). Daily dose is 2-4 g. Two 500-mg capsules taken 30 min before travel, then 1-2 more capsules every 4 hr as needed. The 1000 mg standardized extract is equivalent to:
a. 1 teaspoon fresh grated rhizome
b. 2 droppers liquid extract (2 mL)
c. 2 teaspoons syrup (10 mL)
d. 8 ounces ginger ale, made with real ginger
e. 4 cups ginger tea (made by steeping 1/2 teaspoon grated ginger for 5-10 min in hot water)

I. Ginkgo (*Ginkgo biloba*)
1. Commission E indications
a. Treatment for cerebral circulatory disturbances resulting in reduced functional capacity and vigilance (vertigo, tinnitus, weakened memory, and mood swings accompanied by anxiety)
b. Treatment of peripheral arterial circulatory disturbance such as intermittent claudication
2. Mechanism of action
a. Ginkgo contains flavonoids (quercetin, kaempferol, and isorhamnetin) and terpenoids (ginkgolides A, B, and C and bilobalide).
b. Flavonoids provide the antioxidant activity, reduce capillary fragility, and increase the threshold of blood loss from capillaries.
c. Ginkgolides antagonize platelet-activating factor (PAF), which induces platelet aggregation, the degranulation of neutrophils, and the production of oxygen radicals.
d. Bilobalide protects nerve cells.
3. Efficacy
a. In a review of the clinical and pharmacological studies on ginkgo and cerebral insufficiency, eight were found to be of good quality (Kleijnen). Seven of the trials showed positive effects of ginkgo compared to placebo. Symptoms of cerebral insufficiency evaluated were difficulties of concentration and memory, absentmindedness, confusion, lack of energy, tiredness, decreased physical performance, depression, anxiety, dizziness, tinnitus, and headaches.
b. For intermittent claudication, there were 15 controlled trials, 2 of acceptable quality (Rittler et al.).
(1) One showed an increase in walking distance (Bauer et al.)—ginkgo, 112-222 m; placebo, 145-176 m.
(2) The other demonstrated amelioration of pain at rest (Saudreau et al.). The use of ginkgo showed a decrease on a 100-mm visual analog scale for pain from 61 to 30 mm (placebo 51 to 39 mm).
c. A randomized, double-blind, placebo-controlled study included 202 patients with either Alzheimer disease or multi-infarct dementia. These patients were given

ginkgo 40 mg three times daily or placebo for 1 year. Ginkgo had a statistically significant improvement by at least two points or better on the Alzheimer Disease Assessment Scale—Cognitive (a 70-point subscale) compared to placebo (50% versus 29%). Ginkgo showed statistically significant improvement on the Geriatric Evaluation by Relative's Rating Instrument (37% versus 23%). There was no difference between ginkgo and placebo on the Clinical Global Impression of Change scale (LeBars et al.).

4. Contraindications/precautions.

a. Epilepsy. Ginkgotoxin may cause neurotoxicity and seizures.

b. Bleeding disorders. Discontinue 2 weeks before surgery

c. Diabetes (hypoglycemia)

d. Infertility. Caution in difficulty conceiving.

4. Drug interactions

a. Ginkgo may potentiate the bleeding properties of antiplatelets—there is a case report of spontaneous hyphema (bleeding from the iris into the anterior chamber) from ginkgo and aspirin.

b. Aminoglycosides (increased ototoxicity)

c. Thiazide (increases blood pressure)

d. Trazodone (Desyrel) (coma)

e. Seizure threshold lowering drugs.

f. Anticonvulsants

g. Antidiabetic drugs (hypoglycemia)

h. Ginkgo may mildly affect the cytochrome P450 isoenzymes 1A2, 2C19, 2C9, 2D6, and 3A4.

5. Side effects

a. Gastric disturbances, headache, dizziness, and vertigo

b. Toxic ingestion may produce tonic-clonic seizures and loss of consciousness

c. Spontaneous bleeding

6. Dosage. Recommended dose is 40 mg three times daily with meals for at least 4-6 weeks. Standardized preparations that contain 6% terpene lactones and 24% ginkgo flavone glycosides are recommended.

J. Asian ginseng (*Panax ginseng, P. quinquefolius*)

1. Commission E indications. Tonic to combat feelings of lassitude and debility, lack of energy, and ability to concentrate, and during convalescence

2. Mechanism of action

a. At least 28 active ingredients, known as ginsenosides, have been identified.

b. Ginseng effects vary with extract derivative, drying method, dose, duration of treatment, and animal species that was studied. Each ginsenoside produces different pharmacological effects on the central nervous system, cardiovascular system, and other body systems. Different ginsenosides are capable of producing biological effects in direct opposition with those produced by others. For example,

the ginsenoside Rb_1 has been shown to have a suppressive effect on the central nervous system, whereas Rg_1 produces a stimulatory effect.

3. Efficacy

a. A randomized, double-blind, placebo-controlled, crossover study included 50 male sports teachers who performed a treadmill exercise test. Volunteers received 2 ginseng capsules (Geriatric Pharmaton) daily for 6 weeks or placebo. Volunteers used energy more efficiently and had greater endurance while taking ginseng (Pieralisi et al.).

b. A case-controlled study including 1987 pairs evaluated ginseng's effect on various human cancers. Individuals who took ginseng had a significant decreased risk for cancer compared with nonintakers. There may be a dose-response relationship; as the frequency and duration of ginseng use increased, the risk of cancer decreased. According to cancer site, ginseng significantly reduced the risk of cancer of the lip, oral cavity, and pharynx; esophagus; stomach; colon and rectum; liver; pancreas; lung; and ovaries. There was no risk reduction for cancers of the female breast, uterine cervix, urinary bladder, and thyroid gland (Yun et al.).

4. Contraindications/precautions

a. Pregnancy and lactation

b. Children

c. Avoid in patients with hypertension, emotional/psychological imbalances, headaches, heart palpitations, insomnia, asthma, inflammation, or infections with high fever.

d. Caution should be used in patients with a history of bleeding. Discontinue 2 weeks before surgery

e. Diabetes (hypoglycemia)

f. Schizophrenia

g. Caution should be used in patients with a history of breast cancer. Ginseng may stimulate breast cancer cells.

5. Drug interactions

a. Ginseng may interact with phenelzine (Nardil), producing hallucinations and psychosis.

b. Ginseng may decrease the INR of warfarin (Coumadin).

c. Ginseng may interact with stimulants, including caffeine (Cafcit).

d. Ginseng may interact with hypoglycemics, causing hypoglycemia.

e. It is unknown whether ginseng interacts with hormonal therapy, antihypertensives, or cardiac medications.

f. It may inhibit cytochrome P450 2D6. Caution should be used with drugs that are metabolized via cytochrome P450 2D6, such as amitriptyline (Elavil) and fluoxetine (Prozac).

g. It may interfere with immunosuppressants.

6. Side effects

a. Nervousness and excitation for the first 4 days

b. Inability to concentrate with long-term use

c. Diffuse mammary nodularity and vaginal bleeding may be caused by ginseng's estrogen-like effect in women.

d. Hypertension, euphoria, restlessness, nervousness, insomnia, skin eruptions, edema, and diarrhea have been reported with long-term ginseng use with an average dose of 3 g ginseng root daily.
e. May increase the QT interval.
7. Dosage. 1-2 g crude herb daily or 100-300 mg ginseng extract three times daily. Standardized products that contain at least 4%-5% ginsenosides are recommended.
K. Siberian ginseng (*Eleutherococcus senticosus*)
1. Commission E indications. Tonic for fatigue, convalescence, decreased work capacity, or difficulty in concentration
2. Mechanism of action. Animal research suggests that Siberian ginseng may stimulate the hypothalamic-pituitary-adrenal cortex. It may bind to progestin, mineralocorticoid, and glucocorticoid receptors.
3. Efficacy
a. A randomized, double-blind, placebo-controlled study evaluated 20 highly trained distance runners who received *E. senticosus* extract 60 drops daily for 6 weeks or placebo. Subjects underwent a maximal treadmill test and a 10K race. No significant difference was observed between treatment and placebo for heart rate, oxygen consumption, expired minute volume, ventilatory equivalent for oxygen, or respiratory exchange ratio (Dowling et al.).
b. A randomized, placebo controlled prospective study evaluated 96 subjects with chronic, unexplained fatigue who received standardized *E. senticosus* 2000 mg daily for 2 months. No statistically significant difference was observed (Hartz et al.).
4. Contraindications/precautions
a. Not recommended in patients with febrile states, hypertonic crisis, or myocardial infarction
b. Diabetes (hypoglycemia)
c. Bleeding disorders. Discontinue 2 weeks before surgery
d. Cardiovascular conditions: hypertension, tachycardia.
e. Hormone-sensitive conditions.
f. Psychiatric conditions: schizophrenia, mania
5. Drug interactions
a. Serum levels of digoxin (Lanoxin) may increase when taken with Siberian ginseng.
b. Barbiturates. Hexobarbital and Siberian ginseng increase sleep latency and duration.
c. Siberian ginseng may increase the risk of hypoglycemia with diabetic agents
d. Siberian ginseng may interact with anticoagulants and antiplatelets.
e. Theoretically, Siberian ginseng may interact with stimulants, such as caffeine.
f. Theoretically, Siberian ginseng may interact with antihypertensives
g. May inhibit the following cytochrome P450 isoenzymes: 1A2, 2C9, 2D6, and 3A4.
6. Side effects
a. Mild, transient diarrhea, and insomnia

b. Siberian ginseng may lower blood glucose.
c. Tachycardia, hypertension, palpitations.
7. Dosage. Two capsules (each capsule containing 400-500 mg of powdered root) three times daily for a total of 2-3 g daily. Solid concentrated extract standardized on eleutherosides B and E 300-400 mg daily are recommended. Recommended not to use longer than 3 weeks.
L. Milk thistle (*Silybum marianum*)
1. Commission E indications. Chronic inflammatory liver conditions and cirrhosis
2. Mechanism of action
a. Milk thistle produces antioxidants, such as silybin.
b. It stimulates the activity of RNA polymerase A.
c. It alters the outer liver membrane cell structure.
3. Efficacy. In an evaluation of 13 trials for the efficacy of milk thistle in the treatment of alcoholic and/or hepatitis B or C virus liver diseases, milk thistle had no significant effect on overall mortality, complications of liver disease, or liver histology (Cochrane Database of Systematic Reviews). Liver-related mortality was significantly reduced with milk thistle

when all trials were evaluated but was not significantly reduced when only high-quality trials were evaluated.
4. Contraindications/precautions
a. Avoid in pregnancy.
b. Allergy to chrysanthemums
c. Hormone-sensitive cancers
5. Drug interactions
a. Milk thistle may inhibit cytochrome P450 2C9 and 3A4.
b. Milk thistle does not interact with indinavir (Crixivan).
6. Side effects include diarrhea and other gastrointestinal reactions (nausea, dyspepsia, flatulence) and allergic reactions
7. Dosage. Recommended dose of milk thistle is 200-400 mg/day divided into three doses using a standardized product that includes 70%-80% silymarin.
M. Saw palmetto (*Serenoa repens*)
1. Commission E indications. Treatment of micturition difficulties associated with benign prostatic hyperplasia
2. Mechanism of action
a. Saw palmetto inhibits dihydrotestosterone to androgen receptors in prostate cells.
b. It may inhibit testosterone-5-α-reductase, the enzyme responsible for the conversion of testosterone to dihydrotestosterone.
3. Efficacy. A randomized, multicenter study evaluated 1069 men with moderate benign prostatic hyperplasia who received saw palmetto 160 mg twice daily or finasteride 5 mg daily for 6 months. There was no significant difference between saw palmetto and finasteride (Proscar) for the patients' self-rated quality-of-life score and the International Prostate Symptom score (Carraro et al.).

4. Contraindications/precautions

a. Avoid in pregnancy

b. Avoid in children

c. Discontinue 2 weeks before surgery

5. Drug interactions

a. Theoretically, saw palmetto may interact with anticoagulants or antiplatelets.

b. Theoretically, saw palmetto may interact with contraceptive drugs or hormone-replacement therapy.

6. Side effects

a. Intraoperative hemorrhage

b. Headache

c. Stomach upset

d. Acute hepatitis and pancreatitis

7. Dosage. Recommended 1-2 g saw palmetto or 320 mg of lipophilic extract daily, usually given 160 mg twice daily and taken with food. Products standardized to contain 90% free and 7% esterified fatty acids are recommended.

N. St. John's wort (*Hypericum perforatum*)

1. Commission E indications. In supportive treatment for anxiety and depression

2. Mechanism of action

a. Active ingredients include hypericin, pseudohypericin, quercetin, quercitrin, isoquercitrin, hyperoside, rutin, amentoflavone, hyperin, hyperforin, adhyperforin, and xanthones.

b. Hypericin, flavonoids, and xanthones show in vitro irreversible monoamine oxidase inhibitor (MAOI) type A and B activity.

c. St. John's wort may inhibit serotonin reuptake.

d. St. John's wort may inhibit synaptic γ-aminobutyric acid (GABA) uptake and GABA-receptor binding.

e. It may reduce cytokine expression, such as interleukin 6. This may be helpful in depression because interleukins may induce depression.

3. Efficacy. An evaluation of 37 trials for the efficacy of St. John's wort in the treatment of depression showed the herb may be more effective than placebo for mild to moderate depression (Cochrane Database of Systematic Reviews). St. John's wort may be as effective as other antidepressants for mild to moderate depression. St. John's wort may not be effective for major depression.

4. Contraindications/precautions

a. Caution in fair-skinned persons when exposed to bright sunlight

b. Caution in pregnancy (emmenagogue and abortifacient)

c. No negative influence on general performance or the ability to drive a car or operate heavy machinery has been reported.

d. Psychiatric conditions such as bipolar, schizophrenia may be exacerbated.

e. Hypothyroidism

f. Anesthesia. St. John's wort may cause cardiovascular collapse.

g. Infertility. St. John's wort may inhibit oocyte fertilization and alter sperm DNA.

5. Drug interactions

a. Antidepressants such as paroxetine (Paxil), sertraline (Zoloft), and nefazodone have been reported to cause serotonin syndrome when taken with St. John's wort.

b. Antiretroviral (protease inhibitors and nonnucleoside reverse transcriptase inhibitors) levels may decrease.

c. St. John's wort may decrease the efficacy of barbiturates.

d. St. John's wort may increase the efficacy of clopidogrel (Plavix).

e. Cyclosporine (Sandimmune) levels may decrease.

f. St. John's wort may interact with other drugs metabolized through the cytochrome P450 isoenzymes 1A2, 2C9, and 3A4.

g. Digoxin (Lanoxin) levels may decrease.

h. Irinotecan (Camptosar) and imatinib (Gleevec) levels may decrease.

i. Methadone (Dolophine) levels may decrease.

j. St. John's wort may decrease the efficacy of omeprazole (Prilosec).

k. Oral contraceptives may have a decreased effect.

l. St. John's wort may decrease the efficacy of HMG coenzyme reductase inhibitors.

m. Tacrolimus (Prograf) levels may decrease.

n. Theophylline levels may decrease.

o. Theoretically, St. John's wort may interact with the triptans.

p. Verapamil (Calan, Covera-HS, Isoptin, Verelan) levels may decrease.

q. St. John's wort may decrease the INR of warfarin (Coumadin).

r. Serotonergic Agents, such as dextromethorphan, fenfluramine, narcotics.

6. Food interactions

a. Older studies suggested that St. John's wort was an MAOI (Suzuki et al.).

b. Newer studies suggest St. John's wort is a weak MAOI (Muller et al.).

c. One case report published of MAO-type food interactions such as tyramine-containing foods: cheeses, beer, wine, herring, and yeast.

7. Side effects

a. Photodermatitis

b. Gastrointestinal irritations

c. Allergic reactions

d. Tiredness

e. Restlessness

f. Elevated thyroid-stimulating hormone

g. Elevated blood pressure

h. Mania or hypomania

i. May cause infertility

8. Dosage. Recommended 2-4 g daily in two to three divided doses. Standardized products containing 0.4-2.7 mg hypericin/day or 0.3% hypericin are recommended.

O. Valerian (*Valeriana officinalis*)

1. Commission E indications. Restlessness and nervous disturbance of sleep

2. Mechanism of action

a. Several active compounds have been isolated from valerian and grouped into three categories: volatile oil, valepotriates, and alkaloids. It is believed that the sedative activity of valerian is secondary to the valepotriates.

b. Valepotriates, valeranone 6, kessane derivatives 3a-f, valerenic acid 5a, and valerenal 5b have been reported to prolong barbiturate-induced sleeping time.

c. Valerenic acid 5a has been shown to possess pentobarbital-like central depressant activity rather than muscle relaxant or neuroleptic effects. It has also been shown to inhibit the enzyme that triggers the breakdown of GABA.

d. Valtrate and isovaltrate have exhibited antidepressant properties.

e. Didrovaltrate possesses a tranquilizing ability similar to the benzodiazepines.

3. Efficacy. A double-blind, randomized study included eight volunteers suffering from mild insomnia who received valerian aqueous extract 450 mg or 900 mg or placebo at bedtime. Valerian 450 mg significantly improved sleep quality, sleep latency, and sleep depth compared to placebo. The 900-mg dose offered no advantage over the 450-mg dose (Leathwood et al.).

4. Contraindications/precautions.

a. Caution while driving or performing other tasks requiring alertness and coordination is recommended.

b. Pregnancy and lactation.

5. Drug interactions.

a. CNS depressants. Valerian may potentiate the sedative effect of barbiturates, benzodiazepines, opiates, alcohol, or other sedatives.

b. Valerian inhibits cytochrome P450 3A4.

6. Side effects

a. Headaches, hangover, excitability, insomnia, uneasiness, and cardiac disturbances

b. Hepatotoxicity

c. Toxicity includes ataxia, decreased sensibility, hypothermia, hallucinations, and increased muscle relaxation

d. Patients may experience a benzodiazepine-like withdrawal; so doses should be tapered down slowly.

7. Dosage. Dried root: 2-3 g per cup, one to three times daily. Standardized to contain 0.8%-1% valeremic acids/dose extract: 400-900 mg 30-60 min before bedtime.

III. OTHER DIETARY SUPPLEMENTS THAT ARE POTENTIALLY SAFE

A. Chondroitin

1. Nonapproved indications. Viscoelastic agent in ophthalmic procedures and the treatment of osteoarthritis

2. Mechanism of action

a. It concentrates in cartilage, where it can be used in the synthesis of new cartilaginous matrix.

b. It increases the RNA synthesis of chondrocytes, which may increase the synthesis of proteoglycans and collagens.
c. It may inhibit leukocyte elastase activity. Leukocyte elastase is found in high concentrations in the blood and synovial fluid of patients with rheumatic diseases.
3. Efficacy. A multicenter, double-blind, randomized study included 1583 patients with symptomatic knee osteoarthritis who received glucosamine 1500 mg daily, chondroitin 1200 mg daily, both glucosamine and chondroitin, celecoxib 200 mg daily, or placebo for 24 weeks. Glucosamine and chondroitin sulfate alone or in combination did not significantly reduce pain. The combination may be helpful in a subgroup of patients with moderate-to-severe knee pain (Clegg et al.).

4. Contraindications/precautions
a. Previous hypersensitivity to chondroitin sulfate
b. Bleeding disorders
c. Use caution because chondroitin is usually produced from bovine cartilage (possible transmission of mad cow disease)
d. Pregnancy and lactation
e. Use caution in asthma
5. Drug interactions
a. May interact with heparin
b. Theoretically, may interact with warfarin (Coumadin)
6. Side effects. Nausea, epigastric pain, and headache
7. Dosage. Recommended: 400 mg three times daily

B. Coenzyme Q_{10} (ubiquinone or ubidecarenone)
1. Nonapproved indications. Heart failure (HF), hypertension, stable angina, ventricular arrhythmias, cancer, heart surgery, and periodontal disease
2. Mechanism of action
a. It is a naturally occurring coenzyme that has a predominant role in oxidative phosphorylation and synthesis of adenosine triphosphate (ATP), which is needed for muscle contraction and relaxation.
b. It may have antioxidant properties.
c. It has been shown to reduce myocardial injury from ischemia and to reduce toxic myocardial damage from anthracyclines, such as doxorubicin (Adriamycin).
3. Efficacy
a. Heart failure. One randomized, double-blind, placebo-controlled, multicenter study included 641 patients with New York Heart Association class III or IV chronic congestive heart failure who were receiving conventional treatment, such as digoxin (Lanoxin), diuretics, angiotensin-converting enzyme (ACE) inhibitors, and calcium-channel blockers (Morisco et al.). Patients received coenzyme Q_{10} 2 mg/kg/day for 1 year or placebo. The number of patients requiring hospitalization secondary to congestive HF was less in the coenzyme Q_{10} group (n = 73) versus placebo (n = 118); significance: $p < .001$. Episodes of pulmonary edema and cardiac asthma were reduced with coenzyme Q_{10} ($p < .001$).

b. Studies suggest that there is a 20-50% reduction in serum levels of coenzyme Q_{10} in hypercholesterolemic patients after a statin has been initiated. The reduction in coenzyme Q_{10} concentration is believed to be dose related. However, it is still uncertain how much statins affect muscle coenzyme Q_{10} concentrations. Muscle coenzyme Q_{10} may affect statin-induced myopathy (Nawarskas).

c. Several studies have evaluated the effect of coenzyme Q_{10} supplementation in patients taking statins. When coenzyme Q_{10} is given 30-300 mg per day, coenzyme Q_{10} serum concentrations significantly elevate. However, this elevation has not been evaluated to see whether it correlates to decreasing statin-related side effects (Nawarskas).

4. Contraindications/precautions

a. Biliary obstruction

b. Diabetes mellitus (hypoglycemia)

c. Hepatic insufficiency

d. Renal insufficiency

e. Hyper and hypotension

f. Pregnancy and lactation

5. Drug interactions

a. Hypolipidemic agents lower plasma concentrations of coenzyme Q_{10}.

b. Oral hypoglycemic agents potentially inhibit effects of exogenous administration.

c. Doxorubicin toxicity may be increased.

d. Antihypertensives (additive effect)

e. Warfarin. Coenzyme Q_{10} is structurally related to vitamin K_2 so may have coagulant effects.

6. Side effects

a. Rash and gastrointestinal disturbances, such as nausea, anorexia, epigastric pain, and diarrhea

b. Elevations of serum aminotransferases have occurred with relatively high oral doses.

7. Dosage. Depends on indication: 100 mg daily, up to 3000 mg daily in 2-3 divided doses.

C. Glucosamine

1. Nonapproved indication. Osteoarthritis

2. Mechanism of action

a. Glucosamine enhances cartilage proteoglycan synthesis.

b. It inhibits the deterioration of cartilage secondary to osteoarthritis.

c. It maintains an equilibrium between cartilage catabolic and anabolic processes.

d. It may have an anti-inflammatory action unlike cyclooxygenase.

3. Efficacy. A double-blind trial included 40 patients with unilateral osteoarthritis of the knee. Patients were given glucosamine 500 mg three times daily or ibuprofen 400 mg three times daily for 8 weeks. Pain scores decreased faster during the first

2 weeks in the ibuprofen group than in the glucosamine group. No significant difference in swelling was observed between the two groups (Vaz).

4. Contraindications/precautions

a. Hypersensitivity to glucosamine or shellfish

b. Diabetes. Glucosamine may impair insulin secretion.

c. Pregnancy and lactation

d. Asthma

5. Drug interactions

a. Fluoxetine (Prozac) may increase glucosamine serum concentrations.

b. Glucosamine may interact with antidiabetic agents.

c. Glucosamine may induce resistance to antimitotic chemotherapy (etoposide-VePesid), doxorubicin).

d. Theoretically, glucosamine may interact with warfarin.

6. Side effects

a. Gastrointestinal side effects such as epigastric pain and tenderness, heartburn, diarrhea, and nausea

b. Central nervous system side effects such as drowsiness, headache, and insomnia

c. Long-term side effects are unknown.

d. Elevated blood glucose

7. Dosage. Recommended: 500 mg three times daily

D. Melatonin

1. Orphan drug status. Treatment of circadian rhythm sleep disorders in blind people who have no light perception

2. Nonapproved indications. Jet lag, insomnia, depression, and cancer

3. Mechanism of action

a. It is a hormone made from serotonin and secreted by the pineal gland. Melatonin controls the periods of sleepiness and wakefulness.

b. It may possess antioxidant properties.

4. Efficacy

a. Jet lag. A randomized, placebo-controlled trial evaluated the effect of melatonin in 52 aircraft personnel. Melatonin was given either 5 mg daily 3 days before departure until 5 days after arrival (early group) or 5 mg daily upon arrival and for 3 additional days (late group). The late group had significantly less jet lag, fewer overall sleep disturbances, and a faster recovery of energy compared to the placebo group and the early group (Petrie et al.).

b. Insomnia. A meta-analysis on 17 randomized, double-blind, placebo-controlled trials that evaluated the sleep effect of melatonin in subjects showed that melatonin significantly decreased time to sleep onset, increased sleep efficiency, and increased total sleep

duration compared to placebo (Brzezinski et al.). Unfortunately, melatonin preparations were varied and study designs differed.

c. Children. Melatonin may be effective in decreasing the time to sleep onset in children with neurodevelopmental disabilities. Melatonin does not improve total sleep time or nighttime awakenings (Phillips et al.).

5. Contraindications/precautions

a. Avoid in pregnancy and lactation

b. Melatonin may aggravate depressive symptoms.

c. Melatonin may increase the incidence of seizures.

d. Diabetes (hyperglycemia)

e. Hypertension (exacerbated)

f. Caution while driving or performing other tasks requiring alertness and coordination.

6. Drug interactions

a. Vitamin B_{12} influences melatonin secretion. Low levels of vitamin B_{12} will produce low levels of melatonin.

b. MAOIs may increase melatonin serum concentrations.

c. Selective serotonin reuptake inhibitors may increase melatonin serum concentrations.

d. β-Blockers may decrease nocturnal secretion of melatonin.

e. Other sedatives may exacerbate the sedative effects of melatonin.

f. Melatonin may interact with immunosuppressants.

g. Antidiabetic agents may be less effective.

h. Anticoagulants and antiplatelets (increased effect)

i. Caffeine (theoretically, efficacy of melatonin may be decreased)

j. Contraceptives (theoretically, efficacy of melatonin may be increased)

k. Verapamil (increased melatonin excretion)

7. Side effects

a. Side effects include drowsiness, daytime fatigue, headache, and transient depression.

b. Long-term side effects are unknown.

8. Dosage. 0.3-5 mg at bedtime

STUDY QUESTIONS

Directions for questions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following herbs is known to cause cancer?

(A) chaparral

(B) comfrey

(C) Ma huang

(D) licorice

(E) St. John's wort

View Answer***1. The answer is B[see].*****2. Which of the following is a correct statement?**

(A) Dietary supplements must be proven safe and effective before marketing in the United States.

(B) The following statement is optional for labeling of herbal products: “This product has not been evaluated by the FDA. It is not intended to diagnose, treat, cure, or prevent.”

(C) Herbs must be standardized to be considered dietary supplements.

(D) Dietary supplement manufacturers may claim that their products affect the structure and function of the human body.

View Answer***2. The answer is D[see].*****3. Tom would like to try echinacea to prevent colds and flus during the winter months. Which of the following statements is true about echinacea?**

(A) It is contraindicated in patients allergic to parsley.

(B) It should be taken continuously only for 3 months.

(C) It is contraindicated in patients with lupus and leukosis.

(D) Prolonged use of echinacea will upregulate the immune system.

(E) Side effects include headache, rash, and dizziness.

View Answer***3. The answer is C[see].*****4. Mary has a family history of heart disease and wonders if garlic would be beneficial to her. Which of the following statements is correct about garlic?**

(A) Enteric-coated tablets release their contents in the stomach.

(B) Side effects include heartburn, flatulence, and sweating.

(C) The safety of garlic in pregnancy is unknown.

(D) Garlic does not interact with warfarin.

View Answer***4. The answer is B[see].*****5. An 80-year-old man takes warfarin for his mechanical heart valve. He would also like to take the following herbs: Asian ginseng, feverfew, garlic, and dong quai. Which of the these herbs may decrease the effectiveness of warfarin?**

(A) Asian ginseng

(B) feverfew

(C) metronidazole

(D) garlic

(E) dong quai

View Answer***5. The answer is A[see].*****6. A 30-year-old female is 10 weeks pregnant with her second child. During her first pregnancy, she became depressed and was started on Prozac 20** mg **every day. She is already beginning to notice early symptoms of depression during her second pregnancy. She would like to try St. John's wort for her depression. Which of the following statements is correct regarding St. John's wort?**

(A) The safety of St. John's wort in pregnancy is unknown.

(B) St. John's wort is not helpful in treating mild depression.

(C) St. John's wort may interact with serotonin reuptake inhibitors.

(D) St. John's wort may interact with dairy products like milk and eggs.

View Answer***6. The answer is C[see].*****7. A 65-year-old is interested in taking ginkgo. Which of the following statements is correct regarding ginkgo?**

(A) There are no contraindications with ginkgo.

(B) There is a drug-herb interaction between ginkgo and aspirin.

(C) Toxic effects include hypertension and cardiac arrest.

(D) There is a drug-herb interaction between ginkgo and phenelzine.

(E) Ginkgo is contraindicated in patients with gallstone pain.

View Answer***7. The answer is B[see].***P.739

8. A 20-year-old athletic man would like to take Asian and Siberian ginseng to increase his physical stamina. His girlfriend suggested that he ask a pharmacist about the safety of Asian and Siberian ginseng. Which of the following statements is correct?

(A) Siberian ginseng may interact with phenelzine, warfarin, and digoxin.

(B) Asian ginseng is potentially harmful in patients with autoimmune diseases.

(C) Asian and Siberian ginseng are the same ginseng but grown in different countries.

(D) Asian and Siberian ginseng should be avoided in patients with hypertension.

View Answer***8. The answer is D[see].***P.740

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* I.B.1*].*

Comfrey may be carcinogenic. Chaparral may be hepatotoxic. High doses of licorice for long periods may cause pseudoaldosteronism. Ma huang may cause myocardial infarction, strokes, or seizures. St. John's wort has many drug interactions.

2. The answer is D *[see* I.A.3*].*

The Dietary Supplement Health and Education Act of 1994 states that dietary supplements are not considered drugs or food. Since dietary supplements are not regulated as drugs, their safety and efficacy are not mandated by the FDA. Dietary supplements are intended to supplement the diet, do not have to be standardized, may make claims regarding only the effects on structure or function of the body. The following is the correct required labeling statement: “This product has not been evaluated by the FDA. It is not intended to diagnose, treat, cure, or prevent.”

3. The answer is C *[see* II.E.4*].*

Echinacea is contraindicated in infectious and autoimmune diseases such as tuberculosis, leukosis, collagenosis, multiple sclerosis, AIDS, HIV, and lupus. Caution should be used in patients who are allergic to members of the ragweed family. Therapy should not exceed 8 weeks. Theoretically, prolonged use of echinacea may depress the immune system, possibly through over stimulation. Side effects include nausea, vomiting, allergic reactions, anaphylaxis, and interference with male fertility.

4. The answer is B *[see* II.G.4*].*

Garlic should be avoided in pregnancy because it is an emmenagogue and abortifacient. It may interact with anticoagulants, increasing the risk of bleeding. Side effects include gastrointestinal discomfort (heartburn, flatulence), sweating, lightheadedness, allergic reactions, and menorrhagia. Enteric-coated tablets or capsules allow more absorption because they pass through the stomach and release their contents in the alkaline medium of the small intestine.

5. The answer is A *[see* II.J.5*].*

Asian ginseng may decrease the INR of warfarin. Feverfew, garlic, and dong quai may increase the INR of warfarin. Metronidazole may increase the INR, but it is not considered to be an herb.

6. The answer is C *[see* II.N.4*].*

St. John's wort is indicated in by Commission E for depression and anxiety. St. John's wort should be avoided in pregnancy because it is an emmenagogue and abortifacient. St. John's wort interacts with many medications, including serotonin reuptake inhibitors. Food interactions may be similar to those of the MAOIs (tyramine-containing foods: cheese, beer, wine, herring, and yeast).

7. The answer is B *[see* II.I.5*].*

Contraindications and precautions for ginkgo include diabetes, epilepsy, bleeding disorders, and infertility. Ginkgo may potentiate the bleeding properties of antiplatelets. Side effects include gastric disturbances, headache, dizziness, and vertigo. Toxic ingestion may produce tonic-clonic seizures and loss of consciousness.

8. The answer is D *[see* II.J.4; II.K.4*].*

Asian ginseng's contraindications include patients with hypertension. Asian ginseng may interact with phenelzine, producing hallucinations and psychosis; may decrease the INR of warfarin; and may interfere with immunosuppressants. Siberian ginseng's contraindications/precautions include hypertension. It may interact with anticoagulants and antihypertensives and may inhibit cytochrome P450 isoenzymes. Asian and Siberian ginseng are not the same plant and are not of the same genus.

Clinical Pharmacokinetics and Therapeutic Drug Monitoring

Gerald E. Schumacher

I. INTRODUCTION

A. Objectives

1. Therapeutic drug monitoring (TDM) in a general sense is about using serum drug concentrations (SDCs), pharmacokinetics, and pharmacodynamics to individualize and optimize patient responses to drug therapy.

2. TDM aims to promote optimum drug treatment by maintaining SDC within a **therapeutic range,** above which drug-induced toxicity occurs too often and below which the drug is too often ineffective.

B. Definitions

1. Specifically, **TDM** is a practice applied to a small group of drugs in which there is a direct relation between SDCs and pharmacological response, as well as a narrow range of concentrations that are effective and safe and for which SDCs are used in conjunction with other measures of clinical observation to assess patient status.

2. Clinical pharmacokinetics, a term often used interchangeably with TDM, is more generally the application of pharmacokinetic principles for the rational design of an individualized dosage regimen.

3. For definitions of the terms used and the concepts applicable in basic and clinical pharmacokinetics, see Chapter 6 on pharmacokinetics.

C. Rationale and reasons

1. The rationale for TDM makes three assumptions.

a. Measuring patient SDC provides an opportunity to adjust for variations in patient pharmacokinetics by individualizing drug dosage.

b. The SDC is a better predictor of patient response than is dose.

c. There is a good relation between SDCs and pharmacological response.

2. Reasons for measuring SDC

a. Drug levels are used in conjunction with other clinical data to assist practitioners in determining how a patient is responding.

b. Drug levels provide a basis for **individualizing** patient dosage regimens.

c. Drug levels assist in determining if a change in **patient-specific** pharmacokinetics has occurred during a course of treatment, either as a result of a change in physiological state, a change in diet, or addition of other drugs.

d. Assuring **drug compliance** is often cited as a reason for measuring SDC, but it is unreliable for this purpose. In truth, a noncompliant patient may outwit practitioners by manipulating preappointment behavior to induce an SDC that is nonreflective of the patient's drug-taking behavior.

II. APPLYING CLINICAL PHARMACOKINETICS IN TDM

A. What the practitioner controls and does not control in TDM

1. Figure 36-1 shows the relation between dose rate of drug administered, pharmacokinetic variables, SDC, and pharmacological response.

2. Note that the only variables that the practitioner controls are the amount of drug administered and how often it is given. These variables may be manipulated to compensate for the patient's pharmacokinetic and pharmacodynamic variables (i.e., bioavailability, clearance, steady-state SDC, pharmacological response), which the practitioner does not control, to achieve some designated SDC that yields a pharmacological response usually observed within the drug's commonly accepted therapeutic SDC range.

B. The concept of therapeutic range

1. For many drugs, a specific serum concentration range can be designated for each drug that maximizes effectiveness and minimizes toxicity. The range of SDC is called the **therapeutic range** for the drug.

2. The notion of a therapeutic range is more a **probabilistic concept** than an absolute entity. It is probable that the majority of patients will show effective and safe responses within the therapeutic range. However, a minority of patients will need SDC above or below the upper or lower limits, respectively, of the therapeutic range to achieve an effective response. Similarly, a minority of patients will not show toxicity at SDC modestly above the therapeutic range, whereas others will show toxicity below the therapeutic range.

3. Therefore, TDM is about **individualizing** patient dosage regimens to achieve SDC within patient-specific therapeutic ranges for a drug. More often than not, a patient-specific range will fall within the generally stated therapeutic range.

C. The concept of population pharmacokinetic values

1. A population pharmacokinetic value or parameter refers to the mean (average) value noted for a given cohort of people (e.g., adults 20-60 years of age, patients with a defined range of renal impairment). Usually, this population value is normalized on a weight basis (e.g., theophylline volume of distribution in adult normals of 0.5 L/kg). When a population parameter is stated without defining the target population, it usually refers to adults; further, when the value also is not normalized (e.g., volume of distribution of theophylline of 35 L), it usually refers to adults of average weight (approximately 60-80 kg).

2. Hardly anyone is average. Individual values of the population studied are summed to determine a mean value that is then reported as the **population value.** Individualizing patient dosage regimens takes this into account by

adjusting observed patient-specific values and responses to expected population measures.

3. So the practitioner starts the determination of a patient-specific dosage regimen by assuming that the patient behaves like the average member of his or her population with respect to

P.743

pharmacokinetics, serum level, and expected response, and uses population pharmacokinetic parameters to calculate the dosage regimen needed to meet the desired SDC objective.

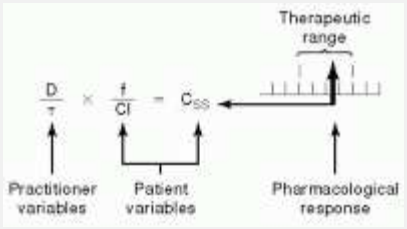

Figure 36-1. Pharmacokinetic factors influencing serum drug concentration and pharmacological response. Bioavailability is f, clearance is Cl, steady-state serum drug concentration is C_{ss}, D is dose, and τ is frequency of administration of dose.

4. If after administering the dosage regimen until steady state is reached, based on using population values, the patient is responding appropriately, then no adjustment in regimen is necessary.

5. If, however, the starting assumption of using average values turns out to be incorrect, because the patient's response is either subtherapeutic or toxic due to patient-specific pharmacokinetic and/or pharmacodynamic values that are atypical for the population, the practitioner's only option (except for changing the drug) is to manipulate the practitioner-controlled input variables, **dose and frequency,** to bring the pharmacological response within the desired range.

D. Timing of SDC measurements

1. SDCs are sometimes measured **early in a course of therapy,** before steady state is reached, to determine patient-specific pharmacokinetic parameters, rather than relying on population values.

2. More commonly, SDCs are measured **during a steady-state dosage interval** (τ_{ss}), because the objective is to determine if the SDC is within a desired therapeutic range, a range that has previously been determined almost invariably during τ_{ss}.

3. Because SDCs are most commonly measured at steady state and referenced to values obtained at steady state, it is necessary to wait after starting drug administration until at least three to four assumed half-life

($t_{1/2}$) values (88%-94% of reaching full steady state) so that SDC will be measured during a period when steady state may be assumed, for clinical purposes, to have been reached or approximated (e.g., approximately 90% of steady state or greater; so for an assumed $t_{1/2}$ of 6 hours, wait 18-24 hours after initiating drug treatment to measure SDC).

4. If there are no changes in patient response, there is usually **no need to take subsequent daily SDC measurements,** once an appropriate SDC has been achieved. Only if something occurs that may be expected to alter the patient's pharmacokinetic values (e.g., co-administration of another potentially modifying drug, change in physiological state), are frequent measurements necessary.

5. If a steady-state SDC ($\mathbf{C_{ss}}$) is used appropriately to relate a patient's C_{ss} to a population or patient-specific therapeutic range, then it is important to note when during the steady-state dosage interval (τ_{ss}) the C_{ss} was measured in studies determining the therapeutic range. In other words, is the therapeutic range the practitioner is using as a basis for individualizing regimens based on C_{ss} measured **early** (apparent $\mathbf{C_{max,ss}}$), near the **midpoint** (apparent $\mathbf{C_{avg,ss}}$),or near the end (apparent $\mathbf{C_{min,ss}}$) of τ_{ss}?

6. Errors in interpretation occur when C_{ss} for a patient is measured at a time during τ_{ss} that is markedly different than the time used for establishing the therapeutic range [e.g., measuring C_{ss} in a patient 1 hour after giving a dose on a q12h regimen when the C_{ss} for the referenced therapeutic range was actually taken at the end of τ_{ss} ($\mathbf{C_{min,ss}}$)].

7. Errors in timing of C_{ss} are of greater concern for drugs with a short $t_{1/2}$ than for drugs with a long $t_{1/2}$. C_{ss} fluctuation during τ_{ss} is much greater in the former than the latter case.

III. TDM DRUGS AND COMMON CHARACTERISTICS

A. TDM drugs

1. Drugs for which TDM is commonly used are noted in Table 36-1, along with the population therapeutic range.

2. Drugs for which TDM is infrequently used in general situations, but perhaps commonly used by specialty practitioners or clinics, are noted in Table 36-2.

B. Common characteristics of TDM drugs. Drugs that qualify for TDM have, as a minimum, the following characteristics in common.

Table 36-1. Drugs Often Monitored Using Serum Drug Concentrations

Drug	Therapeutic Range for C_{ss}
Amikacin	$C_{max,ss}$[a] = 20-30 µg/mL; $C_{min,ss}$ <10 mcg/mL
Cyclosporine	Varies with transplanted organ, time after transplant, time of sampling during dosage interval, and method of analysis
Digoxin	0.8-2[b] ng/mL
Gentamicin	$C_{max,ss}$[a] = 5-10 µg/mL; $C_{min,ss}$ <2 mcg/mL
Phenytoin	10-20 µcg/mL
Theophylline	5-20 µcg/mL
Tobramycin	$C_{max,ss}$[a] = 5-10 µg/mL; $C_{min,ss}$ <2 mcg/mL
Vancomycin	$C_{max,ss}$[a] = 30-50 µg/mL; $C_{min,ss}$ = 5-10 mcg/mL

[a] End of 30- to 60-min infusion.

[b] Levels for atrial fibrillation often exceed 2 ng/mL.

Table 36-2. Drugs Monitored Using Serum Drug Concentrations in Specialty Situations

Amitriptyline
Carbamazepine
Indinavin
Lidocaine
Lithium

Methotrexate
Nortriptyline
Salicylates
Valproic acid

1. SDC is the most practical intermediate end point to be used when there is no clearly observable therapeutic or toxic end point.
2. SDC is a reasonable proxy for drug concentration at the site of action.
3. The range of therapeutic and safe serum concentrations is narrow.
4. There is no predictable dose-response relation.
5. The pharmacological effect observed persists for a relatively long time. Acute, short, or intermittent effects are not well regulated by using serum drug levels.
6. A drug assay is available that is accurate, precise, specific, rapid, and relatively inexpensive.

IV. EQUATIONS FREQUENTLY USED IN TDM

A. Linear pharmacokinetic drug clearance—normal renal function.
Linear clearance assumes that a **proportional** change in dose leads to the same **proportional** change in SDC. It also assumes that $t_{1/2}$ and drug clearance remain **constant** as the dose changes. See IV.D for an example of using some of the following equations.

1. Estimating drug clearance (Cl):

$$Cl = \frac{V}{1.4t_{1/2}} \qquad (1)$$

where V is the apparent volume of distribution of drug.

2. Maximum concentration ($C_{max,ss}$) during τ_{ss}, when absorption is assumed to be much faster than elimination:

$$C_{max,ss} = \frac{(S)(f)(dose/V)}{1 - 10^{-0.3(\tau/t_{1/2})}} \quad (2)$$

where S is the fraction of the dosage form that is the active moiety and f is the bioavailability.

3. Minimum concentration ($C_{min,ss}$) during τ_{ss}, when absorption is assumed to be much faster than elimination:

$$C_{min,ss} = (C_{max,ss})\,[10^{-0.3(\tau/t_{1/2})}] \quad (3)$$

4. Average concentration resulting from intermittent administration ($C_{avg,ss}$) during τ_{ss}:

$$C_{avg,ss} = \frac{(S)(f)(dose/\tau)}{Cl} \quad (4)$$

where dose/τ is the amount of drug administered during each selected unit of time (e.g., hours, minutes).

5. Steady-state concentration resulting from continuous administration ($C_{inf,ss}$). For the same dose rate (dose/τ), ($C_{avg,ss}$) for intermittent administration **is the same as** ($C_{inf,ss}$) for continuous administration:

$$C_{inf,ss} = \frac{(S)(f)(dose/t_{inf})}{Cl} \quad (5)$$

B. Linear pharmacokinetic drug clearance—impaired renal function

1. Estimating creatinine clearance from serum creatinine when serum creatinine is assumed to be stable, not changing daily, and weight is expressed by the patient's total weight, unless total weight is equal to or more than 20% of ideal (lean) body weight, in which case ideal weight should be used in the calculation:

$$Cl_{cr}\,(mL/min, males) = \frac{(140 - age)(weight)}{(Cr_s)(72)}$$

where Cr_s denotes serum creatinine in mg/dl. The female value is 85% of the estimated male value in (6).

2. Estimating prolonged drug $t_{1/2}$ or reduced drug Cl associated with reduced Cl_{cr}:

$$\frac{(Cl)_{ri}}{(Cl)_n} = \frac{(t_{1/2})_n}{(t_{1/2})_{ri}} = 1 - F + F[(Cl_{cr})_{ri}/(Cl_{cr})_n]$$

where ri and n denote the renal impaired and normal conditions, respectively; F is the fraction of drug administered that is eliminated

unchanged (unmetabolized); and Cl_{cr} represents creatinine clearance in mL/min. Important F values for some common TDM drugs are: aminoglycosides = 0.98, digoxin = 0.98, and vancomycin = 0.95.

3. Using $C_{avg,ss}$ as a target so that $C_{avg,ss}$ in the renal impaired patient is maintained the same as $C_{avg,ss}$ in normals:

$$\frac{(\text{dose}/\tau)_{ri}}{(\text{dose}/\tau)_{n}} = \frac{\text{dose}_{ri} \times \tau_{n}}{\text{dose}_{n} \times \tau_{ri}} = 1 - F + F[(Cl_{cr})_{ri}/(Cl_{cr})_{n}]$$

4. Using $C_{max,ss}$ as a target so that $C_{max,ss}$ in the renal impaired is maintained the same as $C_{max,ss}$ in normals:

$$\text{dose per } \tau_{ri} = (\text{dose}_{L})[1 - 10^{-0.3(\tau_{ri}/t_{1/2ri})}]$$

where $dose_L$ is a loading dose intended to achieve the same $C_{max,ss}$ in the renal impaired as in the normal patient.

C. Nonlinear pharmacokinetic drug clearance—normal renal function.

Nonlinear clearance assumes that a proportional change in dose leads to a **disproportional** change in SDC. It also assumes that $t_{1/2}$ and Cl **change** as the dose changes and also as the amount of drug in the body from a given dose changes. Drugs exhibiting nonlinear clearance present a much greater challenge than linear clearance drugs because the assumptions in the latter case of proportional changes in dose yielding same proportional changes in C_{ss} and constant Cl and $t_{1/2}$ do not apply for nonlinear drugs. For nonlinear drugs, increases in dose lead to increases in $t_{1/2}$, decreases in Cl, and changes in C_{ss} that are excessive compared to the proportionate change in dose.

1. Estimating drug clearance:

$$Cl = \frac{V_{max}}{K_m + C_{avg,ss}} \quad (10)$$

where V_{max} is the maximum amount of drug that can be eliminated per unit of time (e.g., day) and K_m is the drug serum concentration at which the rate of elimination is 50% of V_{max}.

2. Estimating $C_{avg,ss}$ resulting from a given dose/τ:

$$C_{avg,ss} = \frac{(K_m)(S)(f)(\text{dose}/t)}{V_{max} - (S)(f)(\text{dose}/\tau)} \quad (11)$$

3. Estimating dose/τ needed for a desired $C_{avg,ss}$:

$$\text{dose}/\tau = \frac{(V_{max})(C_{avg,ss})}{(K_m + C_{avg,ss})(S)(f)} \qquad (12)$$

D. An example of applying some of the above equations to developing and modifying dosage regimens

1. A common dosage regimen for intravenous (IV) gentamicin is 1.7 mg/kg q8h (as a 30-minute infusion). Regimens are usually adjusted to achieve $C_{max,ss}$ and $C_{min,ss}$ within 5-10 mcg/mL and less than 2 mcg/mL, respectively. Does the above regimen meet the target concentration objectives in normal patients? Assume the following population parameters in normals: Cl = 0.09 L/kg/hr, $t_{1/2}$ = 2.5 hr, V = 0.25 L/kg. For IV administration, f = 1, and S = 1 for the dosage form (label amount represents the actual amount of gentamicin).

2. In normals, using equations (2) and (3):

$$C_{max,ss} = \frac{(1)(1)(1.7 \text{ mg/kg})/(0.25 \text{ L/kg})}{1 - 10^{-0.3\ (8 \text{ hr}/2.5 \text{ hr})}} = 7.6 \text{ mcg/mL}$$

$$C_{min,ss} = 7.6 \text{ mcg/mL} \times 10^{-0.3\ (8 \text{ hr}/2.5 \text{ hr})} = 0.8 \text{ mcg/mL}$$

These values fall within the target concentration ranges for the average patient with normal renal function.

3. In the renal impaired, what should be done to modify the above regimen for a patient who is 60 years old, 70 kg, male, with a Cr_s of 2.5 mg/dl? In this patient, if the above regimen were used, the prolonged $t_{1/2}$ would yield $C_{max,ss}$ = 15.2 mcg/mL and $C_{min,ss}$ = 8.4 mcg/mL, values clearly above the target concentration ranges.

a. Using equation (6) for estimating Cl_{cr} in this patient:

$$Cl_{cr} = \frac{(140 - 60 \text{ yr})(70 \text{ kg})}{(2.5 \text{ mg/dl})(72)} = 31 \text{ mL/min}$$

b. Then using equation (7) for estimating $t_{1/2}$ in this patient, assuming F = 0.98 and $(Cl_{cr})_n$ = 120 mL/min:

$$\frac{(2.5 \text{ hr})}{(t_{1/2})_{ri}} = 1 - 0.98 + 0.98(31/120) = 0.27$$

$$(t_{1/2})_{ri} = 9.3 \text{ hr}$$

c. Then using equation (9), first determine a loading dose (D_L) to achieve the same $C_{max,ss}$ of approximately 8 mcg/mL as estimated in IV.D.2 for a patient with normal renal function:

$D_L = (C_{max,ss})(V)/(S)(f)$

D_L = (8 mcg/mL)(0.25 L/kg)/(1)(1) = 2 mg/kg

Next, determine fraction of drug lost during τ, assuming a τ_{ri} of 24 hours, and using the $(t_{1/2})_{ri}$ of 9.3 hours estimated in IV.D.3.b:

Fraction lost = $1 - 10^{-0.3(\tau/t_{1/2})} = 1 - 10^{-0.3(24/9.3)} = 0.84$

Lastly, calculate D per τ_{ri}:

P.747

D per τ_{ri}	=	$(D_L)[1 - 10^{-0.3(\tau/t_{1/2})}]$
	=	(2 mg/kg)(0.84) = 1.7 mg/kg

Thus, a D_L of 2 mg/kg followed by 1.7 mg/kg q24h is expected to maintain levels in this patient similar to that in normals.

V. EFFECT OF PHYSIOLOGICAL ALTERATIONS ON PHARMACOKINETIC VARIABLES

A. General considerations. It is apparent from Figure 36-1 and the equations in Section IV, that any changes in pharmacokinetic variables result in changes in C_{ss} and perhaps pharmacodynamic outcomes. This may necessitate changes in D/τ compared to normals. For renal impairment, **quantitative** estimates of resulting changes in Cl and $t_{1/2}$, compared to normal values, are available using the equations in Section IV. For hepatic, cardiac, pulmonary, and other impairments potentially inducing changes in normal pharmacokinetic variables, only **qualitative** estimates are possible.

B. Renal impairment, when marked, reduces drug clearance for drugs primarily dependent on the kidney for elimination. As noted in the equations in Section IV.B, physiological markers like serum creatinine and creatinine clearance are used to estimate the changes in Cl and $t_{1/2}$ resulting from reductions in Cr_s and Cl_{cr}.

C. Hepatic impairment exerts a complex influence on drug pharmacokinetics. Two processes may be altered, blood flow rate in delivering drug to the liver and the capacity of enzymes to metabolize the drug. In general terms, moderate to severe hepatic impairment is expected

to slow overall Cl and prolong $t_{1/2}$ for drugs highly dependent on the liver for elimination.

D. Cardiac impairment, when substantial, decreases hepatic and renal clearances, reduces volume of distribution, and may slow absorption for some drugs. The effect of compromised perfusion is most critical for drugs that are both highly dependent on the liver for clearance and efficiently metabolized by the liver in normal patients.

E. Aging results in reductions in renal (consistently) and hepatic (inconsistently) clearances. The clearance of drugs primarily dependent on the kidney declines by nearly 50% and the half-life nearly doubles over a 40-50-year period from young adulthood. On the other hand, some drugs primarily dependent on the liver for clearance show no age-related changes, while others do. Changes with age in absorption, volume of distribution, and serum protein binding of drugs show no consistent pattern.

F. From a clinical viewpoint, serum **protein binding** of drugs becomes an important issue in TDM for drugs bound more than 80% to serum proteins. Because hepatic and renal clearances, volume of distribution, and pharmacological response are mediated by the free (unbound) form of the drug in serum, interpatient variations in protein binding not only result in variations in pharmacokinetics in normals, but also loss of serum proteins during renal and hepatic impairments may result in modified drug clearance and pharmacological response.

VI. THE TOTAL TESTING PROCESS APPLIED TO TDM

A. Defining the total testing process (TTP)

1. TDM involves both the laboratory for analysis and clinicians for interpretation of SDC. TTP refers to all aspects of the steps of laboratory testing beginning with a clinical question that is prompted by the patient-clinician encounter and concluding with the impact of the test result on patient care.

2. TTP emphasizes that TDM is a process involving a series of steps and interrelated activities and should not be viewed simply as a numerical value for an SDC.

3. TTP focuses on identifying all steps of the TDM testing process, highlighting where variations and errors can occur, interpreting SDC results in light of the steps involved, and improving the contribution of testing to achieving desired patient outcomes.

B. Components and steps in TTP. There are 4 components and 11 steps in TTP.

1. The preanalytical component consists of four steps:

(1) clinical question, (2) test selected, (3) test ordered, and (4) specimen collection.

2. The analytical component then follows with three steps:
(5) sample prepared, (6) analysis performed, and (7) result verified.

3. The postanalytical component then concludes with four steps: (8) result reported, (9) clinical answer, (10) action taken, and (11) effect on patient care.

4. The three components are affected by the fourth component, the **regulatory environment** within which TDM is performed.

C. Contributions of TDM to TTP

1. TDM has the potential to improve many of the steps in TTP: providing education, drug information, interpretation of TDM results, assessing the appropriateness of the TDM order, scheduling specimen collection, developing drug dosage guidelines, and providing written and oral consultation concerning TDM results.

2. The pharmacist's greatest involvement in TTP is in steps (2) assessing the appropriateness of TDM for a given situation, (4) timing of specimen collection, and (9) clinical interpretation of TDM results.

VII. USING TEST PERFORMANCE CHARACTERISTICS IN TDM

A. Rationale and reasons

1. In TDM, the SDC functions like a diagnostic test to assist in classifying patient status.

2. On the one hand, the patient's SDC may be used, in conjunction with a population SDC cutoff value measure for the drug, which acts as a separator, to classify the patient as a member of either drug-induced toxic (patient SDC > upper cutoff value) or therapeutic (within therapeutic range) subpopulations.

3. Alternately, the patient's SDC may classify the patient as part of the therapeutic or subtherapeutic (SDC < lower cutoff value) subpopulations.

4. Although classifying patients in subpopulations is the most common use of SDC in TDM, a more informed application of SDC is to use the result to modify the clinician's probability of patient status. This is the use of SDC as part of a Bayesian approach to diagnostic test interpretation.

B. Test performance characteristics. Test performance indices are not perfect classifiers of patient status and should never be used as the sole measure for determining how the patient is reacting to the drug. A number of test performance indices characterize the accuracy of a diagnostic test to accurately classify patients as toxic, therapeutic, or subtherapeutic. Four of these indices are most useful in interpreting SDC.

1. Positive predictive value (PPV)

a. Comparing drug-induced toxic versus nontoxic patients (using upper SDC cutoff level). PPV denotes the proportion of patients with a **positive test** (patient SDC > upper cutoff SDC) who are in a drug-induced **toxic**

condition. So, the value of PPV represents the probability of a positive test being accurate in classifying the patient as toxic.

b. Comparing therapeutic versus subtherapeutic patients (using lower SDC cutoff level). PPV denotes the proportion of patients with a **positive test** (patient SDC > lower cutoff SDC) who are **responding appropriately.** So, the value of PPV in this case represents the probability of a positive test being accurate in classifying the patient as therapeutic.

2. Negative predictive value (NPV)

a. Comparing drug-induced toxic versus nontoxic patients (using upper SDC cutoff level). NPV denotes the proportion of patients with a **negative test** (patient SDC < upper cutoff SDC) who are **not** manifesting drug-induced **toxicity.** So, the value of NPV represents the probability of a negative test being accurate in classifying the patient as nontoxic.

b. Comparing therapeutic versus subtherapeutic patients (using lower SDC cutoff level). NPV denotes the proportion of patients with a **negative test** (patient SDC < lower cutoff SDC) who are **subtherapeutic.** So, the value of NPV in this case represents the probability of a negative test being accurate in classifying the patient as subtherapeutic.

3. Positive likelihood ratio (PLR). In defining conditions as + or - (as in + = toxic and - = negative, or + = therapeutic and - = subtherapeutic), **PLR** is the probability that a + **patient** has a + **test** divided by the probability that a - **patient** has a + **test** (e.g., the probability that a **toxic** patient has an SDC > cutoff divided by the probability that a **nontoxic** patient has an SDC > cutoff). The **higher** the **PLR,** the **more** discriminating the test.

4. Negative likelihood ratio (NLR). NLR is the probability that a + **patient** has a - **test** divided by the probability that a - **patient** has a - **test.** The **lower** the **NLR,** the **more** discriminating the test.

5. Illustrating the use of PPV, NPV, PLR, and NLR. For theophylline, using a test upper cutoff of 20 mcg/mL, PPV is 0.5, NPV is 0.95, PLR is 6, and NLR is 0.4.

a. For PPV, this means that the proportion of patients with a positive test result (SDC > upper cutoff) who truly have theophylline-induced toxicity is 50%. For an individual patient with SDC > cutoff, the probability of toxicity is 0.5.

b. For NPV, this means that the proportion of patients with a negative test result (SDC < upper cutoff) who truly are nontoxic is 95%. For an individual patient with SDC < cutoff, the probability of nontoxicity is 0.95.

c. For PLR, toxic patients will have a positive test result six times more often than do nontoxic patients.

d. For NLR, toxic patients will have a negative test result 40% as often as will nontoxic patients.

e. These results suggest that a negative theophylline test result rules out toxicity (0.95) about twice as effectively as a positive test rules in toxicity (0.5). A positive test appears to be unreliable as an indicator of toxicity, but a negative test appears to be highly predictive of nontoxicity. Furthermore, the PLR suggests that a positive SDC test is six times more likely to come from a toxic than a nontoxic patient. On the other hand, the NLR implies that it is considerably less than one-half as likely (0.4) that a negative test comes from a toxic compared to a nontoxic patient.

f. Knowledge of test performance characteristics of SDC measures provides the practitioner with an index of the usefulness of the SDC in categorizing patients.

C. Using a Bayesian approach. Using SDC in conjunction with likelihood ratio information enhances the application of the SDC in decision making. A Bayesian approach to probability revision allows the practitioner to make a pretest assessment of patient status, order a diagnostic test, and use the probability information contained in the test result to revise the assessment of status.

1. The relation between pretest, test, and posttest assessment is shown in the following equation:

$$(\text{pretest odds})(\text{likelihood ratio}) = (\text{posttest odds})$$

where pretest refers to the pretest odds of the condition being present prior to obtaining the patient's SDC and posttest refers to the posttest odds of the condition being present after learning the SDC.

2. Odds are defined as + results divided by - results (+/-). **Probability** is defined as + results divided by total results (+/total, where total is the sum of + and - results).

3. Odds are converted to probability as follows:

$$\text{Probability} = \text{odds}/(1 + \text{odds})$$

4. Probability is converted to odds as follows:

$$\text{Odds} = \text{probability}/(1 - \text{probability})$$

5. An example of applying a Bayesian approach to modifying the probability of patient status. Using the theophylline test performance characteristics noted in VII.B.5:

a. Assume that a practitioner assesses by visual inspection that the probability of theophylline-induced toxicity in a patient is 0.25 (the pretest probability). She orders a serum theophylline concentration (STC), and uses the measurement to revise her assessment of toxicity in the patient (the posttest probability).

b. Further assume that the test performance characteristics for the STC are: PLR = 6 and NLR = 0.4.
c. Using equations (13), (14), and (15), a pretest probability of 0.25 is the same as pretest odds of toxicity of 1/3 [0.25/(1 - 0.25)], using equation (15).
d. If the STC test for the patient comes back positive (STC > 20 mcg/mL), then PLR = 6 is used to revise the odds of toxicity. If the STC test is negative (STC ≤ 20 mcg/mL), then NLR = 0.4 is used.
e. Assume the patient's **STC =** 22 mcg/mL, then using equation (13) yields (1/3)(6) = 2. So, the posttest odds of toxicity are 2/1. Converting these odds to probability using equation (14): [2/(1 + 2)] = 0.67. The **posttest probability of toxicity is 0.67.** The pretest probability of 0.25 has nearly tripled using the STC as feedback.
f. Assume instead that the patient's STC = **14** mcg/mL; then using equation (13) yields (1/3)(0.4) = 0.13. So, the posttest odds of toxicity are 0.13/1. Converting these odds to probability using equation (14): [0.13/(1 + 0.13)] = 0.12. **The posttest probability of toxicity is 0.12.**
g. While a positive STC test nearly tripled the probability of toxicity above, a negative test cuts the probability in half. This demonstrates the usefulness of using SDC in combination with practitioner assessment as a guide to quantifying the probability of patient status.

VIII. SUMMARY

A. TDM applies to a small number of drugs with a narrow range of effective and safe SDC wherein optimum drug treatment is promoted by maintaining SDC within a population or patient-specific therapeutic range, above which drug-induced toxicity occurs too often and below which the drug is too often ineffective.
B. A practitioner initiates drug treatment using a dose rate that assumes that the patient shows mean population values for the pharmacokinetic variables, even though it is expected that few patients will ever possess the mean value being used. If the resulting C_{ss} and/or pharmacological response is other than expected and the patient becomes at risk for subtherapeutic or drug-induced toxicity, it is likely due to the interpatient variability in pharmacokinetic values and pharmacodynamic response that characterizes the need for TDM; therefore, the dose rate is modified to produce a patient-specific C_{ss} that represents the best tradeoff of effectiveness and toxicity.
C. Timing of sampling of SDC is critical to reduce errors in interpretation of the measurement. SDC should be sampled at steady state, after postabsorption and postdistribution equilibrium is achieved, and a time during τ_{ss} that matches the time at which the therapeutic range was established.

D. The choice of $C_{max,ss}$, $C_{min,ss}$, $C_{avg,ss}$, or $C_{inf,ss}$ to estimate dosage regimens depends on the therapeutic range objective and, in the latter case, intravenous rather than intermittent administration.
E. For the renal-impaired patient, the dosage reduction factor is calculated to achieve, depending on the therapeutic range objective, a $C_{max,ss}$ or $C_{avg,ss}$ in the renal-impaired patient that is similar to that desired if the patient had normal renal function.
F. The TTP is the systematic sequence of events in which TDM is practiced from identification of the need for an SDC measurement, to proper timing of sample collection, laboratory analysis, interpretation of results, and dosage regimen modification, if indicated.
G. The SDC measure is more than a number used to relate the patient's value to a population therapeutic range. The SDC is a form of diagnostic test used (1) to assist in classifying patient status and (2) as feedback to revise practitioner estimates of patient status. Therefore, it is important to know the predictive values and likelihood ratios of SDC tests.

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the one lettered answer or completion that is **best** in each case.

1. Define therapeutic drug monitoring. What is meant by the term TDM?

(A) The use of drug serum concentration measurements, for drugs in which there is (1) a correlation between serum concentration and response, as well as (2) a narrow range of effective and safe concentrations, to assess patient status as an adjunct to clinical observation

(B) The use of drug serum concentration measurements to determine population values for a drug's half-life value

(C) The use of drug serum concentration measurements to assess the accuracy of the drug concentration assay

(D) Observing the effects of drugs in man

(E) Using drug serum concentration measurements to differentiate effective from ineffective drugs

View Answer***1. The answer is A[1.B].*****2. The therapeutic range for theophylline is often stated as 10-20** mcg/mL**. What does this mean?**

(A) Fifty percent of people taking theophylline show a safe and effective response when the serum drug concentration is between 10-20 mcg/mL.

(B) Most people achieve the desired response to theophylline, with minimum adverse effects when the serum theophylline concentration is maintained between 10-20 mcg/mL. Fewer patients are managed

effectively at <10 mcg/mL, but some may respond quite appropriately at lower levels. The frequency of adverse effects increases as the level increases above the upper limit of the therapeutic range, but a few patients are managed effectively, without adversity, above the range.

(C) Twenty-five percent of people show an effective response to theophylline at 10 mcg/mL, and 75% show an effective response at 20 mcg/mL.

(D) Twice daily administration of theophylline, but not three times daily, requires that serum drug concentrations stay within 10-20 mcg/mL.

(E) Theophylline serum drug concentrations outside of the 10-20 mcg/mL range are ineffective and/or unsafe.

View Answer***2. The answer is B[].*****3. Assume that for a digoxin, the therapeutic range is cited as $C_{avg,ss}$ = 0.8-2 ng/mL. If the patient is assumed to have an estimated digoxin $t_{1/2}$ of 48 hours, how long would you wait to take a serum digoxin concentration measurement, and when during τ would you schedule it?**

(A) 28 days, then 3-4 hours after the dose is administered

(B) 14 days, then 6-8 hours after the dose is administered

(C) 7 days, then 10-14 hours after the dose is administered

(D) 3 days, then 1-2 hours after the dose is administered

(E) 1 day, then 18-22 hours after the dose is administered

View Answer***3. The answer is C[].*****4. Differentiate linear from nonlinear drug clearance. What is the effect on TDM?**

(A) Linear drug clearance is first order, the Cl and $t_{1/2}$ are independent of drug dosage, and proportional changes in dose result in the same proportional changes in C_{ss}. Nonlinear drug clearance is zero order, Cl and $t_{1/2}$ change as dose changes (or as the amount of drug in the body changes), and proportional changes in dose yield disproportionate changes in C_{ss}.

(B) Linear drug clearance presents fewer serum concentration peaks and troughs during the dosage interval than does nonlinear drug clearance.

(C) Linear drug clearance is zero order, the Cl and $t_{1/2}$ are dependent on drug dosage, and proportional changes in dose do not result in the same proportional changes in C_{ss}. Nonlinear drug clearance is first order, and equations are not available to predict drug serum concentration from the dose rate.

(D) Drugs with linear clearance have shorter $t_{1/2}$ values than drugs with nonlinear clearance.

(E) Drugs with linear clearance are administered less often than drugs with nonlinear clearance.

View Answer***4. The answer is A[].***

5. What is the positive predictive value of a diagnostic test?

(A) The fraction of patients with a positive outcome who have a positive test result

(B) Being more than 50% correct in predicting success or failure upon using a drug regimen

(C) The fraction of patients who achieve a successful response in using a drug

(D) The fraction of patients with a positive test result who turn out to have a positive outcome

(E) The probability that knowledge of a drug serum concentration results in a successful response to treatment

View Answer***5. The answer is D[].*****6. A 70-year-old, 80-kg male, with serum creatinine of 3** mg/dL**, is scheduled to start tobramycin therapy. What regimen is recommended to achieve $C_{max,ss}$ within 5-10** mcg/mL **(use the midpoint of 7.5** mcg/mL **for the calculation) and $C_{min,ss}$ <2** mcg/mL**. Try a q24h regimen to start and, if unsuccessful in achieving the target concentration goals, alter τ and recalculate. Assume in normals the following values: $t_{1/2}$ = 2.5 hr, V = 0.25 L/kg, F = 0.98, S = 1, f = 1, Cl_{cr} = 120** mg/dL**.**

(A) A loading dose of 1.8-2.0 mg/kg followed by 1.0 mg/kg qd

(B) A loading dose of 1.8-2.0 mg/kg followed by 1.5 mg/kg qd

(C) 2.0 mg/kg qd

(D) 1.0 mg/kg qd

(E) 0.5 mg/kg qd

View Answer***6. The answer is B[].***

D per τ_{ri}	=	(D_L)(fraction lost per τ_{ri})
	=	(1.9 /kg)(0.78) = 1.5 /kg

ANSWERS AND EXPLANATIONS

1. The answer is A *[1.B].*

2. The answer is B *[*II.B*].*

3. The answer is C *[*II.D.3*].*

If the patient's estimated $t_{1/2}$ is 48 hours, 90% of steady state is expected to be achieved between 3-4 $t_{1/2}$ intervals or 6-8 days in this case. For clinical purposes, we choose 90% attainment of steady state as the minimum time to estimate drug accumulation. A level drawn at 7 days seems reasonable. Once a τ_{ss} has been selected, the time for scheduling a level should correspond with the reference time for the therapeutic range. In this case, $C_{avg,ss}$ was cited as the reference time, so a measurement scheduled for sometime near the midpoint of τ_{ss} (around 12 hours) is reasonable.

4. The answer is A *[*IV.A, C*].*

This presents challenges in TDM, because for linear drugs the clinician can expect a change in C_{ss} proportional to a change in dose, but for nonlinear drugs this is not true.

5. The answer is D *[*VII.B.1*].*

The positive predictive value of a diagnostic test is an index of how effective the test is in classifying patients correctly. For example, using a C_{ss} measure for a given drug, knowing that the positive predictive value is 0.8, given a group of patients with a C_{ss} above the test cutoff value, 80% of the patients will be accurately classified as having a positive outcome. If the test is being used to classify toxic versus nontoxic patients, 80% of the patients with C_{ss} above the test cutoff will experience drug-induced toxicity. If, instead, the test is being used to classify effective versus subeffective response in patients, 80% of the patients with C_{ss} above the test cutoff will experience effective response.

6. The answer is B *[*IV.D.3*].*

Using the equation for estimating Cl_{cr} in this patient from IV B 1:

$$Cl_{cr} = \frac{(140 - 70\ \text{yr})(80\ \text{kg})}{(3\ \text{mg/dL})(72)} = 26\ \text{mL/min}$$

then, using the equation for estimating $t_{1/2}$ in this patient from IV.B.2:

$$\frac{(2.5\ \text{hr})}{(t_{1/2})_n} = 1 - 0.98 + 0.98\,(26/120) = 0.23$$

$$(t_{1/2})_n = 10.9\ \text{hr}$$

Then, using equation [IV.D.3.b], first determine a loading dose: (D_L) to achieve the desired $C_{max,ss}$ of 7.5 mcg/mL:

$D_L = (C_{max,ss})(V)/(S)(f)$

$D_L = (7.5\ \text{mcg/mL})(0.25\ \text{L/kg})/(1)(1) = 1.9\ \text{mg/kg}$

Then, determine fraction of drug lost during τ, assuming a τ_{ri} of 24 hr, and using the $(t_{1/2})_{ri}$ of 10.9 hr estimated above using the equation in IV.D.3.c:

fraction lost = $1 - 10^{-0.3(24/10.9)} = 0.78$

Lastly, calculate D per τ_{ri}:

D per τ_{ri}	=	(D_L)(fraction lost per τ_{ri})
	=	(1.9 mg/kg)(0.78) = 1.5 mg/kg

Thus, a D_L of 1.9 mg/kg followed by 1.5 mg/kg q24h is expected to attain the desired $C_{max,ss}$ and $C_{min,ss}$ levels in this patient. Of course, many estimates were made along the way (Cl_{cr}, $t_{1/2}$, V), so if the patient's $C_{max,ss}$ and $C_{min,ss}$ vary from what has been expected from the calculations, it is likely due to the estimates being at variance with the actual value(s) in the patient.

Drug Use in Special Patient Populations: Pediatric, Pregnant, and Geriatric

Marcia L. Buck

Julie J. Kelsey

I. PEDIATRIC PHARMACOTHERAPY

A. General considerations

1. Most pharmacists in community and hospital settings provide care for children. In the United States, children make up nearly one third of the total population. Although children typically require fewer medications than adults because of their relative good health, approximately 30% of all prescriptions filled in community pharmacies are for pediatric patients. As a result, **pharmacists need to have a basic knowledge of pediatric pharmacotherapy to appropriately assess and monitor drug therapy.**

2. Providing care for children is often a challenge. There is **limited information on the selection, dosing, and monitoring of drugs** in this population. It is estimated that only 25% of the drugs available on the market in the United States carry a Food and Drug Administration (FDA) approved indication for use in pediatric patients, although nearly 75% have been used to treat children. As a result, most pediatric dosing is considered off-label. Dosing information typically comes directly from case reports and small clinical trials published in the medical literature. In addition to being able to obtain pediatric-specific drug information, pharmacists must also be familiar with differences in pediatric pharmacokinetics and pharmacodynamics as well as the unique aspects of medication monitoring and compliance in this population.

B. Pharmacokinetic considerations

1. Unlike the relatively stable pharmacokinetic profile of most drugs in adults, children's **pharmacokinetic parameters change during maturation from neonates into adolescents** (Table 37-1). As a result, the pediatric population is a diverse and dynamic group. Each aspect of drug disposition is affected, including absorption, distribution, metabolism, and elimination. None of these processes is fully mature at birth, and they develop at different rates over the first years of life. The study of these changes is known as developmental pharmacology.

2. Drug absorption. For many routes of administration, the absorption of a drug is most greatly altered during infancy. Differences in drug absorption during this period may affect the choice of delivery method, dose, or monitoring.

a. Gastrointestinal absorption. Oral drug absorption is most greatly altered during the first year of life. Several aspects of absorption are age dependent, including gastric pH, gastric emptying time, intestinal motility, bile salt production, and pancreatic enzyme function.

(1) Elevated gastric pH. At birth, gastric pH is elevated (pH > 4). This results from a relative decrease in gastric acid production and an overall decrease in the volume of gastric secretions. As a result, acid-labile drugs such as penicillin G may have a greater bioavailability in neonates than in older infants. Conversely, drugs that are

weak acids such as phenobarbital (Luminal) may not be as well absorbed. To compensate for this effect, neonates may require larger oral doses of these drugs than older infants to produce the desired therapeutic effect. Acid production rises steadily after birth, reaching adult levels within 2 months.

Table 37-1. Age Definitions

Age Group		Age
Newborn		
	Preterm or premature	< 36 weeks' gestation[a]
	Term	> 36 weeks' gestation[a]
Neonate		< 1 month
Infant		1 month-1 year
Child		1-11 years
Adolescent		12-16 years

[a] Gestational age as measured from the time of the mother's last menstrual period.

(2) Prolonged gastric emptying and intestinal motility. The rate of passage of drugs through the gastrointestinal tract is also important in determining the rate and extent of their absorption. Coordination of contractions within the stomach begins to improve shortly after birth, while intestinal peristalsis increases more slowly, over the first 4 months of life. As a result of this prolonged transit time, absorption of drugs may be significantly slowed.

(a) Preterm neonates typically have more delayed gastric emptying time than term neonates, so that changes in oral absorption may be most pronounced in these patients.

(b) Breast-fed infants empty their stomachs approximately twice as fast as formulafed infants. The increased caloric density of formula feedings delays gastric emptying.

(3) Bile salt and pancreatic enzyme production. The rate of bile salt synthesis in preterm and term infants is reduced to approximately 50% of adult values.

Decreased fat absorption from enteral feedings, as well as decreased drug absorption, can occur. For example, when lipid-soluble vitamin D is administered to neonates, bioavailability is only 30% as compared with 70% in adults. The absorption of lipid-soluble drugs is further reduced as a result of lower levels of pancreatic enzymes.

(4) Other factors affecting oral drug absorption include reduced splanchnic blood flow in the 1st month of life and reduced activity of intestinal metabolic enzymes (altering the first-pass effect). In addition, neonates lack normal gut microflora. Although bacterial colonization normally occurs shortly after birth, it may be significantly delayed in preterm neonates who are being cared for in the sterile environment of an intensive care unit.

b. Percutaneous absorption

(1) Absorption of drugs through the skin is enhanced in infants and young children owing to better hydration of the epidermis, greater perfusion of the subcutaneous layer, and the larger ratio of total body surface area to body mass compared to adults.

(2) In preterm neonates, the stratum corneum is also thinner, further increasing the potential for the absorption of topical products.

(3) This route of administration should be used with caution in infants and young children to avoid overdosage. There are numerous accounts of toxicity resulting from percutaneous absorption. For example, repeated applications of topical hydrocortisone cream for diaper rash or eczema can produce adrenal axis suppression after as little as 2 weeks of use in an infant.

c. Intramuscular absorption

(1) The absorption of drugs administered by this route may be reduced in neonates as a result of reduced blood flow to skeletal muscles. In addition, weak or erratic muscle contractions in neonates may result in reduced drug distribution. These factors may be partially offset by the higher density of capillaries in skeletal muscle during infancy, which increases blood circulation.

(2) Intramuscular administration of drugs is generally discouraged in the pediatric population because of the pain associated with the injection and the risk of nerve damage from inadvertent injection into nerve tissue.

(3) This route is generally reserved for the administration of vitamin K, vaccines, and occasionally antibiotics when intravenous access is not available. If it is used, the volume should not exceed 0.5 mL for infants and younger children and 1 mL for older children.

d. Rectal administration. Absorption by this route is fairly reliable, even for preterm neonates. Administration may be complicated in infants, however, by the increased number of pulsatile contractions in the rectum compared to adults, making expulsion of a suppository more likely.

e. Pulmonary administration. Inhalation of medications is increasingly being used in infants and older children to avoid systemic exposure. While developmental

changes in the pulmonary vasculature and respiratory mechanics likely alter the pharmacokinetics of drugs given by inhalation, little is known about the effects of growth and maturation on this route of drug administration.

3. Drug distribution. Growth and maturation affect many of the factors that determine drug distribution. Body water content, fat stores, plasma protein concentrations, organ size and perfusion, hemodynamic stability, tissue perfusion, acid-base balance, and cell membrane permeability all undergo significant changes from infancy to adolescence.

a. Body water and fat content. Total body water content decreases with increasing age. This is primarily the result of a larger extracellular body water content in neonates and young infants which decreases with age. Approximately 80% of a newborn's weight is body water. By 1 year of age, this value declines to 60%, similar to that of an adult. Highly water-soluble compounds, such as gentamicin (Garamycin), have a larger volume of distribution in neonates than in older children. As a result, larger milligram per kilogram doses are often needed to achieve desired therapeutic concentrations. Conversely, body fat increases with age, from 1%-2% in a preterm neonate to 10%-15% in a term neonate and 20%-25% in a 1-year-old. Lipophilic drugs, such as diazepam (Valium), have a smaller volume of distribution in infants than in older children and adults.

b. Protein binding. Acidic drugs bind to **albumin,** while basic substances bind primarily to **α_1-acid glycoprotein** (AGP). The quantity of total plasma proteins, including both of these substances, is reduced in neonates and young infants. In addition, the serum albumin of newborns may have a reduced binding affinity. These two factors result in an increase in the free fraction of many drugs (Table 37-2). The increase in the free fraction may result in enhanced pharmacological activity for a given dose. **The relative decrease in serum proteins may also produce increased competition by drugs and endogenous substances, such as bilirubin, for binding sites.** Drugs that are highly bound to albumin, such as the sulfonamides, may displace bilirubin from its binding sites and allow deposition in the brain, referred to as kernicterus. As a result, these drugs are considered contraindicated in the first 2 months of life.

4. Metabolism. The most significant research in developmental pharmacology during the past decade has come in the area of drug metabolism. **Developmental changes have been identified for many phase I** (oxidation, reduction, hydroxylation, and hydrolysis) and **phase II** (conjugation) **reactions.** The maturation of metabolic function results in the need for age-related dosage alterations for many common therapies and may explain the increased risk for drug toxicity in infants and young children.

a. The activity of **phase I enzymes, such as the cytochrome P450 (CYP) enzymes, changes significantly during maturation.** The primary isoenzyme during the prenatal period, CYP3A7, peaks soon after birth and then declines rapidly. This enzyme exists in barely measurable quantities in adults. It may appear early in fetal life to detoxify retinoic acid,

a potential ratogen. Also at the time of birth, CYP2E1 and CYP2D6 levels begin to rise. Enzymes associated with the metabolism of many common drugs—CYP3A4, CYP2C9, and CYP2C19—appear within the first weeks of life, but their levels increase slowly. The last of the enzymes to develop, CYP1A2, is present by 1-3 months of life. The activity of these enzymes does not appear to increase in a direct linear manner with age, but varies over time. By 3-5 years of age, most patients have CYP isoenzyme activity levels similar to that of adults.

Table 37-2. Protein-Bound Drugs with a High Free Fraction in Neonates

Ampicillin (Principen)	Penicillin G (Pfizerpen)
Digoxin (Lanoxin)	Phenobarbital
Diazepam (Valium)	Phenytoin (Dilantin)
Lidocaine (Xylocaine)	Propranolol (Inderal)
Morphine (Duramorph)	Theophylline
Nafcillin (Nallpen)	

(1) The altered pharmacokinetic profiles of drugs in children may, in large part, be explained by these developmental changes in the CYP enzyme system. One of the most well studied enzymes is **CYP1A2.** This enzyme is nearly nonexistent in fetal liver cells, and activity is minimal in neonates. As a result, the rate of metabolism of caffeine in the neonate is slow, resulting in an elimination half-life of 40-70 hr. Enzyme activity increases by 4-6 months of age. Within the first year of life it exceeds adult values, producing a caffeine half-life of approximately 5 hr. Infants receiving caffeine (Calfcit) for apnea of prematurity or chronic lung disease must have periodic adjustments in their dose to account for these changes in metabolism and maintain therapeutic serum concentrations.

(2) Genetic polymorphism also plays a significant role in determining metabolic function in children. Recent studies with atomoxetine (Strattera) have shown that children with reduced CYP2D6 function (i.e., poor metabolizers) had greater improvement in their attention deficit hyperactivity disorder (ADHD) symptoms than children who were extensive metabolizers, using a standard weight-based dose. The poor metabolizers also had an increased incidence of adverse effects as a result of having higher atomoxetine serum concentrations.

(3) Alcohol dehydrogenase activity is only 3%-4% of adult values at birth and does not achieve adult values until approximately 5 years of age. Because of this,

newborns have a reduced ability to detoxify benzyl alcohol, a preservative found in many injectable products. Newborns exposed repeatedly to these products will accumulate benzyl alcohol, which may lead to a potentially fatal condition referred to as “gasping syndrome,” with metabolic acidosis, respiratory failure, seizures, and cardiovascular collapse. Because of this risk, it is recommended that neonates receive preservative-free products or those containing alternative preservatives.

b. Phase II reactions (conjugation with glycine, glucuronide, or sulfate to form more water-soluble compounds) have not been studied as extensively in the pediatric population.

(1) Glucuronidation is generally decreased in neonates, compared with older children and adults. The rate of metabolism increases with increasing age. This can be seen in the decreasing half-life of morphine (Duramorph) during the 1st year of life. The average half-life in a preterm neonate is 10-20 hr, compared to 4-13 hr in a neonate, 5-10 hr in infants between 1 and 3 months of age, and 1-8 hr in older infants and young children.

(2) Unlike glucuronidation, **sulfation develops in utero and is well developed in the neonate.** The variation in the function of these two phase II reactions can be seen with the developmental changes in acetaminophen (Tylenol) metabolism. In early infancy, acetaminophen is converted primarily through formation of sulfate conjugates; but with increasing age, glucuronidation becomes the predominate form of metabolism.

c. While most of the recent research into pediatric drug metabolism has focused on the development of enzyme function in neonates, several new studies highlight additional changes in metabolic function during adolescence. For example, lopinavir (marketed with ritonavir as Kaletra) pharmacokinetics undergoes significant age and gender-related changes at the time of puberty. Lopinavir clearance increases by more than 30% in boys after age 12, compared to girls, which may result in a need to adjust the recommended dose.

5. Elimination. Development of renal function is a complex and dynamic process. Nephrons begin forming as early as the 9th week of gestation and are complete by 36 weeks. Although the functional units of the kidneys are present, their capacity is significantly reduced at birth. Glomerular filtration rate in neonates is approximately half that of adults. Values are further reduced in preterm neonates. Glomerular filtration rate increases rapidly during the first 2 weeks of life and typically reaches adult values by 8-12 months of age. Tubular secretion

rate is also reduced at birth to approximately 20% of adult capacity, but matures by 12 months of age.

(a) Immature renal function results in significant alterations in the elimination of many drugs. Pharmacokinetic studies for several drugs, including the aminoglycosides and vancomycin (Vancocin), have shown a direct correlation between clearance and patient age. Prolongation of the half-life should be anticipated for all renally eliminated drugs administered to neonates and is most pronounced in preterm neonates.

(b) To account for the reduced ability of a neonate to eliminate these drugs, longer dosing intervals are often required. Failure to account for the reduction in renal function may result in drug accumulation and toxicity.

C. Pharmacodynamic considerations. Unlike the rapidly accelerating knowledge of the pharmacokinetic changes associated with development, little is known of the pharmacodynamic changes associated with maturation. Preliminary investigations of warfarin (Coumadin) pharmacodynamics have demonstrated a relationship between anticoagulant response and patient age. Other examples include the increased incidence of certain adverse drug reactions in younger children, such as hepatoxicity with valproic acid (Depakene). Future research in age-related pharmacodynamic changes is needed to optimize the safe and effective use of drugs in infants and children.

D. Pediatric drug administration and monitoring. Drug administration, including the selection of agent and dose as well as the preparation of the dose and therapeutic drug monitoring are complicated in the pediatric population. Pharmacists caring for children must incorporate not only the changes in pharmacokinetics and pharmacodynamics described previously but also the need to carefully check dosage calculations and, if necessary, alter available dosage formulations to suit an infant or child's needs.

1. Accurate dosage calculations are critical in the care of infants and children. Pharmacists should use pediatric dosing information available in general drug references or pediatric-specific references such as *The Pediatric Dosage Handbook* (Lexi-Comp), or the *Harriet Lane Handbook* (Mosby). To account for differences in pharmacokinetic parameters, most pediatric doses are based on body weight. In the case of some drugs, such as chemotherapy, doses are based on body surface area (BSA). This value can be determined from the patient's height and weight, using either a nomogram or the following equation:

$$\text{BSA } (m^2) = \sqrt{\frac{\text{height (cm)} \times \text{weight (kg)}}{3600}}$$

There is no absolute rule for when adolescent patients should start to be dosed as adults. In general, adult dosing guidelines may be used in patients weighing more than 40-50 kg or when the calculated weight-based pediatric dose exceeds the standard adult dose.

2. The need to calculate pediatric doses introduces a greater risk for dosage errors. Dosing errors have been found to be more common in medication orders for children than in any other patient population. The need to calculate individual doses, along with potential decimal errors and transcription errors, increases the potential for mistakes. In addition, there is often a wide range of patient ages and weights within a single hospital or clinic. It is not uncommon to have patient doses vary by 10-fold, as an infant weighing 5 kg and an adolescent weighing 50 kg may be cared for by the same healthcare providers. All calculations should be double-checked, and orders outside of the normal pediatric dosage range verified with the prescriber.

3. Dosage formulations may need to be altered to make them useful for infants and children. Because young children cannot typically swallow tablets and

capsules, these solid dosage formulations must often be converted to oral solutions or suspensions. Several compounding resources, including *Extemporaneous Formulations* (American Society of Health-System Pharmacists), are available to provide pharmacists with formulations that have been tested to ensure drug stability.

4. Intravenous (IV**) medications may be prepared as more concentrated solutions, because of the limits on fluid administration to infants and young children.** While a typical adult may receive up to 4-5 L of IV fluids per day, the total daily fluid requirements for a preterm neonate may be as little as 20-50 mL. Special equipment, such as syringe pumps and

microbore tubing, is used to ensure accurate delivery of drugs in small fluid volumes. Currently available syringe pumps can deliver volumes as small as 0.1 mL over 1 hr. Microbore IV tubing is used to minimize the amount of dead space between the delivery device and the patient, further improving the accuracy of drug delivery. Pharmacists must also be capable of assessing literature on the compatibility with drugs and IV fluids because pediatric patients often have limited IV access, so that multiple solutions may need to be infused through the same IV site.

E. Therapeutic drug monitoring is often essential to optimizing drug therapy in infants and children. For most drugs, the therapeutic ranges developed for and used in adults are also appropriate for monitoring pediatric patients. A potential complication in interpreting serum drug concentrations is the **presence of endogenous substances,** which may cross-react with analytical drug assays. This has been demonstrated for digoxin (Lanoxin) in neonates and infants, for whom endogenous digoxin-like reactive substances (EDLRS) may produce falsely elevated serum digoxin concentrations. Standard assay techniques can be modified to exclude EDLRS as a complicating factor.

F. Pharmacists should also be aware of differences in adverse drug reactions between children and adults. Most of the adverse reaction information available in drug product labeling or cited in pharmacy references has been obtained from clinical trials in adults. As several studies have demonstrated, the adverse reaction profile in children may be significantly different from that observed in older subjects. For example, severe dermatologic reactions to lamotrigine (Lamictal), including Stevens-Johnson syndrome, were infrequent during premarketing phase III clinical trials. When the drug was introduced onto the market in the United States and began to be used in children off-label, a higher rate of dermatologic reactions was reported in children. Subsequent research revealed the incidence of severe dermatologic reactions to be 0.8% in children compared to 0.3% in adults. Differences such as these further highlight the need for clinical research in children.

G. In addition, **pharmacists should take an active role in promoting medication adherence (compliance) in children.** Several studies have shown compliance rates in pediatric patients to be 30%-70%. It is surprising that some of the poorest compliance rates have been associated with chronic diseases such as asthma,

epilepsy, and diabetes and in children requiring immunosuppressive therapy after organ transplantation. As in adults, counseling about medication adherence should include efforts to identify and overcome barriers to therapy, education about the importance of medical management, and programs to incorporate medication regimens into normal daily tasks. When working with families of younger children, pharmacists should also explore problems with dosage formulation (taste or texture aversion), and dosing frequency, particularly with medications requiring administration at school or day care. In older children, pharmacists should be aware of their need for autonomy, and work with the patient's family to foster the goal of self-care. Pharmacists can serve a vital role in improving medication adherence in patients of all ages.

II. DRUG USE IN PREGNANT PATIENTS.

Most women would like to avoid pharmacologic therapy during pregnancy if at all possible. However, > 80% of women are exposed to substances, such as medication during their pregnancies. Preexisting conditions and other problems occurring during the pregnancy may require continuation or initiation of drug therapy. In rare circumstances, fetal therapy can be administered through the mother. It is important to understand maternal pharmacokinetic changes, placental drug transfer, eventual disposition of the drug, and limitations of the FDA classification system to safely treat pregnant women.

A. Fetal development. The effects of drug therapy in pregnancy depend largely on the stage of fetal development during which the exposure occurs. Pregnancies are normally dated from the first day of the last menstrual cycle; however, when discussing fetal development, fertilization occurs on day 1.

1. Weeks 1-2. During the first days after fertilization, the zygote forms in the fallopian tube. Over the next few days, division of the zygote eventually results in the formation of the blastocyst, which travels through the tube into the uterus. The blastocyst contains numerous types of relatively undifferentiated tissues that will ultimately become the fetus, the placenta,

and the fetal membranes. Superficial implantation in the endometrium occurs within the first 5 days. During the 2nd week, differentiation begins and the placenta has started to form. During these weeks, there is an “all or none” phenomenon. With no placenta to transfer substances to the blastocyst, there is no susceptibility to teratogens. Exposure to environmental agents during this time will have either little or no effect on the embryo or will destroy most cells leading to pregnancy termination.

2. Weeks 3-8. It is during this time that the placenta becomes fully functional and organogenesis occurs. This is the most critical period of development, when the embryo is most susceptible to teratogens. All major organ systems develop structurally during these weeks. All are completely formed by the end of the 9th week, with the exception of the central nervous system. Major congenital anomalies, such as cardiac abnormalities, spina bifida, and limb defects occur during this time.

3. Weeks 9-38 (the fetal period). At the 9th week, the embryo is referred to as a fetus. Development during this time is primarily functional, with overall growth occurring throughout. The fetus may be at risk during exposure to potentially fetotoxic drugs or viruses. Exposure to a drug is generally not associated with major congenital malformations; however, minor congenital anomalies and functional defects may occur during this time.

B. Placental transfer of drugs. The placenta is the functional unit between the fetal and the maternal blood supply. There is no mixing of the two systems, but exchange of nutrients, oxygen, and waste products occurs primarily via passive diffusion. This process is driven by the concentration gradient between the two systems. There are a few substances that are actively transported across the placenta (e.g., amino acids); drugs that are structurally similar to these compounds will also be transported by this mechanism.

1. Placental metabolism. The placenta produces a number of pregnancy-related hormones that are mainly secreted into the maternal circulation. Some of the other substances produced by the placenta are enzymes that metabolize drugs. A common example of this is prednisone metabolism, so that very little steroid reaches the fetus.

2. Factors affecting placental drug transfer. For a drug to cause a teratogenic or pharmacological effect in the embryo or fetus, it must cross from the maternal circulation to the fetal circulation or tissues. Generally, the principles that apply to drug transfer across any lipid membrane can be applied to placental transfer of a drug. Most substances administered for therapeutic purposes have, by design, the ability to cross the placenta to the fetus. The critical factor is whether the rate and extent of transfer are sufficient to cause significant drug concentrations in the fetus. There are many factors that affect the rate and extent of placental drug transfer.

(a) Molecular weight. Low molecular weight drugs (< 500 Da) diffuse freely across the placenta. Drugs of a higher molecular weight (500-1000 Da) cross less easily. Drugs composed of very large molecules (e.g., heparin) do not cross the placental membranes.

(b) Drug pKa. Weakly acidic and weakly basic drugs tend to rapidly diffuse across the placental membranes. Ionized compounds do not cross the placenta.

(c) Lipid solubility. Moderately lipid-soluble drugs easily diffuse across the placental membranes. It is important to note that many drugs that have been formulated for oral administration and are designed for optimal lipid membrane transfer.

(d) Drug absorption. During pregnancy, gastric tone and motility are decreased, which results in delayed gastrointestinal emptying time. This typically does not affect drug absorption. However, nausea and vomiting, which are most common in the first trimester but may continue throughout pregnancy, may affect absorption.

(e) Drug distribution. The volume of distribution increases significantly during pregnancy and increases with advancing gestational age. The alteration in volume of distribution is the result of an increased plasma volume. Total body fluid (intravascular and extravascular volume) increases, as does adipose tissue. The placenta itself may also be a site for distribution. Hydrophilic drugs will have a

higher volume of distribution leading to lower peak levels. Plasma concentrations of drugs that are widely distributed are usually lower than those with a small volume of distribution. Therefore, less drug is available to cross the placenta.

(f) Plasma protein binding. Placental transfer of a highly plasma-protein-bound drug is less likely because only the free drug crosses the placenta. During pregnancy,

a reduction in the levels of two major drug-binding proteins—albumin and AGP—is observed. A dilutional effect occurs with albumin and other protein concentrations, which can increase the free fraction of drugs.

(g) Physical characteristics of the placenta. As a pregnancy progresses, the placental membranes become progressively thinner, resulting in a decrease in diffusion distance. The placenta also expands, causing a greater surface area for the transfer of substances.

(h) Maternal pharmacokinetic changes. The dramatic increase in blood volume that occurs primarily during the first 30 weeks of pregnancy enhances blood flow through the kidneys and liver. Drugs that are excreted renally will experience a more rapid clearance, which could decrease the overall exposure time of the drug to the placenta. Metabolism of some drugs is increased; however, the elevated levels of estrogen and progesterone present during the pregnancy can competitively inhibit the metabolism of other drugs.

3. Teratogenic drugs

a. Teratogens are defined as agents that increase the risk of or cause a congenital anomaly to occur. These defects can be structural, functional, or behavioral in nature. Women may blame a specific exposure during their pregnancy as the cause of a fetal anomaly; however, the defect may have no known cause, as is the case in 3% of all births in the United States.

b. It may take years of exposures to actually link a specific drug to certain defects. Animal studies can only suggest potential problems in humans but are often the only source of information regarding safety of agents during early pregnancy. The dose that animals often receive exceeds the normal human dose, which diminishes the applicability of these data to humans.

c. The fetus is unable to metabolize or eliminate drugs as quickly as the mother. Some substances may be excreted into the amniotic fluid and then resorbed in the fetal intestines after the fluid is swallowed. Therefore, some drugs may have a longer exposure time in the fetus, whereas others are eliminated more rapidly.

c. Because fetal organ systems develop at different times, specific teratogenic effects depend mainly on the point of gestation when the drug was ingested.

d. The teratogenic rate of substances indicates how frequently anomalies occur and over what exposure period. For example, one of the most potent known teratogens, thalidomide, had a teratogenic rate of 20% with a single exposure, yet only one third of women who ingested the drug gave birth to affected infants. Other agents may increase the rate of specific defects over the general population, but the absolute incidence may be extremely low.

e. The FDA developed a classification system that groups drugs according to the degree of their potential risk during pregnancy.[1]

(1) Category A. Adequate, well-controlled studies in pregnant women have not shown an increased risk of fetal abnormalities.

(2) Category B. Animal studies have revealed no evidence of harm to the fetus; however, there are no adequate and well-controlled studies in pregnant women. Or animal studies have shown an adverse effect, but adequate and well-controlled studies in pregnant women have failed to demonstrate a risk to the fetus.

(3) Category C. Animal studies have shown an adverse effect and there are no adequate and well-controlled studies in pregnant women. Or no animal studies have been conducted, and there are no adequate and well-controlled studies in pregnant women.

(4) Category D. Studies, adequate well-controlled or observational, in pregnant women have demonstrated a risk to the fetus. However, the benefits of therapy may outweigh the potential risk.

(5) Category X. Studies, adequate well-controlled or observational, in animals or pregnant women have demonstrated positive evidence of fetal abnormalities. The use of the product is contraindicated in women who are or may become pregnant.

d. Problems with the current system. The current system was created in 1979 and has not been revised since its inception. With many agents there is a paucity of human data, despite the fact the drug may carry a category B rating. Most newly marketed agents will

be placed in category C, amid other agents with little data in humans or animals. This is the most difficult category to assess. Although there may be case reports of drug exposures, these tend to bias information toward fetal risk; most publish only outcomes with potential drug-related effects. Few drugs will ever be assigned a category A status because large, randomized, well-controlled trials are rarely conducted in pregnant women.

f. Examples of teratogenic agents.

(1) Vitamin A derivatives. Drugs such as isotretinoin (Accutane) and etretinate (Tegison) are potent teratogens in humans. These agents should be discontinued several months before pregnancy.

(2) Warfarin (Coumadin) is most teratogenic in the first trimester (weeks 6-9), but can also cause malformations during the second and third trimesters as well. Early exposure is associated with a pattern of defects known as fetal warfarin syndrome. These defects can include hypoplasia of the nose and extremities, congenital heart disease, and seizures. Central nervous system abnormalities are increased with later use. Heparins may be an appropriate substitute when anticoagulation is necessary; however, they are not as effective for preventing thrombosis in women with artificial heart valves.

(3) Androgenic agents can cause virilization of female fetuses, creating ambiguous genitalia. Finasteride (Propecia) can cause genital abnormalities in male offspring. Estrogen and progestins, fortunately, do not have this effect. Many women continue

to take birth control pills during the first month or two after conception until the pregnancy is discovered.

(4) Ethanol. Alcohol consumed in large amounts for prolonged periods during pregnancy (> 4-5 drinks/day) is known to cause fetal alcohol syndrome (FAS). Features of FAS include growth restriction, craniofacial dysmorphology and central nervous system malfunctions, along with various other abnormalities. At least 30% of women who abuse alcohol will deliver an infant affected by FAS. Moderate alcohol consumption (2 drinks/day) can also lead to similar defects, although usually not the complete syndrome. Even though the most problematic time is during the first 2 months of pregnancy, moderate drinking during the second trimester is associated with an increased rate of spontaneous abortions.

(5) Antineoplastics. Many agents in this class are associated with fetal anomalies after first trimester chemotherapy administration. Growth restriction often occurs regardless of the timing of exposure. Owing to the mechanism of action of these agents, many are embryocidal.

(6) Anticonvulsants. Drugs such as phenytoin (Dilantin), valproic acid (Depakene), and carbamazepine (Tegretol) have all been associated with fetal anomalies. However, maternal benefit from these agents often outweighs the risk to the fetus. Anticonvulsants should not be stopped during pregnancy, but if appropriate, they should be discontinued several months before fertilization. Valproic acid and carbamazepine can increase the risk of neural tube defects; women taking these agents should receive folic acid supplementation starting before conception. Toxic epoxide radicals are thought to be the mechanism of teratogenicity with several of these agents. Genetic alterations in the epoxide hydrolase enzyme activity can reduce or increase the severity of abnormalities.

(7) Infections. Viral infections, such as rubella, cytomegalovirus, parvovirus, coxsackie, and varicella can be associated with growth restriction, congenital anomalies, premature delivery, and potential embryotoxicity or fetal demise. Nearly all maternal infections have been thought to cause growth restriction.

(8) Cigarette smoking. Cigarettes contain many toxic and carcinogenic compounds in addition to nicotine. Nicotine is a potent vasoconstricting agent capable of reducing uterine blood flow and increasing uterine vascular resistance. Smoking not only increases the risk of a growth restricted fetus but also increases the risk of spontaneous abortions, premature delivery, placental abruption, and premature rupture of the membranes. Small increases in defects of the heart, limbs and feet, skull, urinary system, abdomen, intestines, and muscles have also been associated with cigarettes. Smoking may also alter the effects of other substances, perhaps enhancing toxicity of both agents.

4. Other problematic therapies. Some agents given during pregnancy may result in pharmacological effects that are not necessarily toxic, yet need to be considered when medications are given during the later weeks of pregnancy.

a. Central nervous system (CNS) depression may occur with barbiturates, tranquilizers, antidepressants, and narcotics. Also, anesthetics and other agents commonly given during labor may cause significant CNS and respiratory depression in newborns (e.g., magnesium sulfate or opioid analgesics).

b. Neonatal bleeding. Maternal ingestion of agents such as nonsteroidal anti-inflammatory drugs (NSAIDs) and anticoagulants at therapeutic doses near term may cause bleeding problems in the newborn.

c. Drug withdrawal. Habitual maternal use of barbiturates, narcotics, benzodiazepines, alcohol, and other substances of abuse may lead to withdrawal symptoms in newborns.

d. Constriction of the ductus arteriosus. Maternal use of NSAIDs in the third trimester may cause the ductus arteriosus to close prematurely and could result in pulmonary hypertension in the newborn.

III. DRUG EXCRETION IN BREAST MILK.

Today, > 60% of women choose to breast-feed their infants. Of these women, 90%-95% receive a medication during the first postpartum week, most commonly for pain control after delivery. It is important to understand the principles of drug excretion in breast milk and specific information on the various medications to minimize risks from drug effects in the nursing infant.

A. Transfer of drugs from plasma to breast milk. Drug transfer into breast milk is governed by many of the same principles that influence human placental drug transfer.

1. Most drugs cross into breast milk via passive diffusion along a concentration gradient formed by the un-ionized drug content on each side of the membrane.

2. Breast milk contents change throughout a feeding. Colostrum, the very first milk produced, is much higher in protein than mature milk and the fat content is minimal. Mature milk consists of fore-milk at the beginning of a feeding and hind-milk at the end. The protein and fat content increase throughout the nursing session. Therefore drugs that partition into more lipid solutions will have the highest concentration in hind milk.

3. A milk to plasma ratio can be determined for specific agents when both blood and milk concentrations are known. Most drugs have a ratio < 1; lower numbers indicate that less drug crosses into breast milk. Because the milk to plasma ratio may change within a feeding, the average breast milk concentration is usually used, if available.

4. It is possible to calculate the dose an infant receives if the breast milk concentration is known. A typical infant drinks 150 mL/kg per day. Multiplying the average concentration by the breast milk volume consumed will give the total daily exposure. It is important to remember that this drug must now be ingested by the infant, so the bioavailability of the drug is critical to calculate the actual daily dose. Doses < 10% of the maternal dose on a milligram per kilogram per day basis are preferable.

5. Some medications are not absorbed orally, but may pass into breast milk when administered intravenously to the mother. Although the drug may not enter the

infant's blood, it may have effects on the gastrointestinal tract. For example, the bioavailability of gentamicin is negligible; however, it may cause diarrhea or sterilize the bowel.

B. Drug factors. The drug and its environment influence the rate and extent of drug passage into the breast milk.

1. Molecular weight. Drugs weighing < 200 Da cross into milk easily. Larger molecules can dissolve in the lipid membrane or pass through small pores. Large molecules, such as insulin, do not cross into breast milk.

2. pH gradient. Human milk is more acidic than plasma.

a. Weak acids may diffuse across the membrane and remain un-ionized, allowing for passage back into the plasma. Lower amounts of these drugs will cross than those that are weak bases.

b. Weak bases may diffuse into the breast milk and ionize, which causes drug trapping. This creates higher levels of drug in the breast milk; these drugs will have a milk to plasma ratio > 1. This effect though, is not usually clinically significant, especially when the maternal serum concentration is very low.

3. Drug pKa. Only the un-ionized form of a drug is able to pass through the lipid membrane.

4. Plasma protein binding. The free fraction of a drug is available to pass into the breast milk. In general, drugs with high plasma-protein-binding properties tend to remain in the plasma and pass into the milk in low concentrations. Milk proteins and lipids also may bind drugs when they are created in the mammary glands; this may represent another route of entry, rather than passive diffusion.

5. Lipid solubility. Lipid solubility is necessary for a drug to pass into the breast milk. Highly lipid-soluble drugs (e.g., diazepam, Valium) may pass into the breast milk in relatively high amounts and, therefore, may present a significant dose of drug to the nursing infant.

6. Equilibration. Some drugs may rapidly equilibrate between maternal plasma and breast milk. These agents will diffuse across the membrane as the drug concentration changes in the maternal system. Other agents may never reach an equilibrium between milk and plasma. These drugs tend to slowly diffuse into breast milk and will respond gradually to changes in maternal concentrations.

C. Maternal factors. Maternal pharmacology plays a significant role in the rate and extent of drug passage into breast milk. The extent of plasma protein binding and changes in the mother's ability to metabolize or eliminate the drug influence the amount of drug that is available to pass into the breast milk. Equally important are the maternal dose of the drug, the dosing schedule or frequency, and the route of administration.

D. Drugs affecting hormonal influence of breast milk production. The primary hormone responsible for controlling breast milk production is prolactin. A decrease in milk production may result in diminished weight gain in the nursing infant, the need for supplementation, or premature cessation of breast-feeding.

1. Drugs that decrease serum prolactin levels. Drugs such as bromocriptine have been used to suppress lactation in women who choose not to breast-feed. This practice has long been abandoned because myocardial infarctions, seizures, and stroke were attributed to its use. Other drugs include

a. Ergot alkaloids

b. L-dopa

2. Drugs that increase serum prolactin levels. Metoclopramide (Reglan) has been useful therapeutically to enhance milk production. The following drugs are known to increase serum prolactin levels, but they are not used for this purpose. These drugs include

a. Methyldopa (Aldomet)

b. Haloperidol (Haldol)

c. Phenothiazines

E. Factors to assess. In assessing the safety of an agent during breast-feeding, several considerations should be addressed:

1. Inherent toxicity of the drug

2. Drug safety data in infants

3. Amount of drug ingested

4. Duration of therapy

5. Age of the infant or degree of prematurity

6. Drug pharmacokinetics in the mother and child

F. Factors to minimize drug exposure to the infant. One of the goals when using medications in the breast-feeding mother is to maintain a natural, uninterrupted pattern of nursing. In many instances, it may be possible to withhold a drug when it is not essential or delay therapy until after weaning. Other factors include

1. Medication selection. When a specific product is being selected, it is important to choose the agent that is distributed into the milk the least, if possible.

a. Other desirable characteristics include a short half-life, inactive metabolites, and high protein binding.

b. In addition, it is desirable to select agents with lower plasma concentrations, which may involve an alternative route of administration.

c. Single doses may be preferable to a longer therapy course if the agent is contraindicated in breast-feeding. This can allow for the mother to pump and discard her milk for a defined period of time, often 12-24 hr, rather than discontinue breast-feeding altogether.

2. Maternal dose relative to infant feeding. One of the goals of drug dosing in lactating women is minimal infant exposure to the drug. It is desirable to adjust the dosing and nursing schedules so that a drug dose is administered at the time of or immediately after the infant's feeding. Medications should be dosed before the infant's longest sleep.

G. Examples of drugs that readily enter breast milk. These agents should be used with caution in nursing mothers.

1. Narcotics, barbiturates, and benzodiazepines. CNS active agents, such as diazepam, may have a hypnotic effect on the nursing infant. These effects are related to the maternal dose. Alcohol consumption may have a similar effect.
2. Antidepressants and antipsychotics. These classes of drugs appear to pass into the breast milk; however, no serious adverse effects have been reported. The long-term behavioral effects of chronic exposure to these drugs on developing newborns are unknown.
3. Anticholinergic compounds. These drugs may result in adverse CNS effects in the infant and may reduce milk volume in the mother. Dicyclomine (Bentyl) is contraindicated in nursing mothers because it may result in neonatal apnea.

IV. DRUG USE IN GERIATRIC PATIENTS.

In 2000, more than 12% of the American population was > 65 years of age, representing more than 35 million Americans. It is estimated that three out of every four elderly people are taking prescription medications. Anticipated total drug usage, including nonprescription medications, reveals that 50% of all drugs used in the United States are used by the geriatric population.
A. Adverse drug reactions. Geriatric patients are at increased risk for drug-induced adverse effects. Incidence of adverse drug reactions (ADRs) in patients over the age of 65 is two to three times greater compared to younger patients. The risk is five times higher in people approaching age 90. One in five of all elderly patients experiences an ADR. In some patients, these are overlooked because they mimic the characteristics of other diseases.
1. Factors that are responsible for the higher prevalence of ADRs in the geriatric population include polypharmacy, poor relationship with healthcare providers, multiple disease states, increasing severity of illness, reduced drug elimination, and increased sensitivity to drug effects.
a. Studies have shown that > 35% of geriatric patients living in the community use six or more medications; approximately one half of patients residing in long-term-care facilities use five or more medications. People 65 and older use approximately 40% of the drugs prescribed and 50% of the over-the-counter (OTC) medications taken.
b. Patients taking multiple medications have a greater chance of experiencing ADRs owing to drug-drug interactions and the potential for overlap or synergy between adverse effect profiles.
c. Patients with multiple disease states are at higher risk of having a drug-disease state interaction.
d. In addition to the aforementioned risk factors for developing an ADR, it is difficult to predict how geriatric patients will respond to any given medication owing to altered pharmacokinetic and pharmacodynamic profiles.
e. Another issue complicating geriatric drug therapy is adherence. Factors that have been shown to increase nonadherence include poor relationships with healthcare providers, lower socioeconomic status, living alone, polypharmacy, complicated drug regimens, and multiple comorbidities. As many as 60% of geriatric patients do not take their medications as prescribed and may self-medicate as often as once a

week. If patients are hospitalized, their prescribed drug doses may represent a significant overdosage or underdosage, which could cause unintended effects.
f. Elderly patients can have diseases that make adhering to drug therapy difficult. Conditions that affect vision, such as macular degeneration or cataract formation, can make reading

prescription labels and medication instructions troublesome. Hearing loss can prevent patients from understanding and healthcare professionals from effectively communicating medication information and patient instructions. Arthritis can add to the difficulty of opening medication bottles. In these instances, providing patients with medication or “pill” boxes and written medication lists may limit potential barriers to patient adherence. Recognizing these factors, pharmacists can increase adherence in elderly patients.
2. Pharmacists can provide recommendations to eliminate unnecessary drug therapy and monitor medication profiles to avoid potential drug-drug or drug-disease state interactions that may prove harmful. Efforts to optimize drug therapy, including simplifying and employing more cost-effective regimens, may ultimately afford better patient adherence.
B. Pharmacokinetics. Pharmacokinetic parameters may be altered in the elderly owing to age-related physiological changes. Specific age-related physiological changes affecting drug therapy are given in Table 37-3.
1. Absorption. Physiological changes that can alter absorption in the geriatric population include delayed gastric emptying, decreased splanchnic blood flow, elevated gastric pH, and impaired intestinal motility. Although the rate of drug absorption may be altered in some patients, the extent of absorption is rarely affected.
2. Distribution. Several age-related physiological changes may affect drug distribution.
a. Elderly patients have a decrease in total body water, causing water-soluble drugs (e.g., acetaminophen, Tylenol) to have a smaller volume of distribution. Peak concentrations of these agents will be higher, and loading doses may need to be adjusted to incorporate this change.
b. The volume of distribution of lipid-soluble drugs (e.g., diazepam, Valium; propranolol, Inderal) is increased because geriatric patients tend to have a greater ratio of adipose tissue to lean muscle mass. These medications may accumulate in fat stores, increasing their duration of action.
c. Aging may also affect the pharmacokinetics of drugs that are highly protein bound. For example, drugs that are highly bound to albumin (e.g., warfarin, Coumadin; phenytoin, Dilantin) may have a greater free concentration because albumin can be decreased in the elderly who are chronically ill.
d. Medications may have altered binding affinity in the elderly or albumin may experience a change in configuration, which can also lower binding capacity. Competition for acidic

binding sites could occur with accumulated endogenous substances, altering the free fraction of drugs.

Table 37-3. Age-Related Physiological Changes Affecting Drug Therapy

Factors	Change	Clinical Significance
Pharmacokinetic		
Gastrointestinal motility	↓	May affect the rate but not the extent of drug absorption
Gastric pH	↑	No significant change in drug absorption
Renal function	↓	Reduced elimination of renally excreted drugs
Serum albumin	↓	Decreased protein binding leading to an increased free fraction of drug
Phase I hepatic metabolism	↓	Potential accumulation of drugs metabolized by oxidation, reduction, or hydrolysis reactions
Body fat to lean muscle mass ratio	↑	Increased volume of distribution of fat-soluble drugs
Total body water	↓	Decreased volume of distribution of water-soluble drugs
Pharmacodynamic		
β-receptor sensitivity	↓	Potential diminished response to β-blockers
Baroreceptor sensitivity	↓	Greater risk of orthostatic hypotension

Response to benzodiazepines and opioid analgesics	↑	Increased risk of adverse effects with typical doses

e. Although AGP concentrations tend to increase with age, the increase in the concentrations of basic drugs (e.g., lidocaine, Xylocaine; propranolol, Inderal) that bind to AGP are usually clinically meaningful only in acutely ill patients.

3. Renal excretion. Perhaps the best documented age-related physiological change is the decline in renal function, specifically glomerular filtration rate and the tubular secretion rate.

a. In patients without renal dysfunction, it is estimated that there is a 50% decline in renal function by age 80. Renal blood flow is reduced by approximately 10% each decade of life.

b. Serum creatinine may not be a good predictor of renal function, as creatinine production also declines with age and lower activity levels (such as the bedridden or debilitated).

c. Medications primarily eliminated by the kidneys may have increased concentrations of both the active drug and its metabolites, possibly leading to subsequent adverse effects. All renally eliminated drugs used in geriatric patients should be monitored for the need for dose reductions and potential toxicity.

4. Hepatic metabolism. Age-related changes affecting the liver include a reduction in hepatic blood flow and a decline in hepatic metabolism.

a. Phase II reactions (glucuronidation, acetylation, and sulfation) are relatively unchanged in the elderly.

b. A reduction in phase I reactions (oxidation, reduction, and hydrolysis) can occur. Benzodiazepines and certain analgesics, which depend on phase I reactions for metabolism, represent situations in which changes in hepatic metabolism may be important. The elimination half-lives of these agents are prolonged and may result in drug accumulation and possible adverse effects.

c. Liver volume and cell mass decrease in the elderly. It appears that this change in size enhances the reduced activity of oxidative and demethylation metabolism. Conjugation reactions do not appear to be affected by liver mass.

C. Pharmacodynamics

1. Geriatric patients can be more or less responsive to certain drugs, compared to younger patients. Reasons for this may include altered receptor sensitivity, receptor

number, or receptor response. Studies have shown that elderly patients may show a diminished response to β-blockers.

2. In contrast, geriatric patients seem to have an exaggerated response to agents affecting the CNS, narcotic analgesics, benzodiazepines, and warfarin. Elderly patients should be monitored carefully when taking these medications. Initiation of any of these therapies should be at lower doses than recommended for younger patients. Avoidance of these drugs may not be possible, but if better alternatives exist they should be used first.

D. Drug therapy considerations

1. Drug therapy in geriatric patients is involved and can be very complex because of age-related changes in pharmacokinetics and pharmacodynamics.

2. A lack of clinical trials designed to evaluate the safety and efficacy of drug therapy in the elderly population increases the problem.

3. The higher incidence of adverse effects in geriatric patients may be in part the result of the complexity of drug therapy and the relative lack of clinical trials in this population. Table 37-4 lists several drugs and doses that should be avoided in the elderly owing to higher risks of adverse effects and/or lack of efficacy.

4. Owing to alterations in gait, balance, and mobility, falls and consequent adverse events are frequent occurrences in geriatric patients.

a. The high prevalence of osteoporosis in the elderly results in an increased incidence of fractures. Complications associated with fractures, particularly hip fractures, are significant causes of morbidity and mortality.

b. Medications causing orthostatic hypotension, drowsiness, dizziness, blurred vision, or confusion have the potential to cause or worsen postural instability and increase falls in the elderly.

Table 37-4. Target Drugs and Doses to Avoid in Geriatric Patients

Drug	Comments
Analgesics	
Pentazocine (Talwin)	Avoid; safer and more effective alternatives
Propoxyphene (Darvon)	Avoid; lack of efficacy (no more effective then acetaminophen and potential for accumulation and adverse narcotic effects
Meperidine (Demerol)	Avoid; safer and more effective alternatives
Antidepressants	
Amitriptyline (Elavil)	Avoid; anticholinergic adverse effects, increased risk of falls, and QT prolongation; use nortriptyline or desipramine as alternatives
Amitriptyline, perphenazine (Triavil)	Avoid; use separate antidepressant and antipsychotic agents in appropriate geriatric doses as necessary
Doxepin (Sinequan)	Avoid; safer and more effective alternatives
Antiemetics	
Trimethobenzamide (Tigan)	Avoid; more effective alternatives available
Antihistamines	
Sedating OTC agents, cold preparations	Avoid; potent anticholinergic effects

Hydroxyzine (Atarax)	Avoid; potent anticholinergic effects
Cyproheptadine (Periactin)	Avoid; potent anticholinergic effects
Chlorpheniramine (Chlor-Trimeton)	Avoid; potent anticholinergic effects
Antihypertensives	
Hydrochlorothiazide (HydroDIURIL)	Doses > 25 mg/day should be avoided
Methyldopa (Aldomet)	Avoid; safer alternatives
Propranolol (Inderal)	Lipophilic nonselective β-blocker with increased potential for adverse effects; avoid; use a cardioselective β-blocker instead
Reserpine	Avoid; risk of adverse effects (e.g., sedation, depression)
Antipsychotics	
Haloperidol (Haldol)	Avoid unless indicated for psychotic disorder; use in small doses (1 mg); risk of sudden death in higher doses
Thioridazine	Avoid unless indicated for psychotic disorder
Antispasmodics	
Belladonna	Avoid long-term use; anticholinergic adverse effects
Dicyclomine (Bentyl)	Avoid long-term use; anticholinergic

	adverse effects
Hyoscyamine (Pyridium)	Avoid long-term use; anticholinergic adverse effects
Decongestants	
Oxymetazoline (Afrin)	Daily use for > 3 days should be avoided
Phenylephrine (Neo-Synephrine)	Daily use for > 3 days should be avoided
Pseudoephedrine (Sudafed)	Avoid; anticholinergic effects and potential to raise blood pressure
Dementia treatments	
Isoxsuprine	Avoid; lack of efficacy
H_2-antagonists	
Cimetidine (Tagamet)	Avoid; adverse CNS effects
Hypoglycemic agents	
Chlorpropamide (Diabinese)	Avoid; long half-life can cause prolonged hypoglycemic episodes and can induce SIADH
Muscle relaxants	
Carisoprodol (Soma)	Risk of adverse events greater than potential benefits; all use should be avoided
Cyclobenzaprine (Flexeril)	Risks of adverse events greater than

	potential benefits
Methocarbamol (Robaxin)	Risks of adverse events greater than potential benefits
Orphenadrine (Norflex)	Risks of adverse events greater than potential benefits
NSAIDs	
Indomethacin (Indocin)	Avoid; CNS adverse effects; use alternative NSAID
Phenylbutazone	Avoid; hematological adverse effects; use alternative NSAID
Non-cyclooxygenase selective NSAIDS	Avoid long-term use of naproxen, oxaprozin and piroxicam; increased risks of adverse effects
Platelet inhibitors	
Dipyridamole (Persantine)	Avoid; lack of efficacy and adverse effects (orthostatic hypotension) at high doses; aspirin is safer and more effective
Sedative hypnotics	
Long-acting benzodiazepines Chlordiazepoxide (Librium) Diazepam (Valium) Flurazepam (Dalmane)	Avoid; accumulation and increased risk of falls, sedation, and delirium
Short-acting benzodiazepines Alprazolam (Xanax) Oxazepam (Serax) Triazolam (Halcion)	Nightly use should be avoided; increased risk of falls, daytime sedation, and delirium

Meprobamate (Miltown)	All use should be avoided
Barbiturates	All use should be avoided; safer alternatives exist

CNS, central nervous system; *NSAIDs,* nonsteroidal anti-inflammatory drugs; *OCT,* over the counter; *SIADH,* syndrome of inappropriate antidiuretic hormone secretion.

Table 37-5. Drugs and Drug Classes Possessing Anticholinergic Effects

Antidiarrheal agents	Propantheline (Pro-Banthine)
Diphenoxylate/atropine (Lomotil)	Oxybutynin (XL formulation has fewer effects) (Ditropan)
Antiemetics/antivertigo agents	
Meclizine (Antivert)	Tolterodine (Detrol)
Scopolamine (Transderm scopolamine)	Class Ia antiarrhythmic agents
	Disopyramide (Norpace)
Trimethobenzamide (Tigan)	Quinidine
Promethazine (Phenergan)	Parkinson's agents
Prochlorperazine	Amantadine (Symmetrel)

	(Compazine)		
Antihistamines, sedating types			Benztropine (Cogentin)
Antipsychotic agents			Procyclidine (Kemadrin)
Antispasmodics			Trihexyphenidyl
	Belladonna alkaloids	Skeletal muscle relaxants	
	Clidinium bromide		Cyclobenzaprine (Flexeril)
	Dicyclomine (Bentyl)		Orphenadrine (Norflex)
	Hyoscyamine (Pyridium)	Tricyclic antidepressants	

c. It is well established that many psychoactive agents, especially long-acting benzodiazepines, are associated with an increased risk of falls in the elderly. If a benzodiazepine must be prescribed, low-dose lorazepam (Ativan) or oxazepam (Serax) are better choices because of the lack of active metabolites and their metabolism involves phase II hepatic reactions only.

5. Geriatric patients tend to be sensitive to medications that possess anticholinergic effects. Dry mouth, urinary retention, blurry vision, constipation, tachycardia, memory impairment and confusion are typical anticholinergic adverse effects associated with several classes of drugs (Table 37-5). These agents can also induce delirium in some people.

a. When possible, drugs with anticholinergic effects should be avoided in the elderly. In those instances when this is not an option, the least anticholinergic agent should be chosen and initiated at the lowest effective dose. For example, if a tricyclic antidepressant is needed, desipramine (Norpramin) and nortriptyline (Pamelor) possess less anticholinergic activity than amitriptyline (Elavil) and imipramine (Tofranil), and therefore would be better initial therapeutic options.

b. Frequent monitoring for and patient and family education on signs and symptoms of possible anticholinergic adverse effects is always warranted when these drugs are prescribed in the elderly.

E. General principles. To aid clinicians in providing appropriate geriatric drug therapy, some general principles have been developed.

a. Start with a low dose, and titrate the medication dose slowly.

b. Owing to reduced renal and hepatic function, the half-lives of many drugs are prolonged in the elderly. Selection of agents should involve consideration of the specific pharmacokinetics of each drug in the geriatric population.
c. Rapid dose escalations prevent attainment of the optimal therapeutic response because a steady-state concentration of the drug is not reached and increases the risks for developing an ADR.
d. The fewest number of drugs should always be used to treat patients.
e. Always evaluate possible drug toxicity. Geriatric patients can have atypical presentations of ADRs, which may manifest as CNS changes (e.g., altered mental status).
f. Review concomitant medications and diseases to evaluate the possible interactions with new drugs.
g. Reassess the need for each medication on a regular basis.
P.771

STUDY QUESTIONS

Directions for questions 1-14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.
For questions 1-4: AH is a 1.2-kg female born prematurely at 30 weeks of gestational age. Her mother had an infection with a fever at the time of delivery. AH was admitted to the neonatal intensive care unit for presumed sepsis and placed on empiric antibiotic therapy with ampicillin (50 mg/kg IV every 12 hr) and gentamicin (2.5 mg/kg IV every 8 hr).
1. Which of the following variables will *most* likely be used to calculate doses for AH's antibiotics?
(A) height
(B) hepatic function
(C) weight
(D) age
(E) serum creatinine

View Answer***1. The answer is C[see].*****2. After the administration of four doses of gentamicin, a serum concentration obtained 5 min before the next dose was 2.5** µg/mL**. Which of the following answers best describes the pharmacokinetic differences observed in premature neonates (compared to older children and adults) that might explain this value?**
(A) larger volume of distribution, longer half-life
(B) larger volume of distribution, shorter half-life
(C) smaller volume of distribution, longer half-life
(D) smaller volume of distribution, shorter half-life
(E) similar volume of distribution, shorter half-life

View Answer***2. The answer is A[see; I.B.3.d].*****3. Ampicillin may exhibit pharmacokinetic differences in AH because of its protein binding**

characteristics. Which of the following answers best describes the effect of AH's age on ampicillin protein binding?

(A) increased protein binding, resulting in a greater free fraction

(B) increased protein binding, resulting in a reduced free fraction

(C) decreased protein binding, resulting in a greater free fraction

(D) decreased protein binding, resulting in a reduced free fraction

(E) decreased protein binding, resulting in no significant change in free fraction

View Answer***3. The answer is C[see].*****4. As the pharmacist providing services for the neonatal intensive care unit, you evaluate medication orders and make recommendations to the medical team. Which of the following would be the *most* appropriate recommendation for AH's care?**

(A) Change to oral antibiotics for better absorption.

(B) Double-check the calculations to avoid decimal errors.

(C) Dilute the gentamicin with a larger volume of IV fluids to make it easier to measure.

(D) Use a pediatric-specific therapeutic range for monitoring gentamicin.

(E) Change to sulfamethoxazole and trimethoprim (Bactrim) for single-agent antibacterial coverage.

View Answer***4. The answer is B[seeand].*****5. You are counseling the grandmother of a 3-year-old boy who has a prescription for amoxicillin/clavulanate (Augmentin) to treat uncomplicated otitis media. Which of the following issues would be *least* likely to affect medication adherence (compliance)?**

(A) lack of education about the medication

(B) cost

(C) dosing interval (frequency)

(D) taste

(E) autonomy

View Answer***5. The answer is E[see].*****6. Which of the following medications is safe to use in the third trimester of pregnancy?**

(A) acetaminophen

(B) nonsteroidal anti-inflammatory drugs

(C) warfarin

(D) OxyContin

(E) aspirin

View Answer***6. The answer is A[seeand-b,-d].***P.772

7. Which of the following medications may have the potential to cause falls in a geriatric patient?

(A) amitriptyline (Elavil)

(B) trazodone (Desyrel)

(C) acetaminophen with codeine

(D) diazepam

(E) All of the above

View Answer***7. The answer is E[seeand].*****8. Placental transfer of a drug is affected by all of the following characteristics *except***

(A) molecular weight.

(B) fetal gender.

(C) gestational age.

(D) lipid solubility of the drug.

(E) plasma protein binding.

View Answer***8. The answer is B[see].*****9. When selecting a benzodiazepine product for a woman who has chronic panic disorder, all of the following drug properties are desirable for breast-feeding her 8-month-old infant who was born at term *except***

(A) hepatic metabolism to inactive metabolites.

(B) a short half-life.

(C) a rapid onset of action.

(D) high lipid solubility.

View Answer***9. The answer is D[see].*****10. Drug safety in pregnancy of a specific agent can be assessed best by**

(A) the FDA classification system, especially category C drugs.

(B) case reports.

(C) physician knowledge.

(D) databases, such as REPROTOX.

View Answer***10. The answer is D[seeand].Brigg's Drugs in Pregnancy and Lactation.*****11. Which of the following drugs is expected to cause anticholinergic adverse effects in the elderly?**

(A) propoxyphene (Darvon)

(B) ciprofloxacin (Cipro)

(C) amitriptyline (Elavil)

(D) propranolol (Inderal)

(E) cimetidine (Tagamet)

View Answer***11. The answer is C[see].*****12. Which of the following antihypertensive agents should be avoided in elderly patients?**

(A) amlodipine (Norvasc) 5 mg every day

(B) atenolol (Tenormin) 25 mg every day

(C) benazepril (Lotensin) 10 mg every day

(D) hydrochlorothiazide (HydroDIURIL) 25 mg every day

(E) methyldopa (Aldomet) 250 mg three times a day

View Answer***12. The answer is E[see].*****13. Which of the following benzodiazepines is expected to cause the *least* amount of adverse effects in the elderly?**

(A) chlordiazepoxide (Librium)

(B) diazepam (Valium)

(C) flurazepam (Dalmane)

(D) oxazepam (Serax)

(E) temazepam (Restoril)

View Answer***13. The answer is D[see].*****14. Which of the following factors is associated with an increased risk of noncompliance in the elderly?**

(A) polypharmacy

(B) hypertension

(C) living with a spouse in an isolated environment

(D) expensive medications

(E) good relationship with physician

View Answer***14. The answer is A[see].*****Directions for questions 15-16:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

15. According to the principles of drug excretion into the breast milk, which combination of the following properties would result in the *highest* drug concentration in breast milk?

I. low molecular weight, moderately lipophilic

II. low plasma protein bound, weakly basic

III. highly plasma protein bound, weakly acidic

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***15. The answer is C[seeand].*****16. Following principles of teratogenicity, drug exposure during the following times could cause fetal abnormalities?**

I. first 2 weeks of gestation

II. weeks 3-8 of gestation

III. the fetal period

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***16. The answer is D[seeand].***P.773

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* I.D.1*].*

Most pediatric doses are based on body weight. This single variable incorporates growth and maturation, while allowing a simple calculation for dose. Height is often difficult to measure accurately in children, and the calculation of body surface area is typically reserved for those drugs with narrow therapeutic indices, such as chemotherapy.

2. The answer is A *[see* I.B.3.a; I.B.3.d*].*

Aminoglycosides such as gentamicin exhibit a larger volume of distribution in neonates because of their larger body water content. Neonates also typically have a longer elimination half-life as the result of having reduced renal function during the first 6 months of life.

3. The answer is C *[see* I.B.3.b; Table 37-2*].*

Neonates have both a reduced quantity of plasma proteins, as well as a reduction in the affinity of albumin to bind to other substances. As a result, the free fraction of many drugs, including ampicillin, is increased.

4. The answer is B *[see* I.D.1 *and* 2*].*

All pediatric orders should be carefully checked for calculation errors. Errors are more common in the pediatric population as the result of weight-based dosing and the need for mathematical calculations. The use of the oral route would not be advisable in this patient, because of the potential reduced drug absorption. Likewise, the dilution of the dose with more IV fluid or the use of a sulfa drug would not be appropriate for this patient's age. Finally, the therapeutic range for gentamicin is the same in pediatric patients as in adults.

5. The answer is E *[see* I.G*].*

While the other options are all important aspects of counseling to enhance medication adherence in children, autonomy (the ability to provide self-care or give medications independently) would not be a consideration for a 3-year-old child. Autonomy becomes a much more critical issue in determining adherence in adolescence.

6. The answer is A *[see* II.B.3.e.(1) *and* (2); II.4a, b-*c and* d*].*

Acetaminophen is a safe and effective analgesic that can be used in therapeutic doses during pregnancy. NSAIDs may interfere with the onset or progress of labor when used in the third trimester. NSAIDs and warfarin, when used near delivery, may cause bleeding problems in the newborn infant. In addition, warfarin use in the third trimester may be associated with fetal CNS abnormalities. OxyContin use in the third trimester may induce neonatal withdrawal following delivery.

7. The answer is E *[see* IV.D.4.b *and* c*].*

Medications that can cause orthostatic hypotension, drowsiness, dizziness, blurred vision, or confusion have the potential to cause falls in geriatric patients. Thus all of the medications listed may put the patient at a fall risk.

8. The answer is B *[see* II.B.2*].*

Fetal gender does not affect placental transfer of a drug. The molecular weight and the lipid solubility of a drug greatly influence its ability to cross the placental membranes. Plasma protein binding affects the amount of free drug available to cross the placenta. Gestational age influences the volume of distribution of the drug as well as the thickness of the placental membranes.

9. The answer is D *[see* III.C; III.F.1.a*].*

When any drug is used by a nursing mother, it is desirable to have the least amount of active drug available in the maternal circulation to diffuse into the breast milk. A rapidly acting (for maternal onset of action), rapidly eliminated (i.e., short half-life) drug with inactive metabolites is optimal. If the drug is highly lipid soluble, it is more likely to pass into breast milk.

10. The answer is D *[see* II.B.3.c *and* d*].*
The FDA classification system does not assess risk well in category C drugs. Category A and to some extent category B drugs have been shown to be safest in pregnancy. Case reports of pregnancy exposures tend to bias data toward adverse outcomes. The best source of information is from available databases, such as REPROTOX or Teris, or with published books such as *Brigg's Drugs in Pregnancy and Lactation.*

11. The answer is C *[see* IV.D.5.a; Table 37-5*].*
Tricyclic antidepressants are an established cause of anticholinergic adverse effects in the elderly. When these agents are indicated, nortriptyline and desipramine are associated with a lower incidence of anticholinergic ADRs and are more desirable alternatives.
12. The answer is E *[see* IV; Table 37-4*].*
The use of methyldopa should be avoided in elderly patients owing to risk of CNS adverse effects and hypotension.
13. The answer is D *[see* IV.D.4.c; Table 37-4*].*
Chlordiazepoxide, diazepam, and flurazepam should be avoided in elderly patients owing to active metabolites and long-elimination half-lives. Oxazepam represents the safest alternative because of a relatively short half-life, absence of active metabolites, and it is devoid of phase I hepatic metabolism.
14. The answer is A *[see* IV.A.1.e*].*
Lower socioeconomic status, living alone, polypharmacy, complicated drug regimens, poor relationships with healthcare providers, and multiple disease states are all risk factors for noncompliance in the geriatric population.
15. The answer is C (I, II) *[see* III.B.1, 2, 3, 4 *and* 5*].*
High-molecular-weight substances are less likely to pass into breast milk because of their size. Drugs that are highly plasma protein bound may reach the breast milk only in small amounts, because a large portion of the drug is bound to the maternal plasma proteins and, therefore, only a small amount is free to diffuse into breast milk. A low-molecular-weight, moderately lipophilic drug passes easily into breast milk. A drug that has a low degree of plasma protein binding has a significant amount of drug free to diffuse into breast milk. A weakly basic drug may ionize after reaching the breast milk and therefore remain trapped in the milk.
16. The answer is D (II, III) *[see* II.A.1, 2 *and* 3*].*
During first 2 weeks after fertilization, the embryo is impervious to teratogens. Any exposure during this time will have either no effect or the embryo will be destroyed. During the remaining weeks of the pregnancy, teratogens may exert effects on the fetus. Teratogenic effects are not always structural in nature; they can be functional or behavioral. Therefore, exposures during the fetal period can also be problematic.

38

Clinical Laboratory Tests

Byron D. May

I. GENERAL PRINCIPLES

A. Laboratory tests are performed for multiple purposes, including to discover a disease, confirm or differentiate a diagnosis, stage or classify a disease, and monitor effectiveness of therapy.

B. Laboratory tests are classified as screening or diagnostic. Screening tests are used in patients with no signs or symptoms of a disease (e.g., serum cholesterol for assessing cardiovascular disease risk). Diagnostic tests are done in patients with signs and symptoms of disease or with an abnormal screening test.

C. Monitoring drug therapy

1. Laboratory test results are used to investigate potential problems with a patient's anatomy or physiology. Pharmacists usually monitor laboratory tests to

a. Assess the therapeutic and adverse effects of a drug (e.g., monitoring the serum uric acid level after allopurinol is administered, checking for increased liver function test values after administration of isoniazid)

b. Determine the proper drug dose (e.g., assessment of the serum creatinine or creatinine clearance value before use of a renally excreted drug)

c. Assess the need for additional or alternate drug therapy (e.g., assessment of white blood cell count after an antibiotic is administered)

d. Prevent test misinterpretation resulting from drug interference (e.g., determination of a false-positive result for a urine glucose test after cephalosporin administration)

2. These tests can be **expensive,** and requests for them must be balanced against potential benefits for patients and how the laboratory test will affect your decision regarding therapy. Generally, lab tests should be ordered only if the results will affect the decisions about the management of the patient.

B. Definition of normal values

1. Normal laboratory test results fall within a predetermined range of values, and **abnormal values** fall outside that range. The normal range of a laboratory test is usually determined by applying statistical methods to results from a representative sample of the general population. Usually, the mean ± 2 standard deviations is taken as the normal range.

a. Normal limits may be defined somewhat arbitrarily; thus values outside the normal range may not necessarily indicate disease or the need for treatment (e.g., asymptomatic hyperuricemia).

b. Many factors (e.g., age, sex, time since last meal) must be taken into account when evaluating test results.

c. Normal values also vary among institutions and may depend on the method used to perform the test.

d. The goal is *not* to make all laboratory values normal; resist urges to do something in a clinically stable patient.

e. Attempts have been made in recent years to standardize the presentation of laboratory data by using the International System of Units (SI units). Controversy surrounds this issue in the United States, and resistance to adopt this system continues. The SI unit of measure is a method of reporting clinical laboratory data in a standard metric format. The basic unit of mass for the SI is the mole. The mole is not influenced by the addition of excess weight of salt or ester formulations. Technically and pharmacologically, the mole is more meaningful than the gram because each physiological reaction occurs on a molecular level.
Efforts to implement the SI system began in the 1970s, resulting in the adoption of full SI-transition policies by a few major medical and pharmaceutical journals in the 1980s. Reluctance

to use this system by many clinicians in the United States has forced changes in the policies by some journals to report both conventional and SI units or to report the conversion factor between the two systems. It is still controversial which method should be used to report clinical laboratory values. There are arguments for and against the universal conversion to the SI system. Readers should be aware that some journals report SI and/or conventional units in their text. Particular attention should be paid to the units associated with a reported laboratory value, and access to a conversion table may be necessary to avoid confusion in the interpretation of the data. When appropriate, both conventional and SI units will be reported in this chapter.
2. Laboratory error must always be considered when **test results do not correlate with expected results for a given patient.** If necessary, the test should be repeated. Common sources of laboratory error include spoiled specimens, incomplete specimens, specimens taken at the wrong time, faulty reagents, technical errors, incorrect procedures, and failure to take diet or medication into account.
3. During hospital admission or routine physical examination, a **battery of tests** is usually given to augment the history and physical examination. Basic tests may include an electrocardiogram (ECG), a chest x-ray, a sequential multiple analyzer **(SMA) profile, electrolyte tests, a complete blood count (CBC),** and **urinalysis.**
C. Quantitative tests, qualitative tests, and analytical performance
1. Tests with normal values reported in ranges (i.e., 3.5-5.0 mEq/L) are called **quantitative.**
2. Tests with positive (+) or negative (-) outcomes are called **qualitative.**
3. Those with varying degrees of positivity (e.g., 1+, 2+, 3+ glucose in the urine) are termed **semiquantitative.**
4. The quality of a quantitative assay is measured in terms of **accuracy** (accuracy is defined as the extent to which mean measurement is close to the true value). **Precision** refers to the reproducibility of the assay.

II. HEMATOLOGICAL TESTS.

Blood contains three types of formed elements: red blood cells (RBCs), white blood cells (WBCs), and platelets (Figure 38-1). A CBC includes hemoglobin (Hb), hematocrit (Hct), total WBCs, total RBCs, mean cell volume (MCV), and platelet count.

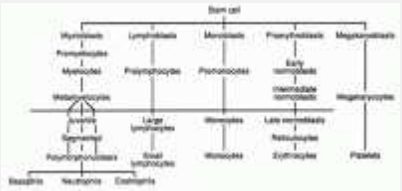

Figure 38-1. Derivation of blood elements from stem cells. Cells located below the *horizontal* line are found in normal peripheral blood, with the exception of the late normoblasts.

P.777

A. RBCs (erythrocytes)

1. The **RBC count,** which reports the number of RBCs found in a cubic millimeter (mm^3) of whole blood, provides an indirect estimate of the blood's Hb content.

Normal values are

a. 4.3-5.9 million/mm^3 of blood for men ($\times 10^{12}$/L)

b. 3.5-5.0 million/mm^3 of blood for women ($\times 10^{12}$/L)

2. The **Hct or packed cell volume (PCV)** measures the percentage by volume of packed RBCs in a whole blood sample after centrifugation. The Hct value is usually three times the Hb value (see II.A.3) and is given as a percent or fraction of 1 (42%-52% or 0.42-0.52 for men; 37%-47% or 0.37-0.47 for women).

a. Low Hct values indicate such conditions as anemia, overhydration, or blood loss.

b. High Hct values indicate such conditions as polycythemia vera or dehydration.

3. The **Hb test** measures the grams of Hb contained in 100 mL (1 dL) or 1 L of whole blood and provides an estimate of the oxygen-carrying capacity of the RBCs. The Hb value depends on the **number of RBCs** and the **amount of Hb in each RBC.**

a. Normal values are 14-18 g/dL for men and 12-16 g/dL for women.

b. Low Hb values indicate anemia.

4. RBC indices (also known as **Wintrobe indices**) provide important information regarding RBC size, Hb concentration, and Hb weight. They are used primarily to categorize anemias, although they may be affected by average cell measurements. A peripheral blood smear can provide most of the information obtained through RBC indices. Observations of a smear may show variation in RBC shape (**poikilocytosis**), as might occur in sickle-cell anemia, or it may show a variation in

RBC size (**anisocytosis**), as might occur in a mixed anemia (folic acid and iron deficiency).

a. MCV is the ratio of the Hct to the RBC count. It essentially assesses average RBC size and reflects any anisocytosis.

$$\text{MCV} = \frac{\text{Hct (\%)} \times 10}{\text{RBC (millions)}}$$

(1) Low MCV indicates **microcytic** (undersize) **RBCs,** as occurs in iron deficiency.

(2) High MCV indicates **macrocytic** (oversize) **RBCs,** as occurs in a vitamin B_{12} or folic acid deficiency.

(3) Normal range for MCV is 90 ± 10.

b. Mean cell hemoglobin (MCHb) assesses the amount of Hb in an average RBC.

(1) MCHb is defined as:

$$\text{MCHb} = \frac{\text{Hb} \times 10}{\text{RBC (millions)}}$$

(2) Normal range for MCH is 30 ± 4.

c. Mean cell hemoglobin concentration (MCHbC) represents the average concentration of Hb in an average RBC, defined as:

$$\text{MCHbC} = \frac{\text{Hb} \times 100}{\text{Hct}}$$

(1) Normal range for MCHC is 34 ± 3.

(2) Low MCHbC indicates **hypochromia** (pale RBCs resulting from decreased Hb content), as occurs in iron deficiency.

d. Red blood cell distribution width (RDW) is a relatively new index of RBCs. Normally, most RBCs are approximately equal in size, so that only one bell-shaped histogram peak is generated. Disease may change the size of some RBCs—for example, the gradual change in size of newly produced RBCs in folic acid or iron deficiency. The difference in size between the abnormal and the less abnormal RBCs produces either more than one histogram peak or a broadening of the normal peak. This value is used primarily with other tests to diagnose iron-deficiency anemia.

(1) An increased RDW is found in factor-deficiency anemia (e.g., iron, folate, vitamin B_{12}).

(2) A normal RDW is found in such conditions as anemia of chronic disease.

(3) The **RDW index** is never decreased.

5. The **reticulocyte count** provides a measure of immature RBCs (reticulocytes), which contain remnants of nuclear material (reticulum). Normal RBCs circulate in the blood for about 1-2 days in this form. Hence, this test provides an index of bone marrow production of mature RBCs.

a. Reticulocytes normally make up 0.1%-2.4% of the total RBC count.

b. Increased reticulocyte count occurs with such conditions as hemolytic anemia, acute blood loss, and response to the treatment of a factor deficiency (e.g., an iron, vitamin B_{12}, or folate deficiency). **Polychromasia** (the tendency to stain with acidic or basic dyes) noted on a peripheral smear laboratory report usually indicates increased reticulocytes.

c. Decreased reticulocyte count occurs with such conditions as drug-induced aplastic anemia.

6. The **erythrocyte sedimentation rate (ESR)** measures the rate of RBC settling of whole, uncoagulated blood over time, and it primarily reflects plasma composition. Most of the sedimentation effect results from alterations in plasma proteins.

a. Normal ESR rates range from 0 to 20 mm/hr for males and from 0 to 30 mm/hr for females.

b. ESR values increase with acute or chronic infection, tissue necrosis or infarction, well-established malignancy, and rheumatoid collagen diseases.

c. ESR values are used to

(1) Follow the clinical course of a disease

(2) Demonstrate the presence of occult organic disease

(3) Differentiate conditions with similar symptomatology—for example, angina pectoris (no change in ESR value) as opposed to a myocardial infarction (increase in ESR value)

B. WBCs (leukocytes)

1. The **WBC count** reports the number of WBCs in a cubic millimeter of whole blood.

a. Normal values range from 4,000 to 11,000 WBC/mm^3.

b. Increased WBC count (leukocytosis) usually signals infection; it may also result from leukemia, tissue necrosis or administration of corticosteroids. It is most often found with **bacterial infection.**

c. Decreased WBC count (leukopenia) indicates bone marrow depression, which may result from metastatic carcinoma, lymphoma, or toxic reactions to substances such as antineoplastic agents.

2. The **WBC differential** evaluates the distribution and morphology of the five major types of WBCs: the **granulocytes** (**neutrophils, basophils, eosinophils**) and the **nongranulocytes** (**lymphocytes, monocytes**). A certain percentage of each type makes up the total WBC count (Table 38-1).

a. Neutrophils may be mature or immature. Mature neutrophils are **polymorphonuclear leukocytes** (PMNs), also referred to as polys, segmented neutrophils, or segs; immature neutrophils are referred to as **bands** or stabs.

(1) Chemotaxis. Neutrophils that **phagocytize and degrade many types of particles** serve as the body's first line of defense when tissue is damaged or foreign material gains entry. They congregate at sites in response to a specific stimulus, through a process known as chemotaxis.

Table 38-1. Normal Percentage Values for White Blood Cell (WBC) Differential

Cell Type	Normal Range of Values (%)
Polymorphonuclear leukocytes	50-70
Bands	3-5
Lymphocytes	20-40
Monocytes	0-7
Eosinophils	0-5
Basophils	0-1

Table 38-2. Examples of Changes in Total White Blood Cell (WBC) Count and WBC Differential in Response to Bacterial Infection

Cell Type	WBC Count	
	Normal	With Bacterial Infection
Total WBCs	8,000 (100%)	15,500 (100%)
Neutrophils		
Polymorphonuclear leukocytes	60%	82%
Bands	3%	6%
Lymphocytes	30%	10%
Monocytes	4%	1%

Eosinophils	2%	1%
Basophils	1%	0%

(2) Neutrophilic leukocytosis. This describes a response to an appropriate stimulus in which the total neutrophil count increases, often with an increase in the percentage of immature cells (**a shift to the left**). This may represent a systemic bacterial infection, such as pneumonia (Table 38-2).

(a) Certain viruses (e.g., chickenpox, herpes zoster), some **rickettsial diseases** (e.g., Rocky Mountain spotted fever), some **fungi,** and **stress** (e.g., physical exercise, acute hemorrhage or hemolysis, acute emotional stress) may also cause this response.

(b) Other causes include **inflammatory diseases** (e.g., acute rheumatic fever, rheumatoid arthritis, acute gout), **hypersensitivity reactions to drugs, tissue necrosis** (e.g., from myocardial infarction, burns, certain cancers), **metabolic disorders** (e.g., uremia, diabetic ketoacidosis), **myelogenous leukemia,** and **use of certain drugs** (e.g., epinephrine, lithium).

(3) Neutropenia, a decreased number of neutrophils, may occur with an **overwhelming infection of any type** (bone marrow is unable to keep up with the demand). It may also occur with **certain viral infections** (e.g., mumps, measles), with **idiosyncratic drug reactions,** and as a result of chemotherapy. Neutropenia is defined as an absolute neutrophil count (ANC) of < 1000 cells/mm^3. Some define absolute neutropenia as an ANC of < 500 cells/mm^3. The ANC is calculated by multiplying the percent of neutrophils by the total WBC count:

WBC = 4000/mm^3

neutrophils = 60%

ANC = 4000 × 0.6 = 2400 cells/mm^3

b. Basophils stain deeply with blue basic dye. Their function in the circulation is not clearly understood; in the tissues, they are referred to as **mast cells.**

(1) Basophilia, an increased number of basophils, may occur with chronic myelogenous leukemia (CML) as well as other conditions.

(2) A decrease in basophils is generally not apparent because of the small numbers of these cells in the blood.

c. Eosinophils stain deep red with acid dye and are classically associated with immune reactions. **Eosinophilia,** an increased number of eosinophils, may occur

with such conditions as **acute allergic reactions** (e.g., **asthma, hay fever, drug allergy**) and **parasitic infestations** (e.g., trichinosis, amebiasis).

d. Lymphocytes play a dominant role in immunological activity and appear to produce antibodies. They are classified as B lymphocytes or T lymphocytes; T lymphocytes are further divided into helper-inducer cells (T_H4 cells) and suppressor cells (T_H8 cells).

(1) Lymphocytosis, an increased number of lymphocytes, usually accompanies a normal or decreased total WBC count and is most commonly caused by **viral infection.**

(2) Lymphopenia, a decreased number of lymphocytes, may result from **severe debilitating illness, immunodeficiency,** or from **AIDS,** which has a propensity to attack T_H4 cells.

(3) Atypical lymphocytes (i.e., T lymphocytes in a state of immune activation) are classically associated with **infectious mononucleosis.**

e. Monocytes are phagocytic cells. **Monocytosis,** an increased number of monocytes, may occur with **tuberculosis (TB), subacute bacterial endocarditis,** and during the recovery phase of some **acute infections.**

C. Platelets (thrombocytes). These are the smallest formed elements in the blood, and they are involved in **blood clotting** and vital to the formation of a hemostatic plug after vascular injury.

1. Normal values for a platelet count are 150,000-300,000/mm^3 (1.5-3.0 × 10^{11}/L).

2. Thrombocytopenia, a decreased platelet count, can occur with a variety of conditions, such as idiopathic thrombocytopenic purpura or, occasionally, from such drugs as quinidine and sulfonamides.

a. Thrombocytopenia is **moderate** when the platelet count is < 100,000/mm^3.

b. Thrombocytopenia is **severe** when the platelet count is < 50,000/mm^3.

III. COMMON SERUM ENZYME TESTS.

Small amounts of enzymes (catalysts) circulate in the blood at all times and are released into the blood in larger quantities when tissue damage occurs. Thus serum enzyme levels can be used to **aid in the diagnosis of certain diseases.**

A. Creatine kinase (CK)

1. Creatine kinase—formerly known as creatine phosphokinase (CPK)—is found primarily in heart muscle, skeletal muscle, and brain tissue.

2. CK levels are used primarily to **aid in the diagnosis of acute myocardial** (Figure 38-2) **or skeletal muscle damage.** However, vigorous exercise, a fall, or deep intramuscular injections can cause significant increases in CK levels.

3. The **isoenzymes** of CK—**CK-MM,** found in skeletal muscle; **CK-BB,** found in brain tissue; and **CK-MB,** found in heart muscle—can be used to differentiate the source of damage.

a. Normally, serum CK levels are virtually all the **CK-MM isoenzyme.**

b. Increase in **CK-MB** levels provides a sensitive indicator of myocardial necrosis.

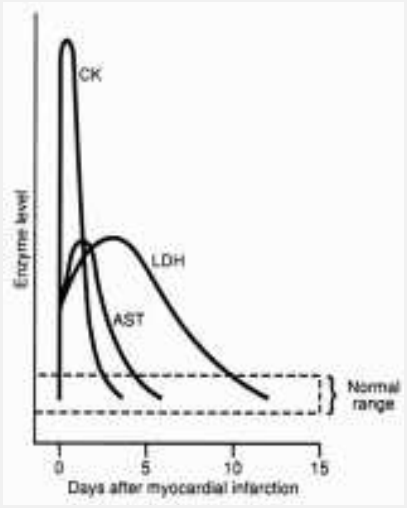

Figure 38-2. The increase of serum creatine kinase (*CK*), lactate dehydrogenase (*LDH*), and aspartate aminotransferase (*AST*) levels after a myocardial infarction.

P.781

B. Lactate dehydrogenase (LDH)

1. LDH catalyzes the interconversion of lactate and pyruvate and represents a group of enzymes present in almost all metabolizing cells.

2. Five individual **isoenzymes** make up the total LDH serum level.

a. **LDH_1** and **LDH_2** appear primarily in the heart.

b. **LDH_3** appears primarily in the lungs.

c. **LDH_4** and **LDH_5** appear primarily in the liver and skeletal muscles.

3. The distribution pattern of LDH isoenzymes may aid in diagnosing myocardial infarction, hepatic disease, and lung disease.

C. Alkaline phosphatase (ALP)

1. ALP is produced primarily in the **liver** and **bones.**

2. Serum ALP levels are **particularly sensitive to partial or mild biliary obstruction**—either extrahepatic (e.g., caused by a stone in the bile duct) or intrahepatic, both of which cause levels to increase.

3. Increased osteoblastic activity, as occurs in Paget disease, hyperparathyroidism, osteomalacia, and others, also increases serum ALP levels.

D. Aspartate aminotransferase (AST)

1. Aspartate aminotransferase—formerly known as **serum glutamic-oxaloacetic transaminase (SGOT)**—is found in a number of organs, primarily in heart and liver tissues and, to a lesser extent, in skeletal muscle, kidney tissue, and pancreatic tissue.

2. Damage to the heart (e.g., from **myocardial infarction**) results in increased AST levels about 8 hr after injury (Figure 38-2).

a. Levels are **increased markedly** with **acute hepatitis;** they are **increased mildly** with **cirrhosis** and a **fatty liver.**

b. Levels are also **increased** with **passive congestion of the liver,** such as occurs in congestive heart failure (CHF).

E. Alanine aminotransferase (ALT)

1. Alanine aminotransferase—formerly known as **serum glutamic-pyruvic transaminase (SGPT)**—is found in the liver, with lesser amounts in the heart, skeletal muscles, and kidney.
2. Although ALT values are **relatively specific for liver cell damage,** ALT is **less sensitive than AST,** and extensive or severe liver damage is necessary before abnormally increased levels are produced.
3. ALT also **increases less consistently and less markedly than AST after an acute myocardial infarction.**

F. Cardiac troponins (I, T, and C)

1. Troponins are a relatively new method to identify myocardial cell injury and thus assist in the diagnosis of acute myocardial infarction. These troponins may possess superior specificity in situations in which false-positive elevations of CK-MB are likely.
2. Troponin T is found in cardiac and skeletal muscle, troponin I is found only in cardiac muscle, and troponin C is present in two isoforms found in skeletal and cardiac muscle. Troponin T has shown prognostic value in unstable angina and in detecting minor myocardial cell injury with greater sensitivity than CK-MB.
3. The normal value for troponin T is < 0.1 ng/mL and I is < 1.5 ng/mL.

IV. LIVER FUNCTION TESTS

A. Liver enzymes

1. Levels of certain enzymes (e.g., LDH, ALP, AST, ALT) **increase with liver dysfunction** (see III).
2. These **enzyme tests indicate only that the liver has been damaged.** They do not assess the liver's ability to function. Other tests provide indications of liver dysfunction.

B. Serum bilirubin

1. Bilirubin, a breakdown product of Hb, is the **predominant pigment in bile.** Effective bilirubin conjugation and excretion depend on **hepatobiliary function** and on the **rate of RBC turnover.**
2. Serum bilirubin levels are reported as **total bilirubin** (conjugated and unconjugated) and as **direct bilirubin** (conjugated only).
a. Bilirubin is released by Hb breakdown and is bound to albumin as water-insoluble **indirect bilirubin** (unconjugated bilirubin), which is not filtered by the glomerulus.
b. Unconjugated bilirubin travels to the liver, where it is separated from albumin, conjugated with diglucuronide, and then actively secreted into the bile as **conjugated bilirubin** (direct bilirubin), which is filtered by the glomerulus (Figure 38-3).
3. Normal values of total serum bilirubin are 0.1-1.0 mg/dL (2-18 mmol/L); of **direct bilirubin,** 0.0-0.2 mg/dL (0-4 mmol/L).
4. An increase in serum bilirubin results in **jaundice** from bilirubin deposition in the tissues. There are three major causes of increased serum bilirubin.

a. Hemolysis increases total bilirubin; direct bilirubin (conjugated) is usually normal or slightly increased. Urine color is normal, and no bilirubin is found in the urine.

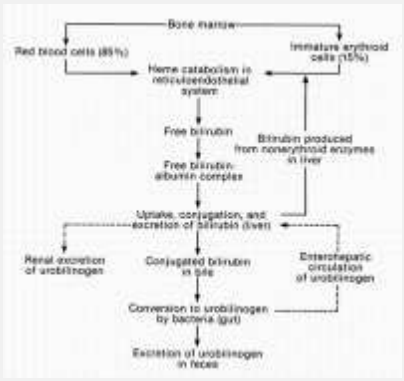

Figure 38-3. Bilirubin metabolism.

P.783

b. Biliary obstruction, which may be intrahepatic (as with a chlorpromazine reaction) or extrahepatic (as with a biliary stone), increases total bilirubin and direct bilirubin; intrahepatic cholestasis (e.g., from chlorpromazine) may increase direct bilirubin as well. Urine color is dark, and bilirubin is present in the urine.

c. Liver cell necrosis, as occurs in viral hepatitis, may cause an increase in both direct bilirubin (because inflammation causes some bile sinusoid blockage) and indirect bilirubin (because the liver's ability to conjugate is altered). Urine color is dark, and bilirubin is present in the urine.

C. Serum proteins

1. Primary serum proteins measured are **albumin** and the **globulins** (i.e., α, β, γ).

a. Albumin (4.0-6.0 g/dL) maintains serum oncotic pressure and serves as a transport agent. Because it is primarily manufactured by the liver, liver disease can decrease albumin levels.

b. Globulins (23-35 g/L) function as transport agents and play a role in certain immunological mechanisms. A decrease in albumin levels usually results in a compensatory increase in globulin production.

2. Normal values for total serum protein levels are 6.0-8.0 g/dL (60-80 g/L).

V. URINALYSIS.

Standard urinalysis provides basic information regarding renal function, urinary tract disease, and the presence of certain systemic diseases. Components of a standard urinalysis include appearance, pH, specific gravity, protein level, glucose level, ketone level, and microscopic examination.

A. Appearance. Normal urine is **clear** and ranges in color from **pale yellow to deep gold. Changes in color** can result from drugs, diet, or disease.

1. A **red color** may indicate, among other things, the presence of blood or phenolphthalein (a laxative).
2. A **brownish yellow color** may indicate the presence of conjugated bilirubin.
3. Other shades of red, orange, or brown may be caused by ingestion of various drugs (e.g., rifampin).

B. pH

1. Normal pH ranges from 4.5 to 9 but is typically **acidic** (around 6).
2. Alkaline pH may indicate such conditions as alkalosis, a **Proteus** infection, or acetazolamide use. It may also reflect changes caused by leaving the urine sample at room temperature.

C. Specific gravity

1. Normal range for specific gravity is 1.003-1.035; it is usually between 1.010 and 1.025.
2. Specific gravity is influenced by the number and nature of solute particles in the urine.
a. Increased specific gravity may occur with such conditions as diabetes mellitus (excess glucose in the urine) or nephrosis (excess protein in the urine).
b. Decreased specific gravity may occur with diabetes insipidus, which decreases urine concentration.
c. Specific gravity, fixed at 1.010 (the same as plasma), occurs when the kidneys lose their power to concentrate or dilute.

D. Protein

1. Normal values for urine protein are 50-80 mg/24 hr because the glomerular membrane prevents most protein molecules in the blood from entering the urine.
2. Proteinuria occurs with many conditions (e.g., renal disease, bladder infection, venous congestion, fever).
a. The presence of a **specific protein** can help identify a specific disease state (e.g., Bence Jones protein may indicate multiple myeloma).

b. Most often, the protein in urine is **albumin.** Albuminuria may indicate abnormal glomerular permeability.

E. Glucose

1. The normal **renal threshold** for glucose is a blood glucose level of about 180 mg/dL; **glucose does not normally appear in urine** as detected by popular testing methods.
2. Glycosuria usually indicates diabetes mellitus (DM). There are certain less common causes (e.g., a lowered renal threshold for glucose).

F. Ketones

1. Ketones **do not normally appear in urine.** They are excreted when the body has used available glucose stores and begins to metabolize fat stores.
2. The **three ketone bodies** are **β-hydroxybutyric acid** (80%), **acetoacetic acid** (about 20%), and acetone (a small percentage). Some commercial tests (e.g., Ames

products) measure only acetoacetic acid, but usually all three are excreted in parallel proportions.

3. Ketonuria usually indicates uncontrolled DM, but it may also occur with starvation and with zero- or low-carbohydrate diets.

G. Evaluation. Microscopic examination of centrifuged urine sediment normally reveals 0-1 RBC, 0-4 WBCs, and only an occasional cast per high-power field (HPF).

1. Hematuria (i.e., the presence of RBCs) may indicate such conditions as trauma, a tumor, or a systemic bleeding disorder. In women, a significant number of **squamous cells** suggests vaginal contamination (menstruation).

2. Casts (i.e., protein conglomerations outlining the shape of the renal tubules in which they were formed) may or may not be significant. Excessive numbers of certain types of casts indicate renal disease.

3. Crystals, which are pH dependent, may occur normally in acid or alkaline urine. **Uric acid crystals** may form in acid urine; **phosphate crystals** may form in alkaline urine.

4. Bacteria do not normally appear in urine. The finding of 50 or more bacteria per HPF may indicate a urinary tract infection (UTI); smaller values may indicate urethral contamination.

VI. COMMON RENAL FUNCTION TESTS

A. Introduction

1. Renal function may be assessed by measuring **blood urea nitrogen (BUN)** and **serum creatinine.** Renal function decreases with age, which must be taken into account when interpreting test values.

a. These tests primarily evaluate glomerular function by assessing the **glomerular filtration rate (GFR).**

b. In many **renal diseases,** urea and creatinine accumulate in the blood because they are not excreted properly.

c. These tests also aid in determining **drug dosage** for drugs excreted through the kidneys.

2. Azotemia describes excessive retention of nitrogenous waste products (BUN and creatinine) in the blood. The clinical syndrome resulting from decreased renal function and azotemia is called **uremia.**

a. Renal azotemia results from renal disease, such as glomerulonephritis and chronic pyelonephritis.

b. Prerenal azotemia results from such conditions as severe dehydration, hemorrhagic shock, and excessive protein intake.

c. Postrenal azotemia results from such conditions as ureteral or urethral stones or tumors and prostatic obstructions.

3. Clearance—a theoretical concept defined as the volume of plasma from which a measured amount of substance can be completely eliminated, or cleared, into the urine per unit time—can be used to estimate glomerular function.

B. BUN

1. Urea, an end product of protein metabolism, is produced in the liver. From there, it travels through the blood and is excreted by the kidneys. Urea is **filtered at the glomerulus,** where the tubules reabsorb approximately 40%. Thus under normal conditions, **urea clearance** is about 60% of the true GFR.

2. Normal values for BUN range from 8 mg/dL to 18 mg/dL (3-6.5 mmol/L).

a. Decreased BUN levels occur with **significant liver disease.**

b. Increased BUN levels may indicate **renal disease.** However, factors other than glomerular function (e.g., protein intake, reduced renal blood flow, blood in the gastrointestinal tract) readily affect BUN levels, sometimes making interpretation of results difficult.

C. Serum creatinine

1. Creatinine (CR), the metabolic breakdown product of muscle creatine phosphate, has a relatively constant level of daily production. Blood levels vary little in a given individual.

2. Creatinine is **excreted** by glomerular filtration and tubular secretion. **Creatinine clearance** parallels the GFR within a range of ± 10% and is a **more sensitive indicator of renal damage than BUN levels** because renal impairment is almost the only cause of an increase in the serum creatinine level.

3. Normal values for serum creatinine range from 0.6 to 1.2 mg/dL (50 to 110 mmol/L).

a. Values vary with the **amount of muscle mass**—a value of 1.2 mg/dL in a muscular athlete may represent normal renal function, whereas the same value in a small, sedentary person with little muscle mass may indicate significant renal impairment.

b. Generally, the **serum creatinine value doubles with each 50% decrease in GFR.** For example, if a patient's normal serum creatinine is 1 mg/dL, 1 mg/dL represents 100% renal function, 2 mg/dL represents 50% function, and 4 mg/dL represents 25% function.

D. Creatinine clearance

1. Creatinine clearance, which represents the **rate at which creatinine is removed from the blood by the kidneys,** roughly approximates the GFR.

a. The value is given in units of milliliters per minute, representing the volume of blood cleared of creatinine by the kidney per minute.

b. Normal values for men range from 75 to 125 mL/min.

2. Calculation requires knowledge of **urinary creatinine excretion** (usually over 24 hr) and concurrent **serum creatinine levels. Creatinine clearance is calculated** as follows:

$$Cl_{CR} = \frac{C_U V}{C_{CR}}$$

where Cl_{CR} is the creatinine clearance in milliliters per minute, C_U is the concentration of creatinine in the urine, V is the volume of urine (in milliliters per minute of urine formed over the collection period), and C_{CR} is the serum creatinine concentration.

3. Suppose the serum creatinine concentration is 1 mg/dL, and 1440 mL of urine was collected in 24 hr (1440 min) for a urine volume of 1 mL/min. The urine contains 100 mg/dL of creatinine. Creatinine clearance is calculated as:

$$\frac{100 \text{ mg/mL} \times 1 \text{ mL/min}}{1 \text{ mg/dL}} = 100 \text{ mL/min}$$

4. Incomplete bladder emptying and other problems may interfere with obtaining an accurate timed urine specimen. Thus **estimations of creatinine clearance** may be necessary. These estimations require only a serum creatinine value. One estimation uses the method of **Cockroft and Gault,** which is based on body weight, age, and gender.

a. This formula provides an **estimated value,** calculated for **males** as:

$$Cl_{CR} = \frac{[140 - \text{age (in years)}] \times \text{body weight (in kg)}}{72 \times C_{CR} \text{ (in mg/dL)}}$$

b. For **females,** use 0.85 of the value calculated for males.

c. Example: A 20-year-old man weighing 72 kg has a C_{CR} of 1.0 mg/dL; thus

$$C_{CR} = \frac{(140 - 20 \text{ years}) \times 72 \text{ kg}}{72 \times 1 \text{ mg/mL}} = 120 \text{ mL/min}$$

5. Determination of GFR. The modified diet in renal disease (MDRD) equation is considered a more accurate measurement of GFR than other equations used to estimate renal function (e.g., Cockcroft-Gault) in patients with *reduced* GFR and is used in staging renal disease. Patients must have a serum creatinine concentration.

a. The MDRD equation for **males** is as follows:

$GFR = 186 \ (Pcr)^{-1.154} \times age^{-0.203}$

where Pcr is serum creatinine. For **females,** multiply the result by 0.742; for **African Americans,** multiply by 1.210.

b. The MDRD has been validated in Caucasians, patients with diabetic kidney disease, kidney transplant recipients, and African Americans and Asians with nondiabetic kidney disease.

c. The MDRD equation has *not* been validated in patients < 18 years of age, pregnant women, patients > 70 years of age, other ethnic groups, patients with normal kidney function who are at an increased risk for chronic kidney disease, and patients with normal renal function.

d. Many institutions are routinely reporting an MDRD-derived GFR estimation for patients as a routine component of a blood chemistry study. This value should be used to assist the clinician in staging a patient's degree of renal dysfunction and is not a substitute for creatinine clearance as estimated by the Cockroft and Gault equation, which should be used for drug dosing in renal impairment. The MDRD estimate has not been evaluated for the purpose of drug dosing.

VII. ELECTROLYTES

A. Sodium (Na)

1. Sodium is the major cation of the **extracellular** fluid. Sodium along with chloride (Cl), potassium (K), and water is important in the regulation of osmotic pressure and water balance between intracellular and extracellular fluids. **Normal values** are 135-147 mEq/L or mmol/L.

2. The sodium concentration is defined as the ratio of sodium to water, not the absolute amounts of either. Laboratory tests for sodium are used mainly to detect disturbances in water balance and body osmolality. The kidneys are the major organs of sodium and water balance.

3. An increase in sodium concentration (**hypernatremia**) may indicate impaired sodium excretion or dehydration. A decrease in sodium concentration (hyponatremia) may reflect overhydration, abnormal sodium loss, or decreased sodium intake.

4. Patients with kidney, heart, or pulmonary disease may have difficulty with sodium and water balance. In adults, changes in sodium concentrations most often reflect changes in water balance, not salt imbalances. Therefore, sodium concentration is often used as an indicator of fluid status, rather than salt imbalance.

5. Control of sodium by the body is accomplished mainly through the hormones aldosterone and antidiuretic hormone (ADH).

a. ADH is released from the pituitary gland in response to signals from the hypothalamus. ADH's presence in the distal tubules and collecting ducts of the kidney causes them to become more permeable to the reabsorption of water; therefore, concentrating urine.

b. Aldosterone affects the distal tubular reabsorption of sodium as opposed to water. Aldosterone is released from the adrenal cortex in response to low sodium, high potassium, low blood volume, and angiotensin II. Aldosterone causes the spilling of potassium from the distal tubules into the urine in exchange for sodium reabsorption.

6. Hyponatremia is usually related to total body depletion of sodium—as in mineralocorticoid deficiencies, sodium-wasting renal disease, replacement of fluid loss with nonsaline solutions, gastrointestinal (GI) losses, renal losses, or loss of sodium through the skin—or to

dilution of serum sodium—as in cirrhosis, CHF, nephrosis, renal failure, excess water intake, or syndrome of inappropriate antidiuretic hormone (SIADH) secretion.

7. Hypernatremia usually results from a loss of free water or hypotonic fluid or through excessive sodium intake. Free water loss is most often associated with diabetes insipidus, but fluid loss can be via the GI tract, renal, skin, or respiratory systems. Excess sodium intake can occur through the administration of hypertonic intravenous (IV) solutions, mineralocorticoid excess, excessive sodium ingestion, or after administration of drugs high in sodium content (e.g., ticarcillin, sodium bicarbonate []).

B. Potassium (K)

1. Potassium is the most abundant **intracellular** cation (intracellular fluid potassium averages 141 mEq/L). Approximately 3500 mEq of potassium is contained in the body of a 70-kg adult. Only 10% of the body's potassium is extracellular. Normal values are 3.5-5.0 mEq/L or mmol/L.

2. The serum potassium concentration is not an adequate measure of the total body potassium because most of the body's potassium is intracellular. Fortunately, the clinical signs and symptoms of potassium deficiency—malaise, confusion, dizziness, electrocardiogram (ECG) changes, muscle weakness, and pain—correlate well with serum concentrations. The serum potassium concentration is buffered by the body and may be “normal” despite total body potassium loss. Potassium depletion causes a shift of intracellular potassium to the extracellular fluid to maintain potassium concentrations. There is approximately a 100 mEq total body potassium deficit when the serum potassium concentration decreases by 0.3 mEq/L. This may result in misinterpretation of serum potassium concentrations as they relate to total body potassium.

3. The role or function of potassium is in the maintenance of proper electrical conduction in cardiac and skeletal muscles (muscle and nerve excitability), it exerts an influence on the body's water balance (intracellular volume) and plays a role in acid-base equilibrium.

4. Potassium is regulated by:

a. Kidneys (renal function)

b. Aldosterone

c. Arterial pH

d. Insulin

e. Potassium intake

f. Sodium delivery to distal tubules

5. Hypokalemia can occur. The kidneys are responsible for approximately 90% of the daily potassium loss. Other losses occur mainly through the GI system. Even in states of no potassium intake, the kidneys still excrete up to 20 mEq of potassium daily. Therefore, prolonged periods of potassium deprivation can result in hypokalemia. Hypokalemia can also result from potassium loss through vomiting or diarrhea, nasogastric suction, laxative abuse, and by diuretic use (mannitol, thiazides, or loop diuretics). Excessive mineralocorticoid activity and glucosuria can also result in hypokalemia. Potassium can be shifted into cells with alkalemia and after administration of glucose and insulin.

6. Hyperkalemia most commonly results from decreased renal elimination, excessive intake, or from cellular breakdown (tissue damage, hemolysis, burns,

infections). Metabolic acidosis may also result in a shift of potassium extracellularly as hydrogen ions move into cells and are exchanged for potassium and sodium ions. As a general guideline, for every 0.1 unit pH change from 7.4, the potassium concentration will change by about 0.6 mEq/L. If a patient has a pH of 7.1 and a measured potassium of 4.5 mEq/L, the actual potassium concentration would be
0.3 (units less than 7.4) × 0.6 = 1.8
Potassium concentration = 4.5 - 1.8 = 2.7 mEq/L
Correction of the acidosis in this situation will result in a dramatic decrease in potassium unless supplementation is instituted.
P.788

C. Chloride (Cl)

1. Chloride is the major anion of the extracellular fluid and is important in the maintenance of acid-base balance. Alterations in the serum chloride concentration are rarely a primary indicator of major medical problems. Chloride itself is not of primary diagnostic significance. It is usually measured to confirm the serum sodium concentration. The relationship among sodium, chloride, and is described by the following:

Cl^- + + *R* = Na^+

where *R* is the anion gap. The **normal value** for Cl is 95-105 mEq/L or mmol/L.

2. Hypochloremia is a decreased chloride concentration, and it is often accompanied by metabolic alkalosis or acidosis caused by organic or other acids. Other causes include chronic renal failure, adrenal insufficiency, fasting, prolonged diarrhea, severe vomiting, and diuretic therapy.

3. Hyperchloremia is an increased chloride concentration that may indicate hyperchloremic metabolic acidosis. Hyperchloremia in the absence of metabolic acidosis is unusual because chloride retention is often accompanied by sodium and water retention. Other causes include acute renal failure, dehydration, and excess chloride administration.

D. Bicarbonate ([)/carbon dioxide (CO_2) content

1. The carbon dioxide (CO_2) content represents the sum of the bicarbonate () concentration and the concentration of CO_2 dissolved in the serum. The /CO_2 system is the most important buffering system to maintain pH within physiological limits. Most disturbances of acid-base balance can be considered in terms of this system. Normal values are 22-28 mEq/L or mmol/L.

2. The relationship among this system is defined as follows:

+ H^+ × H_2CO_3 × H_2O + CO_2

(bicarbonate ions bind hydrogen ions to form carbonic acid). Clinically, the serum concentration is measured because acid-base balance can be inferred if the patient has normal pulmonary function.

3. Hypobicarbonatemia is usually caused by metabolic acidosis, renal failure, hyperventilation, severe diarrhea, drainage of intestinal fluid, and by drugs such as acetazolamide. Toxicity caused by salicylates, methanol, and ethylene glycol can also decrease the level.

4. Hyperbicarbonatemia is usually caused by alkalosis, hypoventilation, pulmonary disease, persistent vomiting, excess intake with poor renal function, and diuretics.

VIII. MINERALS

A. Calcium (Ca)

1. Calcium plays an important role in nerve impulse transmission, muscle contraction, pancreatic insulin release, hydrogen ion release from the stomach, as a cofactor for some enzyme reactions and blood coagulation, and most important bone and tooth structural integrity. Normal total calcium values are 8.8-10.3 mg/dL or 2.20-2.56 mmol/L.

2. The total calcium content of normal adults is 20-25 g/kg of fat-free tissue, and about 44% of this calcium is in the body skeleton. Approximately 1% of skeletal calcium is freely exchangeable with that of the extracellular fluid. The reservoir of calcium in bones maintains the concentration of calcium in the plasma constant. About 40% of the calcium in the extracellular fluid is bound to plasma proteins (especially albumin), 5%-15% is complexed with phosphate and citrate, and 45%-55% is in the unbound, ionized form. Most laboratories measure the total calcium concentration; however, it is the free, ionized calcium that is important physiologically. Ionized calcium levels may be obtained from the laboratory. Clinically, the most important determinant of ionized calcium is the amount of serum protein (albumin) available for binding. The normal serum calcium range is for

a serum albumin of 4 g/dL. A good approximation is that for every 1 g/dL decrease in albumin, 0.8 g/dL should be added to the calcium laboratory result. Doing this corrects the total plasma concentration to reflect the additional amount of free (active) calcium.

3. Hypocalcemia usually implies a deficiency in either the production or response to parathyroid hormone (PTH) or vitamin D. PTH abnormalities include hypoparathyroidism, pseudo-hypoparathyroidism, or hypomagnesemia. Vitamin D abnormalities can be caused by decreased nutritional intake, decreased absorption of vitamin D, a decrease in production, or an increase in metabolism. Administration of loop diuretics causing diuresis can also decrease serum calcium.

4. Hypercalcemia is an increased calcium concentration, and it is usually associated with malignancy or metastatic diseases. Other causes include hyperparathyroidism, Paget disease, milk-alkali syndrome, granulomatous disorders, thiazide diuretics, excessive calcium intake, or vitamin D intoxication.

B. Phosphate (PO_4)

1. Phosphate is a major intracellular anion and is the source of phosphate for adenosine triphosphate (ATP) and phospholipid synthesis. Serum calcium and PO_4 are influenced by many of the same factors. It is useful to consider calcium and PO_4 together when interpreting lab results. Normal PO_4 values are 2.5-5.0 mg/dL or 0.80-1.60 mmol/L.

2. Hyperphosphatemia and **hypophosphatemia** can occur. The extracellular fluid concentration of phosphate is influenced by PTH, intestinal absorption, renal

function, nutrition, and bone metabolism. Hyperphosphatemia is usually caused by renal insufficiency, although increased vitamin D or phosphate intake, hypoparathyroidism, and hyperthyroidism are also causes. Hypophosphatemia can occur in malnutrition, especially when anabolism is induced, after administration of aluminum-containing antacids or calcium acetate, in chronic alcoholics, and in septic patients. Hyperparathyroidism and insufficient vitamin D intake can also induce hypophosphatemia.

C. Magnesium (Mg)

1. Magnesium is the second most abundant intracellular and extracellular cation. It is an activator of numerous enzyme systems that control carbohydrate, fat and electrolyte metabolism, protein synthesis, nerve conduction, muscular contractility, as well as membrane transport and integrity. Normal values are 1.6-2.4 mEq/L or 0.8-1.20 mmol/L.

2. Hypomagnesemia and **hypermagnesemia** can occur. **Hypomagnesemia** is found more often than hypermagnesemia. Depletion of magnesium usually results from excessive loss from the GI tract or the kidneys. Depletion can occur from either poor intestinal absorption or excessive GI fluid loss. Signs and symptoms include weakness, muscle fasciculations with tremor, tetany, and increased reflexes. Decreased intracardiac magnesium may manifest as an increased QT interval with an increased risk of arrhythmia. **Hypermagnesemia** is most commonly caused by increased magnesium intake in the setting of renal insufficiency. Other causes include excess magnesium intake, hepatitis, and Addison disease. Signs and symptoms of hypermagnesemia include bradycardia, flushing, sweating, nausea and vomiting, decreased calcium level, decreased deep-tendon reflexes, flaccid paralysis, increased pulse rate and QRS intervals, respiratory distress, and asystole.

STUDY QUESTIONS

Directions for questions 1-16: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Hematological testing of a patient with AIDS is most likely to show which of the following abnormalities?

(A) basophilia
(B) eosinophilia
(C) lymphopenia
(D) reticulocytosis
(E) agranulocytosis

View Answer***1. The answer is C[see].*****2. Hematological studies are most likely to show a low reticulocyte count in a patient who has which of the following abnormalities?**

(A) aplastic anemia secondary to cancer chemotherapy

(B) acute hemolytic anemia secondary to quinidine treatment
(C) severe bleeding secondary to an automobile accident
(D) iron-deficiency anemia 1 week after treatment with ferrous sulfate
(E) megaloblastic anemia owing to folate deficiency 1 week after treatment with folic acid

View Answer***2. The answer is A[see].*****3. All of the following findings on a routine urinalysis would be considered normal *except* which one?**
(A) pH: 6.5
(B) glucose: negative
(C) ketones: negative
(D) white blood cells (WBCs): 3 per high-power field (HPF), no casts
(E) red blood cells (RBCs): 5 per HPF

View Answer***3. The answer is E[see V.B;and].*****4. A 12-year-old boy is treated for otitis media with cefaclor (Ceclor). On the 7th day of therapy, he spikes a fever and develops an urticarial rash on his trunk. Which of the following laboratory tests could best confirm the physician's suspicion of a hypersensitivity (allergic) reaction?**
(A) complete blood count (CBC) and differential
(B) serum hemoglobin (Hb) and reticulocyte count
(C) liver function test profile
(D) lactate dehydrogenase (LDH) isoenzyme profile
(E) red blood cell (RBC) count and serum bilirubin

View Answer***4. The answer is A[see].*****5. An increased hematocrit (Hct) is a likely finding in all of the following individuals *except* which one?**
(A) a man who has just returned from a 3-week skiing trip in the Colorado Rockies
(B) a woman who has polycythemia vera
(C) a hospitalized patient who mistakenly received 5 L of intravenous (IV) dextrose 5% in water (D5W) over the last 24 hr
(D) a man who has been rescued from the Arizona desert after spending 4 days without water
(E) a woman who has chronic obstructive pulmonary disease

View Answer***5. The answer is C[see].*****6. A 29-year-old white man is seen in the emergency room. His white blood cell (WBC) count is 14,200 with 80% polys. All of the following conditions could normally produce these laboratory findings *except* which one?**
(A) a localized bacterial infection on the tip of the index finger
(B) acute bacterial pneumonia caused by *Streptococcus pneumoniae*
(C) a heart attack
(D) a gunshot wound to the abdomen with a loss of 2 pints of blood
(E) an attack of gout

View Answer***6. The answer is A[see].*****7. A 52-year-old male construction worker who drinks “fairly heavily” when he gets off work is seen in the emergency room with, among other abnormal laboratory results, an increased creatine kinase (CK) level. All of the following circumstances could explain this increase *except* which one?**

(A) he fell against the bumper of his car in a drunken stupor and bruised his right side
(B) he is showing evidence of some liver damage owing to the heavy alcohol intake
(C) he has experienced a heart attack
(D) he received an intramuscular (IM) injection a few hours before the blood sample was drawn
(E) he pulled a muscle that day when lifting a heavy concrete slab

View Answer***7. The answer is B[see].***P.791

8. A 45-year-old man with jaundice has spillage of bilirubin into his urine. All of the following statements could apply to this patient *except* which one?
(A) His total bilirubin is increased.
(B) His direct bilirubin is increased.
(C) He may have viral hepatitis.
(D) He may have hemolytic anemia.
(E) He may have cholestatic hepatitis.

View Answer***8. The answer is D[see].*****For questions 9-11:** A 70-year-old black man weighing 154 lb. complains of chronic fatigue. Several laboratory tests were performed with the following results:

blood urea nitrogen (BUN)	15 mg/dL
aspartate aminotransferase (AST)	within normal limits
white blood cell (WBC) count	7500/mm^3
red blood cell (RBC) count	4.0 million/mm^3
hematocrit (Hct)	29%
hemoglobin (Hb)	9.0 g/dL

9. This patient's mean cell hemoglobin concentration (MCHbC) is
(A) 27.5.
(B) 28.9.
(C) 31.0.
(D) 33.5.
(E) 35.4.

View Answer***9. The answer is C[see].*****10. His mean cell volume (MCV) is**
(A) 61.3.

(B) 72.5.
(C) 77.5.
(D) 90.2.
(E) 93.5.

View Answer***10. The answer is B[see].*****11. From the data provided and from the calculations in questions 9 and 10, this patient is best described as**
(A) normal except for a slightly increased blood urea nitrogen (BUN).
(B) having normochromic, microcytic anemia.
(C) having sickle-cell anemia.
(D) having hypochromic, normocytic anemia.
(E) having folic acid deficiency.

View Answer***11. The answer is B[see].*****12. All of the following statements about sodium (Na) are true *except* which one?**
(A) The normal range for sodium is 135-147 mEq/L.
(B) Sodium is the major cation of the extracellular fluid, and the laboratory test is used mainly to detect disturbances in water balance.
(C) Hyponatremia usually results from the total body depletion of sodium or through a dilutional effect.
(D) Control of the sodium concentration is mainly through regulation of arterial pH.

View Answer***12. The answer is D[seeand].*****13. A 53-year-old woman with diabetes mellitus is seen in the emergency room. Her blood glucose is 673** mg/dL **and ketones are present in her blood. A diagnosis of diabetic ketoacidosis (DKA) is made. Other important laboratory values are potassium of 4.8** mEq/**L, 4+ glucose in urine, and an arterial pH of 7.1. All of the following statements apply to this patient *except* which one?**
(A) Her potassium value is normal; therefore, no potassium supplementation is likely to be necessary.
(B) Her potassium value should be corrected owing to her acidosis; a corrected potassium would be 3.0 mEq/L.
(C) Potassium supplementation should be instituted because her total body potassium is depleted.
(D) Factors affecting potassium in this patient include glycosuria and arterial pH.

View Answer***13. The answer is A[see].***P.792

14. A 50-year-old man presents with bicarbonate of 18 mEq/**L. All of the following could be a cause of his low bicarbonate level *except***
(A) metabolic acidosis.
(B) salicylate toxicity.
(C) diuretic therapy.
(D) diarrhea.

View Answer***14. The answer is C[seeand].*****15. All of the following statements about calcium (Ca) and phosphorus (PO_4) are true *except* which one?**

(A) An alcoholic with a serum albumin of 2 g/dL and a serum total calcium of 8.0 mg/dL has a corrected total calcium of 9.6 mg/dL.
(B) Calcium and PO_4 levels should be interpreted together because many of the same factors influence both minerals.
(C) Metastatic cancer often induces a decrease in serum calcium levels
(D) A patient with renal failure may present with hypocalcemia and hyperphosphatemia.

View Answer***15. The answer is C[seeand].*****16. All of the following are important functions of magnesium (Mg) *except***
(A) nerve conduction.
(B) phospholipid synthesis.
(C) muscle contractility.
(D) carbohydrate, fat, and electrolyte metabolism.

View Answer***16. The answer is B[see].*****Directions for questions 17-19:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**
17. Factors likely to cause an increase in the blood urea nitrogen (BUN) level include
I. intramuscular (IM**) injection of diazepam (Valium).**
II. severe liver disease.
III. chronic kidney disease.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***17. The answer is B[see].*****18. A patient who undergoes serum enzyme testing is found to have an increased aspartate aminotransferase (AST) level. Possible underlying causes of this abnormality include**
I. methyldopa-induced hepatitis.
II. congestive heart failure (CHF).
III. pneumonia.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***18. The answer is C[see].*****19. Serum enzyme tests that may aid in the diagnosis of myocardial infarction include**
I. alkaline phosphatase.
II. creatine kinase (CK).
III. lactate dehydrogenase (LDH).
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***19. The answer is D[seeand].***P.793

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* II.B.2.d.(2)*].*

Valuable diagnostic information can be obtained through quantitative and qualitative testing of the cells of the blood. A finding of lymphopenia (i.e., decreased number of lymphocytes) suggests an attack on the immune system or some underlying immunodeficiency. AIDS attacks the T_H4 population of lymphocytes and thus may result in lymphopenia.

2. The answer is A *[see* II.A.5*].*

The reticulocyte count measures the amount of circulating immature RBCs, which provides information about bone marrow function. A low reticulocyte count is a likely finding in a patient with aplastic anemia—a disorder characterized by a deficiency of all cellular elements of the blood owing to a lack of hematopoietic stem cells in bone marrow. A variety of drugs (e.g., those used in anticancer therapy) and other agents produce marrow aplasia. A high reticulocyte count would likely be found in a patient with hemolytic anemia or acute blood loss or in a patient who has been treated for an iron, vitamin B_{12}, or folate deficiency.

3. The answer is E *[see V.B;* V.E, F *and* G*].*

Microscopic examination of the urine sediment normally shows < 1 RBC and from 0 to 4 WBCs per HPF. Other normal findings on urinalysis include an acid pH (i.e., around 6) and an absence of glucose and ketones.

4. The answer is A *[see* II.B.2.c*].*

An allergic drug reaction will usually produce an increase in the eosinophil count (eosinophilia). This could be determined by ordering a WBC differential.

5. The answer is C *[see* II.A.2*].*

Overhydration with an excess infusion of D5W produces a low Hct. The other situations described in the question result in increases of the Hct.

6. The answer is A *[see* II.B.2.a*].*

The patient has leukocytosis with an increased neutrophil count (neutrophilia). A localized infection does not normally result in an increase in the total leukocyte count or neutrophil count. The other situations given in the question can produce a neutrophilic leukocytosis.

7. The answer is B *[see* III.A*].*

Because CK is not present in the liver, alcoholic liver damage would not result in an increase in the level of this enzyme. CK is present primarily in cardiac and skeletal muscle. The other situations described in the question could all result in the release of increased amounts of CK into the bloodstream.

8. The answer is D *[see* IV.B*].*

The patient with jaundice (deposition of bilirubin in the skin) usually has an increase in the total bilirubin serum level. Spillage of bilirubin into the urine requires an

increased level of direct bilirubin, which is likely with viral hepatitis or cholestatic hepatitis. In hemolytic anemia, direct bilirubin is not usually increased, and therefore, there would be no spillage of bilirubin into the urine.

9. The answer is C *[see* II.A.4.c*].*

10. The answer is B *[see* II.A.4.a*].*

11. The answer is B *[see* II.A.4; CI.B.2*].*

The MCHbC is calculated as follows:

$$\text{MCHbC} = \frac{\text{Hb} \times 100}{\text{Hct}} = \frac{9 \times 100}{29} = 31.0$$

The mean cell volume (MCV) is calculated as follows:

$$\text{MCV} = \frac{\text{Hct (\%)} \times 10}{\text{RBC (millions)}} = \frac{29 \times 10}{4} = 72.5$$

The patient described in the question is anemic because his Hb is 9 (normal: 14-18). The anemia is normochromic because the patient's MCHbC of 31 is normal (normal range: 31-37), but the anemia is microcytic because the patient's MCV is 72.5 (normal: 80-100). The patient's BUN, 15 mg/dL, is within the normal range of 10-20 mg/dL.

12. The answer is D *[see* VII.A.1; VII.A.5, 6 *and* 7*].*

Sodium, the major extracellular cation, is measured mainly to assist in the determination of fluid status and water balance. Regulation of sodium is mainly through the kidneys via ADH and aldosterone.

13. The answer is A *[see* VII.B.2; VII.B.4; VII.B.6*].*

A “normal” potassium level in the setting of metabolic acidosis, especially in a patient with DKA should be treated appropriately. If the serum potassium level is corrected for the patient's acidosis, the corrected level is 3.0 mEq/L. This corresponds to a depletion in total body potassium stores. Once the acidosis and hyperglycemia begin to correct with appropriate treatment, potassium levels will decrease precipitously unless supplementation is begun. It is important to recognize that a laboratory value in the “normal” range may not actually be normal, especially when potassium is involved.

14. The answer is C *[see* VII.D.3 *and* 4*].*

Low is usually found in patients with acidosis or renal failure and after hyperventilation or severe diarrhea. In general, disturbances in acid-base balance cause alteration in the serum or CO_2 content. Diuretic therapy can cause an alkalosis and an increase in .

15. The answer is C *[see* VIII.A.2, 3 *and* 4; B.2*].*

Malignancy or other metastatic diseases are most often associated with hypercalcemia, not hypocalcemia. Ionized calcium is the free active form, and this level is increased in the setting of a low albumin. Therefore, the total calcium level must be adjusted to account for an increased ionized calcium in this setting. Both minerals are influenced by many of the same factors and thus are often interpreted

together. Renal function is one such factor whereby a decrease in renal function (i.e., renal failure) can result in a low level of calcium and a high level of PO_4.

16. The answer is B *[see* VIII.C.1*].*

Magnesium is the second most abundant intracellular and extracellular cation. It is an activator of numerous enzyme systems that control carbohydrate, fat, and electrolyte metabolism, protein synthesis, nerve conduction, muscular contractility, as well as membrane transport and integrity. PO_4, on the other hand, is important for ATP and phospholipid synthesis.

17. The answer is B (III) *[see* VI.B.2*].*

Chronic kidney disease can cause an increase in the BUN level; a heavy protein diet and bleeding into the GI tract are other factors that can produce this finding. Severe liver disease can prevent the formation of urea and, therefore, is likely to cause a decrease in the BUN level. Although an IM injection of diazepam (Valium) may cause an increase in the serum CK or AST level, it would have no effect on the BUN.

18. The answer is C (I, II) *[see* III.D*].*

A lung infection, such as pneumonia, normally would not cause an increase in the release of AST, an enzyme primarily found in the liver and heart. In acute hepatitis, a marked increase of AST is a likely finding. AST levels also can be increased with passive congestion of the liver, as occurs in CHF.

19. The answer is D (II, III) *[see* III.A, B *and* C*].*

Usually, the CK, aALT, AST, and LDH enzyme levels are increased after a myocardial infarction. Alkaline phosphatase is not present in cardiac tissue and, therefore, would not be useful in the diagnosis of a myocardial infarction.

Coronary Artery Disease

Alan H. Mutnick

Barbara Szymusiak-Mutnick

I. INTRODUCTION

A. Definition. Coronary artery disease (CAD) is a general term that refers to a number of diseases other than atherosclerosis, which causes a narrowing of the major epicardial coronary arteries. **Ischemic heart disease (IHD)** is a form of heart disease with primary manifestations that result from myocardial ischemia owing to atherosclerotic CAD. This term encompasses a spectrum of conditions, ranging from the asymptomatic preclinical phase to acute myocardial infarction and sudden cardiac death, and is used throughout the chapter.

B. Incidence

1. IHD continues to be the leading single cause of death in the United States (231.1-297.9 deaths per 100,000); cancer is the second leading cause of death (159.1-228.1 deaths per 100,000).

2. Each year more than 5 million patients present to emergency rooms with chest discomfort and related symptoms, and approximately 1.5 million are hospitalized for acute coronary syndromes. Each year in the United States, more than 1 million patients suffer an acute myocardial infarction (MI).

C. Economics. Based on models evaluating the costs associated with the treatment of Medicare patients with common IHD-related diagnosis, it has been estimated that the direct costs of hospitalization are > $15 billion yearly, with an additional $4.5 billion yearly in diagnostic procedures.

D. Clinical guidelines. Owing to the clinical, humanistic, and economic effect that IHD has in the United States, evidenced-based practice guidelines have evolved based on the differences in the diagnosis and management of IHD. The authors of this chapter have relied heavily on the use of those guidelines to ensure the most up-to-date recommendations based on the clinical literature. Guidelines that are pertinent to daily pharmacy practice include the following:

1. Gibbons RJ, Abrams J, Chatterjee K, Daley J, Deedwania PC, Douglas JS, Ferguson TB Jr, Fihn SD, Fraker TD Jr., Gardin JM, O'Rourke RA, Pasternak RC, Williams SV. implementation of the guidelines for unstable angina/non-ST-segment elevation myocardial infarction in the emergency department: a scientific statement from the American Heart Association Council on Clinical Cardiology (Subcommittee on Acute Cardiac Care), Council on Cardiovascular Nursing, and Quality of Care and Outcomes Research Interdisciplinary Working Group, in Collaboration With the Society of Chest Pain Centers. Circulation, May 2005; 111:2699-2710. Available at http://circ.ahajournals.org/cgi/citemap?id=circulationaha;111/20/2699.

E. Manifestations

1. Angina pectoris, an episodic, reversible oxygen insufficiency, is the most common form of IHD (see II).

2. The term **acute ischemic (coronary) syndromes** describes a group of clinical symptoms representing acute myocardial ischemia. The clinical symptoms include acute myocardial infarction, including ST-segment elevation (STEMI), non-ST-segment elevation (NSTEMI), and unstable angina (UA) (see III).

F. Etiology. The processes, singly or in combination, that produce IHD include decreased blood flow to the myocardium, increased oxygen demand, and decreased oxygenation of the blood. Generally, significant IHD is defined via angiography as a stenosis that is ≥ 70% of the diameter of at least one major coronary artery segment or 50% of the diameter of the left main coronary artery.

1. Decreased blood flow (Figure 39-1)

a. Atherosclerosis, with or without coronary thrombosis, is the most common cause of IHD. In this condition, the coronary arteries are progressively narrowed by smooth muscle cell proliferation and the accumulation of lipid deposits (plaque) along the inner lining (intima) of the arteries.

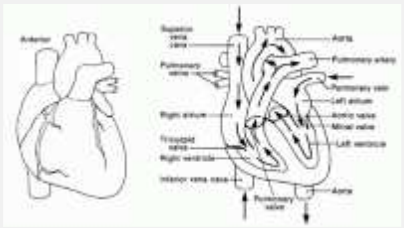

Figure 39-1. Oxygen and other nutrients are borne to the myocardium through the two major coronary arteries (the left and right) and their tributaries. The hemodynamic consequences of ischemic heart disease depend on which of the coronary vessels are involved and what part of the myocardium those vessels supply.

b. Coronary artery spasm, a sustained contraction of one or more coronary arteries, can occur spontaneously or be induced by irritation (e.g., by coronary catheter or intimal hemorrhage), exposure to the cold, and ergot-derivative drugs. One long-term study demonstrated that coronary spasm was most often associated

with an atypical chest pain syndrome and cigarette smoking. These spasms can cause Prinzmetal angina and even MI. Variant angina (Prinzmetal angina) is a form of unstable angina that usually occurs spontaneously, is characterized by transient ST-segment elevation, and most commonly resolves without progression to MI.

c. Traumatic injury, whether blunt or penetrating, can interfere with myocardial blood supply (e.g., the impact of a steering wheel on the chest causing a myocardial contusion in which the capillaries hemorrhage).

d. Embolic events, even in otherwise normal coronary vessels, can abruptly restrict the oxygen supply to the myocardium.

2. Increased oxygen demand usually in the presence of a fixed restricted oxygen supply can occur with exertion (e.g., exercise, shoveling snow) and emotional stress as well as under circumstances external to the coronary arterial bed, which increases sympathetic stimulation and thus heart rate. Some factors affecting cardiac workload, and therefore myocardial oxygen supply and demand, are listed in Table 39-1.

Table 39-1. Factors Affecting Cardiac Parameters That Control Myocardial Oxygen Demand

Factor	Heart Rate	Blood Pressure	Ejection Time	Ventricular Volume	Inotropic Effect
Exercise	Increase	Increase	Decrease	Increase or decrease	Increase
Cold	Increase	Increase	—	—	—
Smoking	Increase	Increase	Increase	—	Increase
Nitroglycerin	Increase	Decrease	Decrease	Decrease	Increase
β-blockers	Decrease	Decrease	Increase	Increase	Decrease

a. Diastole. Under normal circumstances, almost all of the oxygen is removed (during diastole) from the arterial blood as it passes through the heart. Thus little remains to be extracted if oxygen demand increases. To increase the coronary

oxygen supply, blood flow has to increase. The normal response mechanism is for the blood vessels, particularly the coronary arteries, to dilate, thereby increasing blood flow.

b. Systole. The two phases of systole—contraction and ejection—strongly influence oxygen demand.

(1) The **contractile (inotropic) state of the heart** influences the amount of oxygen it requires to perform.

(2) Increases in systolic wall tension, influenced by left ventricular volume and systolic pressure, increase oxygen demand.

(3) Lengthening of ejection time (i.e., the duration of systolic wall tension per cardiac cycle) also increases oxygen demand.

(4) Changes in heart rate influence oxygen consumption by changing the ejection time.

3. Reduced blood oxygenation. The oxygen-carrying capacity of the blood may be reduced, as occurs in various anemias or hypoxemia.

G. Risk factors for IHD and goals for secondary prevention have been updated with the recently released 2007 Focused Update of the ACC/AHA 2004 Guidelines for the Management of Patients with ST-Elevation Myocardial Infarction, and are provided in Table 39-2.

H. Therapeutic considerations. Because most IHD occurs secondary to atherosclerosis, which is a long-term, cumulative process, medical efforts focus on reducing risk factors through individual patient education and media campaigns. Once manifestations occur, treatment addresses their specific variables.

II. ANGINA PECTORIS

A. Definition. The term **angina pectoris** is applied to varying forms of transient chest discomfort that are attributable to insufficient myocardial oxygen.

1. Angina is a clinical syndrome characterized by discomfort in the chest, jaw, shoulder, back, and arms, which is usually aggravated by exertion or stress and relieved by nitroglycerin.

2. Angina can occur in patients with valvular heart disease, uncontrolled hypertension, as well as in noncardiac organ systems such as the chest wall, esophagus, or lungs.

B. Common causes. Atherosclerotic lesions that produce a narrowing of the coronary arteries are the major cause of angina. However, tachycardia, anemia, hyperthyroidism, hypotension, and arterial hypoxemia can all cause an oxygen imbalance.

C. Types

1. Stable (classic) angina

a. In this most common form, has a more predictable pattern, which is brought on by exertion, emotional stress, or a heavy meal, which is usually relieved by rest, nitroglycerin, or both.

b. Five components are usually considered: quality, location, and duration of pain; factors provoking pain; and factors that relieve pain.

c. Pain has been referred to as “squeezing,” “grip-like,” “pressure-like,” “suffocating,” and “heavy,” and is usually referred to as a discomfort rather than “pain.”
d. The anginal episode typically lasts for “minutes” and is usually substernal but has a tendency to radiate to the neck, jaw, epigastrium, or arms.
e. Characteristically, the discomfort builds to a peak, radiating to the jaw, neck, shoulder, and arms, and then subsides without residual sensation. Angina is normally related to physical exertion, and the discomfort usually subsides quickly (i.e., in 3-5 min) with rest; if precipitated by emotional stress, the episode tends to last longer (i.e., about 10 min).
f. Stable angina is characteristically the result of a fixed obstruction in a coronary artery.

Table 39-2. Risk Factors for Ischemic Heart Disease and Guidelines for Their Modification, When Applicable

I.	**Risk Factors: Not necessarily modifiable**	
		Family history of ischemic heart disease
		Age and gender (i.e., prevalence is higher among men than among premenopausal women and increases for both genders with age)
		Chronic stress or type A personality (i.e., aggressive, ambitious, chronically impatient, competitive)
		Gout
II.	**Secondary Preventive Goals: As recommended in the 2007 Smoking-Complete cessation, no exposure to environmental tobacco smoke. *Class 1 Recommendation**	
		Status of tobacco use should be asked about at every visit.
		Every tobacco user and family members who smoke should be advised to quit at every visit.

		The tobacco user's willingness to quit should be assessed.
		The tobacco user should be assisted by counseling and developing a plan for quitting.
		Follow-up, referral to special programs, or pharmacotherapy (including nicotine replacement and pharmacological treatment) should be arranged.
		Exposure to environmental tobacco smoke at work and home should be avoided.
Blood pressure control: Blood pressure should be reduced to less than 140/90 mm Hg or less than 130/90 mm Hg if chronic kidney disease or diabetes mellitus. *Class 1 Recommendation		
		Initiate or maintain lifestyle modification (weight control, increased physical activity, alcohol moderation, decreased sodium intake, and increased emphasis on consumption of fresh fruits, vegetables, and low-fat dairy products).
		Add blood pressure medication, as tolerated, treating initially with β-adrenoreceptor blockers and/or ACE inhibitors.
		The addition of other blood pressure lowering drugs such as thiazides as needed to achieve the goal blood pressure.
Blood Lipid management: Low density lipoprotein-cholesterol (LDL-C) levels should be less than 100 mg/dL. (If triglycerides are greater than or equal to 200 mg/dL, total cholesterol minus high density lipoprotein cholesterol (HDL-C) should be less than 130 mg/dL.) *Class I Recommendation		
		Initiate dietary therapy in all patients; which includes reducing intake of saturated fats, (<7% of total calories), trans fatty acids and cholesterol (<200 mg/d).
		The addition of plant stanol/sterols (2 g/d) and/or viscous fiber (>10 g/d) to further lower LDL-C.

		Promotion of daily physical activity and weight management.
		It may be reasonable to encourage the increase in the consumption of omega-3 fatty acids in the form of fish or in capsule form (1 g/d) for risk reduction.
		A fasting lipid profile should be assessed in all patients and within 24 hours of hospitalization for those with an acute cardiovascular or coronary event.
Physical activity: Participate in 30 minutes of Physical Activity 7 days a week *Class 1 Recommendation		
		It is recommended that all patients have a risk assessment with a physical activity history and/or an exercise test to guide prescription.
		All patients should be encouraged to participate in 30 to 60 minutes of moderate-intensity aerobic activity, (i.e., brisk walking) on most, preferably all, days of the week, supplemented by an increase in daily lifestyle activities (e.g., walking breaks at work, gardening, household work).
		Advise medically supervised programs for high-risk patients (e.g., recent acute coronary syndrome or revascularization, heart failure).
Weight management: Body Mass Index (BMI) of 18.5 to 24.9 kg/m^2 with waist circumference of less than 35 inches (women) and less than 40 inches (men) *Class 1 Recommendation		
		Assessment of body mass index and/or waist circumference on each visit and consistently.
		Encourage weight maintenance/reduction through an appropriate balance of physical activity, caloric intake, and formal behavioral programs when indicated to maintain/achieve a body mass index between 18.5 and 24.9 kg/m^2.

		The initial goal of weight loss therapy should be to reduce body weight by approximately 10% from baseline.
		With success, further weight loss can be attempted if indicated.
		If waist circumference is greater than or equal to 35 inches in women and greater than or equal to 40 inches in men, it is useful to initiate lifestyle changes and consider treatment strategies for metabolic syndrome as indicated.
Diabetes management: Achieve a glycosylated hemoglobin (HbA1c) level of less than 7% *Class 1 Recommendation		
		It is recommended to initiate lifestyle and pharmacotherapy to achieve near-normal levels of HbA1c.
		Aggressive modification of other risk factors such as physical activity, weight management, blood pressure control, and cholesterol management, as recommended above is beneficial.
		Coordination of diabetic care with patient's primary care physician or endocrinologist is beneficial.

* Class I recommendation: The benefits of the intervention/treatment are much greater than the risk, and the procedure/treatment should be performed.

2. Unstable angina. (See also III.)

a. In many patients who experience unstable angina, symptoms will be caused by significant coronary artery disease. Angina is considered unstable and requires further evaluation if patients experience

(1) Rest angina, which usually is prolonged > 20 min occurring within a week of presentation

(2) Severe new-onset angina refers to angina of at least Canadian Cardiovascular Society Classification (CCSC) to class III severity, with onset within 2 months of initial presentation

(3) Increasing angina refers to previously diagnosed angina that is distinctly more frequent, longer in duration, or lower in threshold

(4) Decreased response to rest or nitroglycerin

b. Unstable angina predicts a higher short-term risk, represents a progressive clinical entity, may signal incipient MI, is referred to as an acute coronary syndrome, and should be reported promptly to a physician.

3. Angina decubitus (nocturnal angina)

a. This angina occurs in the recumbent position and is not specifically related to either rest or exertion.

b. Gravitational forces shift fluids within the body with a resultant increase in ventricular volume, which increases oxygen needs and produces angina decubitus, and which may indicate cardiac decompensation.

c. Diuretics alone or in combination effectively reduce left ventricular volume and may aid the patient.

d. Nitrates such as nitroglycerin may relieve the paroxysmal nocturnal dyspnea associated with angina decubitus by reducing preload, owing to venous pooling, and improving left ventricular dysfunction.

4. Prinzmetal's angina (vasospastic or variant angina)

a. Coronary artery spasm that reduces blood flow precipitates this angina. The spasm may be superimposed on a coronary artery that already has a fixed obstruction owing to thrombi or plaque formation.

b. It usually occurs at rest (i.e., pain may disrupt sleep) rather than with exertion or emotional stress, and usually resolves without progression to an acute MI. However, if the attack

is prolonged, MI, life-threatening ventricular arrhythmias, and sudden cardiac death can occur.

c. Characteristically, an electrocardiogram (ECG) taken during an attack reveals a transient ST-segment elevation, which returns toward normal after the acute attack.

d. Calcium-channel blockers, rather than β-blockers, are most effective for this form of angina. Nitroglycerin may not provide relief, depending on the cause of vasospasm.

D. Physical examination is usually not revealing, especially between attacks. However, the patient's history, risk factors, and full description of attacks—precipitation pattern, intensity, duration, relieving factors—usually prove diagnostic.

E. Diagnostic test results

1. The **ECG** is normal in 50% or more of patients with stable angina pectoris, and a normal resting ECG does not exclude severe IHD. However, an ECG with evidence of left ventricular hypertrophy or ST-T-wave changes consistent with myocardial ischemia favor the diagnosis of angina pectoris. The presence of Q waves from a previous MI makes the diagnosis of IHD very likely. An ECG obtained during chest pain is abnormal in 50% of patients with angina who have a normal resting ECG. The ST segment can be either elevated or depressed.

2. Stress testing (exercise ECG) is a well-established procedure, which aids the diagnosis in patients who have normal resting ECGs. The most commonly used definition for a positive test is a ≥ 1-mm ST-segment depression or elevation for ≥

60-80 msec either during or after exercise. Exercise stress testing is preferable to other variations of the stress test (pharmacological) in patients who are able to exercise.

3. Pharmacological stress testing is performed in suspected IHD patients when they are not able to perform more than moderate exercise due to various reasons (i.e., severe arthritis, prior injury, reduced exercise tolerance as a result of debilitating illnesses, etc.), or in patients who are unable to increase the heart rate.

a. Intravenous dipyridamole (coronary vasodilation), adenosine (coronary vasodilation) by inhibiting cellular uptake and degradation of adenosine increase coronary blood flow, and high-dose dobutamine (20-40 μg/kg/min) increase oxygen demand through increased heart rate, systolic blood pressure, and myocardial contractility causing an increase in myocardial blood flow are all able to induce detectable cardiac ischemia in conjunction with ECG testing.

b. Side effects occur for each of the agents and include **dipyridamole** (angina, 18%-42%; arrhythmias, 2%; headache, 5%-23%; dizziness, 5%-21%; nausea, 8%-12%; and flushing, 3%), **adenosine** (chest pain, 57%; headache, 35%; flushing, 25%; shortness of breath, 15%; and first-degree atrioventricular [AV] heart block, 18%), **dobutamine** (premature ventricular beats, 15%; premature atrial beats, 8%; supraventricular tachycardia and nonsustained ventricular tachycardia, 3%-4%; nausea, 8%; anxiety, 6%; headache, 4%; and tremor, 4%).

4. Stress perfusion imaging with thallium-201 or technetium-99m (^{99m}Tc) can diagnose multivessel disease, localized ischemia, and may be able to determine myocardial viability. The added expense of the test makes it reserved for patients who have ECG abnormalities at rest. Coronary arteriography and cardiac catheterization are very specific and sensitive but are also invasive, expensive, and risky (the mortality rate is 1%-2%); therefore, they must be used judiciously when trying to confirm suspected angina and to differentiate its origin.

5. Various drugs can have an effect on the ECG and should be considered before, during, and after an exercise test is carried out. Examples include

a. Digoxin produces abnormal exercise-induced ST depression in 25%-40% of apparently healthy, normal subjects without ischemia.

b. β-adrenergic blockers may delay the development of an abnormal ECG if patients receive them before or during a stress test. If possible, therapy should be slowly withheld from the patient at least four to five half-lives before the exercise testing. If it is not possible to withdraw therapy, the clinician needs to recognize that the test might be less reliable.

c. Antihypertensives such as vasodilators can alter the stress test by altering the normal hemodynamic response of blood pressure. In addition, short-term use of nitrates can attenuate angina and ST-segment changes associated with myocardial ischemia.

F. Treatment goals

1. To prevent MI and death, thereby increasing a patient's quality of life

2. To reduce symptoms of angina and occurrence of ischemia, which should improve a patient's quality of life

3. To remove or reduce **risk factors**

4. The management of angina pectoris includes therapies aimed at reversing cardiac risk factors.

a. Hyperlipidemia, if present, should be treated. Reducing cholesterol and low-density lipoprotein (LDL) is associated with a reduced risk of cardiovascular disease and incidence of ischemic cardiac events, as demonstrated by several recent studies using β-hydroxy-β-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors. The NCEP has published updated guidelines for treatment of high blood cholesterol (Adult Treatment Panel III).

(1) Total cholesterol is no longer the primary target of treatment; LDL cholesterol is now the primary target.

(2) Current recommendations include the completion of a lipoprotein profile—total cholesterol, LDL cholesterol, high-density lipoprotein (HDL) cholesterol, and triglycerides—as the preferred initial test, rather than screening for total cholesterol and HDL alone.

(3) Persons are categorized into one of four levels of risk, to identify group-specific treatment modalities: (1) *high-risk,* established IHD or IHD risk equivalents (diabetes, noncoronary forms of atherosclerotic disease); (2) *moderately high-risk,* multiple (more than two) risk factors and a calculated 10-year risk of 10%-20%; (3) *moderate risk,* multiple (more than two) risk factors and a calculated 10-year risk of 10%; and (4) *lower-risk,* zero to one risk factor.

(4) All individuals with IHD or IHD risk equivalents have been called “high risk,” and the treatment goals is to have LDL-cholesterol (LDL-C) levels < 100 mg/dL. Other recommendations are as follows:

(a) If baseline LDL-C is < 100 mg/dL (goal of treatment), patients with IHD should be given instructions on diet and exercise and have levels monitored annually. Though the guidelines suggest an optional goal of obtaining an LDL-C of < 70 mg/dL.

(b) If baseline LDL-C is ≥ 100 mg/dL, an LDL-lowering drug should be started along with therapeutic lifestyle changes (TLCs). Lifestyle-related risk factors include things such as obesity, physical inactivity, elevated triglyceride, low-HDL-C, or metabolic syndrome.

(c) Adult Treatment Panel III did not mandate LDL-lowering drugs for patients with baseline LDL-C levels between 100 and 129 mg/dL but suggested intensifying lifestyle and the optional use of drug therapies to lower LDL to < 100 mg/dL. However, if the patient had elevated triglycerides or low high-density lipoprotein cholesterol (HDL-C), a drug should be started that targets these abnormalities—for example, nicotinic acid or fibric acid if the patient has elevated triglycerides (> 200 mg/dL) or low HDL levels (< 40 mg/dL). If triglycerides are ≥ 500 mg/dL, consider fibrate or niacin before LDL-lowering therapy.

(5) For moderately high risk patients, the recommended LDL-C goal is < 130 mg/dL, but a goal of < 100 mg/dL is an optional goal, based on recent clinical trial

evidence. In addition, a recommendation to initiate TLCs when the patient has an LDL-C ≥ 130 mg/dL.

(6) For moderate risk patients, the recommended LDL-C goal is < 130 mg/dL. In addition, a recommendation to initiate TLC when the patient has an LDL-C ≥ 160 mg/dL.

(7) For lower risk patients, the recommended LDL-C goal is < 160 mg/dL, but again, a recommendation to initiate TLC for those patients with an LDL ≥ 190 mg/dL.

(8) The **metabolic syndrome** is closely linked to insulin resistance, when the normal actions of insulin are impaired. Excess body fat and physical inactivity promote the development of the syndrome; however, some individuals may be predisposed genetically. Patients with three or more of the following characteristics are referred to as having the metabolic syndrome and should be treated accordingly: abdominal obesity, triglycerides > 150 mg/dL, HDL levels of < 40 mg/dL for men and 50 mg/dL for women, blood pressure readings ≥ 130/85 mm Hg, and a fasting serum glucose level ≥ 110 mg/dL.

G. Individual drug classes

1. Bile acid sequestrant resins

a. Mechanism of action. These insoluble, nonabsorbable, anion-exchange resins bind bile acids within the intestines. Bile acids are synthesized from cholesterol.

b. Indications. These agents have been shown to be safe and effective in lowering LDL-C especially in patients with modestly elevated levels, in primary prevention, in young adult men, and postmenopausal women. They are effective in combination with other agents.

c. Currently available agents include the following:

(1) Cholestyramine (Questran): 2-8 g by mouth in two daily doses

(2) Colestipol (Colestid): 2-16 g by mouth in one or two daily doses

(3) Colesevelam (WelChol): 6-7 tablets (625 mg/tablet) by mouth in one daily dose

d. Precautions and monitoring effects

(1) These resins are taken just before meals and present palatability problems in patients.

(2) Gastrointestinal (GI) intolerance, especially constipation, flatulence, and dyspepsia are frequent.

(3) Absorption of many other drugs can be affected. Other drugs should be taken 1 hr before or 4-6 hr after resins.

2. Statins or HMG-CoA reductase inhibitors

a. Mechanism of action. These agents inhibit the enzyme HMG-CoA and reduce cholesterol production.

b. Indications. These agents are effective in lowering LDL levels, while increasing HDL levels and lowering triglyceride levels. They are primarily used to lower LDL cholesterol levels.

c. Currently available agents include the following:

(1) Atorvastatin (Lipitor): 10-80 mg by mouth daily

(2) Fluvastatin (Lescol): 20-80 mg by mouth at bedtime
(3) Lovastatin (Mevacor, various): 10-80 mg by mouth in the evening
(4) Pravastatin (Pravachol): 10-80 mg by mouth daily
(5) Rosuvastatin (Crestor): 5-40 mg by mouth daily
(6) Simvastatin (Zocor, various): 5-80 mg by mouth in the evening

d. Precautions and monitoring effects

(1) GI adverse effects are less frequently seen than with other classes of agents. Headache and dyspepsia frequently occur and should be evaluated, then followed up in 6-8 weeks, and then at each follow-up visit thereafter.
(2) These agents can elevate liver function tests—alanine aminotransferase (ALT) and aspartate aminotransferase (AST), which requires initial evaluation, then after approximately 12 weeks of therapy, then annually thereafter.
(3) Though the incidence of myopathy is believed to be low (0.08%) for lovastatin and simvastatin, elevations of creatine kinase (CK) > 10 times the upper limit of normal have been reported with pravastatin, with similar potential for the other members of the group. Most recently, cerivastatin (Baycol) was voluntarily removed from the market owing to the reported deaths of 31 patients from rhabdomyolysis while receiving the drug alone or in combination with gemfibrozil (Lopid). Consequently, routine monitoring is necessary in all patients, as follows:
(a) Evaluate muscle symptoms and check CK before starting therapy, evaluate in 6-12 weeks after starting therapy, and then at each follow-up visit.
(b) Patients presenting with muscle soreness, tenderness, or pain should have a CK measurement on presentation, to minimize the develop of myopathies.
(c) Concurrent therapy with other agents, including cyclosporine, macrolide antibiotics, azole antifungals, niacin, fibrates, or nefazodone, may increase the risk.

3. Fibric acid derivatives

a. Mechanism of action. These agents are presumed to inhibit cholesterol synthesis and lower LDL-C. They are effective at lowering triglycerides. In some patients, they modestly lower LDL-C and raise HDL-C.

b. Precautions and monitoring effects

(1) GI effects are the most commonly experienced adverse effect.
(2) These agents can elevate liver function tests; routine monitoring should be carried out.

(3) Use with statins can lead to elevated CK, and monitoring is necessary to identify myopathies or rhabdomyolysis.

c. Currently available agents include the following:
(1) Fenofibrate (Tricor, various): 145-160 mg by mouth daily
(2) Gemfibrozil (Lopid, various): 600 mg by mouth twice daily

4. Niacin

a. Mechanism of action. Numerous studies have demonstrated the role of niacin in the lowering of LDL-C and triglycerides through various mechanisms such as participation in tissue respiration oxidation-reduction reactions, which decreases

hepatic LDL and very low-density lipoprotein (VLDL) production; inhibition of adipose tissue lipolysis, decreased hepatic triglyceride esterification, and increases in lipoprotein lipase activity. Table 39-3 presents several agents and their effects on lipoproteins.

b. Indications. Niacin is valuable in treating patients with elevated total cholesterol and low LDL-C levels. It is used in combination therapy.

c. Currently available agents include the following:

(1) Niacin controlled release (Niaspan): 1000-2000 mg by mouth at bedtime

(2) Niacin controlled release (Slo-Niacin): 1-2 grams by mouth at bedtime

(3) Niacin immediate release (Various): 1000-2000 mg by mouth 2-3 times daily.

d. Precautions

(1) Adverse GI effects are experienced with the use of niacin.

(2) Patients may experience flushing and itchy skin, which may be reduced with the administration of 325 mg aspirin about 30 min before the dose.

(3) Cases of severe liver toxicity have been reported. Liver function tests should be performed in patients receiving this drug.

Table 39-3. Selected Agents and Their Effects on Lipoproteins

Class/Agent	Lipid/Lipoprotein Effects	Daily Dose	Adverse Drug Effects
HMG-CoA reductase inhibitors (statins)	LDL: 18%-55% reduction HDL: 5%-15% increase TG: 7%-30% reduction	Lovastatin: 10-80 mg Pravastatin: 20-40 mg Simvastatin: 5-80 mg Fluvastatin: 20-80 mg Atorvastatin: 10-80 mg Rosuvastatin: 5-40 mg	Myopathy, increased liver enzymes
Bile acid sequestrants	LDL: 15%-30% reduction HDL: 3%-5% increase TG: No change or increase	Cholestyramine: 4-16 g Colestipol: 5-20 g Colesevelam: 2.6-3.8 g	GI distress, constipation, decreased absorption of other drugs
Nicotinic acid	LDL: 5%-25% reduction HDL: 15%-	Immediate-release: 1.5-3 g Extended-	Flushing, hyperglycemia, hyperuricemia

	35% increase TG: 20%-50% reduction	release: 1-2 g Sustained-release: 1-2 g	(or gout), upper-GI distress, hepatotoxicity
Fibric acids	LDL: 5%-20% reduction HDL: 10%-20% increase TG: 20%-50% reduction	Gemfibrozil: 600 mg twice daily Fenofibrate: 145-160 mg Clofibrate: 1000 mg twice daily	Dyspepsia, gallstones, myopathy, unexplained non-CHD deaths in WHO study

CHD, coronary heart disease; *GI,* gastrointestinal; *HDL,* high-density lipoprotein; *HMG-CoA,* β-hydroxy-β-methylglutaryl-coenzyme A; *LDL,* low-density lipoprotein; *TG,* triglycerides; *WHO,* World Health Organization.

Third Report of the National Cholesterol Education Program (NCEP): Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III) [NIH Publication No. 01-3670]. Washington DC, U.S. Department of Health and Human Services, May 2001. Available at: www.nhlbi.nih.gov/guidelines/cholesterol/atp3xsum.pdf.

5. Ezetimibe (Zetia)

a. Mechanism of action. First in a new class of lipid-lowering compounds approved by the U.S. Food and Drug Administration (FDA), which works by selectively inhibiting the intestinal absorption of cholesterol and related phytosterols, with a resultant decrease in intestinal cholesterol delivered to the liver, decreased hepatic cholesterol stores, and an increase in the clearance of cholesterol from the blood. Ezetimibe has demonstrated the ability to reduce total cholesterol, LDL-C, apolipoprotein B, and triglyceride levels while increasing HDL levels in patients with hypercholesterolemia.

b. Indications. Ezetimibe as adjunctive therapy along with dietary measures, alone in patients with primary heterozygous familial and nonfamilial hypercholesterolemia, or in combination with the HMG-CoA reductase inhibitors in homozygous familial hypercholesterolemia.

c. Dose. Normal dosing recommendations are a 10-mg dose given once daily.

d. Precautions. As monotherapy, studies to date have not revealed significant side effects above those seen with placebo administration. However, when used in

combination with HMG-CoA reductase inhibitors, reports have described an increased incidence (approximately 1.4%) in the elevation of liver transaminase levels (three times the upper limit of normal) as compared to the incidence of 0.4% with HMG-CoA agents used alone.

6. Combination products

a. Ezetimibe/simvastatin (Vytorin) uses the individual class properties of the HMG-CoA reductase inhibitors (simvastatin) to reduce cholesterol production with the absorption-inhibiting properties of ezetimibe to target cholesterol with two differing mechanisms, which might aid in improving patient compliance.

(1) Available product is supplied as 10/10, 10/20, 10/40, 10/80 combinations of ezetimibe and simvastatin, respectively, and the daily recommended dose is 1 tablet by mouth every evening.

(2) Side effects reflect the additive side effect properties of ezetimibe and simvastatin and warrant consideration when occurring during therapy.

b. Lovastatin/niacin (Advicor) is a product that incorporates the actions of the HMG-CoA reductase inhibitor lovastatin with an extended release niacin component into a single product, using differing mechanisms, which might aid in improving patient compliance.

(1) Available product is supplied as 20/500, 20/750, 20/1000 sustained-release tablet combinations of lovastatin and niacin, respectively. The recommended daily dose is 1-2 tablets by mouth at bedtime.

(2) Side effects reflect the additive side effect properties for both lovastatin and niacin and warrant consideration during therapy.

c. Amlodipine/atorvastatin (Caduet) is a combination product that incorporates the actions of the dihydropyridine calcium channel blocker amlodipine with the lipid-lowering properties of the HMG-CoA reductase inhibitor atorvastatin. The calcium channel blocker offers no benefit for lipid lowering but represents a potentially beneficial product for a patient with coexisting disease states, such as IHD and hypertension, for which the use of a calcium channel blocker would be warranted.

(1) Available product is supplied as 20/500, 20/750, and 20/1000 tablets, which consist of 20 mg of lovastatin and 500, 750, or 1000 mg of an extended release form of niacin. The recommended daily dose is 1-2 tablets by mouth at bedtime.

(2) Side effects reflect the additive side effect properties for both amlodipine and atorvastatin and warrant consideration during therapy.

d. Aspirin, buffered/pravastatin (Pravigard PAC) is a combination product that incorporates the actions of the HMG-CoA reductase inhibitor pravastatin with the antiplatelet properties of aspirin. This product is no longer available in the U.S.

(1) Available product is supplied as 81/20, 81/40, 81/80, 325/20, 325/40, and 325/80 tablet combinations of buffered aspirin and pravastatin, respectively. The recommended daily dose is 1 tablet by mouth daily.

(2) Side effects reflect the additive side effect properties for both aspirin and pravastatin and warrant consideration during therapy.

e. Omega-3-acid ethyl esters (Lovaza) is the first FDA-approved omega 3-fatty acid, which is indicated for patients with elevated levels of triglycerides (> 500 mg/dL).

(1) Available product is supplied as a 1-g capsule; the recommended daily dose is 4 capsules by mouth daily in one-two doses.
P.806

(2) Side effects that have been reported include burping, infection, flu-like symptoms, upset stomach, change in one's sense of taste, back pain, and rash.
f. Hypertension. Treatment of hypertension according to the Joint National Conference VII guidelines has received a class I recommendation based on data from multiple randomized clinical trials with large numbers of patients (A, high) and should be controlled. Class I recommendations are based on evidence or general agreement that a given procedure or treatment is useful and effective (see Chapter 41).
g. Smoking should be stopped if at all possible and has received a class I recommendation based on data derived from a limited number of randomized trials with small numbers of patients (B, intermediate).
(1) Transdermal use of nicotine-containing patches has become one strategy for aiding the cessation of smoking. Products such as Nicotrol, Habitrol, NicoDerm, and others are available in varying strengths to wean patients off the use of cigarettes over an 8- to 12-week period, using descending doses.
(2) Nicotine gum (oral nicotine polacrilex chewing pieces) is available in 2-mg or 4-mg pieces. Nicorette is usually used for 3 months to aid in cessation of smoking.
(3) Bupropion is a prescription antidepressant, which is also marketed under the brand name of Zyban as an aid to smoking cessation.
(4) Varenicline (Chantix) is a recently approved product, which works as agonizers and blocks alpha-4-beta-2 nicotinic acetylcholine receptors in the brain to reduce the craving for nicotine. Therapy is started with a dose of 0.5 mg by mouth daily for 3 days, followed by 0.5 mg tablets twice daily for 4 days, then 1 mg twice daily thereafter for 12 weeks, which can be given for an additional 12 weeks if successful.
h. Obesity should be reduced through diet and an appropriate exercise program in patients with hypertension, hyperlipidemia, or diabetes mellitus and has received a class I recommendation based on expert consensus as the primary basis (C, low).
H. Therapeutic agents
1. Recent evidence-based guidelines have provided recommendations for the treatment of patients with chronic stable angina. (See ID.1. Fraker, TD et. al). Recommendations use four levels of recommendations: Class I (evidence demonstrates that the benefit of the effect/treatment is much greater [>>>] than the risk and should be performed/utilized); Class IIa (evidence demonstrates that the benefit of the effect/treatment is greater [>>] than the risk and it is reasonable to perform or utilize the treatment); Class IIb (evidence demonstrates that the benefit of the effect/treatment is greater than or equal to [≥] risk associated with the effect/treatment, and additional studies would be helpful); and Class III (evidence demonstrates that the risk associated with the effect/treatment is greater than or equal to [≥] the benefit, and should not be utilized or administered). Additionally,

the recommendations include 3 levels of evidence, based on the availability from the literature and include Level A-high level, multiple populations studied, Level B-limited populations studied, and Level C-very limited population studied. For the purposes of this review, we have only included the overall Class recommendation for the respective therapies.

2. Nitrates (e.g., nitroglycerin)

a. Mechanism of action

(1) The primary value of nitrates is venous dilation, which reduces left ventricular volume (preload) and myocardial wall tension, decreasing oxygen requirements (demand).

(2) Nitrates may also reduce arteriolar resistance, helping reduce afterload, which decreases myocardial oxygen demand.

(3) By reducing pressure in cardiac tissues, nitrates also facilitate collateral circulation, which increases blood distribution to ischemic areas.

(4) Pharmacological effects have been shown to improve exercise tolerance, prolong the time to onset of angina, and the appearance of ST-segment depression during exercise testing.

b. Indications

(1) Acute attacks of angina pectoris can be managed with sublingual, transmucosal (Nitrolingual spray or buccal tablets), or intravenous delivery.

(2) Indications include the prevention of anticipated attacks, using tablets (oral or buccal) or transdermal paste or patches. Sublingual nitrates (Nitrostat) can be used before eating, sexual activity, or a known stressful event.

(3) Nitrates are used in treatment of stable angina. They may not be effective as a single agent for treatment of Prinzmetal angina, although some studies have shown nitrates to prevent or reverse vasospasm at varying doses. Intravenous nitroglycerin is used in the immediate treatment of unstable angina and is used for long-term therapeutic relief.

(4) Nitrates used in combination with β-adrenergic blockers have been shown to be more effective than nitrates or β-adrenergic blockers used alone.

c. Choice of preparation should be based on onset of action, duration of action, and patient compliance and preference because all nitrates have the same mechanism of action.

d. Precautions and monitoring effects

(1) To maximize the therapeutic effect, patients should thoroughly understand the use of their specific dosage forms (e.g., sublingual tablets, transdermal patches or pastes, tablets, capsules).

(2) Blood pressure and heart rate should be monitored because all nitrates can increase heart rate while lowering blood pressure.

(3) Preload reduction can be assessed through reduction of pulmonary symptoms such as shortness of breath, paroxysmal nocturnal dyspnea, or dyspnea.

(4) Nitrate-induced headaches are the most common side effect.

(a) Patients should be warned of the nature, suddenness, and potential strength of these headaches to minimize the anxiety that might otherwise occur.
(b) Compliance can be enhanced if the patient understands that the effect is transient and that the headaches usually disappear with continued therapy.
(c) Acetaminophen ingested 15-30 min before nitrate administration may prevent the headache.
e. Effective therapy should result in fewer anginal attacks without inducing significant adverse effects (e.g., postural hypotension, hypoxia). If maximal doses are reached and the patient still experiences attacks, additional agents should be administered.
f. Nitrate tolerance is a major problem with the long-term use of nitroglycerin and long-acting nitrates. Several agents such as ACE inhibitors (sulfhydryl-containing drugs), acetylcysteine, and diuretics have been shown to reverse nitrate tolerance by increasing the availability of sulfhydryl radicals. However, practical considerations suggest that less frequent administration (8-12 hr of nitrate-free intervals) is effective without introducing additional agents.
3. β-Adrenergic blockers. Based on the recently released 2007 Focused guidelines for patients with Chronic Stable Angina, a Class 1A recommendation states that it is beneficial to start and continue beta-blocker therapy indefinitely in all patients who have had MI, acute coronary syndrome, or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.
a. Mechanism of action. β-Blockers reduce oxygen demand, both at rest and during exertion, by decreasing the heart rate and myocardial contractility, which also decreases arterial blood pressure.
b. Indications
(1) These agents reduce the frequency and severity of exertional angina that is not controlled by nitrates.
(2) Nitrates have been combined with calcium antagonists, when slow-release dihydropyridines (e.g., felodipine-Plendil, amlodipine-Norvasc) are preferred over diltiazem (Cardizem) or verapamil (Calan). If patients need to receive a β-adrenergic blocker along with verapamil or diltiazem owing to the added effects, they have the potential to induce bradycardia, AV heart block, and fatigue.
c. Precautions and monitoring effects
(1) Doses should be increased until the anginal episodes have been reduced or until unacceptable side effects occur.
(2) β-Blockers should be avoided in Prinzmetal angina (caused by coronary vasospasm) because they increase coronary resistance and may induce vasospasm.
(3) Asthma is a relative contraindication because all β-blockers increase airway resistance and have the potential to induce bronchospasm in susceptible patients.
(4) Patients with diabetes and others predisposed to hypoglycemia should be warned that β-blockers mask tachycardia, which is a key sign of developing hypoglycemia.
(5) Patients should be monitored for excessive negative inotropic effects. Findings such as fatigue, shortness of breath, edema, and paroxysmal nocturnal dyspnea may signal

developing cardiac decompensation, which also increases the metabolic demands of the heart.

(6) Sudden cessation of β-blocker therapy may trigger a withdrawal syndrome that can exacerbate anginal attacks (especially in patients with IHD) or cause MI.

d. Choice of preparations. All β-blockers are likely to be equally effective for stable (exertional) angina. For further review of β-adrenergic blockers, see Chapter 40. For a list of agents and doses, see Table 39-4.

4. Calcium-channel blockers

a. Mechanism of action. Two actions are most pertinent in the treatment of angina.

(1) These agents prevent and reverse coronary spasm by inhibiting calcium influx into vascular smooth muscle and myocardial muscle. This results in increased blood flow, which enhances myocardial oxygen supply.

(2) Calcium-channel blockers decrease coronary vascular resistance and increase coronary blood flow, resulting in increased oxygen supply.

(3) Calcium-channel blockers decrease systemic vascular resistance and arterial pressure; in addition, they decrease inotropic effects, resulting in decreased myocardial oxygen demand.

b. Indications

(1) Calcium-channel blockers are used in stable (exertional) angina that is not controlled by nitrates and β-blockers and in patients for whom β-blocker therapy is inadvisable. Combination therapy—with nitrates, β-blockers, or both—may be most effective.

(2) These agents, alone or with a nitrate, are particularly valuable in the treatment of Prinzmetal angina. They are considered the drug of choice in treatment of angina at rest.

c. Individual agents

(1) Diltiazem (Cardizem) and verapamil (Calan)

(a) These drugs produce negative inotropic effects, and patients must be monitored closely for signs of developing cardiac decompensation (i.e., fatigue, shortness of breath, edema, paroxysmal nocturnal dyspnea). When coadministered with β-blockers or other agents that produce negative inotropic effects (e.g., disopyramide, quinidine, procainamide, flecainide), the negative effects are additive.

(b) Patients should be monitored for signs of developing bradyarrhythmias and heart block because these agents have negative chronotropic effects.

(c) Verapamil frequently causes constipation, which must be treated as needed to prevent straining at stool, which could cause an increased oxygen demand (Valsalva maneuver). Verapamil is not recommended in patients with sick sinus syndromes, AV nodal disease, or heart failure (HF).

(2) Nifedipine (Procardia)

(a) This calcium-channel blocker is believed to possess the greatest degree of negative inotropic effects compared to the newer second-generation members of this group, amlodipine (Norvasc) and felodipine (Plendil); Nifedipine 10 mg (chewed or swallowed) has been used to treat Prinzmetal angina or refractory spasm in

patients who are not hypotensive. Controversy still exists about the use of short-acting, rapid-release agents such as nifedipine in patients with IHD.

(b) Because nifedipine increases the heart rate somewhat, it can produce tachycardia, which would increase oxygen demand. Coadministration of a β-blocker should prevent reflex tachycardia.

(c) Its potent peripheral dilatory effects can decrease coronary perfusion and produce excessive hypotension, which can aggravate myocardial ischemia.

(d) Dizziness, light-headedness, and lower extremity edema are the most common adverse effects, but these tend to disappear with time or dose adjustment.

(3) Amlodipine (Norvasc), felodipine (Plendil), isradipine (Dynacirc), nicardipine (Cardene), and nisoldipine (Sular) are second-generation dihydropyridine derivative, calcium-channel blockers. They have been used effectively as once- or twice-a-day agents owing to their long activity. Because of the potent negative inotropic effects of these agents, they are not recommended in patients with HF (amlodipine has been shown to have less negative potential in HF than other members of the class).

5. Antiplatelet agents

a. Aspirin: Based on the recently released 2007 Focused Guidelines for patients with Chronic Stable Angina, a Class IA recommendation states that aspirin should be started at 75 to 162 mg per day and continued indefinitely in all patients unless contraindicated.

Table 39-4. Selected Agents and Their Doses in the Treatment of Coronary Artery Disease

Class/Agent	Dose/Dosage Schedule	Comments
Nitrates		
Nitroglycerin sublingual tablets (Nitrostat)	0.3-0.6 mg up to 1.5 mg	Short-term effects: 1-7 min
Nitroglycerin spray (Nitrolingual)	0.4 mg as needed	Similar to sublingual tablets
Nitroglycerin transdermal (Nitro-Dur)	0.2-0.8 mg/hr every 12 hr	Remove patch for 8-12 hr to reduce tolerance
Nitroglycerin	5-200 μg/min	Short acting requiring

intravenous infusion (Various)		continuous infusion and monitoring
Isosorbide mononitrate (Imdur, ISMO, Monoket, Various)	10-40 mg daily in 2 doses	Also available as extended release product for single daily dosing
Isosorbide dinitrate SL	2.5-10 mg SL every 2-3 hours	For Acute angina attacks
Isosorbide dinitrate oral tablets (Various)	5-80 mg, 2-3 times daily	Longer acting up to 8 hr
Isosorbide dinitrate slow-release tablets (Dilatrate-SR)	40 mg once or twice daily	Duration of activity up to 8 hr
β-adrenergic blockers		
Propranolol (Inderal, Various)	20-80 mg twice daily	Possesses both β_1- and β_2-blocker effects
Metoprolol (Lopressor, Various)	50-200 mg twice daily	Possesses β_1-blocker effects
Atenolol (Tenormin, Various)	50-200 mg/day	Possesses β_1-blocker effects
Nadolol (Corgard, Various)	40-80 mg/day	Possesses both β_1- and β_2-blocker effects
Timolol (Blocadren, Various)	10 mg twice daily	Possesses both β_1- and β_2-blocker effects
Acebutolol (Sectral, Various)	200-600 mg twice daily	Possesses β_1-blocker effects

Betaxolol (Kerlone, Various)	10-20 mg/day	Possesses β_1-blocker effects
Bisoprolol (Zebeta, Various)	10 mg/day	Possesses β_1-blocker effects
Esmolol (intravenous) (Brevibloc, Various)	50-300 µg/kg/min	Possesses β_1-blocker effects
Labetalol (Trandate, Various)	200-600 mg twice daily	Possesses both α_1-, β_1-, and β_2-blocker effects
Pindolol (Visken, Various)	2.5-7.5 mg three times daily	Possesses both β_1- and β_2-blocker effects
Carvedilol (Coreg, Various)	25 mg twice daily	Possesses both α_1- β_1-, and β_2-blocker effects
Penbutolol (Levatol)		Possesses both β_1- and β_2-blocker effects
Calcium-channel blockers		
Dihydropyridine derivatives		
Nifedipine (Procardia, Various)	Immediate release; 30-90 mg daily	Short duration of action of 4-6 hr
Amlodipine (Norvasc, Various)	5-10 mg once daily	Long duration of action
Felodipine (Plendil, Various)	5-10 mg once daily	Long duration of action

Isradipine (Dynacirc, Various)	2.5-10 mg twice daily	Intermediate duration of action
Nicardipine (Cardene, Various)	20-40 mg three times daily	Short duration of action
Nisoldipine (Sular)	20-40 mg once daily	Short duration of action
Miscellaneous		
Diltiazem (Cardizem, Various)	Immediate release: 30-80 mg four times daily	Short duration of action; important consideration necessary owing to hypotension, bradycardia, and edema
	Slow release: 120-320 mg once daily	Long duration of action; important consideration necessary owing to hypotension, bradycardia, and edema
Class/Agent		
Verapamil (Calan, Various)	Immediate release: 80-160 mg three times daily	Short duration of action; important consideration necessary owing to hypotension, bradycardia, edema, myocardial depression, and heart failure
	Slow release: 120-480 mg once daily	Long duration of action; important consideration necessary owing to hypotension, bradycardia, edema, myocardial depression, and heart failure

b. Ticlopidine (Ticlid) is a thienopyridine derivative that inhibits platelet aggregation induced by adenosine diphosphate. However, unlike aspirin, it has not been shown to decrease adverse cardiovascular events in patients with stable angina and has been associated with thrombotic thrombocytopenic purpura on an infrequent basis.

c. Clopidogrel (Plavix) is also a thienopyridine derivative related to ticlopidine, but it possesses antithrombotic effects that are greater than those of ticlopidine. Clopidogrel is a therapeutic option in those angina patients who can not take aspirin because of contraindications. Doses of 75 mg daily are recommended to prevent the development of acute coronary syndromes.

d. Based on the recently released 2007 Focused Guidelines for patients with Chronic Stable Angina, a Class IB recommendation states that the use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.

6. ACE inhibitors: Based on the recently released 2007 Focused guidelines for patients with Chronic Stable Angina, the following recommendations have been made for ACE Inhibitors.

a. Class 1A recommendation states that ACE inhibitors should be started and continued indefinitely in all patients with left ventricular ejection fraction ≤40% and in those with hypertension, diabetes, or chronic kidney disease unless contraindicated.

b. Class IB recommendation that ACE inhibitors should be started and continued indefinitely in patients who are not lower risk (lower risk defined as those with normal left ventricular ejection fraction in whom cardiovascular risk factors are well controlled and revascularization has been performed), unless contraindicated.

c. Class IIa recommendation that it is reasonable to use ACE inhibitors among lower-risk patients with mildly reduced or normal left ventricular ejection fraction in whom cardiovascular risk factors are well controlled and revascularization has been performed.

d. Current guidelines do not suggest which agent to use, and it is anticipated that ongoing trials with additional agents will provide additional information regarding dosing regimens and potential differences that might exist among the class of drugs.

7. Angiotensin Receptor Blockers (ARBs): Based on the recently released 2007 Focused guidelines for patients with Chronic Stable Angina, three new recommendations have been made for the use of ARBs in patients with chronic stable angina.

a. Class IA recommendation that ARBs are recommended for patients who have hypertension, have indications for but are intolerant of ACE inhibitors, have heart failure, or have had a myocardial infarction with left ventricular ejection fraction ≤40%.

b. Class IIb recommendation that ARBs may be considered in combination with ACE inhibitors for heart failure due to left ventricular systolic dysfunction.

c. Class IA recommendation that aldosterone blockade is recommended for use in post-MI patients without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a beta blocker, have a left ventricular ejection fraction ≤40%, and have either diabetes or heart failure.

8. Chelation Therapy: Based on the recently released 2007 Focused Guidelines for patients with Chronic Stable Angina, a class IIIC recommendation stated that Chelation therapy (intravenous infusions of ethylenediamine tetraacetic acid or EDTA) is not recommended for the treatment of chronic angina or arteriosclerotic cardiovascular disease and may be harmful because of its potential to cause hypocalcemia. Class IIIC states that the risk is greater than the benefit and should not be used.

III. ACUTE CORONARY SYNDROME (ACS)

A. Definition. ACS is a relatively new term that has been introduced into the medical literature to describe any pattern of clinical symptoms that reflects the development of acute MI (Figure 39-2). This category includes the symptoms related to ST-segment elevated myocardial infarction (STEMI), non-ST-segment elevated myocardial infarction (NSTEMI), and unstable angina.

B. Incidence. It has been estimated that nearly 8 million patients seen in emergency departments each year in the United States are seen for chest pain, and that up to 5 million of these patients are admitted to the hospital. More than 1.5 million of the patients admitted to the hospital are admitted with an ACS (330,000 with STEMI, and 1.24 million with UA and NSTEMI).

C. Classification of patients presenting with presumed ACS is critical to the appropriate determination of prognosis as well as clinical interventions. In ACS owing to STEMI and NSTEMI, a portion of the cardiac muscle suffers a severe and prolonged restriction of oxygenated coronary blood. In the majority of patients, the cause is an occlusive or near-occlusive thrombus overlying or adjacent to a ruptured atherosclerotic plaque. This results in cellular ischemia, tissue injury, and tissue necrosis. About 1.5 million people suffer an AMI each year. UA is believed to indicated an impending AMI, and the goal of treatment is to prevent the development of the AMI.

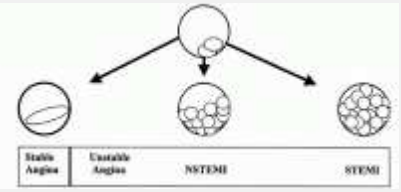

Figure 39-2. Evolutionary progression of ACSs. As atherosclerosis (most common cause of ischemic heart disease) advances, the reduction in myocardial perfusion results in the development of the ACS owing to either unstable angina, NSTEMI, or STEMI. The thrombi, which form in unstable angina, NSTEMI, STEMI, are rich in both fibrin and platelets. [Adapted from Vanscoy G. Integrating new fibrinolytic findings into AMI reperfusion and combination therapy: 2002 and beyond. Paper presented at the meeting of the Delaware Valley Chapter of the Pennsylvania Society of Health-Systems Pharmacists, March 7, 2002.]

1. STEMI. A condition that requires immediate reperfusion therapy, if possible through either thrombolysis or percutaneous coronary intervention (PCI)

a. The introduction of thrombolysis or PCI for the management of STEMI has demonstrated ability to remove the offending thrombus from the affected coronary artery.

b. Damage to the myocardial tissue is not routinely reversible, as in the case of angina pectoris, owing to potential death of myocardial tissue if reperfusion does not take place early enough.

2. UA and NSTEMI. Similar conditions for which there is no evidence showing the benefit to patients of reperfusion therapy. Specific guidelines have been developed for the diagnosis and management of these conditions. Up to 25% of patients who have both NSTEMI and elevated cardiac enzymes eventually develop Q-wave MI; the remaining patients develop non-Q-wave MI. Patients with UA carry a 10%-20% risk of progression to an MI if untreated; treatment has been shown to reduce the risk to 5%-7%.

D. Diagnosis. The ECG is at the center of the decision pathway for the evaluation and management of patients with ACS and is confirmed with serial cardiac markers in > 90% of patents presenting with significant ST-segment elevation. Patients who present without ST-segment elevation are considered to have either UA or NSTEMI; the final diagnosis is made later, after the presence or absence of serial cardiac markers is determined.

1. Diagnostic test results. The development of an ACS is a life-threatening emergency; diagnosis is presumed—and treatment is instituted—based on the patient's complaints and the results of an immediate 12-lead ECG. Laboratory tests and further diagnostic tests can rule out or provide confirmation and help identify the locale and extent of myocardial damage.

2. Serial 12-lead ECG. Abnormalities may be absent or inconclusive during the first few hours after presentation of the ACS and may not aid the diagnosis in about 15% of the cases. When present, characteristic findings show progressive changes.

a. First, ST-segment elevation (injury current) appears in the leads, reflecting the injured area. Peaked upright or inverted T waves usually indicate acute myocardial injury, the early stages of a transmural Q-wave MI. Persistent ST depression may also indicate a non-Q-wave MI.

b. Q waves developing (indicating necrosis) is generally diagnostic of an MI, but can be seen in other conditions.

c. Unequivocal diagnosis can be made only in the presence of all three abnormalities. However, the manifestations depend on the area of injury. For example, in non-Q-wave infarction, only ST-segment depression may appear.

d. The most serious arrhythmic complication of an acute MI is ventricular fibrillation, which may occur without warning.

e. Ventricular premature beats (VPBs) are the most commonly encountered arrhythmias and may require treatment.

3. Cardiac enzymes

a. Creatine kinase-heart muscle (CK-MB) is first elevated 3-12 hr after the onset of pain, peaks in 24 hr, and returns to baseline in 48-72 hr. Other conditions elevate the CK-MB enzyme but do not demonstrate the typical pattern of rise and fall as seen in an MI. Until recently, CK-MB had been the principal serum cardiac marker used in the evaluation of ACS.

b. Cardiac troponin I (cTnI) and **cardiac troponin T** (cTnT) are even more sensitive than MB-CK. They represent a powerful tool for risk stratification and have greater sensitivity and specificity than CK-MB. However, they do provide a low sensitivity in the early phases of an MI (< 6 hr after symptom onset) and require repeat measurements at 8-12 hr, if negative. Levels increase 3-12 hr after the onset of pain, peak at 24-48 hr, and return to baseline over 5-14 days.

c. Lactate dehydrogenase (LDH) is followed for its characteristic patterns of rise and fall. The ratio of LDH_1:LDH_2 is helpful in diagnosing an MI. LDH assays are being replaced by cTnT assays.

4. Cardiac imaging. As cardiac enzymes assays improve, the use of noninvasive cardiac imaging techniques are not indicated for initial diagnosis of an MI. Tests include ^{99m}Tc-pyrophosphate scintigraphy, myocardial perfusion imaging, radionucleotide ventriculography, two-dimensional echocardiography, and coronary angiography.

E. Signs and symptoms

1. Recent evidence-based clinical guidelines indicate a class I recommendation for patients with suspected ACS with chest discomfort at rest for longer than 20 min; hemodynamic instability or recent syncope or presyncope should be strongly considered for immediate referral to an emergency department or specialized chest pain unit. The foremost characteristic of ACS is persistent, severe chest pain or

pressure, commonly described as crushing, squeezing, or heavy (likened to having an elephant sitting on the chest). The pain generally begins in the chest and, like angina, may radiate to the left arm, the abdomen, back, neck, jaw, or teeth. The onset of pain generally occurs at rest or with normal daily activities; it is not commonly associated with exertion.

2. Other common complaints include a sense of impending doom, sweating, nausea, vomiting, and difficulty breathing. In some patients, fainting and sudden death may be the initial presentation of ACS.

3. Observable findings include extreme anxiety, restless, agitated behavior, and ashen pallor.

4. Some patients, particularly those with diabetes or the elderly, may experience only mild or indigestion-like pain or a clinically silent MI, which may only manifest in worsening heart failure, loss of consciousness, acute confusion, dyspnea, a sudden drop in blood pressure, or a lethal arrhythmia.

F. Overall treatment goals in ACS

1. To relieve chest pain and anxiety

2. To reduce cardiac workload and stabilize cardiac rhythm

3. To prevent/reduce myocardial damage by limiting the area affected and preserving pump function

4. To prevent or arrest complications, such as lethal arrhythmias, AMI, HF, or sudden death

5. To reopen (or reperfuse) closed coronary vessels with thrombolytic drugs and/or PCI if indicated

G. Treatment of UA and NSTEMI

1. Anti-ischemic therapy

a. Current evidence-based clinical guidelines indicate class I recommendations for the following therapeutic interventions in patients with UA or NSTEMI:

(1) Bedrest with continuous ECG monitoring for ischemia and arrhythmia detection in patients with ongoing rest pain.

(2) Patients with UA/NSTEMI with ongoing ischemic discomfort should receive SL Nitroglycerin (NTG) 0.4 mg every 5 minutes × 3 doses, after which time reassess for potential need for intravenous nitroglycerin. Intravenous NTG is indicated in the first 48 h in patients with UA/NSTEMI for treatment of persistent ischemia, heart failure, or hypertension.

(3) Supplemental oxygen for patients with cyanosis or respiratory distress and continued need for supplemental oxygen in the presence of hypoxemia.

(4) Aspirin in doses of 162-325 mg (chewable) should be given to patients with UA/NSTEMI as soon as possible, if the patient has not already taken.

(5) An oral β-adrenergic blocker should be administered within the first 24 hours to all patients without contraindications. Intravenous β-adrenergic blockers should only be used for specific indications and not as routine therapy.

(6) In patients with continuing or frequently recurring ischemia when β-adrenergic blockers are contraindicated, a non-dihydropyridine calcium antagonist (i.e., diltiazem or verapamil) is recommended as initial therapy in the absence of severe left ventricular dysfunction or other contraindications. In patients presenting with

left ventricular dysfunction, current evidence shows that these agents might worsen the clinical status.

(7) An ACE inhibitor should be administered orally within the first 24 h to patients with pulmonary congestion or left ventricular ejection fraction ≤40% in the absence of hypotension (systolic blood pressure less than 100 mm Hg or less than 30 mm Hg below baseline) or known contraindications. An ARB may be used for ACE inhibitor intolerant patients.

2. Therapeutic agents. Table 39-4 lists selected agents and dosing regimens.

a. Nitrates (e.g., nitroglycerin). (See II.H.)

b. Morphine. Recent guidelines for UA/NSTEMI and STEMI from 2007 have stated that morphine is still considered a Class I recommendation in patients with STEMI, however, in UA/NSTEMI patients it might increase the rate of adverse events, and has been downgraded from a Class I recommendation to a Class IIa. However, in the absence of contraindications, morphine sulfate can be administered to patients if there is uncontrolled ischemic pain despite the use of NTG provided additional therapy is used to treat the underlying ischemia.

(1) Mechanism of action. Morphine causes venous pooling and reduces preload, cardiac workload, and oxygen consumption. Morphine should be administered intravenously, starting with 2 mg and titrating at 5- to 15-min intervals until the pain is relieved or toxicity becomes evident.

(2) Indications. Morphine sulfate is a reasonable choice for myocardial pain and anxiety in doses of 1-5 mg IV every 5-30 minutes as needed, based on level of patient pain and blood pressure.

(3) Precautions and monitoring effects

(a) Because morphine increases peripheral vasodilation and decreases peripheral resistance, it can produce orthostatic hypotension and fainting.

(b) Patients should be monitored for hypotension and signs of respiratory depression.

(c) Morphine has a vagomimetic effect that can produce bradyarrhythmias. If ECG monitoring reveals excess bradycardia, it should be reversed by administering atropine (0.5-1 mg).

(d) Nausea and vomiting may occur, especially with initial doses, and patients must be protected against aspiration of stomach contents.

(e) Severe constipation is a potential problem with ongoing morphine administration. The patient may need to use a Valsalva maneuver while straining at the stool, which can produce bradycardia or can overload the cardiac system and trigger cardiac arrest. Docusate (100 mg twice daily) is a useful prophylactic.

c. Oxygen is required at 2-4 L/min via nasal cannula in any patient who has chest pain and who may be ischemic. Mild hypoxemia is common in acute MI patients. Increasing the oxygen content of the blood, thus improving oxygenation of the myocardium, is a top priority as continuing hypoxia rapidly increases myocardial damage.

d. Thrombolytic agents have not demonstrated beneficial clinical outcomes in the absence of STEMI. Studies carried out to date have failed to show benefit with using thrombolytics in UA versus standard therapy to prevent MI. In addition, thrombolytic agents actually increased the risk of MI in such patients. Therefore, based on current evidence-based guidelines, thrombolytic agents are not recommended in the management of ACS without ST-segment elevation.

3. Antiplatelet and anticoagulation therapy. Table 39-5 lists selected agents and dosing regimens.

a. Current evidence-based clinical guidelines indicate class I recommendations for the following therapeutic interventions in patients with UA or NSTEMI:

(1) Antiplatelet therapy should be initiated promptly. Aspirin should be administered as soon as possible after presentation and continued indefinitely.

(2) Clopidogrel should be administered to hospitalized patients who are unable to take aspirin because of hypersensitivity or major gastrointestinal intolerance.

(3) In hospitalized patients for whom an early noninterventional approach is planned, clopidogrel should be added to aspirin as soon as possible on admission and administered for at least 1 month and ideally up to 1 year.

(4) In patients for whom a percutaneous coronary intervention (cardiac catheterization) is planned, clopidogrel should be started with a loading dose of 300-600 mg followed by 75 mg daily for at least one month but ideally up to 1 year in patients who are not at high risk for bleeding, or an intravenous Glycoprotein IIb/IIIa inhibitor (GP IIb/IIIa). Abciximab is indicated only if there is no appreciable delay to angiography and PCI is likely to be performed; otherwise, IV eptifibatide or tirofiban is the preferred choice of GP IIb/IIIa inhibitor. In patients unable to take clopidogrel, ticlopidine, 500 mg load followed by 250 mg orally daily is an alternative.

(5) In patients taking clopidogrel in whom elective coronary artery bypass grafting (CABG) is planned, the drug should be withheld for 5-7 days.

Table 39-5. Select Antiplatelet/anticoagulant Agents Used in the Treatment of STEMI Patients

Class/Agent	Dosing Regimen		Level of Evidence (Guidelines)
Oral antiplatelets/anticoagulants			
Aspirin*	**For Acute STEMI patients:**		
	162 mg should be chewed by patients who have not taken aspirin before presentation with STEMI.		Class I
	For all post-PCI STEMI stented patients:		
	1.	162-325 mg daily for at least 1 month after bare-metal stent implantation, 3 months after sirolimus-eluting stent, and 6 months after paclitaxel-eluting stent, and then indefinitely at doses of 75-132 mg daily.	Class IIa
	2.	In patients where there is concern of bleeding, 75 to 162 mg (lower-dose) aspirin is reasonable during the initial period after stent implantation.	Class IIa
Clopidogrel (Plavix)	1.	75 mg orally daily added to ASA in STEMI patients.	Class I-Post STEMI patients
	2.	Treatment should be at least 14 days.	Class I-Post STEMI patients
	3.	Loading dose of 300	Class IIa-Post

		mg orally (patients <75 years who receive fibrinolytic therapy or who do not receive reperfusion therapy)	STEMI patients
	4.	75 mg orally per day, long-term maintenance therapy (e.g., 1 year) (regardless of whether they undergo reperfusion with fibrinolytic therapy).	Class IIa-Post STEMI patients
	For all post-PCI STEMI stented patients:		
	5.	Receive a drug-eluting stent (DES), clopidogrel 75 mg daily should be given for at least 12 months if patients are not at high risk of bleeding.	Class I
	6.	Receive a bare metal stent (BMS), clopidogrel should be given for a minimum of 1 month and ideally up to 12 months (unless the patient is at increased risk of bleeding; then it should be given for a minimum of 2 weeks).	Class I
	7.	For patients taking clopidogrel for whom CABG is planned, if possible, the drug should be withheld for	Class I

		at least 5 days, and preferably for 7, unless the urgency for revascularization outweighs the risks of bleeding.	
Warfarin	1.	Managing warfarin to INR = 2.0 to 3.0 in post-STEMI patients Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with increased risk of bleeding and should be monitored closely.	Class I-Post-STEMI patients
	2.	In patients requiring warfarin, clopidogrel, and aspirin therapy, an INR of 2 to 2.5 is recommended with low dose aspirin (75 to 81 mg) and a 75 mg dose of clopidogrel.	
Parenteral antiplatelets/anticoagulants			
Heparin (UFH)	1.	Bolus of 60 U/kg, maximum 4000 U IV followed by an initial infusion 12 U/kg per hour, (maximum of 1000 U/h) in patient at high risk for systemic emboli (large or anterior MI, atrial fibrillation, previous embolus, known LV thrombus, or cardiogenic shock.	Class I-Post STEMI

	2.	IV or SQ UFH or with subcutaneous LMWH for at least 48 hours. In patients whose clinical condition necessitates prolonged bedrest and/or minimized activities, it is reasonable that treatment be continued until the patient is ambulatory.	Class IIa-Post-STEMI and not undergoing reperfusion, and no contraindications.
	3.	SQ UFH, 7,500 units to 12,500 units twice daily for prophylaxis for deep venous thrombosis (DVT) until completely ambulatory, may be useful, but the effectiveness of such a strategy is not well established in the contemporary era of routine aspirin use and early mobilization.	Class IIb
	For STEMI patients receiving PCI:		
	4.	Bolus of 70-100 U/kg, and maintenance to target 1.5-2 times aPTT, if no GP IIb/IIIa previously given. However, if a GP IIb/IIIa has been given previously, 50-70 U/kg bolus, and maintenance to target, as above.	Class I

Enoxaparin (Lovenox)	**Patients undergoing reperfusion with fibrinolytics:**		
	For patients less than 75 years of age:		
	1.	30 mg intravenous bolus, followed in 15 minutes by 1.0 mg/kg SQ every 12 hours (serum creatinine <2.5 mg per dL in men and 2.0 mg per dL in women).	Class I-Post-STEMI
	For patients ≥75 years of age,		
	2.	0.75 mg/kg SQ every 12 hours. (No loading dose) Maintenance doses with enoxaparin should continue for the duration of the index hospitalization, up to 8 days. Regardless of age, if the creatinine clearance (using the Cockroft-Gault formula) during the course of treatment is estimated to be less than 30 mL per minute, the subcutaneous regimen is 1.0 mg per kg every 24 hours.	Class I-Post-STEMI
Fondaparinux (Arixtra)	**Patients undergoing reperfusion with fibrinolytics:**		
	1.	2.5 mg IV, followed	Class I-Post STEMI

		by 2.5 mg SQ once daily. (serum creatinine is less than 3.0 mg per dL)	
	2.	Maintenance doses with fondaparinux should be continued for the duration of the index hospitalization, up to 8 days.	Class I-Post STEMI
Bivalirudin (Angiomax)	**Patients undergoing PCI:**		
	1.	Initial IV bolus dose of 0.75 mg/kg, followed by 1.75 mg/kg/hour infusion for the duration of the procedure.	Class I-Post STEMI
Abciximab (Reopro)	0.25 mg/kg IV bolus followed by infusion of 0.125 mcg/kg/min for 12-24 hours		Class IIa, for use in addition to aspirin and heparin in STEMI patients for whom catheterization and PCI are planned just before PCI
			Class III, in STEMI patients for whom PCI is not planned
Eptifibatide (Integrilin)	180 mcg/kg IV bolus followed by infusion of 2.0 mcg/kg/minute for 72-96 hours.		Class I, for use in addition to aspirin and heparin in STEMI patients for whom catheterization and PCI are planned,
Tirofiban (Aggrestat)	0.4 mcg/kg/minute for 30 minutes followed by infusion of		

	0.1 mcg/kg/minute for 48-96 hours.	and in patients just before PCI. Class IIa, in addition to aspirin and a LMWH or UFH in STEMI patients without continuing ischemia who have no other high-risk features and for whom PCI is not planned. Class IIb, in addition to aspirin and LMWH or UFH in STEMI patients without continuing ischemia who have no other high-risk features and for whom PCI is not planned.

* Assuming no aspirin resistance, allergy, or increased risk of bleeding.

aPTT, activated partial thromboplastin time; CABG, coronary artery bypass graft; IV, intravenous; PCI, percutaneous coronary intervention; SQ, subcutaneously.

(6) Anticoagulant therapy should be added to antiplatelet therapy in UA/NSTEMI patients as soon as possible after presentation. For patients in whom an invasive strategy is selected, regimens with established efficacy with a high level of evidence include enoxaparin and heparin, and those with a lesser level of established evidence include bivalirudin and fondaparinux. For patients in whom a conservative strategy is selected, regimens using either enoxaparin or heparin or fondaparinux can be utilized. In patients in whom a conservative strategy is selected and who have an increased risk of bleeding, fondaparinux is preferable.
(7) A platelet glycoprotein IIb/IIIa antagonist should be administered, in addition to aspirin and heparin, to patients for whom catheterization and PCI are planned. The agent may also be administered just before PCI.

b. Current evidence-based clinical guidelines indicate a class IIa recommendation for the following therapeutic interventions in patients with UA or NSTEMI:
(1) For patients in whom an initial conservative strategy is selected and who have recurrent ischemic discomfort with clopidogrel, ASA, and anticoagulant therapy, it is acceptable to add a GP IIb/IIIa antagonist before diagnostic angiography.
(2) For patients in whom an initial invasive strategy is selected, it is reasonable to initiate antiplatelet therapy with both clopidogrel (loading dose followed by daily maintenance dose) and an intravenous GP IIb/IIIa inhibitor. Abciximab is indicated only if there is no appreciable delay to angiography and PCI is likely to be performed; otherwise, IV eptifibatide or tirofiban is the preferred choice of GP IIb/IIIa inhibitor.
(3) For patients in whom an initial invasive strategy is selected, it is reasonable to omit administration of an intravenous GP IIb/IIIa antagonist before diagnostic angiography if bivalirudin is selected as the anticoagulant and at least 300 mg of clopidogrel was administered at least 6 h earlier than planned catheterization or PCI.
c. Current evidence-based clinical practice guidelines indicate a class IIb recommendation for the following therapeutic intervention in patients with UA or NSTEMI: Eptifibatide or tirofiban, in addition to aspirin and LMWH or UFH, to patients without continuing ischemia who have no other high-risk features and for whom PCI is not planned.
d. Current evidence-based clinical practice guidelines indicate a class III recommendation for the following therapeutic interventions in patients with UA or NSTEMI:
(1) The risks associated with parenterally administered thrombolytic therapy in patients without acute STEMI are much greater than the benefits and should not be used.
(2) The risks associated with the administration of abciximab in patients for whom PCI is not planned are much greater than the benefits and should not be used.

H. STEMI

1. Of the more than 1.5 million patients admitted to hospitals with acute coronary syndromes (ACS) each year, more than 300,000 of them will be diagnosed with STEMI. Approximately 90% of those diagnosed with STEMI will have complete occlusion of the infarct-related artery by a thombus.
2. When the lesion ruptures, it triggers the release of adenosine diphosphate (ADP), serotonins, and thromboxane A_2, which leads to platelet aggregation and the formation of the primary clot. Thromboplastin, released from the injured vessel initiates the clotting cascade, and the resulting fibrin, traps red blood cells (RBCs), platelets, and plasma protein to form an intraluminal thrombus. The subsequent clot dissolution is caused by the conversion of plasminogen to plasmin, which is mediated by plasminogen activators.
3. According to updated management guidelines (see I.D.6.), all patients with STEMI should receive either primary percutaneous coronary intervention (PCI), within 90 minutes of first medical contact (Class IA recommendation) or fibrinolytic therapy within 30 minutes of hospital presentation if they cannot be transferred to a

PCI center and undergo PCI within 90 min of first medical contact, unless fibrinolytic therapy is contraindicated (Class IB) recommendation.

4. It is beyond the realm of this text to expand on the clinical implications for primary PCI, facilitated PCI, and rescue PCI, as described in the most recent 2007 Focused STEMI guidelines. Consequently the review will focus strictly on the pharmacologic agents recommended for use in the STEMI patient population, which include; fibrinolytics, analgesics, anticoagulants, thienopyridines, antiplatelets, ACE inhibitors, ARBs, and β-adrenergic receptor blockers

as either primary treatment or secondary preventive and long-term management, as discussed in the guidelines.

a. Fibrinolytics. Administration of thrombolytic agents causes the thrombus clot to be lysed when administered early after symptom onset (< 6-12 hr) and to restore blood flow. The conversion of plasminogen to plasmin promotes fibrinolysis and breakdown of the clot.

(1) Indications

(a) Thrombolytic agents were used in patients with STEMI with chest pain < 6-12 hr. Successful early reperfusion has been shown to reduce infarct size, improve ventricular function, and improve mortality. However, benefits may be seen in patients using thrombolytic therapy as late as 12 hr after pain starts.

(b) Intravenous administration of a recombinant tissue-plasminogen activator (t-PA) such as alteplase (Activase), a recombinant plasminogen activator (r-PA) such as reteplase (Retavase), or tenecteplase (TNKase), may restore blood flow in an occluded artery if administered within 12 hr of an acute MI, although < 6 hr is optimal. The goal of treatment of STEMI patients is to initiate thrombolytic therapy within 30-60 min of arrival in an emergency room.

(i) t-PA is relatively fibrin specific and is able to lyse clots without depleting fibrinogen, and TNKase has an even greater fibrin specificity. Streptokinase activates the fibrinolytic system and has a greater likelihood of causing systemic effects than t-PA. This effect may result in a greater degree of systemic bleeding compared with t-PA, r-PA, and TNK.

(ii) Though which agent—t-PA, r-PA, and TNK—is best is still controversial, most studies have shown that each agent, when used early, can reopen (reperfuse) occluded coronary arteries and reduce mortality from STEMI. However, considerations such as ease of use, onset of action, incidence of bleed, and cost are important factors in determining which agent to use for a given hospital and patient.

(2) Individual agents

(a) Alteplase (Activase)

(i) Absolute contraindications to t-PA include active internal bleeding; recent cerebrovascular accident (CVA); intracranial neoplasm; aneurysm; pregnancy; arteriovenous malformations; recent (within 2 months) intracranial surgery, spinal surgery, or trauma; and severe uncontrolled hypertension, bleeding diathesis, or hemorrhagic ophthalmic conditions.

(ii) A **front-loaded regimen**—an accelerated infusion that consists of a total dose of 100 mg or less that is given over 1.5 hr—may be more beneficial. The initial dose of 15 mg is given as an IV bolus, 1-2 min, while an infusion is begun to:
(a) Infuse t-PA at the rate of 0.75 mg/kg over 30 min (not to exceed 50 mg)
(b) Followed by t-PA infused at 0.5 mg/kg over 60 min (not to exceed 35 mg)
(iii) An alternate dosing regimen is based on the patient's weight.
(a) Dosage for patients > 65 kg. A total of 100 mg of t-PA is generally administered to all patients who weigh > 65 kg over a 3-hr period. Though many regimens have been used, generally speaking, 6-10 mg of t-PA is given as an IV bolus over 1-2 min, followed by the remaining infusion rates over the next 3 hr: a 54-60-mg IV infusion over the 1st hr, a 20-mg IV infusion over the 2nd hr, and a 20-mg IV infusion over the 3rd hr.
(b) Dosage for patients < 65 kg. A dose of 1.25 mg/kg is given over a 3-hr period, with 10% of the total dose given initially as a bolus dose over 1-2 min.
(b) Reteplase (Retavase)
(i) Absolute contraindications to reteplase are similar to those for t-PA, though additional cautionary statements are given for patients with severely impaired renal function or liver function.
(ii) Dosing is initiated with the intravenous administration of 10 U over a 2-min period, and then repeated after 30 min, if there are no complications.

(c) Tenecteplase (TNKase)
(i) Absolute contraindications to tenecteplase are similar to those for t-PA and r-PA with the following addition: use with caution in patients recently receiving a glycoprotein IIb/IIIa agent, pregnant patients, elderly patients, patients with endocarditis, and patients with severe liver disease.
(ii) Tenecteplase is approved for use in acute treatment of MI at doses of 30-50 mg (based on the patient's weight) as a single IV bolus over 10-15 sec. Rapid rate of administration, fibrin specificity, fewer bleeding complications compared to t-PA, and superiority over t-PA in late-treated patients make tenecteplase a likely candidate to replace t-PA as the agent of choice in STEMI.
(3) Adjunctive fibrinolysis therapy. The recently released 2007 Focused Guidelines for ST-segment elevated MI discuss the use of analgesia, β-adrenergic receptor blockers, anticoagulants, and thienopyridines, in STEMI patients based on the quality of available literature for their use.
(a) Analgesia
(i) Morphine sulfate in doses of 2-4 mg IV in increments of 2-8 mg IV, repeated in 5-15 minute intervals is the analgesic of choice for the management of pain due to STEMI (Class IC)
(ii) Patients taking NSAIDs with the exception of aspirin, before being treated for STEMI should stop taking them due to increased risk of mortality, reinfarction, hypertension, heart failure, and myocardial rupture associated with their use (Class IC)

(b) Aspirin administered (160-325 mg) during acute thrombolytic therapy has been shown to affect thrombolysis positively by preventing platelet aggregation and has reduced postinfarct mortality. Doses of aspirin, 75-162 mg daily have been recommended for long-term use at hospital discharge. Other agents include ticlopidine (Ticlid), and clopidogrel (Plavix).

(c) β-Adrenergic blockers

(i) Oral β-blocker therapy should be given during the first 24 hours to STEMI patients not having (a) signs of heart failure, (b) evidence of a low output state, (c) increased risk for cardiogenic shock, or other contraindications to receiving β-blockers (Class IB).

(ii) Patients who may initially present with contraindications to receiving β-blockers during the initial 24 hours of their STEMI should be reevaluated for receiving such therapy as a secondary preventive measure (Class IC).

(iii) Patients with moderate or severe left ventricular failure should receive β-blocker therapy as a secondary preventive measure, but with a gradual dose escalation titration (Class IB).

(iv) It is reasonable to administer an IV β-blocker to a STEMI patient at the time of presentation if they have hypertension and do not have any of the above contraindications to receiving them (Class IIa).

(v) IV β-blockers should not be used in STEMI patients who have any of the above mentioned contraindications to their use as the risk is much greater than or equal to their benefit in these patients (Class IIIA).

(d) Anticoagulants

(i) Patients who undergo reperfusion with fibrinolytics should receive anticoagulant therapy for at least 48 hours, and ideally throughout the hospitalization, up to 8 days (Class IC).

(ii) Patients who receive anticoagulants for more than 48 hours should receive an agent other than unfractionated heparin (UFH) due to the increased risk of heparin-induced thrombocytopenia with its prolonged use (Class IA).

(iii) Anticoagulant regimens with established efficacy in STEMI include:

- —Unfractionated heparin (UFH): Initial IV bolus of 60 units per kg (maximum 4,000 units) followed by an IV infusion of 12 units/kg/hour (maximum of 1,000 units/hour) initially. The dose should be adjusted to maintain an activated partial thromboplastin time (aPTT) of 1.5-2 times control (Class IC).
- —Enoxaparin: An initial 30 mg IV bolus, followed in 15 minutes by a subcutaneous injection of 1 mg/kg every 12 hours (assuming serum creatinine is less than 2.5 mg/dL in men, 2.0 mg/dL in women in patients less than

75 years of age). For patients 75 years of age and older, the IV bolus dose

is eliminated and the patient is given a subcutaneous dose of 0.75 mg per kg every 12 hours. CAUTION: In all patients, if the creatinine clearance is estimated to be less than 30 mL per minute, the dosing regimen should be changed to 1 mg per kg every 24 hours. The current guidelines recommend the use of maintenance dosing of enoxaparin for the duration of hospitalization, up to a maximum of 8 days (Class IA).

- —Fondaparinux: An initial dose of 2.5 mg intravenously and subsequent subcutaneous injections of 2.5 mg given once daily (assuming serum creatinine is less than 3.0 mg/dL). The current guidelines, as in the case of enoxaparin, recommend the use of maintenance dosing of fondaparinux for the duration of hospitalization, up to a maximum of 8 days (Class IB).

(iv) Anticoagulants have also been shown to be effective in STEMI patients prior to undergoing PCI, with the following dosing recommendations:

- —UFH: For prior treatment, administer additional boluses of UFH as needed to support the procedure, but take into account whether other agents such as GP IIb/IIIa receptor antagonists (Class IC). Bivalirudin can also be used in patients previously treated with UFH (Class IC).
- —Enoxaparin (Lovenox): For prior treatment, if the last subcutaneous dose of enoxaparin was given within the previous 8 hours, no additional drug is needed; however, if the last dose was administered 8-12 hours earlier, an intravenous dose of 0.3 mg/kg should be given (Class IB).
- —Fondaparinux (Arixtra): For prior treatment, administer additional intravenous treatment with an anticoagulant possessing anti-IIa activity, but take into account whether GP IIb/IIIa receptor antagonists have been administered (Class IC). However, due to the risk of catheter thrombosis, fondaparinux is not recommended as the sole anticoagulant to support PCI and requires the addition of another anticoagulant with anti-IIa activity (Class IIIC).

(v) Anticoagulants (non-UFH regimens) have also been recommended for patients with STEMI who do not undergo reperfusion therapy for the duration of the initial hospitalization (Class IIa). Dosing regimens that can be used include enoxaparin or fondaparinux in the same dosing regimens as in those patients receiving fibrinolytic (see iv above).

(e) Thienopyridines

(i) Clopidogrel (Plavix) should be added to aspirin in STEMI patients regardless of whether they undergo reperfusion with fibrinolytics or do not receive reperfusion (Class IB). Doses of 75 mg by mouth daily should be administered. Treatment should continue for at least 14 days (Class IB).

(ii) Patients receiving clopidogrel (Plavix) who are planning on undergoing CABG should discontinue therapy 5-7 days prior to the surgery, unless the urgency of the procedure outweighs the risks of excess bleeding (Class IB).

(iii) Patients less than 75 years receiving fibrinolytic therapy or who do not receive reperfusion therapy, it is reasonable to administer an oral clopidogrel loading dose of 300 mg. (No data are available to guide decision making regarding an oral loading dose in patients ≥75 years of age.) (Class IIa).
(iv) Long-term maintenance therapy (e.g., 1 year) with clopidogrel (75 mg per day orally) can be useful in STEMI patients regardless of whether they undergo reperfusion with fibrinolytic therapy or do not receive reperfusion therapy (Class IIa).
(4) Secondary Prevention and Long-Term Management: (a) Table 39-2 provides a combination of risk factors as well as disease-based recommendations, which have been incorporated into the recently updated 2007 Focused Guidelines for STEMI patients. Additionally, the guidelines include recommendations made for select pharmacologic agents which include aspirin, clopidogrel, warfarin, ACE inhibitors, angiotensin receptor blockers, aldosterone blockade, and β-blockers, and influenza vaccination.
(a) Aspirin
(i) For all post-PCI STEMI patients receiving a stent (bare metal, sirolimus, paclitaxel), without contraindications to aspirin, should receive aspirin 162 to 325 mg daily for 1-6 months depending on the type of stent used. After the

initial 1-6 months a maintenance dose of aspirin should be continued at a dose of 75 to 162 mg daily, indefinitely (Class IB).
(ii) In those patients where there is concern for a high risk of bleeding, doses of aspirin, 75 mg to 162 mg daily is reasonable during the initial period and after stent implantation (Class IIa).
(b) Clopidogrel (Plavix)
(i) For all post-PCI patients who receive a drug-eluting stent (sirolimus, paclitaxel), clopidogrel 75 mg daily should be given for at least 12 months if patients are not at high risk of bleeding (Class IB).
(ii) For post-PCI patients receiving a bare metal stent clopidogrel should be given for a minimum of 1 month and ideally up to 12 months (unless the patient is at increased risk of bleeding; then it should be given for a minimum of 2 weeks) (Class IB).
(iii) For all STEMI patients not undergoing stenting (medical therapy alone or PTCA without stenting), treatment with clopidogrel should continue for at least 14 days (Class IB).
(iv) Long-term maintenance therapy (e.g., 1 year) with clopidogrel (75 mg per day orally) is reasonable in STEMI patients regardless of whether they undergo reperfusion with fibrinolytic therapy or do not receive reperfusion therapy (Class IIa).
(c) Warfarin
(i) Managing warfarin to an INR = 2.0 to 3.0 in post-STEMI patients when clinically indicated (e.g., atrial fibrillation, left ventricular thrombus) and paroxysmal or chronic atrial fibrillation or flutter, is recommended (Class IA).

(ii) Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with increased risk of bleeding and should be monitored closely (Class IB).
(iii) Patients requiring warfarin, clopidogrel, and aspirin therapy, an INR of 2 to 2.5 is recommended with low-dose aspirin (75 to 81 mg) and a 75 mg dose of clopidogrel (IC).
(d) ACE Inhibitors (see Table 41-4 **for listing of available agents)**
(i) ACE inhibitors should be started and continued indefinitely in all patients recovering from STEMI with LVEF ≤40% and in those patients with hypertension, diabetes, or chronic kidney disease, unless contraindicated (Class IA).
(ii) ACE inhibitors should be started and continued indefinitely in patients recovering from STEMI who are not lower risk (lower risk defined as those with normal LVEF in whom cardiovascular risk factors are well controlled and revascularization has been performed), unless contraindicated (Class IB).
(iii) Among lower risk patients recovering from STEMI (i.e., those with normal LVEF in whom cardiovascular risk factors are well controlled and revascularization has been performed) use of ACE inhibitors is reasonable (Class IIa).
(e) Angiotensin Receptor Blockers (ARBs) (see Table 41-4 **for listing of available agents**
(i) ARBs are recommended in patients who are intolerant of ACE inhibitors and have had an STEMI with LVEF ≤40% or have heart failure (Class IA).
(ii) ARB therapy is beneficial in other patients who are ACE-inhibitor intolerant and have hypertension (Class IB).
(iii) Considering use in combination with ACE inhibitors in systolic dysfunction heart failure may be reasonable (Class IIb).
(f) Aldosterone Blocking Agents (Spironolactone-Aldactone, Eplerenone-Inspra)
(i) Use of aldosterone blockade in post-STEMI patients without significant renal dysfunction or hyperkalemia is recommended in patients who are already receiving therapeutic doses of an ACE inhibitor and beta blocker, have an LVEF of ≤40% and have either diabetes or heart failure (Class IA).
(g) β-Adrenergic Blockers
(i) It is beneficial to start and continue β-blocker therapy indefinitely in all patients who have had an STEMI, acute coronary syndrome, or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated (Class IA).

(h) Influenza Vaccine (Fluvirin, FluMist, Various)
(i) Patients with cardiovascular disease should have an annual influenza vaccination (Class IB).
I. Complications. MI potentiates many complications; the most common of these include the following:
1. Lethal arrhythmias. See Chapter 40 for a detailed discussion.
2. Heart failure. See Chapter 42 for a detailed discussion.
a. Left ventricular failure causes pulmonary congestion. Diuretics, especially furosemide, help reduce the congestion.

b. ACE inhibitors, β-adrenergic blockers, angiotensin receptor blockers, and direct-acting aldosterone antagonists play a key role in the treatment of heart failure.

3. Cardiogenic shock

a. In this life-threatening complication, cardiac output is decreased and pulmonary artery and pulmonary capillary wedge pressures are increased. This typically occurs when the area of infarction exceeds 40% of muscle mass and compensatory mechanisms only strain the already compromised myocardium.

b. Vasopressors: for example, norepinephrine (Levophed), epinephrine (Adrenalin), dopamine (high doses), and vasopressin (Pitressin, various)-enhance blood pressure through β-adrenergic stimulation and V1 receptors (vasopressin) and may be indicated, as per ACLS protocol.

c. Inotropic drugs—for example, epinephrine, dopamine (middle doses), dobutamine, isoproterenol (Isuprel), and digoxin (Lanoxin)—are rapidly acting agents used to increase myocardial contractility and improve cardiac output.

d. Vasodilators—for example, nitroprusside (Nipride)—reduce preload; they lower pulmonary capillary wedge pressure by dilating veins and reduce afterload by decreasing resistance to left ventricular ejection.

e. Additional treatment may include invasive procedures such as intra-aortic balloon pumping.

P.824

STUDY QUESTIONS

Directions for questions 1-16: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Exertion-induced angina, which is relieved by rest, nitroglycerin, or both, is referred to as

(A) Prinzmetal angina.

(B) unstable angina.

(C) stable angina.

(D) variant angina.

(E) preinfarction angina.

View Answer***1. The answer is C[seeand].*****2. Myocardial oxygen demand is increased by all of the following factors *except***

(A) exercise.

(B) smoking.

(C) cold temperatures.

(D) isoproterenol.

(E) metoprolol.

View Answer***2. The answer is E[see].*****3. Which of the following agents used in Prinzmetal angina has spasmolytic actions, which increase coronary blood supply?**

(A) nitroglycerin

(B) diltiazem
(C) timolol
(D) isosorbide mononitrate
(E) propranolol

View Answer***3. The answer is B[see].*****4. Patients with angina pectoris receiving propranolol plus diltiazem must be monitored for which adverse drug effect?**

(A) decreased cardiac output
(B) decreased heart rate
(C) increased heart rate
(D) Both A and B
(E) Both A and C

View Answer***4. The answer is D[see].*****5. The development of ischemic pain occurs when the demand for oxygen exceeds the supply. Determinants of oxygen demand include all of the following choices *except* which one?**

(A) contractile state of the heart
(B) myocardial ejection time
(C) left ventricular volume
(D) right atrial pressure
(E) systolic pressure

View Answer***5. The answer is D[see].*****6. Myopathy is an adverse effect of all the following agents *except***

(A) lovastatin.
(B) simvastatin.
(C) pravastatin.
(D) gemfibrozil.
(E) colestipol.

View Answer***6. The answer is E[see].*****7. Which of the following would not represent current therapeutic options in patients presenting with acute coronary syndrome (ACS) who are classified as having non-ST-segment elevated myocardial infarction (NSTEMI)?**

(A) sublingual nitroglycerin
(B) β-adrenergic blockers
(C) aspirin
(D) morphine
(E) tenecteplase

View Answer***7. The answer is E[see].***P.825

Directions for questions 8-9: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

For questions 8-9: A 55-year-old man arrives in the emergency room of the local hospital approximately 6 hr after developing chest pain with the signs and symptoms of an acute ST-segment elevated myocardial infarction (STEMI). This is the second

such attack within the last 4 months, and the patient has not altered his lifestyle to eliminate important risk factors. Previous therapy included a thrombolytic agent (name unknown), a blood thinner, and daily aspirin.

8. Which of the following agents should be recommended during the acute myocardial infarction to help prevent sudden death?

I. atenolol

II. metoprolol

III. aspirin

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***8. The answer is E[see].*****9. Which of the following is considered a component of acute coronary syndrome (ACS)?**

I. unstable angina

II. non-ST-segment elevated myocardial infarction (NSTEMI)

III. ST-segment elevated myocardial infarction (STEMI)

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***9. The answer is E[see].*****Directions for questions 10-14:** Each of the following descriptions is most closely related to one of the following drugs. The descriptions may be used more than once or not at all. Choose the **best** answer, **A-E.**

10. tirofiban

(A) Inhibition of intestinal absorption of cholesterol

(B) Lowering of low-density lipoproteins (LDLs), triglycerides, and increased high-density lipoprotein (HDL) along with anti-inflammatory effects

(C) Recommendations for this agent have been substantially expanded beyond an alternative for aspirin-intolerant patients, due to recent trials demonstrating its benefit in select ACS patients.

(D) Recommended for acute coronary syndrome (ACS) patients who cannot tolerate aspirin

(E) Recommended over unfractionated heparin (UFH) as an anticoagulant in patients with unstable angina (UA) or non-ST-segment elevated myocardial infarction (NSTEMI)

View Answer***10. The answer is C[see].*****11. enoxaparin**

(A) Inhibition of intestinal absorption of cholesterol

(B) Lowering of low-density lipoproteins (LDLs), triglycerides, and increased high-density lipoprotein (HDL) along with anti-inflammatory effects

(C) Recommendations for this agent have been substantially expanded beyond an alternative for aspirin-intolerant patients, due to recent trials demonstrating its benefit in select ACS patients.
(D) Recommended for acute coronary syndrome (ACS) patients who cannot tolerate aspirin
(E) Recommended over unfractionated heparin (UFH) as an anticoagulant in patients with unstable angina (UA) or non-ST-segment elevated myocardial infarction (NSTEMI)

View Answer***11. The answer is E[see].*****12. simvastatin**

(A) Inhibition of intestinal absorption of cholesterol
(B) Lowering of low-density lipoproteins (LDLs), triglycerides, and increased high-density lipoprotein (HDL) along with anti-inflammatory effects
(C) Recommendations for this agent have been substantially expanded beyond an alternative for aspirin-intolerant patients, due to recent trials demonstrating its benefit in select ACS patients.
(D) Recommended for acute coronary syndrome (ACS) patients who cannot tolerate aspirin
(E) Recommended over unfractionated heparin (UFH) as an anticoagulant in patients with unstable angina (UA) or non-ST-segment elevated myocardial infarction (NSTEMI)

View Answer***12. The answer is B[see].*****13. clopidogrel**

(A) Inhibition of intestinal absorption of cholesterol
(B) Lowering of low-density lipoproteins (LDLs), triglycerides, and increased high-density lipoprotein (HDL) along with anti-inflammatory effects
(C) Recommendations for this agent have been substantially expanded beyond an alternative for aspirin-intolerant patients, due to recent trials demonstrating its benefit in select ACS patients.
(D) Recommended for acute coronary syndrome (ACS) patients who cannot tolerate aspirin
(E) Recommended over unfractionated heparin (UFH) as an anticoagulant in patients with unstable angina (UA) or non-ST-segment elevated myocardial infarction (NSTEMI)

View Answer***13. The answer is D[see III.H.3.e].*****14. ezetimibe**

(A) Inhibition of intestinal absorption of cholesterol
(B) Lowering of low-density lipoproteins (LDLs), triglycerides, and increased high-density lipoprotein (HDL) along with anti-inflammatory effects
(C) Recommendations for this agent have been substantially expanded beyond an alternative for aspirin-intolerant patients, due to recent trials demonstrating its benefit in select ACS patients.
(D) Recommended for acute coronary syndrome (ACS) patients who cannot tolerate aspirin
(E) Recommended over unfractionated heparin (UFH) as an anticoagulant in patients with unstable angina (UA) or non-ST-segment elevated myocardial infarction (NSTEMI)

View Answer***14. The answer is A[see].***

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* II.C.1.a, b, c, d, e *and* f*].*

Classic, or stable, angina refers to the syndrome in which physical activity or emotional excess causes chest discomfort, which may spread to the arms, legs, neck, and so forth. This type of angina is relieved promptly (within 1-10 mins) with rest, nitroglycerin, or both.

2. The answer is E *[see* I.F.2; Table 39-1*].*

Owing to the β-adrenergic blocking effects of metoprolol (e.g., decreased heart rate, decreased blood pressure, decreased inotropic effect), there is a net decrease in myocardial oxygen demand. This is the direct opposite of the effects seen with the β-agonist isoproterenol. Exercise, cigarette smoking, and exposure to cold temperatures have all been shown to increase myocardial oxygen demand.

3. The answer is B *[see* II.H.4.c*].*

Calcium-channel blocking agents such as diltiazem have been shown to be capable of reversing spasm and, therefore, increasing coronary blood flow in Prinzmetal angina. The calcium-channel blockers have proven benefit in the treatment of Prinzmetal angina, a syndrome believed due more to a spastic event than to a fixed coronary occlusion.

4. The answer is D *[see* II.H.4.c.(1).(a); II.H.3.b.(2)*].*

Because propranolol (a β-adrenergic blocker) and diltiazem (a calcium-channel blocker) both reduce heart rate (a negative chronotropic effect) and reduce cardiac contractility (negative inotropic effect), patients receiving both drugs must be monitored for signs of decompensation (reduced cardiac output) and bradyarrhythmias.

5. The answer is D *[see* I.F.2*].*

As with most muscles in the body, the contractile force of the heart dictates the amount of oxygen that the heart needs to perform efficiently. Consequently, as contractility decreases, the oxygen needs of the heart increase. As contractility continues to decrease, the volume of fluid in the left ventricle increases owing to poor muscle performance and increasing tension within the ventricle, resulting in additional oxygen requirements. As the amount of tension within the ventricle increases per cardiac cycle, there is again an added requirement for oxygen by the heart muscle.

6. The answer is E *[see* II.G.2.d.(3)*].*

Myopathy is an adverse effect of all the HMG-CoA reductase inhibitors (lovastatin, simvastatin, pravastatin, atorvastatin, fluvastatin, and rosuvastatin), and the combination of the fibric acid derivatives (gemfibrozil, fenofibrate, and clofibrate) has been shown to increase the creatine kinase levels and predispose patients to myopathies and rhabdomyolysis.

7. The answer is E *[see* III.G.2.d*].*

Tenecteplase is considered a tissue plasminogen activator which converts plasminogen to plasmin, thus promoting fibrinolysis. However, the most recent

national guidelines for the treatment of UA and NSTEMI do not include the use of fibrinolytics as part of the management of patients with UA or NSTEMI. They are primarily indicated for patients with STEMI.

8. The answer is E (I, II, and III) *[see III.H.3.b-c].*

The most recently introduced guidelines for the treatment of STEMI patients include the use of oral beta-blocker therapy initiated within the first 24 hours, assuming that there are no contraindications for their use (heart failure, heart block, asthma, etc.). Additionally, the guidelines add that it is acceptable to administer an IV beta blocker to STEMI patients who are also hypertensive assuming that there are no contraindications for their use, as listed above. Aspirin continues to be a very important part of the initial therapy for STEMI patients. The most recent guidelines provide a Class I recommendation for the administration of aspirin as early as possible, pending no contraindications in a dose of 162-325 mg.

9. The answer is E (I, II, III) *[see* I.E.2*].*

During recent years, there has been an attempt to link the various clinical symptoms of IHD into key categories, based on the presentation and symptoms at the time of evaluation. ACS refers to those situations that reflect an acute ischemic event and includes UA, NSTEMI, and STEMI. Clinical guidelines have incorporated treatment modalities based on these three presentations; UA and NSTEMI have similar recommended therapies and STEMI, has different treatment guidelines. Stable angina is not considered one of the ACS but represents the starting point for the progression of atherosclerosis, resulting in IHD.

10. The answer is C *[see III.H.4.d].*

Tirofiban is an antiplatelet that is referred to as a glycoprotein IIb/III, a receptor antagonist. This class of drugs works to prevent platelet aggregation by inhibiting the interaction between the primary binding site of platelets and has been shown to be effective in the prevention of thrombosis.

11. The answer is E *[see* III.G.3.b.(2); Table 39-5*].*

Enoxaparin is an example of a LMWH. As a group, the major advantage of these drugs over the more traditional heparin is that they exhibit a more predictable anticoagulant response. Owing to their lower molecular weight and decreased binding to plasma proteins, they have better bioavailability than heparin. In addition, their decrease in plasma protein binding and binding to the endothelium results in half-lives that are 2-4 times longer than that of heparin. Current clinical practice guidelines recommend enoxaparin over heparin in patients with UA or NSTEMI, unless CABG is planned within 24 hr.

12. The answer is B *[see* II.G.2.b*].*

Simvastatin is one of the five currently available HMG-CoA reductase inhibitors that have been shown to significantly reduce LDL levels and nonfatal MI or CHD (30%-40% reduction). Recent studies have demonstrated that inflammation is an important mechanism involved in ACS and that statins exert an important anti-inflammatory effect within coronary arteries (independent of their cholesterol-lowering effects).

13. The answer is D *[see* III.H.3.e*].*
The most recently introduced guidelines for the treatment of ACS has incorporated recent trials, which have shown the value of clopidogrel in various patient populations with ACS. It is no longer viewed as merely as an alternative to aspirin in those who can't take aspirin, but rather an “add-on” therapy for patients receiving aspirin who suffer from ACS.
14. The answer is A *[see* II.G.5.a*].*
Ezetimibe is the first in a new class of lipid-lowering compounds approved by the FDA, which reduces cholesterol levels via a different mechanism of action. By selectively blocking the intestinal absorption of cholesterol, it is able to stop one of the major pathways responsible for increasing available cholesterol within the body. Ezetimibe has demonstrated the ability to reduce total cholesterol, LDL, apolipoprotein B, and triglyceride levels while increasing HDL levels in patients with hypercholesterolemia. Simvastatin has recently been incorporated into a combination product with ezetimibe (Vytorin), which uses the individual class properties of the HMG-CoA reductase inhibitors (simvastatin) to reduce cholesterol production with the absorption-inhibiting properties of ezetimibe to target cholesterol with two different mechanisms, which might also aid in improving patient compliance with taking the medication.

Cardiac Arrhythmias

Alan H. Mutnick

I. INTRODUCTION.

Sudden death from cardiac causes is believed to account for approximately 50% of all deaths from cardiovascular causes, with the majority of sudden deaths being caused by acute ventricular tachyarrhythmias. This would appear to create greater need for the knowledge necessary to appropriately use antiarrhythmics for this high-risk patient population. However, previously conducted studies have cast doubt on the true place of antiarrhythmics in the treatment and prevention of cardiac arrhythmias. Studies such as the Cardiac Arrhythmia Suppression Trial (CAST) have demonstrated that certain classes of antiarrhythmics increased mortality in patients treated with antiarrhythmics as compared to placebo. Since the release of the data from the CAST trial, subsequent studies have confirmed the finding that certain antiarrhythmics do possess “proarrhythmic” effects when used injudiciously. Consequently, the use of trial and error to determine antiarrhythmic therapy has given way to an era of outcome-based antiarrhythmic drug decision making. By understanding the causes of arrhythmias and being aware of drug-drug and drug-target interactions, we are more likely to understand the key considerations to maximize therapeutic strategies while minimizing drug-induced toxicities.

A. Definition. Cardiac arrhythmias are deviations from the normal heartbeat pattern. They include **abnormalities of impulse formation,** such as heart rate, rhythm, or site of impulse origin, and **conduction disturbances,** which disrupt the normal sequence of atrial and ventricular activation.

B. Electrophysiology

1. Conduction system

a. Two electrical sequences that cause the heart chambers to fill with blood and contract are initiated by the conduction system of the heart.

(1) Impulse formation, the first sequence, takes place when an electrical impulse is generated automatically.

(2) Impulse transmission, the second sequence, occurs once the impulse has been generated, signaling the heart to contract.

b. Four main structures composed of tissue that can generate or conduct electrical impulses make up the conduction system of the heart.

(1) The **sinoatrial (SA) node,** in the wall of the right atrium, contains cells that spontaneously initiate an action potential. Serving as the main pacemaker of the heart, the SA node initiates 60-100 beats/min.

(a) Impulses generated by the SA node trigger atrial contraction.

(b) Impulses travel through internodal tracts—the anterior tract, middle tract (Wenckebach bundle), posterior tract (Thorel bundle), and anterior interatrial tract (Bachmann's bundle) (Figure 40-1).

(2) At the **atrioventricular (AV) node,** situated in the lower interatrial septum, the impulses are delayed briefly to permit completion of atrial contraction before ventricular contraction begins.

(3) At the **bundle of His—**muscle fibers arising from the AV junction—impulses travel along the left and right bundle branches, located on either side of the intraventricular septum.
(4) The impulses reach the **Purkinje fibers,** a diffuse network extending from the bundle branches and ending in the ventricular endocardial surfaces. Ventricular contraction then occurs.
c. Latent pacemakers. The AV junction, bundle of His, and Purkinje fibers are latent pacemakers; they contain cells capable of generating impulses. However, these regions have a slower firing rate than the SA node. Consequently, the SA node predominates except when it is depressed or injured, which is known as **overdrive suppression.**
2. Myocardial action potential. Before cardiac contraction can take place, cardiac cells must depolarize and repolarize.
P.829

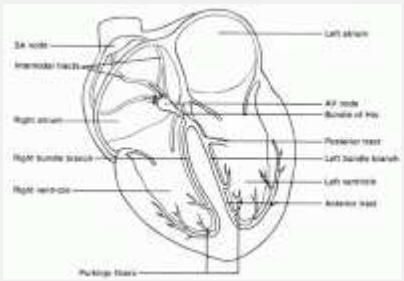

Figure 40-1. Electrical pathways of the heart. *AV,* atrioventricular; *SA,* sinoatrial.

a. Depolarization and **repolarization** result from changes in the electrical potential across the cell membrane, caused by the exchange of sodium and potassium ions.
b. Action potential, which reflects this electrical activity, has five phases (Figure 40-2).
(1) Phase 0 (rapid depolarization) takes place as sodium ions enter the cell through fast channels; the cell membrane's electrical charge changes from negative to positive.
(2) Phase 1 (early rapid repolarization). As fast sodium channels close and potassium ions leave the cell, the cell rapidly repolarizes (i.e., returns to resting potential).
(3) Phase 2 (plateau). Calcium ions enter the cell through slow channels while potassium ions exit. As the cell membrane's electrical activity temporarily stabilizes, the action potential reaches a plateau (represented by the notch at the beginning of this phase in Figure 40-2).

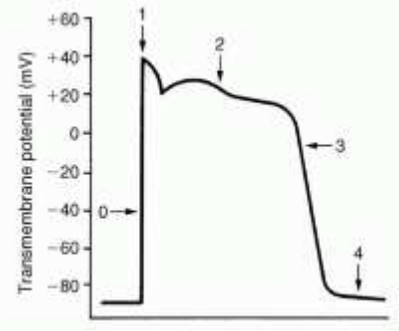

Figure 40-2. Myocardial action potential curve. This curve represents ventricular depolarization-repolarization. Phases: *0,* rapid depolarization; *1,* early rapid repolarization; *2,* plateau; *3,* final rapid repolarization; *4,* slow depolarization.

(4) Phase 3 (final rapid repolarization). Potassium ions are pumped out of the cell as the cell rapidly completes repolarization and resumes its initial negativity.
(5) Phase 4 (slow depolarization). The cell returns to its resting state with potassium ions inside the cell and sodium and calcium ions outside.
c. During both depolarization and repolarization, a cell's ability to initiate an action potential varies.
(1) The cell cannot respond to any stimulus during the **absolute refractory period** (beginning during phase 1 and ending at the start of phase 3).
(2) A cell's ability to respond to stimuli increases as repolarization continues. During the **relative refractory period,** which occurs during phase 3, the cell can respond to a strong stimulus.
(3) When the cell has been completely repolarized, it can again respond fully to stimuli.
d. Cells in different cardiac regions depolarize at different speeds, depending on whether fast or slow channels predominate.
(1) Sodium flows through fast channels; calcium flows through slow channels.
(2) Where fast channels dominate (e.g., in cardiac muscle cells), depolarization occurs quickly. Where slow channels dominate (e.g., in the electrical cells of the SA node and AV junction), depolarization occurs slowly.
3. Electrocardiography. The electrical activity occurring during depolarization-repolarization can be transmitted through electrodes attached to the body and transformed by an **electrocardiograph (ECG) machine** into a series of waveforms (ECG waveform). Figure 40-3 shows a normal ECG waveform.
a. The **P wave** reflects atrial depolarization.
b. The **PR interval** represents the spread of the impulse from the atria through the Purkinje fibers.
c. The **QRS complex** reflects ventricular depolarization. (Phase O)

d. The **ST segment** represents phase 2 of the action potential—the absolute refractory period (part of ventricular repolarization).

e. The **T wave** shows phase 3 of the action potential—ventricular repolarization.

C. Classification. Arrhythmias generally are classified by origin (i.e., supraventricular or ventricular).

1. Supraventricular arrhythmias stem from enhanced automaticity of the SA node (or another pacemaker region, above the bundle of His) or from reentry conduction.

2. Ventricular arrhythmias occur below the bundle of His, when an ectopic (abnormal) pacemaker triggers a ventricular contraction before the SA node fires (e.g., from a conduction disturbance or ventricular irritability).

3. Special note

a. Torsades de pointes has received increased attention during recent years as a major proarrhythmic event, which has been reported with antiarrhythmic drug therapy. It is defined as a polymorphic ventricular tachycardia with a twisting QRS complex morphology, which sometimes occurs with drugs that prolong ventricular repolarization (QT interval widening). Though initial reports of torsades de pointes centered around antiarrhythmic drugs (quinidine), today > 50 drugs, both antiarrhythmic agents and other classes of drugs such as antibiotics, have been shown to affect the duration of the QT interval and have been associated with this arrhythmia.

b. A Web site devoted to providing education and research on drug-induced arrhythmias, especially those due to prolongation of the QT interval on the electrocardiogram (ECG),

is available. The site, http://www.torsades.org/medical-pros/drug-lists/drug-lists.htm, is currently maintained by Dr. Raymond Woosley.

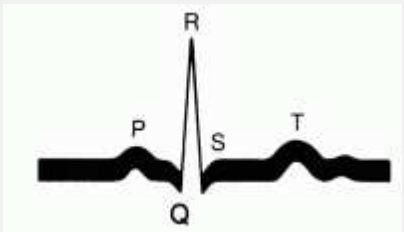

Figure 40-3. Normal ECG waveform.

c. Woosley and colleagues have established the International Registry for Drug-Induced Arrhythmias, to which one can submit a suspected “drug-induced arrhythmia event.” The registry also provides a list of drugs reported to prolong the QT interval or cause torsades de pointes (www.Torsades.org). Four drug lists were created

based on the relative risk of inducing torsades de pointes (TdP) or a prolonged QT interval.

d. It is beyond the intention of this chapter to provide a comprehensive listing, as done on Dr. Woosley's website. However, the four categories of drug lists include the following with select examples.

i. List 1: Drugs that are generally accepted by authorities to have a risk of causing Torsades de Pointes; i.e., amiodarone (Cordarone®), Bepridil (Vascor®), chlorpromazine (Thorazine®), clarithromycin (Biaxin®), disopyramide (Norpace®), dofetilide (Tikosyn®), erythromycin (Erythrocin®), haloperidol (Haldol®), ibutilide (Corvert®), methadone (Dolophine®), pentamidine (NebuPent®), pimozide (Orap®), procainamide (Pronestyl®), and quinidine®) (Quinaglute®).

ii. List 2: Drugs that in some reports have been associated with Torsades de Pointes and/or QT prolongation, but at this time lack substantial evidence for causing Torsades de Pointes; i.e., amantadine (Symmetrel®), azithromycin (Zithromax®), dolasetron (Anzemet®), fosphenytoin (Cerebyx®), gatifloxacin (Tequin®), granisetron (Kytril®), isradipine (DynaCirc®), moxifloxacin (Avelox®), nicardipine (Cardene®), ondansetron (Zofran®), risperidone (Risperdal®), dalmeterol (Serevent®), and voriconazole (Vfend®).

iii. List 3: Drugs to be avoided for use in patients with diagnoses or suspected congenital long QT syndrome. (Drugs on Lists 1,2, and 4 are also included here.) i.e., albuterol (Proventil®), amiodarone (Cordarone®), azithromycin (Zithromax®), bepridil (Vascor®), clarithromycin (Biaxin®), disopyramide (Norpace®), dobutamine (Dobutrex®), dofetilide (Tikosyn®), dolasetron (Anzemet®), dopamine (Intropin®), erythromycin (Erythrocin®), flecainide (Tambocor®), fosphenytoin (Cerebyx®), gatifloxacin (Tequin®), granisetron (Kytril®), isradipine (DynaCirc®), levofloxacin (Levaquin®), methadone (Dolophine®), moxifloxacin (Avelox®), ondansetron (Zofran®), procainamide (Pronestyl®), salmeterol (Serevent®), sotalol (Betapace®), and voriconazole (Vfend®).

iv. List 4: Drugs that, in some reports, have been weakly associated with Torsades de Pointes and/or QT prolongation but that are unlikely to be a risk for Torsades de Pointes when used in usual recommended dosages, and in patients without other risk factor (e.g., concomitant QT prolonging drugs, bradycardia, electrolyte disturbances, congenital long QT syndrome, concomitant drugs that inhibit metabolism). i.e., amitriptyline (Elavil®), amoxapine (Asendin®), ciprofloxacin (Cipro®), citalopram (Celexa®), doxepin (Sinequan®), fluconazole (Diflucan®), intraconazole (Sporanox®), ketoconazole (Nizoral®), sertraline (Zoloft®), and trimethoprim-sulfamethoxazole (Bactrim®).

D. Causes

1. Precipitating causes. Arrhythmias result from various conditions, including

a. Heart disease—for example, infection, coronary artery disease (CAD), valvular heart disease, rheumatic heart disease, ischemic heart disease

b. Myocardial infarction (MI)

c. Toxic doses of cardioactive drugs (e.g., digitalis preparations)

d. Increased sympathetic tone

e. Decreased parasympathetic tone

f. Vagal stimulation (e.g., straining at stool)

g. Increased oxygen demand (e.g., from stress, exercise, fever)

h. Metabolic disturbances

i. Cor pulmonale

j. Systemic hypertension

k. Hyperkalemia/hypokalemia

l. Chronic obstructive pulmonary disease (COPD)—for example, chronic bronchitis, emphysema

P.832

Figure 40-4. Reentry arrhythmias. **A.** Two waves of excitation going in opposite directions. **B.** A unidirectional wave of excitation. **C.** Reexcitation of tissue in a slow conduction area.

m. Thyroid disorders

n. Drug therapy (both antiarrhythmic and non-antiarrhythmic drugs)

2. Mechanisms of arrhythmias. Abnormal impulse formation, abnormal impulse conduction, or a combination of both may give rise to arrhythmias.

a. Abnormal impulse formation may stem from:

(1) Depressed automaticity, as in escape beats and bradycardia

(2) Increased automaticity, as in premature beats, tachycardia, and extrasystole

(3) Depolarization and triggered activity, leading to sustained ectopic firing

b. Abnormal impulse conduction results from:

(1) A conduction block or delay

(2) Reentry occurs when an impulse is rerouted through certain regions in which it has already traveled. Thus the impulse depolarizes the same tissue more than once, producing an additional impulse (Figures 40-4 and 40-5). Reentry sites include the SA and AV nodes as well as various accessory pathways in the atria and ventricles (Figure 40-6). For reentry to occur, the following conditions must exist:

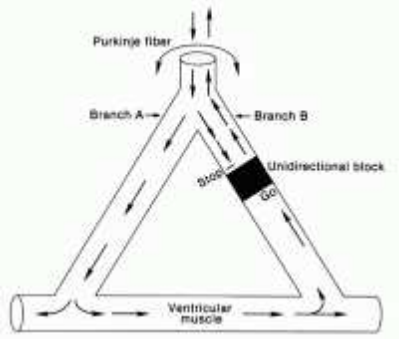

Figure 40-5. Ventricular reentry: a branched Purkinje fiber joining ventricular muscle. The *dark area* represents the site of a unidirectional block. In this depolarization region, the impulse heading toward the atrioventricular node continues upward, whereas the impulse traveling toward the muscle is blocked. Because retrograde conduction in *branch B* is slow, cells in *branch A* have time to recover and respond to the reentrant impulse.

P.833

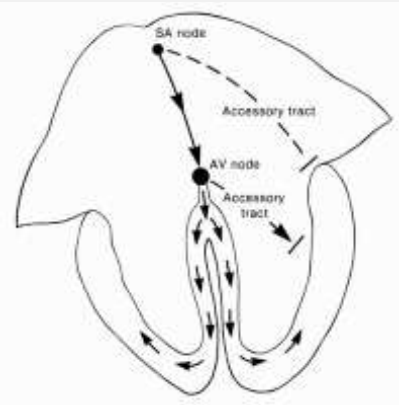

Figure 40-6. Reentry sites. *AV,* atrioventricular; *SA,* sinoatrial.

(a) Markedly shortened refractoriness or a slow conduction area that allows an adequate delay so that depolarization recurs

(b) Unidirectional conduction

E. Pathophysiology. Arrhythmias may decrease cardiac output, reduce blood pressure, and disrupt perfusion of vital organs. Specific pathophysiological consequences depend on the arrhythmia present.

F. Clinical evaluation

1. Physical findings. Although some arrhythmias are silent, most produce signs and symptoms. Only an ECG can definitively identify an arrhythmia. However, physical findings may suggest which arrhythmia is present; they also yield information about the patient's clinical status and may help identify associated complications. **Signs and symptoms** that typically accompany arrhythmias include

a. Chest pain

b. Anxiety and confusion (from reduced brain perfusion)

c. Dyspnea
d. Skin pallor or cyanosis
e. Abnormal pulse rate, rhythm, or amplitude
f. Reduced blood pressure
g. Palpitations
h. Syncope
i. Weakness
j. Convulsions
k. Hypotension
l. Decreased urinary output

2. Diagnostic test results

a. An **ECG** can identify a specific arrhythmia; usually, a 12-lead ECG is used.

b. Electrophysiological (EP) testing. This intracardiac procedure determines the location of

P.834

ectopic foci and bypass tracts and may help assess therapeutic response to antiarrhythmic drug therapy. It also can determine the need for a pacemaker or surgical intervention.

(1) Intracardiac catheters and pacing wires are placed transvenously or transarterially.

(2) The heart is divided into imaginary sections, and each section is stimulated until an arrhythmia is induced. The section in which the arrhythmia occurs is identified as the origin of the ectopic foci.

c. His bundle study, a type of EP testing, can locate the origin of a heart block or reentry pattern.

d. Laboratory findings. Some arrhythmias result from electrolyte abnormalities—most commonly, hyperkalemia and hypocalcemia.

(1) A serum potassium level > 5 mEq/L reflects hyperkalemia; a serum calcium level < 4.5 mEq/L signifies hypocalcemia, and serum magnesium levels < 2.5 mEq/L signify hypomagnesemia.

(2) An ECG tracing may suggest an electrolyte abnormality. For example, prolonged QRS complexes, tented T waves, and lengthened PR intervals may signal hyperkalemia; prolonged QT intervals and flattened, or inverted, T waves suggest hypocalcemia.

G. Treatment objectives

1. Terminate or **suppress the arrhythmia** if it causes hemodynamic compromise or disturbing symptoms.

2. Maintain adequate cardiac output and tissue perfusion.

3. Correct or maintain fluid balance (some arrhythmias cause hypervolemia).

II. THERAPY.

During recent years, several prominent national organizations have formalized a structure which promulgates the dissemination of “clinical practice guidelines,” which focus on “Evidence-based practice.” The overall purpose being to utilize

available literature to quantify, in clinical terms, the strength of evidence and the quality of such evidence, in order to develop a standard of practice for such clinical entities. Evidence-based practice goes beyond drug therapy and includes diagnostic criteria, screening programs, use of laboratory tests, etc. The American College of Cardiology in collaboration with the American Heart Association and European Society of Cardiology have established a routine standard for the evaluation, development, approval, and subsequent distribution of such practice guidelines for a wide array of cardiac situations. Since the publication of the most recent edition of this text; two sets of guidelines have been developed in the area of Cardiac Arrhythmias, and include the following:

ACC/AHA/ESC 2006 Guidelines for the Management of Patients with Atrial Fibrillation which can be found online at http://circ.ahajournals.org/cgi/content/full/114/7/700.

ACC/AHA/ESC Guidelines for the Management of Patients with Ventricular Arrhythmias and the Prevention of Sudden Cardiac Death, which can be found online at http://www.americanheart.org/downloadable/heart/1156943336547VA_PG_FINAL8_28.pdf

Antiarrhythmic agents, directly or indirectly, alter the duration of the myocardial action potential. Most antiarrhythmics fall into one of four classes, depending on their specific effects on the heart's electrical activity (Table 40-1).

A. Class I antiarrhythmics

1. Indications

a. Class IA drugs

(1) Quinidine is used to treat and prevent acute and chronic ventricular and supraventricular arrhythmias, especially paroxysmal supraventricular tachycardias (PSVTs), premature ventricular contractions (PVCs), premature atrial contractions (PACs), and ventricular tachycardia.

(2) Procainamide is used for the same arrhythmias for which quinidine is given. It is used more frequently than quinidine because it can be administered intravenously and in sustained-release oral preparations. Quinidine poses added concern when used intravenously because of increased cardiovascular effects (i.e., hypotension, syncope, myocardial depression).

(3) Disopyramide may be used as an alternative to quinidine or procainamide for treating ventricular arrhythmias (e.g., PVCs, moderate ventricular tachycardia).

Table 40-1. Williams's Classification of Antiarrhythmic Drugs Currently Available in the United States

Class	Action	Drugs
IA (fast-channel blockers)	Moderate depression of conduction, prolongation of repolarization, which results in an increase in the QRS interval and an increase in the QT interval	Disopyramide (Norpace), procainamide (Pronestyl), quinidine
IB	Modest depression of conduction, shortening of repolarization, which results in a decrease in the QT interval	Lidocaine (Xylocaine), mexiletine (Mexitil), phenytoin (Dilantin),
IC	Strong depression of conduction, with mild or no effect on repolarization, which results in a very large increase in the QRS interval	Flecainide (Tambocor), propafenone (Rythmol)
II (β-blockers)	β-adrenergic blockers slow sinus as well as AV nodal conduction, which results in a decrease in heart rate and a prolongation in the PR interval (atrial depolarization)	Propranolol (Inderal), esmolol (Brevibloc), acebutolol (Sectral)[a]
III	Prolongation of repolarization, which results in prolongation of the QT interval	Amiodarone (Cordarone), sotalol[b] (Betapace), ibutilide (Corvert), dofetilide (Tikosyn)
IV (slow-channel blockers)	Calcium-channel blockade in calcium-dependent channels, which results in reduced heart rate and an increase in the PR interval	Verapamil (Calan), diltiazem (Cardizem)
Other		Adenosine (Adenocard), atropine, digoxin (Lanoxin), magnesium

[a] Singh BN, Vaughan Williams EM. Classification of antiarrhythmic drugs. In: Sandoe E, Flensted-Jensen E, Olesen KH, eds. Symposium on Cardiac Arrhythmias. Sodertalige: AB Astra, 1970.

[b] Sotalol is a β-adrenergic blocker that prolongs the action potential of phase 3 and is classified as type III.

b. Class IB drugs

(1) Lidocaine is used therapeutically for ventricular arrhythmias (especially PVCs and ventricular tachycardia) that result from acute MI and open-heart surgery. Controversy still exists as to the benefits of lidocaine when used prophylactically in patients with acute MI to prevent ventricular fibrillation. A recent analysis showed an increase in the number of deaths in patients receiving lidocaine during an acute MI as compared to placebo. Many feel that its current use prophylactically post-MI is no longer justified.

(2) Phenytoin is most commonly used to treat digitalis-induced ventricular and supraventricular arrhythmias. It is also given to suppress ventricular arrhythmias associated with acute MI, open-heart surgery, or ventricular arrhythmias that are refractory to lidocaine or procainamide, but its efficacy is less significant for these indications than it is for digitalis-induced arrhythmias.

(3) Mexiletine is closely related to lidocaine, structurally with modifications, which reduce first-pass liver metabolism, making oral therapy possible. It is most commonly used to treat patients in whom a class I agent has failed and is moderately effective in suppressing ventricular ectopy, although comparable to quinidine.

c. Class IC drugs

(1) Flecainide suppresses PVCs and ventricular tachycardia; it may be used to treat some arrhythmias that are refractory to other agents. Flecainide is reserved for patients with refractory life-threatening ventricular arrhythmias who do not have CAD. It has also been shown to be effective in the treatment of supraventricular arrhythmias.

(2) Propafenone also suppresses PVCs and ventricular tachycardia and has been used successfully for treating sustained ventricular tachycardia when the arrhythmia is life

threatening. It has also been shown to be effective in the treatment of supraventricular arrhythmias.

(3) Moricizine is a difficult antiarrhythmic to classify based on the fact that it has properties of all three class I antiarrhythmic groups. Because it prolongs the QRS interval like other class IC agents, it has been classified as a class IC agent throughout this discussion. Moricizine is effective for suppressing PVCs and may offer some benefits over other agents because of a lower incidence of proarrhythmic effects.

2. Mechanism of action. As a class, all of the agents work by blocking the rapid inward sodium current and thereby slow down the rate of rise of the cardiac tissue's action potential. However, though this is a similar effect for all class I agents, differences in EP effects had led to a subclassification of the class I agents into three subsets (IA, IB, and IC), based on these EP effects.

a. Class IA drugs moderately reduce the depolarization rate and prolong repolarization (refractory period).

b. Class IB drugs shorten repolarization (refractory period); they also weakly affect the repolarization rate.

c. Class IC drugs strongly depress depolarization but have a negligible effect on the duration of repolarization or refractoriness.

3. Administration and dosage

a. Quinidine is administered orally, usually in 3-4 daily doses of 200-400 mg as a rapid-release sulfate salt (83% quinidine). However, sustained-release products in the form of a gluconate (62% quinidine) salt in doses of 324-648 mg, which corresponds to 300-600 mg of the sulfate salt, may be given every 12 hr. (In special circumstances, it has been given intravenously or intramuscularly with caution.) To achieve an effective plasma concentration rapidly, a loading dose of 600-1000 mg may be administered in doses of 200 mg every 2 hr to a maximum of 1000 mg, or a 5-8 mg/kg intravenous infusion can be given at a rate of 0.3 mg/kg/min.

b. Procainamide (Pronestyl) is available for oral, intravenous, or intramuscular use.

(1) For **acute therapy,** intravenous administration is preferred.

(a) Intermittent intravenous administration calls for the administration of an intravenous dose of 3-6 mg/kg infusion (up to 100 mg) over 2-4 min, repeated every 5-10 min until the arrhythmia is abolished, side effects occur, or 1 g has been given. The usual effective dose is 500-1000 mg.

(b) Rapid intravenous administration calls for infusion of 1-1.5 g at a rate of 20-50 mg/min.

(c) Once the arrhythmia is terminated, 1.5-5 mg/min is given as a continuous infusion.

(2) For **long-term therapy,** oral administration is used. The usual daily dosage is 50 mg/kg in divided doses given every 6 hr as a sustained-release product or 3-6 g daily.

(a) Capsules and tablets (Pronestyl) available as 250, 375, and 500 mg given in 4-6 divided doses

(b) Sustained-release tablets (Procanbid) available as 500 and 1000 mg given in 12-hr doses

c. Disopyramide (Norpace, Norpace CR) is available in oral form.

(1) Usually, 300-400 mg is given as a loading dose to attain an effective plasma level rapidly.
(2) For maintenance therapy, doses of 400-800 mg/day are given in 4 doses every 6 hr (non-sustained-release capsule) or in 2 doses every 12 hr (sustained-release capsule).
d. Lidocaine (Xylocaine) may be administered intravenously or intramuscularly.
(1) An intravenous loading dose rapidly achieves a therapeutic plasma level.
(a) Initially, 1-1.5 mg/kg (100 mg) is administered.
(b) A second injection of half the initial dose may be required 5 min later, up to a maximum of 300 mg.
(2) Continuous intravenous infusion of 2-4 mg/min produces an effective plasma level in 7-10 hr.
(3) In an emergency, an intramuscular injection rapidly achieves an effective plasma level. The usual dosage is 300-400 mg injected into the deltoid muscle.
e. Phenytoin (Dilantin) is given orally or in intermittent intravenous doses.
(1) For oral administration, a loading dose of 1 g is divided over the first 24 hr; for the next 2 days, 300-500 mg/day is administered. The maintenance dosage is 300-400 mg/day.

(2) For intermittent intravenous administration, 100 mg is given every 5 min at a rate not exceeding 25-50 mg/min, until the arrhythmia disappears, adverse effects develop, or 1 g has been given. The usual effective dosage is 700 mg.
f. Mexiletine is administered orally and should be initiated in the hospital setting.
(1) A loading dose of 400 mg followed by maintenance dosage in 8 hr.
(2) If this fails to control the arrhythmia, the dosage may be increased to 400 mg every 8 hr. (Alternatively, doses may be given every 12 hr.)
(3) Normal maintenance doses are 200-300 mg every 8 hr.
g. Flecainide (Tambocor) is administered orally and should be initiated in the hospital setting.
(1) Initial dosage is 50 mg every 12 hr, and the dosage may be increased in twice-daily increments of 50 mg every 4 days to a maximum of 300 mg/day.
(2) The usual maintenance dose is 100 mg every 12 hr.
h. Propafenone (Rythmol, Rythmol SR) is administered orally and should be initiated in the hospital setting.
(1) Initial dosage is 150 mg every 8 hr and can be increased every 3-4 days to the desired therapeutic effect or side effects.
(2) The usual maintenance dose is 150-200 mg every 8 hr, (Rythmol) or every 12 hour (Rythmol SR) up to a maximum of 900 mg/day.
4. Precautions and monitoring effects. Note: Proarrhythmia (the ability to cause an arrhythmia) is the most important risk associated with the use of antiarrhythmic drug therapy. Bradyarrhythmias and ventricular tachyarrhythmias, such as torsades de pointes, can occur. These often take place during the initiation of antiarrhythmic

drug treatment and should be considered when decision makers choose between outpatient and inpatient initiation of antiarrhythmic therapy.

a. Quinidine

(1) This drug is contraindicated in patients with

(a) Complete AV block unless a ventricular pacemaker is in place

(b) Marked prolongation of the QT interval or prolonged QT syndrome because ventricular tachyarrhythmia (torsades de pointes) may arise, resulting in quinidine syncope (i.e., syncope or sudden death)

(2) An increase of 50% or more in the duration of the QRS complex necessitates dosage reduction.

(3) Quinidine has a narrow therapeutic index. Therapeutic serum levels are in the range of 2-6 µg/mL, depending on the specificity of the assay. Toxicity may cause acute cardiac effects, such as pronounced slowing of conduction in all heart regions; this, in turn, may lead to SA block or arrest, ventricular tachycardia, or asystole.

(4) The ECG should be monitored during quinidine therapy to detect signs of cardiotoxicity. To counteract quinidine-induced ventricular tachyarrhythmias, catecholamines, glucagon, or sodium lactate may be given.

(5) In patients receiving quinidine for atrial tachyarrhythmias, vagolytic effects may increase impulse conduction at the AV node, resulting in an accelerated ventricular response. To prevent this, agents that slow AV nodal conduction (e.g., verapamil, digoxin) may be administered.

(6) The dosage should be reduced in elderly patients (> 60 years old) and in patients with hepatic dysfunction or congestive heart failure (CHF).

(7) Embolism may occur on restoration of normal sinus rhythm after prolonged atrial fibrillation. To prevent or minimize this complication, anticoagulants may be administered before quinidine therapy begins.

(8) Quinidine may cause cinchonism at high serum concentrations, manifested by tinnitus, hearing loss, blurred vision, and gastrointestinal (GI) disturbances. In severe cases, nausea, vomiting, diarrhea, headache, confusion, delirium, photophobia, diplopia, and psychosis may occur.

(9) GI reactions are the most common adverse reactions to quinidine. About 30% of patients experience diarrhea; nausea and vomiting may also occur. Arising almost immediately after the first dose, these symptoms sometimes warrant discontinuing the drug. However, aluminum hydroxide or use of the polygalacturonate salt may reverse this.

(10) Hypersensitivity reactions include anaphylaxis, thrombocytopenia, respiratory distress, and vascular collapse.

b. Procainamide (Pronestyl)

(1) This drug is contraindicated in patients with hypersensitivity to procaine and related drugs, myasthenia gravis, second- or third-degree AV block with no

pacemaker, a history of procainamide-induced systemic lupus erythematosus (SLE), prolonged QT syndrome, or torsades de pointes.

(2) An increase of 50% or more in the duration of the QRS complex necessitates dosage reduction.

(3) Procainamide has a narrow therapeutic index. Therapeutic serum levels are reported in the range of 4-10 µg/mL. *N*-acetyl procainamide (NAPA) levels of 15-25 µg/mL are considered therapeutic. The active metabolite, NAPA possesses differing pharmacological cardiovascular effects, and serum levels need to be evaluated independently of procainamide. Toxicity may cause acute cardiac effects (e.g., pronounced slowing of conduction in all heart regions), which, in turn, may lead to SA block or arrest, ventricular tachycardia, or asystole.

(4) High serum procainamide levels may induce ventricular arrhythmias (e.g., PVCs, ventricular tachycardia or fibrillation). The ECG should be monitored continuously to detect these problems. Catecholamines, glucagon, or sodium lactate may be administered to counteract these arrhythmias.

(5) Hypotension may occur with rapid intravenous administration.

(6) GI effects are less common than with quinidine therapy.

(7) Hypersensitivity reactions are the most severe adverse effects of procainamide. These reactions include drug fever, agranulocytosis, and an SLE-like syndrome.

(a) An SLE-like syndrome is manifested by fatigue, arthralgia, myalgia, and low-grade fever.

(b) Antinuclear antibody titer is positive in 50%-80% of patients receiving procainamide. However, only 20%-30% of these patients develop symptoms of the SLE-like syndrome.

(c) Drug discontinuation usually is necessary when symptomatic SLE-like syndrome occurs.

(8) The dosage should be reduced and given over 6 hr to patients with renal or hepatic impairment, as the drug half-life is increased in these patients.

(9) Lower doses may be needed in patients with CHF to adjust for the lower volume of distribution.

(10) Embolism may occur on restoration of normal sinus rhythm after prolonged atrial fibrillation. An anticoagulant is frequently administered before procainamide therapy begins to prevent this complication.

c. Disopyramide (Norpace)

(1) This drug may cause marked hemodynamic compromise and ventricular dysfunction. It is contraindicated in patients with cardiogenic shock or second- or third-degree AV block with no pacemaker.

(2) Disopyramide should be avoided or used with extreme caution in patients with CHF. It should also be used cautiously in patients with urinary tract disorders, myasthenia gravis, and renal or hepatic dysfunction.

(3) In patients receiving this drug for atrial tachyarrhythmias, vagolytic effects may increase impulse conduction at the AV node, resulting in an accelerated ventricular response. To prevent this, agents that slow AV nodal conduction (e.g., verapamil, digoxin) may be given.

(4) Anticholinergic effects of this drug include dry mouth, constipation, urinary hesitancy or retention, and blurred vision.
(5) Therapeutic plasma levels range from 2 to 4 µg/mL.

d. Lidocaine (Lidocaine)

(1) This drug may cause hemodynamic compromise in patients with severe cardiac dysfunction. Generally, however, it has few untoward cardiovascular effects.
(2) Lidocaine should be used cautiously and in reduced dosage in patients with CHF or renal or hepatic impairment.
(3) Central nervous system (CNS) reactions are the most pronounced adverse effects of lidocaine. These reactions may range from lightheadedness and restlessness to confusion, tremors, stupor, and convulsions.
(4) Tinnitus, blurred vision, and anaphylaxis have been reported.
(5) Plasma lidocaine levels of 1.5-6.5 µg/mL are therapeutic.
(6) Lidocaine's metabolites—glycinexylidide and monoethylglycinexylidide—may have neurotoxic as well as antiarrhythmic effects.

e. Phenytoin (Dilantin)

(1) This drug is contraindicated in patients with sinus bradycardia or heart block.
(2) Phenytoin must be used cautiously in patients with heart failure (HF), renal or hepatic impairment, myocardial insufficiency, respiratory depression, or hypotension.
(3) During acute therapy, this drug may cause CNS reactions (e.g., drowsiness, vertigo, nystagmus, ataxia, nausea). Cardiotoxicity also may occur, especially with fast intravenous infusion rates.
(4) Chronic phenytoin may lead to vestibular and cerebellar effects, behavioral changes, GI distress, gingival hyperplasia, megaloblastic anemia, and osteomalacia.
(5) Hypersensitivity reactions may be manifested by liver, skin, and hematological problems.
(a) Toxic hepatitis may occur.
(b) Skin reactions include exfoliative dermatitis, Stevens-Johnson syndrome, scarlatiniform or morbilliform rash, SLE, toxic epidermal necrolysis, eosinophilia, and erythema multiforme.
(c) Hematological reactions include agranulocytosis, megaloblastic anemia, leukopenia, thrombocytopenia, and pancytopenia.
(6) Therapeutic plasma phenytoin levels range from 10 to 18 µg/mL.

f. Mexiletine (Mexitil)

(1) This drug is contraindicated in patients with cardiogenic shock or second- or third-degree AV block with no pacemaker.
(2) Tremor is an early sign of mexiletine toxicity. Dizziness, ataxia, and nystagmus indicate an increasing plasma drug concentration.
(3) Hypotension, bradycardia, and widened QRS complexes may develop during mexiletine therapy.
(4) Adverse GI effects include nausea and vomiting.

(5) Therapeutic serum levels range from 0.50 to 2.0 µg/mL.

g. Flecainide (Tambocor)

(1) This drug is contraindicated in patients with cardiogenic shock or second- or third-degree AV block with no pacemaker.

(2) The ECG should be monitored during flecainide therapy because this drug may exacerbate existing arrhythmias or precipitate new ones. Flecainide was shown in the CAST study to increase mortality in patients with asymptomatic ventricular arrhythmias and, therefore, should be reserved for patients with life-threatening ventricular arrhythmias that are refractory to other drugs.

(3) This drug has a significant negative inotropic effect and may bring on or worsen CHF and cardiomyopathy.

(4) Adverse CNS effects (e.g., dizziness, headache, tremor) and GI effects (e.g., nausea, abdominal pain) may occur.

(5) Blurred vision and dyspnea have been reported.

(6) Therapeutic serum levels recommended for flecainide are between 0.2 and 1.0 µg/mL.

h. Propafenone (Rythmol), Rythmol (SR)

(1) This drug, like other antiarrhythmic agents, may cause new or worsened arrhythmias. Such proarrhythmic properties range from an increased frequency of PVCs to the development of severe ventricular tachycardia, ventricular fibrillation, and torsades de pointes. This proarrhythmic effect has been under discussion for the class IC agents; thus, when used, these agents should be monitored closely. The findings from the CAST study must be weighed against the benefits of using these agents for treating significant ventricular arrhythmias.

(2) Dizziness is a side effect that has been reported in as many as 10%-15% of patients taking the drug.

(3) Other associated side effects include vomiting, a metallic bitter taste in the mouth, constipation, headache, and new or worsening CHF and asthma.

(4) Therapeutic serum levels recommended for propafenone are between 0.06 and 1.0 µg/mL.

5. Significant interactions

a. Quinidine

(1) Quinidine may increase serum levels of **digoxin** and increase the effects of **digitalis** on the heart, with a resultant increase in toxicity.

(2) Severe orthostatic hypotension may occur with concomitant administration of **vasodilators** (e.g., **nitroglycerin**).

(3) Phenytoin, rifampin (Rifadin), and **barbiturates** may antagonize quinidine activity and reduce its therapeutic efficacy.

(4) Nifedipine (Procardia) may reduce plasma quinidine levels.

(5) Antacids, sodium bicarbonate (Neut), and **sodium acetazolamide (Diamox)** may increase plasma quinidine levels, possibly resulting in toxicity.

(6) Quinidine may produce additive hypoprothrombinemic effects with **coumarin** anticoagulants.

b. Amiodarone (Cordarone) and **cimetidine (Tagamet)** may increase plasma procainamide levels, possibly leading to drug toxicity.

c. Phenytoin accelerates disopyramide metabolism, possibly reducing its therapeutic efficacy.

d. Lidocaine

(1) Phenytoin may increase the cardiodepressant effects of lidocaine.

(2) β-Blockers (class II antiarrhythmics) may reduce lidocaine metabolism, possibly leading to drug toxicity.

e. Phenytoin

(1) The risk of phenytoin toxicity increases with concomitant administration of **diazepam (Valium), antihistamines, isoniazid (Nydrazid), chloramphenicol (Chloromycetin), cimetidine (Tagamet), salicylates, sulfisoxazole (Gantrisin), amiodarone (Cordarone),** and **valproate (Depacon).**

(2) Carbamazepine (Tegretol) may enhance phenytoin metabolism and thus reduce plasma phenytoin levels and therapeutic efficacy. (Phenytoin has the same effect on carbamazepine.)

f. Mexiletine (Mexitil). Phenobarbital, rifampin (Nydrazid), and **phenytoin (Dilantin)** reduce plasma mexiletine levels and may decrease therapeutic efficacy.

B. Class II antiarrhythmics

1. Indications. These drugs—**β-adrenergic blockers—**are used mainly to treat systemic hypertension. Among the drugs in this class, propranolol, esmolol, and acebutolol are approved for antiarrhythmic use.

a. Propranolol-(Inderal) may be given to:

(1) Control supraventricular arrhythmias (e.g., atrial fibrillation or flutter, PSVTs)

(2) Treat tachyarrhythmias caused by catecholamine stimulation (e.g., in hyperthyroidism, during anesthesia)

(3) Suppress severe ventricular arrhythmias in **prolonged QT syndrome**

(4) Treat digitalis-induced ventricular arrhythmias

(5) Terminate certain ventricular arrhythmias (e.g., PVCs in patients without structural heart disease)

b. Esmolol (Brevibloc) is used to treat supraventricular tachycardias; it possesses a short (9-min) half-life and has been used to control the ventricular response to atrial fibrillation or flutter during or after surgery.

2. Mechanism of action. Class II antiarrhythmics reduce sympathetic stimulation of the heart, decreasing impulse conduction through the AV node and lengthening the refractory period. Additionally, this class of antiarrhythmics slow the sinus rhythm without significantly changing the QT or QRS intervals, resulting in a reduced heart rate and a decrease in myocardial oxygen demand.

3. Administration and dosage

a. Propranolol may be given intravenously or orally when used as an antiarrhythmic.

(1) Emergency therapy calls for slow intravenous administration of 1-3 mg diluted in 50 mL dextrose 5% in water or normal saline solution. This dose is infused slowly (no faster than 1 mg/min). A second dose of 1-3 mg may be given 2 min later.
(2) For oral therapy, 10-80 mg/day is given in 3-4 doses. (However, 1000 mg or more may be required for resistant ventricular arrhythmias.)
b. Esmolol is given intravenously. A loading dose of 500 µg/kg/min is infused over 1 min, followed by a 4-min maintenance infusion of 50 µg/kg/min. If a satisfactory response is not achieved within 5 min, the loading dose is repeated and followed by a maintenance infusion of 100 µg/kg/min.

4. Precautions and monitoring effects
a. Propranolol (Inderal)
(1) This drug is contraindicated in patients with sinus bradycardia, second- or third-degree AV block, cardiogenic shock, severe HF, or asthma.
(2) The β-blocking effects of this drug may lead to marked hypotension, exacerbation of CHF and left ventricular failure, or cardiac arrest.
(3) Blood pressure, heart rate, and the ECG should be monitored during intravenous infusion.
(4) Embolism may occur upon restoration of normal sinus rhythm after sustained atrial fibrillation. An anticoagulant may be given before propranolol therapy begins to prevent this complication.
(5) Propranolol may depress AV node conduction and ventricular pacemaker activity, resulting in AV block or asystole.
(6) This drug may mask the signs and symptoms of hypoglycemia. It also may mask signs of shock.
(7) Fatigue, lethargy, increased airway resistance, and skin rash have been reported.
(8) Nausea, vomiting, and diarrhea may occur.
(9) Sudden withdrawal of propranolol may lead to acute MI, arrhythmias, or angina in cardiac patients. Drug therapy is discontinued by tapering the dose over 4-7 days.
b. Esmolol (Brevibloc)
(1) This drug is contraindicated in patients with severe CHF or sinus bradycardia.
(2) Hypotension occurs in approximately 30% of patients receiving esmolol. This effect can be reversed by reducing the dosage or stopping the infusion.
(3) This drug is for short-term use only and should be replaced by a long-acting antiarrhythmic once the patient's heart stabilizes.
(4) Dizziness, headache, fatigue, and agitation may occur.
(5) Other adverse effects include nausea, vomiting, and bronchospasm.
5. Significant interactions
a. Propranolol
(1) Severe vasoconstriction may occur with concomitant **epinephrine** administration.
(2) Digitalis preparations can cause excessive bradycardia.

(3) Calcium-channel blockers—for example, **diltiazem (Cardizem)** and **verapamil (Calan)**—and other negative **inotropic** and **chronotropic drugs**—such as **disopyramide (Norpace)** and **quinidine**—add to the myocardial depressant effects of propranolol.

b. Esmolol. Morphine (MS Contin) may raise plasma esmolol levels.

C. Class III antiarrhythmics

1. Indications

a. Amiodarone (Cordarone) is given to control malignant ventricular arrhythmias and has most recently within the new advanced cardiac life support (ACLS) guidelines been recommended in the treatment of ventricular fibrillation and pulseless ventricular tachycardia, and may be used prophylactically against both atrial and ventricular tachycardia and fibrillation. Unlike most other antiarrhythmics, with the exception of the β-adrenergic blockers, amiodarone has been shown to reduce arrhythmic deaths in patients after an MI.

b. Sotalol (Betapace) is used to treat supraventricular and ventricular tachyarrhythmias. Sotalol antagonizes both β_1- and β_2- adrenergic receptors, but also prolongs the phase 3 action potential. It is this property that distinguishes it from other β-adrenergic blockers and is the reason why it is classified as a type III antiarrhythmic drug rather than a type II agent (β-adrenergic blocker).

c. Ibutilide (Corvert) is used in the conversion of atrial fibrillation and flutter of recent onset (duration < 30 days).

d. Dofetilide (Tikosyn) is available in the United States under restricted access in the treatment of atrial fibrillation/flutter.

2. Mechanism of action. Class III antiarrhythmic drugs prolong the refractory period and action potential; they have no effect on myocardial contractility or conduction time.

3. Administration and dosage

a. Amiodarone (Cordarone) Available for both oral and intravenous use and should only be initiated in the hospital setting. Amiodarone has been incorporated into the most recent ACLS (2005) guidelines and recommended by the expert panel members as the first-choice antiarrhythmic for shock-refractory ventricular fibrillation/ventricular tachycardia.

(1) It is available for oral use; 800-1600 mg every 12 hr is given for 7-14 days, then 200-400 mg daily thereafter.

(2) Oral treatment is used to suppress ventricular and supraventricular arrhythmias but can take days or weeks to take effect. Oral doses of 100-600 mg/day (usually 300-400 mg/day) for maintenance therapy in ventricular tachycardia and 100-200 mg/day for maintenance therapy for supraventricular tachycardias are given.

(3) Intravenous formulation is available for treatment and prophylaxis of recurrent ventricular fibrillation or hemodynamically unstable ventricular tachycardia in refractory patients.

(4) The intravenous form is rapidly distributed throughout the body. Recommended doses include a rapid loading infusion of 150 mg over 10 min, followed by a slow infusion of 1 mg/min for 6 hr (360 mg), and then a maintenance infusion of 0.5 mg/min for the remainder of the 24-hr period. Patients usually receive 2-4 days of infusions before conversion to oral form. However, a maintenance infusion can be continued for 2-3 weeks.

b. Sotalol (Betapace) is available commercially as an oral tablet, and therapy should be initiated within the hospital setting. Normal dosing of 80 mg twice daily initially and increasing doses at 2- to 3-day intervals to a maximum dose of 640 mg/day, given in 2-3 doses throughout the day.

c. Ibutilide (Corvert) is available only for injection in a 0.1-mg/mL, 10-mL vial. Normal doses for the conversion of recent-onset atrial fibrillation to normal sinus rhythm is a dose of 1 mg (0.01 mg/kg for those < 60 kg) over 10 min, with a repeat dose in 10 min if the arrhythmia does not end.

d. Dofetilide (Tikosyn) is available only for oral administration in 0.125-, 0.25-, and 0.5-mg capsules under the trade name of Tikosyn and should only be initiated in a hospital setting with trained personnel and the equipment necessary to provide continuous cardiac monitoring during initiation of therapy.

(1) A normal dose for the conversion of recent-onset atrial fibrillation to normal sinus rhythm is 0.5 mg twice daily for patients with creatinine clearance values > 60 mL/min; doses are reduced 50% (0.25 mg) for those with creatinine clearance values of 40-60 mL/min, and doses are reduced an additional 50% (0.125 mg) for those with creatinine clearance values of 20-40 mL/min.

(2) Maintenance therapy is based on the ECG; with doses being reduced with QTc prolongation exceeding 15% of the baseline value. Any patient developing a QTc interval exceeding 500 msec should have therapy discontinued immediately.

(3) Dofetilide should not be given to those with creatinine clearance values < 20 mL/min.

4. Precautions and monitoring effects

a. Amiodarone (Cordarone)

(1) Life-threatening pulmonary toxicity may occur during amiodarone therapy, especially in patients receiving > 400 mg/day. Baseline as well as routine pulmonary function tests reveal relevant pulmonary changes.

(2) Most patients develop corneal microdeposits 1-4 months after amiodarone therapy begins. However, this reaction rarely causes visual disturbance, but the patient should be monitored with routine ophthalmological examinations.

(3) Blood pressure and heart rate and rhythm should be monitored for hypotension and bradyarrhythmias.

(4) Patients should be monitored routinely for the possible development of hepatic dysfunction, thyroid disorders (e.g., hyperthyroidism, hypothyroidism), and photosensitivity.

(5) CNS reactions include fatigue, malaise, peripheral neuropathy, and extrapyramidal effects.

(6) Nausea and vomiting have been reported.

(7) This drug has an extremely long half-life (up to 60 days). Therapeutic response may be delayed for weeks after oral therapy begins; adverse reactions may persist up to 4 months after therapy ends.

b. Sotalol (Betapace)

(1) Side effects of this drug are directly related to β-blockade and prolongation of repolarization.

(2) Transient hypotension, bradycardia, myocardial depression, and bronchospasm have all been associated with this drug.

(3) This drug carries all the contraindications associated with other β-blockers along with those owing to its electrophysiologic properties.

c. Ibutilide (Corvert)

(1) Infusion should be discontinued as soon as the atrial arrhythmia is terminated or if sustained or nonsustained ventricular arrhythmia or marked QT prolongation is documented.

(2) Continuous ECG monitoring is required for at least 4 hr after discontinuing the infusion or until the QT interval returns to baseline.

d. Dofetilide (Tikosyn)

(1) Patients need to be monitored closely for the subsequent development of ventricular arrhythmias with increasing doses of dofetilide or with declining renal status. In clinical trials, ventricular tachycardias, including torsades de pointes, are the most frequently occurring arrhythmias due to dofetilide.

(2) Hypokalemia and those situations that might cause hypotension will predispose a patient to prolongation of the QT interval, which could put a dofetilide patient at risk for toxic arrhythmias.

5. Significant interactions

a. Amiodarone

(1) Amiodarone may increase the plasma levels of **quinidine, procainamide, diltiazem, digitalis,** and **flecainide.**

(2) It may increase the pharmacological effect of **β-blockers, calcium-channel blockers,** and **warfarin.**

(3) Special note: Amiodarone has been reported to have numerous drug-drug interactions among all categories of drugs. To avoid the development of a significant drug-drug interaction a thorough patient medication profile should be carried out for each patient having amiodarone therapy initiated, as well as each time a patient currently receiving amiodarone is given an additional drug.

b. Sotalol

(1) Sotalol must be used cautiously in those patients receiving agents with cardiacdepressant properties.

(2) Agents such as sotalol, which prolong the QT interval, may induce malignant arrhythmias when used in combination with other type IA antiarrhythmics, especially in the presence of low potassium levels.

c. Ibutilide should be avoided with other agents that prolong repolarization or within 4 hr of administration.

d. Dofetilide should be avoided in patients who have hypokalemia or preexisting QT prolongation.

D. Class IV antiarrhythmics

1. Indications

a. Calcium-channel blockers (e.g., verapamil, Calan; diltiazem, Cardizem) are used mainly to treat and prevent supraventricular arrhythmias.

(1) They are first-line agents for the suppression of PSVTs stemming from AV nodal reentry.

(2) They can rapidly control the ventricular response to atrial flutter and fibrillation.

b. Other calcium-channel blockers available include nicardipine, nifedipine, bepridil, amlodipine, and felodipine, but these agents have primarily been used in the treatment of angina pectoris and hypertension. For information on these agents, see Chapters 39 and 41.

2. Mechanism of action. Class IV antiarrhythmics are calcium-channel blockers. They inhibit AV node conduction by depressing the SA and AV nodes, where calcium channels predominate.

3. Administration and dosage

a. To control atrial arrhythmias, verapamil usually is administered intravenously. A dose of 2.5-10 mg is given over at least 2 min and may be repeated in 30 min, if necessary. A 5-10 mg/hr continuous intravenous infusion has also been used in treating arrhythmias.

b. To prevent PSVTs, verapamil may be given orally in four daily doses of 80-120 mg each.

c. To control atrial arrhythmias, diltiazem usually is administered intravenously. A dose of 20 mg (0.25 mg/kg) is given over 2 min. If an adequate response is not obtained, a second dose of 25 mg (0.35 mg/kg) is administered after 15 min. A 5-15 mg/hr intravenous continuous infusion has also been used in treating arrhythmias.

4. Precautions and monitoring effects

a. Verapamil and diltiazem are contraindicated in patients with AV block; left ventricular dysfunction; severe hypotension; concomitant, intravenous β-blockers; and atrial fibrillation with an accessory AV pathway.

b. These drugs must be used cautiously in patients with CHF, sick sinus syndrome, MI, and hepatic or renal impairment.

c. Because of the negative chronotropic effect, verapamil and diltiazem must be used cautiously in patients who have slow heart rates or who are receiving digitalis glycosides.

d. The ECG (especially the RR interval) should be monitored during therapy.

e. Patients > 60 years old should receive reduced dosages and slower injection rates.

f. Constipation and nausea have been reported with verapamil.

5. Significant interactions

a. Concomitant administration of **β-blockers** or **disopyramide** may precipitate heart failure.

b. Quinidine may increase the risk of calcium-channel blocker-induced hypotension.

c. Verapamil may increase serum **digoxin** concentrations, and diltiazem may do the same to a lesser extent.

d. Rifampin may enhance the metabolism of calcium-channel blockers, with a resultant decrease in pharmacological effect.

e. Verapamil and diltiazem may inhibit **theophylline** metabolism and may require reductions in theophylline dosage.

f. Diltiazem and verapamil inhibit the metabolism of **cyclosporine (Gengraf)** and may require reductions in cyclosporine dosages.

E. Unclassified antiarrhythmics

1. Atropine

a. Indications. Atropine is therapeutic for symptomatic sinus bradycardia and junctional rhythm.

b. Mechanism of action. An anticholinergic, atropine blocks vagal effects on the SA node, promoting conduction through the AV node and increasing the heart rate.

c. Administration and dosage. For antiarrhythmic use, atropine is administered in a dose of 0.4-1 mg by intravenous push; the dose is given every 5 min to a maximum of 2 mg.

d. Precautions and monitoring effects

(1) Thirst and dry mouth are the most common adverse effects of atropine.

(2) CNS reactions (e.g., restlessness, headache, disorientation, dizziness) may occur with doses over 5 mg.

(3) Tachycardia and ophthalmic disturbances (e.g., mydriasis, blurred vision, photophobia) may occur with doses of 1 mg or more.

(4) Initial doses may induce a reflex bradycardia owing to incomplete suppression of vagal impulses.

2. Adenosine (Adenocard)

a. Indications. Adenosine is indicated for the conversion of acute supraventricular tachycardia to normal sinus rhythm.

b. Mechanism of action. Adenosine is a naturally occurring nucleoside, which is normally present in all cells of the body. It has been shown to:

(1) Slow conduction through the AV node

(2) Interrupt reentry pathways through the AV node

(3) Restore normal sinus rhythm in patients with PSVTs

c. Administration and dosage. For antiarrhythmic effects, adenosine is given as a rapid bolus intravenous injection in a 6-mg dose over 1-2 sec. If the first dose does not eliminate the arrhythmia within 1-2 min, the dose should be increased to 12 mg and again given as a rapid intravenous dose. An additional 12-mg dose may be repeated if necessary.

d. Precautions and monitoring effects

(1) The effects of adenosine are antagonized by methylxanthines, such as caffeine and theophylline. Theophylline has been successfully used for treating adenosine-induced side effects, such as hypotension, sweating, and palpitations. If side effects are encountered, aggressive therapy is not required because of the ultra-short half-life of the drug (10 sec or less).

(2) The main side effect associated with adenosine use in up to 18% of patients is facial flushing, but this effect is normally very short-lived.

(3) Other side effects associated with adenosine use include shortness of breath, chest pressure, nausea, headache, and a metallic taste.

e. Additional use. Adenosine has been used as an adjunctive agent in patients undergoing various types of pharmacological stress testing (e.g., with thallium). In this situation, adenosine is given as a continuous infusion over a period of 4-6 min and is able to provide a form of exercise tolerance test in patients not able to exert themselves owing to age, fatigue, and various other physical handicaps.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Strong anticholinergic effects limit the antiarrhythmic use of

(A) quinidine.

(B) procainamide.

(C) tocainide.

(D) flecainide.

(E) disopyramide.

View Answer***1. The answer is E[see].*****2. A pronounced slowing of phase 0 of the myocardial action potential results in a prolongation of either atrial depolarization causing a prolonged P wave on the electrocardiogram (ECG) or ventricular depolarization causing a prolonged QRS complex characterized by which class of antiarrhythmics?**

(A) type I

(B) type II

(C) type III

(D) type IV

(E) type V

View Answer***2. The answer is A[see].*****3. Which of the following type III antiarrhythmics has been reported as causing the torsades de pointes type of ventricular tachycardia?**

(A) lidocaine

(B) amiodarone

(C) quinidine

(D) flecainide

(E) diltiazem

View Answer***3. The answer is B[see].*****4. A patient receiving a class I antiarrhythmic agent on a chronic basis complains of fatigue, low-grade fever, and joint pain suggestive of systemic lupus erythematosus (SLE). The patient is most likely receiving**

(A) lidocaine.

(B) procainamide.

(C) quinidine.

(D) flecainide.

(E) propranolol.

View Answer***4. The answer is B[see].*****5. Class IA antiarrhythmics do all of the following to the cardiac cell's action potential *except***

(A) slow the rate of rise for phase 0 of depolarization.

(B) delay the fast-channel conductance of sodium ions.

(C) prolong phases 2 and 3 of repolarization.

(D) inhibit the slow-channel conductance of calcium ions.

(E) prolong the refractory period of the action potential.

View Answer***5. The answer is D[see].*****6. Which of the following drugs is a class IV antiarrhythmic that is primarily indicated for the treatment of supraventricular tachyarrhythmias?**

(A) ibutilide

(B) mexiletine

(C) verapamil

(D) quinidine

(E) propranolol

View Answer***6. The answer is C[see].*****7. Which of the following agents was involved in the ARREST trial and for which evidence-based practice justifies its addition as a first-line agent within the 2005 ACLS guidelines?**

(A) lidocaine

(B) diltiazem

(C) bretylium

(D) amiodarone

(E) dofetilide

View Answer***7. The answer is D[see].p*****8. Which of the following drugs is a class III antiarrhythmic agent that is effective in the acute management of atrial fibrillation or atrial flutter of recent onset?**

(A) propranolol

(B) dofetilide

(C) metoprolol

(D) disopyramide

(E) diltiazem

View Answer***8. The answer is B[see].***P.847

9. All of the following problems represent concerns when patients are started on amiodarone *except*

(A) extremely long elimination half-life.

(B) need for multiple daily doses.

(C) development of hyperthyroidism or hypothyroidism.

(D) development of pulmonary fibrosis.

(E) interactions with other antiarrhythmic drugs.

View Answer***9. The answer is B[see].***P.848

ANSWERS AND EXPLANATIONS

1. The answer is E *[see* II.A.4.c.(4)*].*

Disopyramide has anticholinergic actions about one tenth the potency of atropine. Effects include dry mouth, constipation, urinary retention, and blurred vision. Therefore, it cannot be used in patients with glaucoma or with conditions causing urinary retention. Moreover, disopyramide has a negative inotropic effect and must, therefore, be used with great caution, if at all, in patients with preexisting ventricular failure.

2. The answer is A *[see* II.A.2*].*

The class I antiarrhythmics (fast-channel blockers) slow impulse conduction by depressing the flow of sodium ions into cells during phase 0 of the action potential. Class II antiarrhythmics decrease impulse conduction through the AV node and lengthen the refractory period through their direct effects on the sympathetic nervous system. Class III antiarrhythmics prolong the refractory period and action potential and have no effect on conduction time throughout the AV and SA nodes. Class IV antiarrhythmics work directly on low-channel ion conduction, which is more likely to take place during phase 2 (plateau), when calcium ions enter the cell through slow channels. Current classification of antiarrhythmics does not include a group of class V agents.

3. The answer is B *[see* I.C.3; Table 40-1*].*

Torsades de pointes is a form of ventricular tachyarrhythmia characterized by electrocardiographic changes, which include a markedly prolonged QT interval. This potentially fatal reaction has now been reported for both antiarrhythmics and non-antiarrhythmics. Antiarrhythmics, which have been reported to cause torsades de points, include amiodarone, disopyramide, dofetilide, flecainide, ibutilide, procainamide, quinidine, and sotalol. In addition, drug classes such as antibiotics (e.g., erythromycin, levofloxacin, moxifloxacin, pentamidine, sparfloxacin), along with other agents (such as, dolasetron, felbamate, fluoxetine, fosphenytoin, indapamide, isradipine, paroxetine, sumatriptan, and tamoxifen) have been reported to be able to cause either a prolongation in the QT interval and/or induce torsades de pointes (Table 40-1). Of the agents listed, only amiodarone is a class III antiarrhythmic.

4. The answer is B *[see* II.A.4.b.(7)*].*

The patient's complaints are typical of a SLE-like hypersensitivity reaction to procainamide. Symptoms of an SLE-like syndrome include fatigue, arthralgia, myalgia, a low-grade fever, and a positive antinuclear antibody titer. The patient's symptoms should subside if procainamide therapy is stopped and an alternative antiarrhythmic agent is given instead.

5. The answer is D *[see* II.A.2*].*

Class IA antiarrhythmic agents delay phase 0 of depolarization. Fast-channel conduction of sodium and phases 2 and 3 of repolarization are also slowed. The net effect is to extend the refractory period of myocardial tissue. Class IA antiarrhythmic agents do not inhibit the slow-channel conductance of calcium ions—that is an action of class IV agents such as verapamil.

6. The answer is C *[see* II.D.1.a*].*

Of the agents listed, verapamil is a calcium-channel blocker and represents the class IV antiarrhythmics. Verapamil has been used for its direct-acting effects on impulse conduction throughout the heart. Thus verapamil is used to treat and prevent supraventricular arrhythmias. Ibutilide is a class III agent, quinidine is a class IA drug, mexiletine is a class IB agent, and propranolol, a β-adrenergic blocker, is class II. Mexiletine, quinidine, and propranolol are all also effective for supraventricular arrhythmias, and ibutilide is indicated for the treatment of atrial fibrillation/flutter of recent onset.

7. The answer is D *[see* II.C.3.a*].*

In the ARREST trial, 44% of amiodarone-treated patients versus 34% of placebo-treated patients survived to hospital admission (p = 0.03) after shock-refractory cardiac arrest. The benefit was consistently observed in all major subgroups, regardless of the presenting cardiac-arrest rhythm. As a result of the trial, evidence of its findings were cited within the ACLS 2000 Guidelines, describing the lack of similar data for other antiarrhythmics, and the agreement by the expert panel that they would consider amiodarone as a first-line agent for such patients. Lidocaine and bretylium are the only other agents listed, which have been used in this patient population for ventricular tachyarrhythmias. However, the data have been lacking as to their efficacy compared to placebo.

8. The answer is B *[see* II.C.1.d*].*

Dofetilide, ibutilide, amiodarone, and sotalol are class III antiarrhythmic agents. Class III agents, which prolong the refractory period and myocardial action potential, are used to treat ventricular arrhythmias. However, dofetilide and ibutilide are approved as type III agents indicated for the conversion from atrial fibrillation and flutter of recent onset to normal sinus rhythm. Propranolol, along with other β-blockers, is a class II antiarrhythmic; metoprolol is not routinely used in the treatment of arrhythmias; and disopyramide and diltiazem are class Ia and class IV antiarrhythmics, respectively.

9. The answer is B *[see* II.C.3.a; II.C.4.a; II.C.5.a*].*

Amiodarone, like ibutilide and sotalol, is a class III antiarrhythmic agent and acts by prolonging repolarization of cardiac cells. Amiodarone is given orally, often in once-a-day or twice-a-day maintenance dosage. Because of its very long elimination half-life, therapeutic response may be delayed for weeks. Therefore, an initial loading phase is often advisable. This requires hospitalization with close monitoring for desired effects, untoward reactions, and adjustments in dosage. Amiodarone may increase the plasma levels of quinidine, procainamide, diltiazem, and digitalis. During therapy with amiodarone, patients may develop hypothyroidism or hyperthyroidism, pulmonary disorders, hepatic dysfunction, and various other unwanted effects. Because of amiodarone's extremely long half-life, adverse reactions may persist for months after therapy ends.

41

Hypertension

Alan H. Mutnick

I. GENERAL CONSIDERATIONS

A. Definition. Hypertension is blood pressure elevated enough to perfuse tissues and organs. Elevated systemic blood pressure is usually defined as a systolic reading ≥ 140 mm Hg and a diastolic reading ≥ 90 mm Hg (≥ 140/90). The "Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (JNC-7) added a "prehypertension" category, which includes individuals with systolic blood pressure readings of 120-139 or diastolic blood pressure readings of 80-89 mm Hg; this category is now included in contemporary management strategies.

B. Classification of hypertension is shown in Table 41-1. The table reflects the recommendations of the JNC-7.

C. The **relationship between elevated blood pressure and cardiovascular disease** was addressed in the JNC-7, which formalizes the fact that the higher the blood pressure, the greater the chance of a myocardial infarction (MI), heart failure (HF), stroke, or kidney disease. Table 41-2 provides cardiovascular risk factors and/or lifestyle factors that affect the prognosis and treatment of hypertension and the various types of target-organ damage associated with hypertension.

D. Incidence. Hypertension is the most common cardiovascular disorder. Approximately 43 million Americans have blood pressure measurements > 140/90. This number translates to almost 25% of the adult population. The incidence increases with age—that is, 60%-71% of people > 60 years of age have hypertension, according to data obtained from the Third National Health and Nutrition Examination Survey (NHANES III).

1. Primary (or essential) hypertension, in which no specific cause can be identified, constitutes > 90% of all cases of systemic hypertension. The average age of onset is about 35 years.

2. Secondary hypertension, resulting from an identifiable cause, such as renal disease or adrenal hyperfunction, accounts for the remaining 2%-5% of cases of systemic hypertension. This type usually develops between the ages of 30 and 50.

E. Physiology

Blood pressure = (stroke volume × heart rate) × total peripheral vascular resistance (TPR)

Altering any of the factors on the right side of the blood pressure equation results in a change in blood pressure, as shown in Figure 41-1.

1. Sympathetic nervous system. Baroreceptors (pressure receptors) in the carotids and aortic arch respond to changes in blood pressure and influence arteriolar dilation and arteriolar constriction. When stimulated to constriction, the contractile force strengthens, increasing the heart rate and augmenting peripheral resistance, thus increasing cardiac output. If pressure remains elevated, the baroreceptors reset at the higher levels and so sustain the hypertension. Little evidence suggests that epinephrine and norepinephrine have a clear role in the

cause of hypertension. However, many of the drugs used to treat hypertension lower blood pressure by blocking the sympathetic nervous system.

2. Renin-angiotensin-aldosterone system. Sympathetic stimulation, renal artery hypotension, and decreased sodium delivery to the distal tubules stimulate the release of renin by the kidney (juxtaglomerular apparatus of the kidney). Renin (an enzyme) reacts with circulating substrate, angiotensinogen to produce angiotensin I (a weak vasoconstrictor). Within the pulmonary endothelium is another enzyme, referred to as angiotensin-converting enzyme (ACE), which is able to hydrolyze the decapeptide angiotensin I to form the octapeptide angiotensin II (a potent natural vasoconstrictor). Angiotensin II has several important functions in the regulation of fluid volume:

Table 41-1. Classification of Hypertension for Adults ≥ 18 Years of Age

Classification	Systolic (mm Hg)[a]		Diastolic (mm Hg)[a]	Lifestyle Modification	Without Compelling Indication	With Compelling Indications
Normal	< 120	and	< 80	Encourage		
Prehypertension	120-139	or	80-89	Yes	No antihypertensive drug indicated, unless presence of a compelling indication[b] requiring use of drug therapy	Drug(s) for compelling indications
Stage 1 hypertension	140-1	or	90-99	Yes	Thiazide-type diuretics for most; may consider ACE inhibitor, ARB, β-blocker, CCB, or	Drug(s) for compelling indica

	59				combination	tions; other antihypertensive drugs (diuretics, ACE inhibitor, ARB, β-blocker, CCB) as needed
Stage 2 hypertension	≥160	or	≥100	Yes	Two-drug combination for most (usually thiazide-type diuretic and ACE inhibitor, ARB, β-blocker, or CCB)	Drug(s) for compelling indications; other antihypertensive drugs (diuretics, ACE inhibitor, ARB, β-blocker, CCB) as needed

ACE, angiotensin-converting enzyme; *ARB,* angiotensin-receptor blocker; *CCB,* calcium-channel blocker.
[a] Treatment is determined by the patient's highest blood pressure category.

[b] Selected drug therapies have been identified from clinical trials to possess positive clinical outcomes for specific clinical situations and represent compelling indication for their use. Compelling indications (and drug therapies): heart failure (diuretics, β-blockers, ACE inhibitors, ARB, aldosterone antagonists), postmyocardial infarction (β-blockers, ACE inhibitors, and aldosterone antagonists), high coronary disease risk (diuretic, β-blocker, ACE inhibitors, CCB), diabetes (diuretic, β-blockers, ACE inhibitors, ARB, CCB), chronic kidney disease (ACE inhibitors, ARB), and recurrent stroke prevention (diuretic, ACE inhibitors).

Based on Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure: The JNC-7 report [Special communication; Clinician's Corner]. JAMA 2003;289:2560-2572.

Table 41-2. Cardiovascular and/or Lifestyle Risk Factors for Consideration in the Management of Hypertension

Hypertension
Cigarette smoking
Obesity (BMI ≥ 30)
Physical inactivity
Dyslipidemia (as a component of the metabolic syndrome)
Diabetes mellitus (as a component of the metabolic syndrome)
Microalbuminuria or estimated glomerular filtration rate < 60 mL/min

Age (> 55 years for men; > 65 years for women)
Family history of premature cardiovascular disease (men < 55 years; women < 65 years)
BMI, body mass index (calculated as weight in kilograms divided by the square of height in meters).
Based on Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure: The JNC-7 report [Special communication; Clinician's Corner]. JAMA 2003;289:2560-2572.

a. It stimulates the release of aldosterone from the adrenal gland (zona glomerulosa), which results in increased sodium reabsorption, fluid volume, and blood pressure.

b. It constricts resistance vessels, which increases peripheral vascular resistance and arterial pressure.

c. It stimulates the release of vasopressin, or antidiuretic hormone (ADH), from the posterior pituitary, which acts within the kidneys to increase fluid retention.

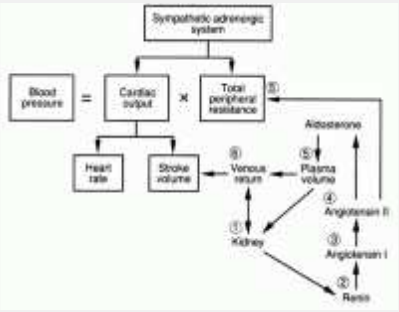

Figure 41-1. Blood pressure regulation: the determinants of blood pressure as they relate to cardiac output and total peripheral resistance. Angiotensin II, a potent vasopressor, not only increases total peripheral resistance but also, by stimulating aldosterone release, leads to an increase in plasma volume, venous return, stroke volume, and ultimately an increase in cardiac output.

d. It stimulates cardiac hypertrophy and vascular hypertrophy.

e. It facilitates norepinephrine release from sympathetic nerve endings and inhibits norepinephrine reuptake by nerve endings, which enhances sympathetic function.

3. Mosaic theory centers around the fact that multiple factors, rather than one factor alone, are responsible for sustaining hypertension. The interactions among the sympathetic nervous system, renin-angiotensin-aldosterone system, and potential defects in sodium transport within and outside the cell may all play a role in long-term hypertension. Additional factors contributing to the development include genetics, endothelial dysfunction, and neurovascular anomalies. Other vasoactive substances that are involved in the maintenance of normal blood pressure have also been identified; these include nitric oxide (vasodilating factor), endothelin (vasoconstrictor peptide), bradykinin (potent vasodilator inactivated by ACE), and atrial natriuretic peptide (naturally occurring diuretic).

4. Fluid volume regulation. Increased fluid volume increases venous system distention and venous return, affecting cardiac output and tissue perfusion. These changes **alter vascular resistance,** increasing the blood pressure.

F. Complications. Untreated systemic hypertension, regardless of cause, results in inflammation and necrosis of the arterioles, narrowing of the blood vessels, and restriction of the blood flow to major body organs (Table 41-3). When blood flow is severely compromised, target-organ damage ensues.

1. Cardiac effects

a. Left ventricular hypertrophy (cardiac remodeling) compensates for the increased cardiac workload. Signs and symptoms of heart failure occur, and the increased oxygen requirements of the enlarged heart may produce angina pectoris.

Table 41-3. Target-Organ Damage Associated with Hypertension

Organ/System and Findings	Basis of Findings
Cardiovascular	
Blood pressure persistently ≥ 140 mm Hg systolic and/or ≥ 90 mm Hg diastolic	Constricted arterioles, causing abnormal resistance to blood flow
Angina pain	Insufficient blood flow to coronary vasculature
Left ventricular hypertrophy/dyspnea on exertion	Heart failure
Edema of extremities	Decrease in blood supply
Neurological	

Severe occipital headaches with nausea and vomiting, drowsiness, anxiety, and mental impairment	Vessel damage within brain characteristic of dizziness, severe mental impairment, hypertension, resulting in transient ischemic attacks or strokes
Renal	
Polyuria, nocturia, and diminished ability to concentrate urine; protein and red blood cells in urine; elevated serum creatinine	Arteriolar nephrosclerosis (hardening of arterioles within kidney)
Ocular	
Retinal hemorrhage and exudates	Damage to arterioles that supply retina
Peripheral vascular	Absence of pulses in extremities with or without intermittent claudication; development of aneurysm

Based on Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure: The JNC-7 report [Special communication; Clinician's Corner]. JAMA 2003;289:2560-2572.

b. Hypertension can be caused by accelerated atherosclerosis. Atheromatous lesions in the coronary arteries lead to decreased blood flow, resulting in angina pectoris. MI and sudden death may ensue.

2. Renal effects

a. Decreased blood flow leads to an increase in renin-aldosterone secretion, which heightens the reabsorption of sodium and water and increases blood volume.

b. Accelerated atherosclerosis decreases the oxygen supply, leading to renal parenchymal damage with decreased filtration capability and to azotemia. The atherosclerosis also decreases blood flow to the renal arterioles, leading to nephrosclerosis and, ultimately, renal failure (acute as well as chronic).

3. Cerebral effects. Decreased blood flow, decreased oxygen supply, and weakened blood vessel walls lead to transient ischemic attacks, cerebral thromboses, and the development of aneurysms with hemorrhage. There are alterations in mobility, weakness and paralysis, and memory deficits.
4. Retinal effects. Decreased blood flow with retinal vascular sclerosis and increased arteriolar pressure with the appearance of exudates and hemorrhage result in visual defects (e.g., blurred vision, spots, blindness).

II. SECONDARY HYPERTENSION

A. Clinical evaluation. Because most patients presenting with high blood pressure have primary rather than secondary hypertension, extensive screening is unwarranted. A thorough history and physical examination followed by an evaluation of common laboratory tests should rule out most causes of secondary hypertension. Patient age (primary hypertension is normally seen between 30 and 55 years of age), sudden onset of worsening of hypertension, and blood pressure elevations not responding to treatment are findings consistent with secondary hypertension. If a secondary cause is not found, the patient is considered to have essential (primary) hypertension.
1. A patient's **history** and **other physical findings** suggest an underlying cause of hypertension. These include the following:
a. Weight gain, moon face, truncal obesity, osteoporosis, purple striae, hirsutism, hypokalemia, diabetes, and increased plasma cortisol may signal Cushing syndrome.
b. Weight loss, episodic flushing, diaphoresis, increased urinary catecholamines, headaches, intermittent hypertension, tremors, and palpitations suggest pheochromocytoma.
c. Steroid or estrogen intake, including oral contraceptives, nonsteroidal anti-inflammatory drugs (NSAIDs), nasal decongestants, tricyclic antidepressants, appetite suppressants, cyclosporine, erythropoietin, and monoamine oxidase (MAO) inhibitors, suggests drug-induced hypertension.
d. Repeated urinary tract infections, elevated serum creatinine levels, nocturia, hematuria, and pain on urinating may signify renal involvement (e.g., chronic kidney disease).
e. Abdominal bruits, recent onset, and accelerated hypertension indicate renal artery stenosis (e.g., renovascular disease).
f. Muscle cramps, weakness, excess urination, and isolated hypokalemia may suggest primary aldosteronism.
g. Sleep apnea, coarctation of the aorta, thyroid disease, and parathyroid disease have been included by the JNC-7 as additional secondary causes of hypertension.
2. Laboratory findings
a. Blood urea nitrogen (BUN) and creatinine elevations suggest renal disease.
b. Increased urinary excretion of catecholamine or its metabolites (e.g., vanillylmandelic acid, metanephrine) confirms pheochromocytoma.
c. Serum potassium evaluation revealing hypokalemia suggests primary aldosteronism or Cushing syndrome.

3. Diagnostic tests

a. Renal arteriography, ultrasound, or renal venography may show evidence of renal artery stenosis.

b. Electrocardiography (ECG) may reveal left ventricular hypertrophy or ischemia.

P.855

B. Cause

1. Primary aldosteronism. Hypersecretion of aldosterone by the adrenal cortex increases distal tubular sodium retention, expanding the blood volume, which increases total peripheral resistance.

2. Pheochromocytoma. A tumor of the adrenal medulla stimulates hypersecretion of epinephrine and norepinephrine, which results in increased total peripheral resistance.

3. Renal artery stenosis. Decreased renal tissue perfusion activates the renin-angiotensin-aldosterone system (see I.E.2).

C. Treatment. Secondary hypertension requires treatment of the underlying cause (e.g., surgical intervention accompanied by supplementary control of hypertensive effects; see III.B).

III. ESSENTIAL (PRIMARY) HYPERTENSION

A. Clinical evaluation requires a thorough history and physical examination followed by a careful analysis of common laboratory test results.

1. Objectives

a. To rule out uncommon secondary causes of hypertension

b. To determine the presence and extent of target-organ damage

c. To determine the presence of other cardiovascular risk factors in addition to high blood pressure

d. To reduce morbidity and mortality through multiple strategies that reduce blood pressure through lifestyle modifications with or without pharmacological treatment with minimal side effects.

2. Predisposing factors

a. Family history of essential hypertension, stroke, and premature cardiac disease

b. Patient history of intermittent elevations in blood pressure

c. Racial predisposition. Hypertension is more common among African Americans than whites.

d. Obesity. Weight reduction has been shown to reduce blood pressure in a large proportion of hypertensive patients who are > 10% above ideal body weight.

e. Smoking, resulting in vasoconstriction and activation of the sympathetic nervous system, is a major risk factor for cardiovascular disease.

f. Stress

g. High dietary intake of saturated fats or sodium

h. Sedentary lifestyle

i. Diabetes mellitus

j. Hyperlipidemia

k. Major risk factors according to the JNC-7 include smoking, diabetes mellitus, age (> 55 for men; > 65 for women), family history of cardiovascular disease, and dyslipidemia.

l. Target-organ damage/clinical cardiovascular disease according to the JNC-7 includes heart disease (e.g., left ventricular hypertrophy, angina, prior MI, heart failure), stroke or transient ischemic attacks, nephropathy, peripheral artery disease, and retinopathy.

3. Physical findings

a. Serial blood pressure readings ≥ 140/90 should be obtained on at least two occasions before specific therapy is begun, unless the initial blood pressure levels are markedly elevated (i.e., > 210 mm Hg systolic; > 120 mm Hg diastolic, or both) or are associated with target-organ damage. A single elevated reading is an insufficient basis for a diagnosis.

b. Essential hypertension usually does not become clinically evident—other than through serial blood pressure elevations—until vascular changes affect the heart, brain, kidneys, or ocular fundi.

c. Examination of the ocular fundi is valuable; their condition can indicate the duration and severity of the hypertension.

(1) Early stages. Hard, shiny deposits; tiny hemorrhages; and elevated arterial blood pressure occur.

(2) Late stages. Cotton-wool patches, exudates, retinal edema, papilledema caused by ischemia and capillary insufficiency, hemorrhages, and microaneurysms become evident.

4. Untreated hypertension increases the likelihood of the development of numerous organ problems, which include left ventricular failure, MI, renal failure, cerebral hemorrhage or infarction, and severe changes in the retina of the eye.

B. Treatment (Tables 41-4 and 41-5; Figure 41-2)

1. General principles. Treatment primarily aims to lower blood pressure toward "normal" with minimal side effects and to prevent or reverse organ damage. Currently, there is no cure for

primary hypertension. Treating systolic and diastolic blood pressures to targets that are < 140/90 mm Hg is associated with a decrease in cardiovascular complications. For patients with hypertension who have diabetes or renal disease, the blood pressure goal recommended by the JNC-7 is 130/80 mm Hg.

Table 41-4. Common Antihypertensive Drugs

I.	**Diuretics**		
	A.	Thiazide diuretics	
			Chlorothiazide (Diuril)
			Chlorthalidone (Hygroton)
			Hydrochlorothiazide (HydroDIURIL)
			Indapamide (Lozol)
			Methyclothiazide (Enduron)
			Metolazone (Zaroxolyn)
	B.	Loop diuretics	
			Bumetanide (Bumex)
			Ethacrynic acid (Edecrin)
			Furosemide (Lasix)
			Torsemide (Demadex)
	C.	Potassium-sparing diuretics	
			Amiloride (Midamor)
			Eplerenone (Inspra)
			Spironolactone (Aldactone)

			Triamterene (Dyrenium)
II.	**Vasodilators (direct acting)**		
		Diazoxide (Proglycem)	
		Hydralazine (Various)	
		Minoxidil (Loniten)	
		Nitroprusside (Nitropress)	
III.	**Angiotensin-converting enzyme (ACE) inhibitors**		
		Benazepril (Lotensin)	
		Captopril (Capoten)	
		Enalapril (Vasotec)	
		Enalaprilat (IV) (Vasotec)	
		Fosinopril (Monopril)	
		Lisinopril (Prinivil, Zestril)	
		Moexipril (Univasc)	
		Perindopril (Aceon)	
		Quinapril (Accupril)	
		Ramipril (Altace)	

		Trandolapril (Mavik)	
IV.	**Angiotensin II receptor antagonists**		
		Candesartan cilexetil (Atacand)	
		Eprosartan (Teveten)	
		Irbesartan (Avapro)	
		Losartan (Cozaar)	
		Olmesartan (Benicar)	
		Telmisartan (Micardis)	
		Valsartan (Diovan)	
V.	**Renin inhibitors**		
		Aliskiren (Tekturna)	
VI.	**Sympatholytics**		
	A.	β-Adrenergic blocking agents	
			Acebutolol (Sectral)
			Atenolol (Tenormin)
			Betaxolol (Kerlone)
			Bisoprolol (Zebeta)

			Carvedilol (Coreg)
			Labetalol (Normodyne, Trandate)
			Metoprolol (Lopressor, Toprol XL)
			Nadolol (Corgard)
			Nebivolol (Bystolic)
			Penbutolol (Levatol)
			Pindolol (Visken)
			Propranolol (Inderal)
			Timolol (Various)
	B.	Centrally acting α-agonists	
			Clonidine (Catapres)
			Guanabenz (Various)
			Guanfacine (Tenex)
			Methyldopa (Various)
	C.	Postganglionic adrenergic neuron blockers	
			Reserpine (various)
	D.	α-Adrenergic blocking agents	

			Doxazosin (Cardura)		
			Prazosin (Minipress)		
			Terazosin (Hytrin)		
	E.	Calcium-channel blockers			
			1.	Benzodiazepine derivatives	
					Diltiazem (Cardizem, Dilacor, Tiazac)
			2.	Diphenylalkylamine derivatives	
					Verapamil (Isoptin, Calan)
			3.	Dihydropyridines	
					Amlodipine (Norvasc)
					Felodipine (Plendil)
					Isradipine (DynaCirc CR)
					Nicardipine (Cardene)
					Nifedipine (Procardia XL, Adalat CC)
					Nisoldipine (Sular)

Table 41-5. Common Combination Products for Hypertension

I.	**Diuretics**	
		Hydrochlorothiazide—spironolactone (Aldactazide)
		Hydrochlorothiazide—triamterene (Dyazide, Maxzide)
		Hydrochlorothiazide—amiloride (Moduretic)
II.	**Diuretics—β-adrenergic blockers**	
		Bendroflumethiazide—nadolol (Corzide)
		Chlorthalidone—atenolol (Tenoretic)
		Hydrochlorothiazide—propranolol (Inderide)
		Hydrochlorothiazide—metoprolol (Lopressor HCT)
		Hydrochlorothiazide—bisoprolol (Ziac)
III.	**Diuretics—angiotensin-converting enzyme (ACE) inhibitors**	
		Hydrochlorothiazide—captopril (Capozide)
		Hydrochlorothiazide—benazepril (Lotensin HCT)
		Hydrochlorothiazide—lisinopril (Prinzide, Zestoretic)
		Hydrochlorothiazide—enalapril (Vaseretic)
		Hydrochlorothiazide—fosinopril (Monopril HCT)
		Hydrochlorothiazide—moexipril (Uniretic)

		Hydrochlorothiazide—quinapril (Accuretic)
IV.	**Diuretics—angiotensin II receptor antagonists**	
		Hydrochlorothiazide—losartan (Hyzaar)
		Hydrochlorothiazide—irbesartan (Avalide)
		Hydrochlorothiazide—valsartan (Diovan HCT)
		Hydrochlorothiazide—telmisartan (Micardis HCT)
		Hydrochlorothiazide—candesartan (Atacand HCT)
		Hydrochlorothiazide—eprosartan (Teveten HCT)
		Hydrochlorothiazide—olmesartan (Benicar HCT)
V.	**Angiotensin-converting enzyme (ACE) inhibitors—Calcium-channel blockers**	
		Enalapril—felodipine (Lexxel)
		Trandolapril—verapamil (Tarka)
		Benazepril—amlodipine (Lotrel)
VI.	**Angiotensin II receptor antagonists-Calcium channel blockers**	
		Olmesartan—amlodipine (Azor)
		Valsartan—amlodipine (Exforge)
VII.	**Other**	

		Hydrochlorothiazide—hydralazine (Apresazide)
		Hydrochlorothiazide—methyldopa (Various)
		Polythiazide-prazosin (Minizide)
		Amlodipine—atorvastatin (Caduet)

a. Candidates for treatment

(1) All patients with a diastolic pressure of > 90 mm Hg, a systolic pressure of > 140 mm Hg, or a combination of both should receive antihypertensive drug therapy.

(2) For those patients with a diastolic pressure of 80-89 mm Hg or a systolic pressure of 120-139 mm Hg (prehypertension), no drug treatment is indicated unless the patient has a compelling indication. However, lifestyle modifications such as weight reduction, dietary sodium reduction, increased physical activity, and moderation of alcohol consumption should be initiated.

b. Nonspecific measures. Before initiating antihypertensive drug therapy, patients are encouraged to eliminate or minimize controllable risk factors (see III.A.2).

c. Pharmacological treatment. The recommendations of the JNC-7 suggest that recent clinical trials have demonstrated that most hypertensive patients will require two or more antihypertensive drugs.

Figure 41-2. Algorithm for the treatment of hypertension. *ACE,* angiotensin-converting enzyme; *ARB,* angiotensin-receptor blocker; *CCB,* calcium-channel blocker. [Based on the recommendations from the Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure (JNC-7).]

(1) Thiazide diuretics should be the initial choice of therapy because they have demonstrated a reduction in morbidity and mortality when used as initial monotherapy. They have been shown to lower morbidity and mortality rates, have shown adequate long-term safety data, and have demonstrated patient tolerability.
(2) Thiazide diuretics should be considered initial agents for treatment unless there are compelling indications for other medications.
(3) Agents such as ACE inhibitors, angiotensin-receptor blockers, β-blockers, and calcium-channel blockers have all been recommended for patients who cannot receive a thiazide diuretic or in combination with a thiazide diuretic for adequate control of blood pressure. This may include the use of ACE inhibitors in hypertensive patients having systolic dysfunction after a myocardial infarction, a diabetic nephropathy patient who might benefit from an ACE inhibitor in combination with a diuretic, or a patient with HF.
d. Monitoring guidelines. Specific monitoring guidelines for the various drug categories are outlined in III.B.2, 3, 4, 5, 6 and 7.

(1) Blood pressure should be monitored routinely to determine the therapeutic response and to encourage patient compliance.
(2) Clinicians must be alert to indications of adverse drug effects. Many patients do not link side effects to drug therapy or are embarrassed to discuss them, especially effects related to sexual function or effects that appear late in therapy.
e. Patient compliance
(1) Because hypertension is usually a symptomless disease, how the patient “feels” does not reflect the blood pressure level. In fact, the patient may actually report “feeling normal” with an elevated blood pressure and “abnormal” during a hypotensive episode because of the light-headedness associated with a sudden drop in blood pressure. Because essential hypertension requires a lifelong drug regimen, it is extremely difficult but necessary to impress on patients the need for compliance with their therapeutic regimen.
(2) Recognizing the seriousness of the consequences of noncompliance is key. Patients should be told that prolonged, untreated hypertension, known as the “silent killer,” can affect the heart, brain, kidneys, and ocular fundi.
2. Diuretics
a. Thiazide diuretics and their derivatives are currently recommended as initial therapy for hypertension. JNC-VII recommends initiating therapy with a low dose (12.5 mg of hydrochlorothiazide (HydroDIURIL or its equivalent), increasing the dose if necessary, and not exceeding a dose of 50 mg of hydrochlorothiazide or its equivalent.
(1) Actions. Antihypertensive effects are produced by directly dilating the arterioles and reducing the total fluid volume. Thiazide diuretics increase the following:
(a) Urinary excretion of sodium and water by inhibiting sodium and chloride reabsorption in the distal convoluted (renal) tubules
(b) Urinary excretion of potassium and, to a lesser extent, bicarbonate

(c) The effectiveness of other antihypertensive agents by preventing reexpansion of extracellular and plasma volumes

(2) Significant interactions. NSAIDs, such as the now common over-the-counter forms of ibuprofen (Advil, Motrin), interact to diminish the antihypertensive effects of the thiazide diuretics.

(3) Precautions and monitoring effects

(a) Potassium ion (K^+) depletion may require supplementation, increased dietary intake, or the use of a potassium-sparing diuretic such as spironolactone (Aldactone).

(b) Uric acid retention may occur; this is potentially significant in patients who are predisposed to gout and related disorders.

(c) Blood glucose levels may increase, which may be significant in patients with diabetes.

(d) Calcium levels may increase because of the potential for retaining calcium ions.

(e) Patients with known allergies to sulfa-type drugs should be questioned to determine the significance of the allergy.

(f) Other common effects include fatigue, headache, palpitations, rash, vertigo, and transitory impotence.

(g) Hyperlipidemia, including **hypertriglyceridemia,** hypercholesterolemia, increased low-density lipoprotein (LDL) cholesterol, and decreased high-density lipoprotein (HDL) cholesterol, must be evaluated routinely to prevent an added risk for coronary artery disease.

(h) Fluid losses must be evaluated and monitored to prevent dehydration, postural hypotension, and even hypovolemic shock.

(i) Alterations in fluids and electrolytes (e.g., hypokalemia, hypomagnesemia, hypercalcemia) may predispose patients to cardiac irritability, with a resultant increase in cardiac arrhythmias. ECG) is performed routinely to detect and prevent the development of life-threatening arrhythmias.

(4) Usual effective doses

(a) Chlorothiazide (Diuril): 250-500 mg daily or twice daily

(b) Chlorthalidone (Hygroton): 12.5-25 mg daily

(c) Hydrochlorothiazide (HydroDIURIL): 12.5-50 mg daily

(d) Indapamide (Lozol): 1.25-2.5 mg daily

(e) Methyclothiazide (Enduron): 2.5-5.0 mg daily

(f) Metolazone (Zaroxolyn): 2.5-5.0 mg daily

b. Loop (high-ceiling) diuretics

(1) Indications. These agents are indicated when patients are unable to tolerate thiazides, experience a loss of thiazide effectiveness, or have impaired renal function (clearance < 30 mL/min).

(2) Actions. Furosemide (Lasix), ethacrynic acid (Edecrin), bumetanide (Bumex), and torsemide (Demadex) act primarily in the ascending loop of Henle; hence they are called “loop” diuretics. By acting within the loop of Henle, they decrease sodium

reabsorption. Their action is more intense but of shorter duration (1-4 hr) than that of the thiazides; they may also be more expensive.

(3) Significant interactions. As with the thiazides, the antihypertensive effect of loop diuretics may be diminished by **NSAIDs.**

(4) Precautions and monitoring effects. Loop diuretics have the same effects as thiazides (see III.B.2.a), in addition to the following:

(a) Loop diuretics have a complex influence on renal hemodynamics; thus patients must be monitored closely for signs of hypovolemia.

(b) Because these agents should be used cautiously in patients with episodic or chronic renal impairment, BUN and serum creatinine levels should be checked routinely.

(c) Transient deafness has been reported. If the patient is taking a potentially ototoxic drug (e.g., an aminoglycoside antibiotic), another class of diuretic (e.g., a thiazide diuretic) should be substituted.

(5) Usual effective doses

(a) Bumetanide (Bumex): 0.5-2.0 mg daily

(b) Ethacrynic acid (Edecrin): 25-100 mg daily

(c) Furosemide (Lasix): 20-80 mg daily

(d) Torsemide (Demadex): 2.5-10 mg daily

c. Potassium-sparing diuretics

(1) Indications. The diuretics in this group—spironolactone (Aldactone), amiloride (Midamor), and triamterene (Dyrenium)—are indicated for patients in whom potassium loss is significant and supplementation is not feasible. These agents are often used in combination with a thiazide diuretic because they potentiate the effects of the thiazide while minimizing potassium loss. **Spironolactone** is particularly useful in patients with hyperaldosteronism, as it has direct antagonistic effects on aldosterone (aldosterone-receptor blocker). **Eplerenone** (Inspra), is another aldosterone-receptor blocker recently approved by the U.S. Food and Drug Administration (FDA) that, similar to spironolactone, blocks aldosterone binding at the mineralocorticoid receptor. Both of these agents have been used in hypertension, and have an increased level of use in the treatment of HF (see Chapter 42).

(2) Actions. Potassium-sparing diuretics achieve their diuretic effects differently and less potently than the thiazides and loop diuretics. Their most pertinent shared feature is that they promote potassium retention.

(3) Significant interactions. Coadministration with **ACE inhibitors** or **potassium supplements** significantly increases the risk of hyperkalemia.

(4) Precautions and monitoring effects

(a) Potassium-sparing diuretics should be avoided in patients with acute renal failure and used with caution in patients with impaired renal function (monitor serum creatinine) because they can retain potassium.

(b) Triamterene should not be used in patients with a history of kidney stones or hepatic disease.

(c) Hyperkalemia is a major risk, requiring routine monitoring of serum electrolytes. BUN and serum creatinine levels should be checked routinely to signal incipient excess potassium retention and impaired renal function.

(5) Usual effective doses

(a) Amiloride (Midamor): 5-10 mg daily

(b) Spironolactone (Aldactone): 25-100 mg daily and 100-400 mg daily to treat hyperaldosteronism

(c) Triamterene (Dyrenium): 50-100 mg daily

(d) Eplerenone (Inspra): 50-100 mg daily

d. Combination products. Several products combine a thiazide and a potassium-sparing diuretic.

P.861

(1) Aldactazide: 25 mg spironolactone plus 25 mg hydrochlorothiazide (one to two tablets daily)

(2) Aldactazide-50: 50 mg spironolactone plus 50 mg hydrochlorothiazide (one tablet daily)

(3) Moduretic: 5 mg amiloride plus 50 mg hydrochlorothiazide (one to two tablets daily)

(4) Dyazide: 37.5 mg triamterene plus 25 mg hydrochlorothiazide (one to two capsules daily)

(5) Maxzide: 75 mg triamterene plus 50 mg hydrochlorothiazide (one half to one tablet daily)

(6) Maxzide-25: 37.5 triamterene plus 25 mg hydrochlorothiazide

3. Sympatholytics

a. β-Adrenergic blockers

(1) Indications. β-Blockers are particularly effective in patients with rapid resting heart rates (i.e., atrial fibrillation, paroxysmal supraventricular tachycardia) or compelling indications such as heart failure, post-MI, high coronary disease risk, and diabetes.

(2) Actions. Proposed mechanisms of action include the following:

(a) Stimulation of renin secretion is blocked.

(b) Cardiac contractility is decreased, thus diminishing cardiac output.

(c) Sympathetic output is decreased centrally.

(d) Reduction in heart rate decreases cardiac output.

(e) β-Blocker action may combine all of the above mechanisms.

(3) Epidemiology. Young (< 45 years) whites with high cardiac output, high heart rate and normal vascular resistance respond best to β-blocker therapy.

(4) Precautions and monitoring effects

(a) Patients must be monitored for signs and symptoms of **cardiac decompensation** (i.e., reduction in cardiac output) owing to the fact that decreased myocardial contractility can trigger compensatory mechanisms, leading to HF (see Chapter 41).

(b) ECGs should be monitored routinely because all β-blockers can decrease electrical conduction within the heart and cause bradyarrhythmias.

(c) Relative cardioselectivity is dose dependent and is lost as dosages are increased. Therefore, **no β-blocker is totally safe in patients with bronchospastic disease**—for example asthma and chronic obstructive pulmonary disease (COPD).
(d) Abrupt stoppage in β-blocker therapy puts the patient at risk for a **withdrawal syndrome** that may produce
(i) Exacerbated anginal attacks, particularly in patients with coronary artery disease
(ii) Myocardial infarction
(iii) A life-threatening rebound of blood pressure to levels exceeding pretreatment readings
(e) β-Blocker therapy should be used with caution in patients with the following conditions:
(i) Diabetes. β-Blockers can mask hypoglycemic symptoms, such as tachycardia.
(ii) Raynaud phenomenon or peripheral vascular disease. Vasoconstriction can occur and, in predisposed patients, might result in a clinically significant problem.
(iii) Neurological disorders. Several β-blockers enter the central nervous system (CNS), potentiating related side effects (e.g., fatigue, lethargy, poor memory, weakness, or mental depression).
(f) Impotence and decreased libido may result in reduced patient compliance.
(5) Significant interactions. β-Adrenergic blockers interact with numerous agents, requiring cautious selection, administration, and monitoring.
(6) β-Blocker terms
(a) Relative cardioselective activity. Relative to propranolol, β-blockers have a greater tendency to occupy the β_1-receptor in the heart, rather than the β_2-receptors in the lungs.
(b) Intrinsic sympathomimetic activity. These agents have the ability to release catecholamines and to maintain a satisfactory heart rate. Intrinsic sympathomimetic activity may also prevent bronchoconstriction and other direct β-blocking actions.

(7) Specific agents
(a) Propranolol (Inderal) was the first β-adrenergic blocking agent shown to block both β_1- and β_2-receptors. The **usual daily dose range** is 40-160 mg. It is available both as a rapid-acting product and a long-acting product (Inderal-LA); the usual daily dose range is 60-180 mg.
(b) Metoprolol (Lopressor) was the first β-adrenergic blocking agent to show relative cardioselective blocking activity, with relatively less blockade of the β_2-receptors in the lung when compared to propranolol. The **usual daily dose** is 50-100 mg. A sustained-release form of the drug is now available, as the succinate salt (Toprol XL), which requires less frequent dosing, (daily versus once or twice daily for immediate-release metoprolol).
(c) Nadolol (Corgard) was the first β-adrenergic blocking agent that allowed once-daily dosing. It blocks both β_1- and β_2-receptors similar to propranolol. The **usual daily dose** is 40-120 mg.

(d) Atenolol (Tenormin) was the first β-adrenergic blocking agent to combine once-daily dosing (nadolol) with relative cardioselective blocking activity (metoprolol). The **usual daily dose** is 25-100 mg.
(e) Timolol (Blocadren) was the first β-adrenergic blocking agent shown to be effective after an acute MI to prevent sudden death. It blocks both β_1- and β_2-receptors. The **usual daily dose** is 20-40 mg.
(f) Pindolol (Visken) was the first β-adrenergic blocking agent shown to have high intrinsic sympathomimetic activity. The **usual daily dose** is 10-40 mg.
(g) Labetalol (Trandate) was the first β-adrenergic blocking agent shown to possess both α- and β-adrenergic blocking activity. The **usual daily dose** is 200-800 mg. Labetalol is also effective for treating hypertensive crisis (Table 41-6).
(h) Acebutolol (Sectral) was the first β-adrenergic blocking agent that combined efficacy with once-daily dosing (nadolol), possessing intrinsic sympathomimetic activity (pindolol) and having relative cardioselective blocking activity (metoprolol). The **usual daily dose** is 200-800 mg.
(i) Esmolol (Brevibloc) was the first β-adrenergic blocking agent to have an ultrashort duration of action. This agent is not used routinely in treating hypertension owing to its duration of action and the need for intravenous administration. However, it has been used for hypertension and or tachycardia during and after surgical procedures. The **usual dose** is 150-300 μg/kg/min up to 300 μg/kg/min intravenously.
(j) Betaxolol (Kerlone) is a β-adrenergic blocker that possesses relative cardioselective blocking activity similar to metoprolol but has a half-life that allows for once-daily dosing. The **usual daily dose** is 5-20 mg.
(k) Penbutolol (Levatol) is a β-adrenergic blocking agent that has weak intrinsic sympathomimetic activity like pindolol and allows for once-daily dosing. The **usual daily dose** is 10-20 mg.
(l) Bisoprolol (Zebeta) is a β-adrenergic blocking agent that is cardioselective and has no intrinsic sympathomimetic activity. It allows for once-daily dosing, and the **usual daily dose** is 2.5-10 mg.
(m) Carvedilol (Coreg) is a β-adrenergic blocking agent that has β-blocking properties as well as α-blocking properties, with a resultant vasodilation. The drug is administered twice daily with a starting dose of 6.25 mg titrated at 7- to 14-day intervals to a dose of 25 mg twice daily. **Usual daily doses** are 12.5-50 mg daily.
(n) Nebivolol (Bystolic) is a β-adrenergic blocking agent that has cardioselective β_1 blocking tendencies, similar to several other agents in the class. Initial reports also suggest that nebivolol has vasodilatory properties through its release of nitric oxide. Nebivolol is administered in a single daily dose of 5 mg with dose titration required based on therapeutic response.
b. Peripheral α_1-adrenergic blockers—for example, prazosin (Minipress), terazosin (Hytrin), and doxazosin(Cardura)
(1) Indications. This group of drugs is available for hypertensive patients who have not responded to initial antihypertensive therapy.
(2) Actions. The α_1-blockers (indirect vasodilators) block the peripheral postsynaptic α_1-adrenergic receptor, causing vasodilation of both arteries and veins.

Also, the incidence of reflex tachycardia is lower with these agents than with the vasodilator hydralazine. These hemodynamic changes reverse the abnormalities in hypertension and preserve organ perfusion. Recent studies have also shown that these agents have no adverse effect on serum lipids and other cardiac risk factors.
P.863

Table 41-6. Rapid-Acting Parenteral Antihypertensive Agents for Hypertensive Crisis

Drug	Dose/Route	Onset of Action	Duration of Action	Comments
Vasodilators				
Sodium nitroprusside (Nitropress)	0.3-10 mg/kg/min as IV infusion	0.5-1 min	1-2 min	Immediate effect, very short duration; nausea, vomiting, muscle twitching, sweating, thiocyanate and cyanide intoxication
Nicardipine hydrochloride (Cardene)	5-15 mg/hr IV	< 5-15 min	1-4 hr	Intermediate onset and duration; tachycardia may occur, headache, flushing, local phlebitis
Fenoldopam mesylate (Corlopam)	0.1-0.3 µg/kg/min as IV infusion	< 5 min	30 min	Intermediate onset and duration; action on dopamine D_1-receptors (dilation of renal/mesenteric vessels might be preferred over nitroprusside for long-term or with renal dysfunction; tachycardia, headache, nausea, flushing
Nitroglycerin	5-200 µg/min (0.3-6.0	2-5 min	3-5 min	Useful in coronary artery disease; headache, vomiting,

	mg/hr) as IV infusion			methemoglobinemia, tolerance with prolonged use
Enalaprilat (Vasotec IV)	0.625-1.25 mg every 6 hr IV	15-30 min	4-6 hr	Useful in HF, but avoid in renal impairment; precipitous fall in blood pressure in high-renin states
Hydralazine	10-40 mg IV/IM	10-20 min	3-8 hr	Afterload reduction through arteriole dilation resulting in increased cardiac output; tachycardia, flushing headache, vomiting, aggravation of preexisting angina
Diazoxide (Proglycem)	1-3 mg/kg over 30 sec as IV bolus, repeated every 5-15 min, or 10-30 mg/min infusion	2-4 min	3-12 hr	Useful in hypertensive encephalopathy, malignant hypertension, and eclampsia; flushing, nausea, tachycardia, and chest pain
Adrenergic inhibitors				
Labetalol hydrochloride (Various)	40-80 mg IV bolus every 10 min, or 0.5-2.0 mg/min IV infusion	5-10 min	3-6 hr	Contraindicated in HF, bronchospastic patients, or bradycardia; predictable hypotensive effect; vomiting, scalp tingling, burning in throat, heart block, orthostatic hypotension

Esmolol (Brevibloc)	250-500 µg/kg/min for 2 min, then 50-100 µg/kg/min for 4 min; may repeat if needed	1-2 min	10-20 min	β-Adrenergic blocker with ultra-short duration of effect; primary use in perioperative situation owing to short duration and quick onset; hypotension, nausea
Phentolamine	5-15 mg IV	1-2 min	3-10 min	α-Adrenergic blocker causing peripheral dilation; tachycardia, flushing, headache

HF, heart failure; IM, intramuscular; IV, intravenous.

(3) Precautions and monitoring effects

(a) First-dose phenomenon. A syncopal episode may occur within 30-90 min of the first dose; similarly associated are postural hypotension, nausea, dizziness, headache, palpitations, and sweating. To minimize these effects, the first dose should be limited to a small dose (1 mg) and administered just before bedtime.

(b) Additional adverse effects include diarrhea, weight gain, peripheral edema, dry mouth, urinary urgency, constipation, and priapism. Doxazosin in doses of 2-8 mg/day was one of the treatment arms in the recent Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial (ALLHAT), and the treatment was discontinued prematurely owing to an apparent 25% increase in the incidence of combined cardiovascular disease outcomes than patients in the control group receiving the diuretic chlorthalidone. The added risk for HF, stroke, and coronary heart disease were the major outcomes affected in the doxazosin arm.

(4) The average daily doses are

(a) Prazosin (Minipress): 2-20 mg

(b) Terazosin (Hytrin): 1-20 mg

(c) Doxazosin(Cardura): 1-16 mg

c. Centrally active α-agonists have been used in the past as alternatives to initial antihypertensives, but their use in mild to moderate hypertension has been reduced primarily owing to other available agents. They act primarily within the CNS on α_2-receptors to decrease sympathetic outflow to the cardiovascular system.

(1) Methyldopa (Aldomet)

(a) Actions. Methyldopa decreases total peripheral resistance through the above mechanism while having little effect on cardiac output or heart rate (except in older patients).

(b) Precautions and monitoring effects

(i) Common untoward effects include orthostatic hypotension, fluid accumulation (in the absence of a diuretic), and rebound hypertension on abrupt withdrawal. Sedation is a common finding upon initiating therapy and when increasing doses; however, the sedative effect usually decreases with continued therapy.

(ii) Fever and other flu-like symptoms occasionally occur and may represent hepatic dysfunction, which should be monitored by liver function tests.

(iii) A positive Coombs test develops in 25% of patients with chronic use (> 6 months). Less than 1% of these patients develop a hemolytic anemia. (Red blood cells, hemoglobin, and blood count indices should be checked.) The anemia is reversible by discontinuing the drug.

(iv) Other effects include dry mouth, subtly decreased mental activity, sleep disturbances, depression, impotence, and lactation in either gender.

(c) The **usual daily dose** is 250 mg-1.0 g

(2) Clonidine (Catapres)

(a) Indications. Clonidine is effective in patients with renal impairment, although they may require a reduced dose or a longer dosing interval.

(b) Actions. Clonidine stimulates α_2-receptors centrally, decreasing vasomotor tone and heart rate.

(c) Precautions and monitoring effects

(i) Intravenous administration causes an initial paradoxical increase in pressure (diastolic and systolic) that is followed by a prolonged drop. As with methyldopa, abrupt withdrawal can cause rebound hypertension.

(ii) Sedation and dry mouth are common but usually disappear with continued therapy.

(iii) Clonidine has a tendency to cause or worsen depression, and it heightens the depressant effects of alcohol and other sedating substances.

(d) The **usual daily dose** is 0.1-0.8 mg.

(e) Patient compliance is a major issue for most hypertensive patients. The recently released once-weekly patch (Catapres-TTS), which provides 0.1-0.3 mg per 24 hr, may improve compliance.

(3) Guanabenz (Wytensin) and **guanfacine (Tenex)**

(a) Indications. These agents are recommended as adjunctive therapy with other antihypertensives for additive effects when initial therapy has failed.

(b) Actions. Guanabenz and guanfacine are centrally active α_2-agonists that have actions similar to clonidine.

(c) Precautions and monitoring effects. These agents should be used cautiously with other sedating medications and in patients with severe coronary insufficiency,

recent MI, cerebrovascular accident (CVA), and hepatic or renal disease. Side effects include sedation, dry mouth, dizziness, and reduced heart rate.

(d) The **usual daily doses** are 4-8 mg in two doses for guanabenz and 1-3 mg in one dose for guanfacine.

d. Postganglionic adrenergic neuron blockers. This class of antihypertensive drugs is best avoided unless it is necessary to treat severe refractory hypertension that is unresponsive to all other medications, because agents in this class are poorly tolerated by most patients.

(1) Reserpine

(a) General considerations. Because of the high incidence of adverse effects, other agents are usually chosen first. When used, reserpine is given in low doses and in conjunction with other antihypertensive agents. Reserpine in very low doses (0.05 mg) combined with a diuretic such as chlorothiazide (50-100 mg) may be an alternative to traditional doses of 0.05-0.25 mg/day.

(b) Actions. Reserpine acts centrally as well as peripherally by depleting catecholamine stores in the brain and in the peripheral adrenergic system.

(c) Precautions and monitoring effects

(i) A history of depression is a contraindication for reserpine. Even low doses, such as 0.25 mg/day, can trigger a range of psychic responses, from nightmares to suicide attempts. Drug-induced depression may linger for months after the last dose.

(ii) Peptic ulcer is also a contraindication for using reserpine. Even a single dose tends to increase gastric acid secretion.

(iii) Common adverse effects include drowsiness, dizziness, weakness, lethargy, memory impairment, sleep disturbances, and weight gain. Nasal congestion is also common but may decrease with continued therapy.

(d) The **usual daily dose** of **reserpine** is 0.1-0.25 mg.

4. ACE inhibitors

a. General considerations. The ACE inhibitors—benazepril (Lotensin), captopril (Capoten), enalapril (Vasotec), fosinopril (Monopril), lisinopril (Zestril), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace), and trandolapril (Mavik)—are a rapidly growing group of drugs. The Heart Outcomes Prevention Evaluation (HOPE) project demonstrated substantial clinical benefits in patients receiving ramipril, which could not be explained through its blood pressure-lowering effects alone. Subsequently, studies, similar to HOPE have been completed, to date, which have demonstrated the benefit of ACE inhibitors in the treatment of hypertension and prevention of cardiac events, renal disease etc.

b. Indications. Previous guidelines used ACE inhibitors as first-line alternatives for treating hypertension in patients unable to tolerate thiazides or β-blockers. However, JNC-7 recommendations have identified specific patient populations that have compelling indications —such as diabetes, postmyocardial infarction, high coronary disease risk, chronic kidney disease, and recurrent stroke prevention—for

which the ACE inhibitors are indicated in the treatment of hypertension or prehypertension. This has been primarily because of studies documenting their clinical efficacy as well as minimal effect on patients' abilities to maintain normal function.

c. Actions

(1) These agents inhibit the conversion of angiotensin I (a weak vasoconstrictor) to angiotensin II (a potent vasoconstrictor), which decreases the availability of angiotensin II.

(2) ACE inhibitors indirectly inhibit fluid volume increases when interfering with angiotensin II by inhibiting angiotensin II-stimulated release of aldosterone, which promotes sodium and water retention. The net effect appears to be a decrease in fluid volume, along with peripheral vasodilation.

d. Significant interactions

(1) The antihypertensive effect of ACE inhibitors may be diminished by **NSAIDs** (e.g., over-the-counter forms of ibuprofen).

(2) Potassium-sparing diuretics increase serum potassium levels when used with ACE inhibitors, and potassium levels need to be closely monitored in these patients.

e. Precautions and monitoring effects

(1) Neutropenia is rare but serious; there is an increased incidence in patients with renal insufficiency or autoimmune disease.

(2) Proteinuria occurs, particularly in patients with a history of renal disease. Urinary proteins should be monitored regularly.

(3) Serum potassium levels should be monitored regularly for hyperkalemia. The mechanism of action tends to increase potassium levels somewhat. Patients with renal impairment are at increased risk.

(4) Renal insufficiency can occur in patients with predisposing factors, such as renal stenosis, and when ACE inhibitors are administered with thiazide diuretics. Renal function should be monitored (e.g., through monitoring levels of serum creatinine and BUN).

(5) A dry cough may occur but disappears within a few days after the ACE inhibitor is discontinued. All ACE inhibitors have the potential to cause this side effect, but switching to an alternative agent may improve the symptoms.

(6) Other untoward effects include rashes, an altered sense of taste (dysgeusia), vertigo, headache, fatigue, first-dose hypotension, and minor gastrointestinal disturbances.

f. Specific agents

(1) Captopril (Capoten). The original ACE inhibitor is given initially as a 12.5-25 mg dose three times daily and is increased to a **usual daily dose** of 25-100 mg in two or three doses. Initial dose is usually lower if patient is on diuretics to avoid initial hypotensive response.

(2) Enalapril (Vasotec) is a prodrug, which is rapidly converted to its active metabolite, enalaprilat. Initial doses are 5.0 mg daily, with a **usual daily dose** of 5-40 mg in one to two doses. In addition, the enalaprilat form (Vasotec IV) of the drug has been used effectively for treating acute hypertensive crisis (Table 41-6).

(3) Lisinopril (Zestril) is a long-acting analog of enalapril, given initially as a 5-10 mg daily dose and adjusted to a **usual daily dose** of 10-40 mg in one dose.
(4) Benazepril (Lotensin), fosinopril (Monopril), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace), and trandolapril (Mavik) have as their major benefit a longer duration of action, which in many patients may result in once-daily dosing and improved compliance. **Average daily doses** for these agents are
(a) Benazepril (Lotensin): 10-40 mg in one to two doses
(b) Fosinopril (Monopril): 10-40 mg in one dose
(c) Moexipril (Univasc): 7.5-30 mg in one dose
(d) Perindopril (Aceon): 4-8 mg in one to two doses
(e) Quinapril (Accupril): 10-80 mg in one dose
(f) Ramipril (Altace): 2.5-20 mg in one dose
(g) Trandolapril (Mavik): 1-4 mg in one dose

(5) Further study of these agents continues, and their use in other cardiovascular as well as noncardiovascular diseases continues to expand.
5. Angiotensin II type I receptor antagonists
a. Indications. This class of drugs has been one of the fastest growing groups of drugs for the treatment of hypertension. Currently, seven agents are available: candesartan cilexetil (Atacand), eprosartan (Teveten), irbesartan (Avaprol), losartan (Cozaar), olmesartan (Benicar), telmisartan (Micardis), and valsartan (Diovan).
b. Actions. This class of drugs works by blocking the binding of angiotensin II to the angiotensin II receptors. By blocking the receptor site, these agents inhibit the vasoconstrictor effects of angiotensin II as well as prevent the release of aldosterone owing to angiotensin II from the adrenal glands. These two properties of angiotensin II have been shown to be important causes for developing hypertension. Clinically, angiotensin receptor blockers appear to be equally effective for the treatment of hypertension as ACE inhibitors.
c. Precautions and monitoring effects
(1) Similar to ACE inhibitors, increases in serum potassium levels can occur, especially in patients receiving potassium-sparing diuretics. When used alone, hyperkalemia has not been reported to be severe enough to require stopping its use. However, as in patients receiving ACE inhibitors, potassium levels need to be monitored closely in those with compromised renal function.
(2) Renal function is an important consideration for patients receiving angiotensin-receptor blockers (ARBs). Similar to ACE inhibitors, declining renal function or acute renal failure will result in elevated serum potassium levels, owing to the kidneys inability to excrete potassium. BUN and serum creatinine levels should be monitored to prevent the development of hyperkalemia.
d. Dosage guidelines for the available agents are as follows:
(1) Candesartan cilexetil (Atacand): 8-32 mg in one to two doses
(2) Eprosartan (Teveten): 400-800 mg in one to two doses

(3) Irbesartan (Avapro): 150-300 mg in one dose
(4) Losartan (Cozaar): 25-100 mg in one to two doses
(5) Olmesartan (Benicar): 20-40 mg in one dose
(6) Telmisartan (Micardis): 20-80 mg in one dose
(7) Valsartan (Diovan): 80-320 mg in one-two doses

e. Current status

(1) Many authorities believe that in the treatment of hypertension, there do not appear to be significant differences between ACE inhibitors and angiotensin receptor blockers.

(2) Familiarity and cost might well provide the basis of the selection of one agent over another at this time.

(3) Angiotensin receptor blockers have found use in special hypertensive populations with compelling indications, such as diabetes, HF, and chronic kidney disease, especially in patients who cannot tolerate an ACE inhibitor.

6. Calcium-channel blockers

a. Indications. The calcium-channel blockers are considered alternative drugs for the initial treatment of hypertension in select patient populations that are unable to take β-adrenergic-receptor blockers, such as patients with a high coronary disease risk or diabetes mellitus who also have bronchospastic disease or Raynaud disease. Currently, eight agents—amlodipine (Norvasc), diltiazem (Cardizem), felodipine (Plendil), isradipine (DynaCirc CR), nicardipine (Cardene), nifedipine (Procardia), nisoldipine (Sular), and verapamil (Calan) are available.

b. Actions

(1) Calcium-channel blockers inhibit the influx of calcium through slow channels in vascular smooth muscle and cause relaxation. Low-renin hypertensive, black, and elderly patients respond well to these agents.

(2) Although the calcium-channel blockers share a similar mechanism of action, each agent produces different degrees of systemic and coronary arterial vasodilation, sinoatrial (SA) and atrioventricular (AV) nodal depression, and a decrease in myocardial contractility.

c. Significant interactions. β-Adrenergic blockers, when used with calcium-channel blockers, may have an additive effect on inducing HF and bradycardia. Electrical conduction to the AV node may be further depressed when patients are given agents such as verapamil or diltiazem along with β-blockers.

d. Precautions and monitoring effects

(1) Diltiazem and verapamil must be used with extreme caution or not at all in patients with conductive disturbances involving the SA or AV node, such as second- or third-degree AV block, sick sinus syndrome, and digitalis toxicity.

(2) Nifedipine use has been associated with flushing, headache, and peripheral edema; the patient may find these troublesome and thus may become noncompliant. Using the sustained-release product once daily has been shown to effectively reduce these effects.

(3) Verapamil use has been associated with a significant degree of constipation, which must be treated to prevent stool straining and noncompliance.

e. Specific agents

(1) Diltiazem (Cardizem). The release of several extended-release products (Cardizem CD, Cardizem-LA, Dilacor XR, Tiazac) has reduced the frequency of daily doses in the treatment of hypertension. A single daily dose of 120-540 mg is effective for treating mild to moderate hypertension. Diltiazem already has proven efficacy as an antiarrhythmic and an antianginal agent.

(2) Nifedipine (Procardia). The release of once-daily sustained-release preparations (Procardia XL, Adalat CC) has made this agent effective as a once-daily therapy for long-term treatment of hypertension. A previously reported long list of side effects has been reduced with the sustained-release product at a single daily dose of 30-90 mg. Immediate-release nifedipine has been reported to cause ischemic events, and the current recommendation is to avoid its use if at all possible.

(3) Verapamil (Calan). This drug is similar to diltiazem in its actions (though with more potent effects on electrical conduction depression). Sustained-release products (Calan SR, Isoptin SR, Covera-HS, Verelan) at doses of 120-480 mg daily have been shown to be efficacious for long-term management of mild to moderate hypertension, while side effects such as dizziness, constipation, and hypotension are reduced.

(4) Amlodipine (Norvasc), isradipine (DynaCirc), felodipine (Plendil), nicardipine (Cardene SR), and nisoldipine (Sular) are second-generation calcium-channel blockers. These agents have been developed to produce more selective effects on specific target tissues than the first-generation agents diltiazem, nifedipine, and verapamil. These agents are chemically similar to nifedipine and are referred to as dihydropyridine derivatives. The daily dose ranges are

(a) Amlodipine (Norvasc): 2.5-10.0 mg in one dose

(b) Isradipine (DynaCirc): 2.5-10 mg in one to two doses

(c) Felodipine (Plendil): 2.5-20 mg in one dose

(d) Nicardipine (Cardene SR): 60-120 mg as an extended-release product twice daily

(e) Nisoldipine (Sular): 10-40 mg in one dose

7. Vasodilators. These drugs are used as second-line agents in patients refractory to initial therapy with diuretics, β-blockers, ACE inhibitors, ARBs, or calcium-channel blockers. Vasodilators directly relax peripheral vascular smooth muscle—arterial, venous, or both. The direct vasodilators should not be used alone owing to increases in plasma renin activity, cardiac output, and heart rate.

a. Hydralazine (Apresoline)

(1) Actions. Hydralazine directly relaxes arterioles, decreasing systemic vascular resistance. It is also used intravenously or intramuscularly in managing hypertensive crisis.

(2) Precautions and monitoring effects

(a) Because hydralazine triggers compensatory reactions that counteract its antihypertensive effects, it is most useful when combined with a β-blocker, central α-agonist, or diuretic as a latter-step agent.
(b) Reflex tachycardia is common and should be considered before initiating therapy.
(c) Hydralazine may induce angina, especially in patients with coronary artery disease and those not receiving a β-blocker.
(d) Drug-induced systemic lupus erythematosus (SLE) may occur.
(i) Baseline and serial complete blood counts (CBCs) with antinuclear antibody titers should be followed routinely to detect SLE.
(ii) Slow acetylators of this drug have an increased incidence of SLE. Their risk may be reduced by administering doses of < 200 mg/day.

(iii) Fatigue, malaise, low-grade fever, and joint aches may signal SLE.
(e) Other adverse effects may include headache, peripheral neuropathy, nausea, vomiting, fluid retention, and postural hypotension.
(3) The **usual daily dose** is 25-100 mg.

b. Minoxidil

(1) Actions. A more potent vasodilator than hydralazine, minoxidil relaxes arteriolar smooth muscle directly, decreasing peripheral resistance. It also decreases renal vascular resistance while preserving renal blood flow. Effective in most patients, minoxidil is commonly used to treat patients with severe hypertension that has been refractory to conventional drug regimens.

(2) Precautions and monitoring effects

(a) Peripheral dilation results in a reflex activation of the sympathetic nervous system and an increase in heart rate, cardiac output, and renin secretion.
(b) Because this agent promotes sodium and water retention, particularly in the presence of renal impairment, patients should be monitored for fluid accumulation and signs of cardiac decompensation. Administering minoxidil along with a sympatholytic agent and a potent diuretic (e.g., furosemide) minimizes increased sympathetic stimulation and fluid retention.
(c) Hypertrichosis (i.e., excessive hair growth) is a common side effect, particularly if the drug is continued for > 4 weeks.
(3) The **usual daily dose** is 2.5-80 mg.

c. Nitroprusside

(1) Actions. A direct-acting peripheral dilator, this agent has potent effects on both the arterial and venous systems. It is usually used only in short-term emergency treatment of acute hypertensive crisis, when a rapid effect is required. Onset of action is almost instantaneous and is maximal in 1-2 min. Nitroprusside is administered intravenously with continuous blood pressure monitoring.

(2) Precautions and monitoring effects. To prevent acute hypotensive episodes, initial doses should be very low, followed by slow titration upward until the desired effect is achieved.

(a) Once the solution is prepared, it should be protected from light. Color changes are a signal that replacement is needed.
(b) Thiocyanate toxicity may develop with long-term treatment—particularly in patients with reduced renal activity—but can be treated with hemodialysis. Symptoms may include fatigue, anorexia, disorientation, nausea, psychotic behavior, or muscle spasms.
(c) Cyanide toxicity can occur (rarely) with long-term, high-dose administration. It may present as altered consciousness, convulsions, tachypnea, or even coma.
(3) The **usual dose** is 0.3-10 µg/kg/min as a continuous intravenous infusion.

d. Diazoxide (Proglycem)

(1) Indications. Diazoxide exerts a direct action on the arterioles but has little effect on venous capacity. It is used intravenously in the emergency treatment of acute hypertensive crisis.

(2) Administration

(a) Because the antihypertensive effect of diazoxide increases with the speed of infusion, recent recommendations suggest that the dose be administered over 30 sec and, if necessary, repeat doses given every 5-15 min.

(3) Precautions and monitoring effects

(a) Diazoxide is closely related to the thiazides chemically; therefore, patients with thiazide sensitivity cross-react to diazoxide. In patients with impaired cerebral or cardiac function, the risks may outweigh the benefits of diazoxide administration.
(b) Diazoxide also produces transient hyperglycemia, requiring caution if administered to patients with diabetes.
(c) Hypotensive reactions may be severe.
(d) Unlike the thiazides, this agent promotes sodium and water retention, potentiating edema.

8. Renin Inhibitors

a. Indications. Aliskiren (Tekturna) is the first of this new class of drugs recently approved by the FDA for the treatment of hypertension.

b. Actions. Unlike angiotensin converting enzyme (ACE) inhibitors and angiotensin II receptor blockers (ARBs), which act during the later stages of the renin-angiotensin system to reduce angiotensin II (see E.2), aliskiren works directly on the enzyme renin, to reduce the eventual production of angiotensin II.
c. Aliskiren, is available in 150 and 300 mg tablets. The usual starting dose is 150 mg daily, and for those who do not respond the dose can be increased to 300 mg daily. Doses greater then 300 mg have not been shown to offer additional blood pressure lowering effects.
d. Significant interactions. Furosemide serum levels have been reported to be reduced significantly when administered in patients receiving aliskiren. This might result in a diminished pharmacologic effect from furosemide.

e. Precautions and monitoring effects

Unlike the ACE inhibitors and ARBs, which have the potential to increase serum potassium levels, patients receiving aliskiren have not shown significant increases in potassium as compared to patients studies receiving placebo. However, in a population of diabetic patients receiving both ACE inhibitors or ARBs in combination with aliskiren close monitoring of serum electrolytes and renal function is required due to an increased frequency of elevated serum potassium levels.

IV. HYPERTENSIVE EMERGENCIES

A. Definition. A hypertensive emergency is a severe elevation of blood pressure (i.e., > 200 mm Hg systolic or > 140 mm Hg diastolic) that demands reduction—either immediate (within minutes) or prompt (within hours) to prevent or limit target-organ damage.

1. Conditions requiring immediate reduction include hypertensive encephalopathy, acute left ventricular failure with pulmonary edema, eclampsia, dissecting aortic aneurysm, acute MI, stroke, and intracranial hemorrhage.

2. Conditions requiring prompt reduction include malignant or accelerated hypertension.

B. Treatment

1. The **reduction in blood pressure must be gradual** (e.g., a 15-mm Hg decrease in mean arterial pressure over the 1st hr) rather than precipitous to avoid compromising perfusion of critical organs, particularly cerebral perfusion.

2. Specific agents used in hypertensive crisis are shown in Table 41-6.

STUDY QUESTIONS

Directions for questions 1-6: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following agents represents a relatively new class of drugs used in treating hypertension?

(A) trandolapril (Mavik)

(B) carvedilol (Coreg)

(C) irbesartan (Avapro)

(D) moexipril (Univasc)

(E) nimodipine (Nimotop)

View Answer***1. The answer is C[see].*****2. Reflex tachycardia, headache, and postural hypotension are adverse effects that limit the use of which of the following antihypertensive agents?**

(A) prazosin (Minipress)

(B) captopril (Capoten)

(C) methyldopa (Aldomet)

(D) guanabenz (Wytensin)

(E) hydralazine (Apresoline)

View Answer***2. The answer is E[see].*****3. A 65-year-old man presents with stage I hypertension. He has diabetes mellitus and chronic kidney disease and is intolerant to lisinopril. Which of the following agents would be an appropriate selection for initial treatment in this patient based on the guidelines from the "Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (JNC-7)?**

(A) chlorothiazide (Diuril)

(B) propranolol (Inderal)

(C) nitroprusside (Nipride)

(D) candesartan (Atacand)

(E) clonidine (Catapres)

View Answer***3. The answer is D[see].*****4. A patient with stage I hypertension who has bronchospastic airway disease and who is noncompliant would be best treated with which of the following β-blocking agents?**

(A) timolol (Blocadren)

(B) penbutolol (Levatol)

(C) esmolol (Brevibloc)

(D) acebutolol (Sectral)

(E) propranolol (Inderal)

(A) heart.

(B) lungs.

(C) kidneys.

(D) brain.

(E) eyes.

View Answer***5. The answer is B[see].*****6. According to the "Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (JNC-7), which of the following agents is suitable as initial therapy for treating stage I hypertension (assuming no compelling indications for another type of drug)?**

(A) chlorothiazide (Diuril)

(B) labetalol (Trandate)

(C) atenolol (Tenormin)

(D) propranolol (Inderal)

(E) bisoprolol (Zebeta)

View Answer***6. The answer is A[see].*****Directions for questions 7-9:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

7. A patient treated with a spironolactone should be monitored regularly for altered plasma levels of

I. potassium.

II. serum creatinine.

III. blood urea nitrogen (BUN).

A if **I only** is correct

B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***7. The answer is E[see].***8. **Before antihypertensive therapy begins, secondary causes of hypertension should be ruled out. Laboratory findings that suggest an underlying cause of hypertension include**
I. a decreased serum potassium level.
II. an increased urinary catecholamine level.
III. an increased blood cortisol level.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***8. The answer is E[see].***P.872

9. In an otherwise healthy adult with stage I hypertension, appropriate initial antihypertensive therapy would be
I. chlorthalidone (Diuril)
II. metoprolol (Lopressor)
III. bisoprolol (Zebeta)
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* III.B.5.a*].*

Irbesartan is one of the relatively new classes of drugs used in the treatment of hypertension referred to as an angiotensin II receptor antagonist, which blocks the production of angiotensin II and consequently its effects as a powerful vasoconstrictor and stimulant for aldosterone release. Trandolapril and moexipril are ACE inhibitors; carvedilol is a β-adrenergic blocking agent; and nimodipine is a calcium-channel blocker.

2. The answer is E *[see* III.B.7.a*].*

Hydralazine is a vasodilator that works by directly relaxing arterioles, thereby reducing peripheral vascular resistance. Its effectiveness as an antihypertensive agent is compromised, however, by the compensatory reactions it triggers (e.g., reflex tachycardia) and by its other adverse effects (e.g., headache, postural hypotension, nausea, palpitations). Fortunately, the unwanted effects of hydralazine are minimized when it is used in combination with a diuretic agent and a β-blocker. Thus hydralazine is most effective as a supplemental antihypertensive drug in combination with first-line therapy.

3. The answer is D *[see* III.B.5.e.(3)*].*

Candesartan, an angiotensin II receptor blocker, which acts by blocking the binding of angiotensin II to the angiotensin II receptors. By blocking the receptor site, this class of drugs inhibits the vasoconstrictor effects of angiotensin II and prevents the release of aldosterone owing to angiotensin II from the adrenal glands. JNC-7 guidelines call for the use of diuretics in the initial treatment of hypertension, unless the patient has compelling indications that have been shown to benefit from the use of specific classes of drugs. This patient has diabetes and chronic kidney disease and is unable to tolerate the ACE inhibitor lisinopril, therefore, an ARB would be an acceptable alternative for this patient rather than a β-blocker (propranolol) or

diuretic (chlorothiazide). Nitroprusside and clonidine are not indicated for the initial treatment of hypertension.

4. The answer is D *[see* III.B.3.a.(7).(a), (b), (c), (d), (e), (f), (g), (h)-(i), (j), (k), (l) *and* (m)*].*

The β-adrenergic blocking agents continue to demonstrate effectiveness in the treatment of hypertension. A major feature of some of these agents is their relative selectivity for β_1-receptors (in the heart) rather than for β_2-receptors (in the lung), which provides advantages in the treatment of certain patients (e.g., those with bronchospastic airway or COPD). Of the β-blockers listed, acebutolol is less likely than the rest to block β_2-receptors because of its relative cardioselective-blocking activity. Acebutolol also has a long duration of action, which could be helpful in the noncompliant patient by requiring fewer doses per day. Penbutolol has weak intrinsic sympathomimetic activity like pindolol but lacks relative cardioselectivity, despite its long duration of action. Esmolol by nature of its continuous intravenous infusion would not lend itself to chronic ambulatory therapy. Timolol is a long-acting β-blocker and lacks the relative cardioselective properties that acebutolol possesses.

5. The answer is B *[see* I.F; Table 41-3*].*

Left untreated, hypertension can be lethal because of its progressively destructive effects on major organs, such as the heart, kidneys, and brain. The eyes also suffer damage; the lungs, however, do not. End-organ damage caused by hypertension includes left ventricular hypertrophy, heart failure, angina pectoris, myocardial infarction, renal insufficiency caused by atherosclerotic lesions, nephrosclerosis, cerebral aneurysm and hemorrhage, retinal hemorrhage, and papilledema.

6. The answer is A *[see* III.B.2.a*].*

Thiazide diuretics are considered the first-line treatment choice for hypertension and should be used alone or in combination with other antihypertensives, if necessary. β-Blockers such as labetalol, atenolol, bisoprolol, nifedipine, and propranolol are no longer considered initial agents for treating hypertension. β-blockers have shown positive clinical outcomes in patients with heart failure, post-myocardial infarction, high coronary disease risk, and diabetes (compelling indications) and would be acceptable options for patients presenting with prehypertension or hypertension with a compelling indication.

7. The answer is E (I, II, III) *[see* III.B.2.c.(4)*].*

Spironolactone is a direct-acting aldosterone-receptor blocker and decreases its effects on sodium and water retention. However, a benefit of spironolactone is its potassium-sparing effect, through the exchange of sodium for potassium in the kidney. Patients with reduced renal function and acute renal failure (evidenced by elevations in serum creatinine) lose their ability to excrete potassium, and this needs to be monitored when patients are started on spironolactone. BUN and creatinine are good indirect indicators of renal function.

8. The answer is E (I, II, III) *[see* II.A.2*].*

Low serum potassium levels in a hypertensive patient suggest primary aldosteronism. Elevated urinary catecholamines suggest a pheochromocytoma; other signs and symptoms of this tumor include weight loss, episodic flushing, and sweating. Elevated serum cortisol levels suggest Cushing syndrome; the patient is also likely to have a round (moon) face and truncal obesity. Secondary hypertension requires treatment of the underlying cause; supplementary antihypertensive drug therapy may also be needed.

9. The answer is A (I) *[see* III.B.2.a*].*

Thiazide diuretics such as chlorthalidone are now considered, based on the JNC-7, first-line therapy for hypertension, barring any compelling indications such as heart failure, diabetes, chronic kidney disease, or post-MI, when other antihypertensive agents would be indicated. β-Adrenergic blockers, such as metoprolol and bisoprolol, are no longer indicated as initial antihypertensive agents for treating hypertension.

10. The answer is C *[see* III.B.7.c.(2)*].*

11. The answer is E *[see* III.B.3.a.(4)*].*

12. The answer is B *[see* III.B.5.c.(2)*].*

13. The answer is A *[see* III.B.3.c.(2).(c)*].*

14. The answer is D *[see* III.B.3.b.(3).(a)*].*

The goal of treatment in hypertension is to lower blood pressure toward normal with minimal side effects. All antihypertensive drugs can cause adverse effects. The primary purpose of the JNC-7 guidelines is to acknowledge the long-term benefits of diuretics in the treatment of hypertension.

15. The answer is E *[see* III.B.3.a.(7).(a), (b), (c), (d), (e), (f), (g), (h)-(i), (j), (k), (l) *and* (m)*].*

16. The answer is B *[see* III.B.3.a.(7).(a), (b), (c), (d), (e), (f), (g), (h)-(i), (j), (k), (l) *and* (m)*].*

17. The answer is A *[see* III.B.3.a.(7).(a), (b), (c), (d), (e), (f), (g), (h)-(i), (j), (k), (l) *and* (m)*].*

18. The answer is D *[see* III.B.3.a.(7).(a), (b), (c), (d), (e), (f), (g), (h)-(i), (j), (k), (l) *and* (m)*].*

19. The answer is C *[see* III.B.3.a.(7).(a), (b), (c), (d), (e), (f), (g), (h)-(i), (j), (k), (l) *and* (m)*].*

The β-adrenergic blocking agents are valuable for managing hypertension and are used as initial antihypertensives. The β-blockers are sympathetic antagonists. They act by blocking various receptors of the sympathetic nervous system. They differ in their selectivity for these sympathetic receptors. For example, β_1-blockers have relative cardioselective activity—that is, they block β_1-receptors (in the heart) rather than β_2-receptors (in bronchial smooth muscle) and, therefore, are highly useful antihypertensive agents. Intrinsic sympathomimetic activity also appears to reduce the problem of bronchoconstriction; moreover, drugs with this property can also maintain a satisfactory heart rate.

42

Heart Failure

Alan H. Mutnick

I. INTRODUCTION

A. Definition. Heart failure (HF) is a complex clinical syndrome that can result from any cardiac disorder that impairs the ability of the ventricle to deliver adequate quantities of blood to the metabolizing tissues during normal activity or at rest. The condition in the past has been referred to as "congestive heart failure," owing to the **edematous state** commonly produced by the fluid backup resulting in shortness of breath, fatigue, limitation of exercise tolerance, and fluid retention. Fluid retention may lead to pulmonary and peripheral edema. More recently, because all patients do not necessarily present with fluid overload at the initial or follow-up evaluations, the term "heart failure" is used to more adequately reflect the clinical syndrome.

B. Mortality rate. Approximately 300,000 patients die as a result of the direct or indirect consequences of HF each year, and the number of deaths owing to HF (primary or secondary causes) has increased steadily, despite treatment advances. The risk of death is 5%-10% annually in patients with mild symptoms and is as high as 30%-40% in patients with advanced disease manifestations.

C. Incidence of HF. HF is a common medical condition that affects almost 5 million people in the United States, with > 500,000 new cases diagnosed each year. Between 1.5% and 2.0% of the population has HF, and the incidence increases to 6%-10% in patients older than age 65. HF makes up 20% of all hospitalizations in patients > 65 years of age. HF is the only major cardiovascular disorder that is increasing in incidence and prevalence. During the last 10 years, there has been a dramatic increase in the number of hospitalizations, primarily owing to HF (500,000 in 1991 to more then 1 million, currently). The reasons for the increased numbers of hospital admissions are listed in Table 42-1.

D. Cost of HF. The total costs (direct and indirect) for the treatment of HF in the United States during 2005 were approximately $27.9 billion. Currently in the United States, more than $2.9 billion is spent annually on drugs used in the treatment of HF.

E. Causes

1. Although the disease occurs most commonly among the elderly (80% of patients hospitalized with HF are > 65 years of age), it may appear at any age as a consequence of underlying cardiovascular disease.

2. There currently is no single diagnostic test for HF, and the clinical diagnosis is normally based on patient history and physical examination.

3. HF should not be considered an independent diagnosis because it is superimposed on an underlying cause.

a. Coronary artery disease (CAD) is the cause of HF in about two thirds of patients with left ventricular systolic dysfunction.

b. The remaining third of patients have a nonischemic cause of systolic dysfunction owing to other causes of myocardial stress, which included trauma, disease, or other abnormal states (e.g., pulmonary embolism, infection, anemia, pregnancy,

drug use or abuse, fluid overload, arrhythmia, valvular heart disease, cardiomyopathies, congenital heart disease).

4. The New York Heart Association (NYHA) developed a classification system, still used today to quantify the functional limitations of HF patients. The NYHA classes are as follows:

a. Class I: Degree of effort necessary to elicit HF symptoms equals those that would limit normal individuals.

b. Class II: Degree of effort necessary to elicit HF symptoms occurs with ordinary exertion.

Table 42-1. Causes for Increased Hospitalization Rates of Heart Failure

Aging of the population in the United States
Rising incidence of chronic heart failure
Improved treatment results obtained for myocardial infarction, coronary artery bypass surgery, and stenting
Unavoidable progression of heart disease in an aging population
Incomplete treatment of heart failure in the hospital setting
Poor application of guidelines for treatment
Noncompliance with diet and drug therapy

Adapted with permission from Hobbs RE. Guidelines for the diagnosis and management of heart failure. Am J Ther 2004;11:467-472.

c. Class III: Degree of effort necessary to elicit HF symptoms occurs with less-than-ordinary exertion.

d. Class IV. Degree of effort necessary to elicit HF symptoms occurs while at rest.

5. A criticism of the NYHA classification is its dependence on subjective assessments by the clinical practitioner, which changes frequently and might not accurately reflect different treatment options based on the degree of symptoms. Consequently, more recently, the “ACC/AHA Guidelines for the Evaluation and Management of Chronic Heart Failure” offered new classification scheme that depicts HF as an evolving clinical entity and details a progression based on risk

factors and structural changes, which may be asymptomatic or symptomatic. Within this classification, specific treatments can be targeted at each stage to affect morbidity and mortality (Table 42-2). The introduction of the four stages of HF are not intended to replace the NYHA classification but rather to complement it.

F. Forms of HF. As mentioned, HF is a complex syndrome and has been described in various ways. The cardinal manifestations of HF are dyspnea and fatigue, which may limit exercise tolerance, result in fluid retention, and lead to pulmonary congestion and peripheral edema. However, the following sections provide several ways that have been used to describe the pathophysiology and the symptomatology involved in the condition. Though the terms *low-output* versus *high-output* and *left-sided* versus *right-sided* are not routinely used in the clinical setting, their use here is to help convey important educational aspects of HF and are presented only for the purpose of simplifying the discussion of the pathophysiology and symptomatology.

1. Low-output versus high-output failure

a. If metabolic demands are within normal limits but the heart is unable to meet them, the failure is designated **low output** (the most common type).

b. If metabolic demands increase (e.g., hyperthyroidism, anemia) and the heart is unable to meet them, the failure is designated **high output.** Compared to low-output failure, correction of the underlying cause of high-output failure is paramount as the initial treatment modality.

2. Left-sided versus right-sided failure

a. General symptomatology. The signs and symptoms of HF usually result from the effects of blood backing up behind the failing ventricle (except in HF owing to increased body demands).

b. Left-sided and right-sided HF do not routinely exist as separate entities; however, the use of separate terms best illustrates the systemic consequences.

c. This progression occurs because the cardiovascular system is a closed system (Figure 42-1); thus, over time, right-sided failure causes left-sided failure and vice versa.

d. Left-sided failure. If blood cannot be adequately pumped from the left ventricle to the peripheral circulation and it accumulates within the left ventricle, the patient is likely to exhibit signs of **left-sided HF.** As the fluid portion of the blood backs up into the pulmonary alveoli the result is the development of pulmonary edema that can present as, shortness of breath, dyspnea on exertion and a third heart sound.

e. Right-sided failure. When blood is not pumped from the right ventricle, the fluid portion of the blood backs up throughout the body (e.g., in the veins, liver, legs, bowels), producing systemic edema. Such signs would include evidence of elevated pressures in the venous system (e.g., peripheral edema, jugular venous distension).

Table 42-2. Stages of Heart Failure (HF) Based on Evolution and Progression of Clinical Findings

Stage	Description	Examples
A	Patients at high risk of developing HF because of the presence of conditions that are strongly associated with the condition; such patients have no identified structural or functional abnormalities of the pericardium, myocardium, or cardiac valves and have never shown signs or symptoms of HF	Hypertension, atherosclerotic disease, diabetes mellitus, obesity, metabolic syndrome, history of cardiotoxic drug therapy or alcohol abuse, personal history of rheumatic fever, family history of cardiomyopathy
B	Patients who have developed structural heart disease that is strongly associated with the development of HF but who have never shown signs or symptoms of the condition	Left ventricular remodeling, including left ventricular hypertrophy or low ejection fraction; asymptomatic valvular disease; previous myocardial infarction
C	Patients who have current or prior symptoms of HF associated with underlying structural heart disease	Known structural heart disease, dyspnea or fatigue, reduced exercise tolerance
D	Patients with refractory HF who require specialized interventions	Patients with marked symptoms at rest despite maximal medical therapy (are frequently hospitalized for HF and cannot be safely discharged from the hospital, patients in the hospital awaiting heart transplantation, patients at home receiving continuous intravenous support for symptom relief or being supported with a mechanical circulatory assist device, patients in a hospice setting for the management of HF)

Adapted from Hunt SA, Abraham WT, Chin MH, et al. ACC/AHA 2005 guidelines for the diagnosis and management of chronic heart failure in the adult. A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Writing Committee to

Update the 2001 Guidelines for the Evaluation and Management of Heart Failure). J Am Coll Cardiol 2005;46:1-82.

3. Diastolic versus Systolic Dysfunction

(a) Diastolic dysfunction refers to an inability for the ventricles to fill with blood during diastole, or ventricular relaxation. Under normal circumstances, blood returns to the right side of the heart from either the upper and lower body (superior vena cava and inferior vena cava, respectively) or left side of the heart from the lungs (via the pulmonary vein, left atria, and mitral valve). An inability for the respective ventricle(s) to accommodate the blood that is returning to it will result in a back up of blood in those areas where it originated from.

(b) The inability of the ventricle(s) to accommodate the blood being presented to it is referred to as *noncompliance,* and occurs due to stiffness occurring within the ventricular walls. Stiffness can result from clinical situations such as hypertension, aortic stenosis, diabetes, myocardial infarction, and cardiac ischemia.

(c) Key to the diagnosis of diastolic heart failure are three conditions: (i) presence of signs or symptoms of heart failure; (ii) presence of normal or slightly reduced LV ejection fraction (EF >50%); and (iii) the presence of increased diastolic filling pressure.

(d) Systolic dysfunction refers to an impaired degree of ventricular contraction resulting in a decrease in cardiac inotropy (contractility) and cardiac stroke volume (see II.Pathophysiology). This sets in motion a series of compensatory mechanisms with the purpose being to increase the ability of the heart to deliver blood to the body (increase stroke volume), but which have a negative effect by increasing plasma volume (preload), and pulmonary capillary wedge pressure. Patients with systolic dysfunction unlike those with diastolic dysfunction have lower then normal cardiac ejection fractions (EF <40%), due to stroke volume reductions along with increases in end diastolic volumes.

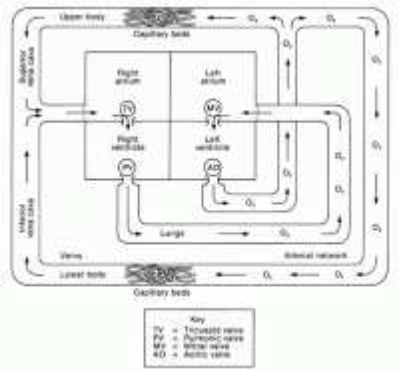

Figure 42-1. An overview of blood flow through the cardiovascular system.

(e) Therapeutic options may overlap between diastolic and systolic patients; however, treatment of underlying pathophysiologic processes can result in different therapeutic strategies between the two clinical entities.

(f) Inotropic agents, preload reducing and afterload reducing agents, and diuretics are utilized to reverse the consequences of systolic dysfunction, i.e., reduced cardiac output due to decreased myocardial contractility. However, ACE inhibitors, ARBs, beta adrenergic blockers have also been included in recent therapeutic guidelines for use in patients with systolic dysfunction.

(g) ACE inhibitors, ARBs, and beta adrenergic blockers represent the backbone of current treatment options recommended for patients with diastolic dysfunction. However, patients identified with signs and symptoms suggestive of fluid accumulation and reduced cardiac ejection fractions have shown benefit from the use of diuretics to decrease fluid retention, and inotropic agents such as digoxin to reduce hospitalizations.

4. Progressive nature of HF

a. Injury to the myocardium or stress placed on it is generally required before the development of left ventricular dysfunction.

b. The primary presentation for the associated signs and symptoms of HF is a change in the shape and structure of the left ventricle, where it dilates and/or hypertrophies into more of a spherical shape, referred to as cardiac remodeling. Such changes in the shape

of the heart result in altered stresses on the cardiac walls owing to size as well as structural changes, which also lend themselves to altered blood flow through the various heart chambers.

Table 42-3. Substances That May Exacerbate Heart Failure

Promote Sodium Retention	Produce Osmotic Effect	Decrease Contractility
Androgens	Albumin	Antiarrhythmic agents (e.g., disopyramide, flecainide, quinidine)
Corticosteroids	Glucose	
Diazoxide	Mannitol	β-adrenergic blockers
Estrogens	Saline	Select calcium channel blockers (e.g., diltiazem, nifedipine, verapamil)
Licorice	Urea	
Lithium carbonate		Direct cardiotoxins (e.g., doxorubicin, ethanol, cocaine, amphetamines)
NSAIDs		
		Tricyclic antidepressants

NSAIDs, nonsteroidal anti-inflammatory drugs.

G. Treatment goals. HF requires a two-pronged therapeutic approach, the overall goals of which are

1. To remove or mitigate the underlying causes or risk factors—for example, by eliminating ingestion of certain drugs or other substances that can produce or exacerbate HF or by correcting an anemic syndrome, which can increase cardiac demands (Table 42-3). In addition, modify risk factors that can cause cardiac injury by treating hypertension and diabetes; managing atherosclerotic disease; and controlling smoking, alcohol, and illicit drug use.

2. To relieve the symptoms and improve pump function by:

a. Reducing metabolic demands through rest, relaxation, and pharmaceutical controls

b. Reducing fluid volume excess through dietary and pharmaceutical controls

c. Administering a combination of diuretics, angiotensin-converting enzyme inhibitors (ACEIs) β-adrenergic blockers, and angiotensin-receptor blockers (ARBs)

d. Promoting patient compliance and self-regulation through education

e. Selecting appropriate patients for cardiac transplantation

3. During recent years, several sets of guidelines have been developed for the treatment of HF. Most recently, a panel of leading physicians and researchers in the field of HF provided recommendations. See within the following citation: Hunt SA,

Abraham WT, Chin MH, et al. ACC/AHA 2005 guidelines for the diagnosis and management of chronic heart failure in the adult. A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Writing Committee to Update the 2001 Guidelines for the Evaluation and Management of Heart Failure). J Am Coll Cardiol 2005;46:1-82; available at content.onlinejacc.org/cgi/reprint/46/6/e1.

4. These guidelines represent the most up-to-date standards for the prevention, diagnosis, and treatment of HF (Table 42-4).

a. The guidelines focus on four stages in the development of HF; stages A and B include patients at risk for HF and stages C and D include patients who have developed HF.

b. Paramount to the new guidelines is the role that ACEIs or ARBs and β-adrenergic blockers play, based on evidence-based practice.

c. Treatment of patients with refractory end-stage HF (stage D) should include the primary therapeutic agents that are used for stages A, B, and C. However, lack of an acceptable response will require specialized nonpharmacologic modalities, such as mechanical circulatory support, transplantation, and end-of-life care for those exhibiting no benefit.

II. PATHOPHYSIOLOGY.

HF and decreased cardiac output trigger a complex scheme of compensatory mechanisms designed to normalize cardiac output (cardiac output = stroke volume × heart rate). The principal manifestation of progression in cardiac dysfunction is a change in the geometry of the left ventricle, resulting in ventricular dilation and hypertrophy, with a resultant increase in a more spherical shape—referred to as *cardiac remodeling.* This results in increases in ventricular wall tension, depression in mechanical performance, and retention of normal cardiac fluid, which worsen the remodeling process.

Table 42-4. Approach to Heart Failure (HF)a

	At Risk for Heart Failure		Heart Failure	
	Stage A	**Stage B**	**Stage C**	**Stage D**
Patients	Patients at high risk of developing HF because of presence of conditions that are strongly associated with development of condition; such patients have no identified structural or functional abnormalities of the pericardium, myocardium, or cardiac valves and have never shown signs or symptoms of HF	Patients who have developed structural heart disease that is strongly associated with development of HF but who have never shown signs or symptoms of the condition	Patients who have structural heart disease with current or prior symptoms of HF	Patients with refractory HF who require specialized interventions
Goals	Treat hypertension	Same as stage A	Same as stage A	Same as stages A and C
	Encourage smoking cessation		Dietary salt restriction	Decision concerning appropriate level of care
	Treat lipid disorders			

	Encourage regular exercise			
	Discourage alcohol intake, illicit drug use			
	Control metabolic syndrome			
Drugs	ACEIs to prevent HF in patients at high risk who have a history of atherosclerotic vascular disease, diabetes mellitus, or hypertension	ACEIs in patients with reduced ejection fractions and no symptoms of HF, even without previous MI	ACEIs and β-blockers, with one proven to reduce mortality (bisoprolol, carvedilol, and sustained-release metoprolol for all stable patients) with current or prior symptoms of HF and reduced LVEF	Referral to an HF program with expertise in the management of refractory HF
	ARBs, as with ACEIs, though evidence not as strong	β-Blockers and ACEIs in all patients with recent or remote history of MI ARBs	ARBs in patients with current or prior symptoms of HF and reduced LVEF who cannot	Drug therapy not considered, instead consideration is given for transplantation, when applicable

		should be administered to post-MI patients without HF who cannot tolerate ACEIs and have low LVEF, though evidence not as strong. β-Blockers for all patients without MI who have reduced LVEF with no HF symptoms, though evidence not as strong.	tolerate ACEIs Diuretics and salt restriction in patients with current or prior symptoms of HF and reduced LVEF who have evidence of fluid retention, though evidence not as strong Addition of an aldosterone antagonist in select patients with moderately severe to severe HF symptoms and reduced LVEF who can be carefully monitored for renal function and potassium concentrations, though evidence not as strong. Current evidence favors combination of	Continuous intravenous infusion of a positive inotropic agent for palliation of symptoms, though evidence not strong

			hydralazine and a nitrate in patients with reduced LVEF and persistent symptoms already receiving ACEIs and β-blockers	

ACEIs, angiotensin-converting enzyme inhibitors; *ARBs,* angiotensin-receptor blockers; *LVEF,* left ventricular ejection fraction; *MI,* myocardial infarction.

[a]The guidelines listed here are definitive, based on available evidence, and are not intended to reflect the entire set of guidelines with less-than-substantial evidence. A complete set of usage guidelines is available at content.onlinejacc.org/cgi/reprint/46/6/e1.

Adapted from Hunt SA, Abraham WT, Chin MH, et al. ACC/AHA 2005 guidelines for the diagnosis and management of chronic heart failure in the adult. A report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Writing Committee to Update the 2001 Guidelines for the Evaluation and Management of Heart Failure). J Am Coll Cardiol 2005;46:1-82.

A. Compensation. These mechanisms are shown in Figure 42-2.

1. Sympathetic responses. Inadequate cardiac output stimulates reflex (norepinephrine and epinephrine) activation of the sympathetic nervous system and an increase in circulating catecholamines. The heart rate increases, and blood flow is redistributed to ensure perfusion of the most vital organs (the brain and the heart).

2. Hormonal stimulation. The redistribution of blood flow results in reduced renal perfusion, which decreases the glomerular filtration rate (GFR). Reduction in GFR results in:

a. Sodium and water retention

b. Activation of the renin-angiotensin-aldosterone system, which further enhances sodium retention and thus volume expansion

3. Concentric cardiac hypertrophy describes a mechanism that thickens cardiac walls, providing larger contractile cells and diminishing the capacity of the cavity in an attempt to precipitate expulsion at lower volumes (ventricular remodeling; see II).

4. Frank-Starling mechanism. The premise of this response is that increased fiber dilation heightens the contractile force, which then increases the energy released.

a. Within physiological limits, the heart pumps all the blood it receives without allowing excessive accumulation within the veins or cardiac chambers.

b. As blood volume increases, the various cardiac chambers dilate (stretch) and enlarge in an attempt to accommodate the excess fluid.

c. As these stretched muscles contract, the contractile force increases in proportion to their distention. Then the extended fibers snap back (as a rubber band would), expelling the extra fluid into the arteries.

d. Additional evidence suggests that the release of cytokines (e.g., tumor necrosis factor) occurs in concert with elevated levels of circulating norepinephrine, angiotensin II, aldosterone, endothelin, and vasopressin, which may all play a role in adversely affecting the heart structure, resulting in depressed performance.

B. Decompensation. Over time, the compensatory mechanisms become exhausted and increasingly ineffective, entering a vicious spiral of decompensation in which the mechanisms surpass their limits and become self-defeating—as they work harder, they only exhaust the system's capacity to respond.

1. As the strain continues, total peripheral resistance and afterload increase, thereby decreasing the percentage of blood ejected per unit of time. Afterload is determined by the amount of contractile force needed to overcome intraventricular pressure and eject the blood.

a. Afterload is the tension in ventricular muscles during contraction. In the left ventricle, this tension is determined by the amount of force needed to overcome pressure in the aorta. Afterload (also known as intraventricular systolic pressure) is sometimes used to describe the amount of force needed in the right ventricle to overcome pressure in the pulmonary artery.

b. Preload is the force exerted on the ventricular muscle at the end of diastole, which determines the degree of muscle fiber stretch. This concept is also known as ventricular end-diastolic pressure. Preload is a key factor in contractility because the more these muscles are stretched in diastole, the more powerfully they contract in systole.

2. As the fluid volume expands, so do the demands on an already exhausted pump, allowing increased volume to remain in the ventricle.

3. The resulting fluid backup (from the left ventricle into the lungs; from the right ventricle into peripheral circulation) produces the signs and symptoms of HF.

III. CLINICAL EVALUATION.

Assessment of fluid status and left ventricular ejection fraction (usually < 40% in patients with HF (Table 42-4).

A. Fluid accumulation behind the left ventricle

1. Signs and symptoms

a. Dyspnea

P.883

Figure 42-2. Compensatory mechanisms in heart failure.

P.884

(1) As HF progresses, the amount of effort required to trigger **exertional dyspnea** lessens.

(2) Both paroxysmal nocturnal dyspnea and **orthopnea** result from volume pooling in the recumbent position and can be relieved by propping up the patient with pillows or having the patient sit upright. (Orthopnea is often gauged by the number of pillows the patient needs to sleep comfortably.)

b. Dry, wheezing cough

c. Exertional fatigue and weakness

d. Nocturia. Edematous fluids that accumulate during the day migrate from dependent areas when the patient is in a recumbent position and renal perfusion increases.

2. Physical findings

a. Rales (or crackles) indicate the movement of air through fluid-filled passages.

b. Tachycardia is an early compensatory response detected through an increased pulse rate.

c. S_3 ventricular gallop is a vibration produced by rapid filling of the left ventricle early in diastole.

d. S_4 atrial gallop is a vibration produced by increased resistance to sudden, forceful ejection of atrial blood in late diastole; it does not vary with inspiration in left-sided failure and is more common in diastolic dysfunction.

3. Diagnostic test results

a. Cardiomegaly (heart enlargement), left ventricular hypertrophy, and pulmonary congestion may be evidenced by chest radiograph, electrocardiogram (ECG), and

reduction in left ventricular function via echocardiography and radionuclide ventriculography.

b. Arm-to-tongue circulation time is prolonged.

c. Transudative pleural effusion may be suggested by radiograph and confirmed by analysis of aspirated pleural fluid.

B. Fluid accumulation behind the right side of the heart

1. Signs and symptoms

a. Complaints by the patient of tightness and swelling (e.g., “My ring is too tight,” “My skin feels too tight”) suggest edema.

b. Nausea, vomiting, anorexia, bloating, or abdominal pain on exertion may reflect hepatic and visceral engorgement, resulting from venous pressure elevation.

2. Physical findings

a. Jugular vein distention reflects increased venous pressure and is a cardinal sign of HF.

b. S_3 ventricular gallop (see III.A.2.c).

c. S_4 atrial gallop intensifies on inspiration in right-sided failure.

d. Hepatomegaly (a tender, enlarged liver) is revealed when pushing on the edge of the liver results in a fluid reflux into the jugular veins, causing bulging (positive hepatojugular reflux).

e. Bilateral leg edema is an early sign of right-sided HF; pitting ankle edema signals more advanced HF. However, edema is common to many disorders, and a pattern of associated findings, such as concurrent neck vein distention, is required for differential diagnosis.

3. Laboratory findings. Elevated levels of hepatic enzymes—for example, alanine aminotransferase (ALT)—reflect hepatic congestion.

4. Evaluation of natriuretic peptides. Measurement of B-type natriuretic peptide (BNP) has been suggested in the evaluation of patients presenting in the acute care setting when a diagnosis of HF is uncertain. Elevated levels of BNP have been associated with a reduction in the left ventricular ejection fraction (LVEF) as well as in left ventricular hypertrophy, acute myocardial infarction, and ischemia, though they are not specific for HF and can occur in patients with obstructive lung disease, and pulmonary emboli.

IV. THERAPY

A. Bedrest

1. Advantages

a. Bedrest decreases metabolic needs, which reduces cardiac workload.

b. Reduced workload, in turn, reduces pulse rate and dyspnea.

c. Bedrest also helps decrease excess fluid volume by promoting diuresis.

2. Disadvantages. Physical activity (except during acute decompensation) should be encouraged to avoid physical deconditioning and exercise intolerance. The risk of venous stasis increases with bedrest and can result in thromboembolism.

Antiembolism stockings help minimize this risk, as do passive or active leg exercises, when the patient's condition permits.

3. Progressive ambulation should follow adequate bedrest.

B. Dietary controls

1. Consuming small but frequent meals (four to six daily) that are low in calories and residue provide nourishment without unduly increasing metabolic demands.

2. Moderate sodium restriction along with daily measurements of weight help maximize the lowest and safest doses of diuretics, a primary tool in reducing central volume in HF.

a. Renal function should be evaluated to assess sodium conservation if severe sodium restriction is contemplated.

b. Moderate sodium restriction (2-4 g of dietary sodium/day) can be achieved with relative ease by limiting the addition of salt during cooking and at the table.

c. The patient should be advised about medications and common products that contain sodium and cautioned about their use (e.g., antacids, sodium bicarbonate or baking soda, commercial diet food products, water softeners). Table 42-3 lists other substances that promote sodium retention.

C. Drug-related considerations. Therapeutic interventions might improve cardiac performance in the following ways:

1. Drugs may increase the cardiac ejection fraction by directly stimulating cardiac contractility. The use of positive inotropic agents such as dopamine, dobutamine, and milrinone can produce immediate benefits; however, the long-term benefit has not been appreciated, and in some cases may actually increase morbidity and mortality.

2. Drugs may increase the ejection fraction by decreasing the impedance to ejection through relaxation of peripheral blood vessels. The use of vasodilators such as hydralazine and other arterial dilators may produce short-term benefit but do not necessarily produce clinical benefits in the long term.

3. Drugs may improve the ejection fraction by affecting the cardiac remodeling process. Neurohormonal antagonists such as ACEIs, β-adrenergic receptor blockers, ARBs, and vasodilatorgrowth inhibitors such as nitrates may not produce immediate benefits, but long-term use might improve clinical status and decrease future cardiac events.

4. ACEIs, ARBs, diuretics, and β-adrenergic blockers usually form the basic core of treatment for HF.

D. ACEIs

1. Recent guidelines recommend the use of ACEIs in all patients with HF owing to left ventricular systolic dysfunction unless the patients have a contraindication to their use or have demonstrated intolerance to their use. Currently, ACEIs are considered the first-line agents in the treatment of HF and have been shown to have a beneficial effect on cardiac remodeling.

2. Relative contraindications include history of intolerance or adverse reactions, serum potassium > 5.5 mEq/L, serum creatinine levels > 3 mg/dL, symptomatic hypotension, severe renal artery stenosis, and pregnancy.

3. ACEIs have been shown to reduce symptoms, improve clinical status, enhance the overall quality of life, and reduce death as well as the risk of death or hospitalization in mild, moderate, and severe HF patients with or without coronary artery disease.
4. They inhibit the enzyme responsible for the conversion of angiotensin I (a weak vasoconstrictor) to angiotensin II (a potent vasoconstrictor). This action significantly decreases total peripheral resistance, which aids in reducing afterload.
5. Inhibiting the production of angiotensin II interferes with stimulation of aldosterone release, thus indirectly reducing retention of sodium and water, which decreases venous return and preload.
P.886

6. In patients with a history of fluid retention or who present with fluid retention, a diuretic can be added to an ACEI. ACEIs are also indicated for patients with left ventricular dysfunction without symptoms of HF.
7. ACEIs are indicated for the long-term management of chronic HF and are generally recommended in combination with a β-adrenergic blocker and diuretic.
8. All ACEIs that have been studied in the treatment of HF have shown benefit. The selection of agent and dose should be based on currently available large-scale studies in which target doses of ACEIs—captopril (Capoten), enalapril (Vasotec), lisinopril (Zestril), perindopril (Aceon), ramipril (Altace), and trandolapril (Mavik)—are different from those used to treat hypertension. Table 42-5 provides a comparative review of ACEIs currently used in the treatment of HF.

Table 42-5. Comparative Doses of Select Agents Used in the Treatment of Heart Failure (HF)

Drug	Initial Daily Dose(s)	Maximal Total Daily Dose
Loop diuretics		
Bumetanide (Bumex)	0.5-1 mg once or twice	10 mg
Furosemide (Lasix)	20-40 mg once or twice	600 mg
Torsemide (Demadex)	10-20 mg once	200 mg
Thiazide diuretics		
Chlorthalidone (Hygroton)	12.5-25 mg once	200 mg

Chlorothiazide (Diuril)	250-500 mg once or twice	2000 mg
Hydrochlorothiazide (Hydrodiuril)	25 mg once or twice	200 mg
Metolazone (Zaroxolyn)	2.5 mg once	20 mg
Potassium-sparing diuretics		
Amiloride (Midamor)	5 mg once	20 mg
Spironolactone (Aldactone)	12.5-25 mg once	50 mg
Triamterene (Dyrenium)	50-75 mg twice	300 mg
ACEIs		
Captopril (Captoten)	6.25 mg three times	450 mg
Enalapril (Vasotec)	2.5 mg twice	40 mg
Fosinopril (Monopril)	5-10 mg once	80 mg
Lisinopril (Zestril)	2.5-5 mg once	40 mg
Perindopril (Aceon)	2 mg once	32 mg
Quinapril (Accupril)	5 mg twice	40 mg
Ramipril (Altace)	1.25-2.5 mg once	10 mg
Trandolapril (Mavik)	1 mg once	4 mg

Angiotensin II receptor blockers		
Candesartan (Atacand)	4-8 mg once	32 mg
Losartan (Cozaar)	25-50 mg once	100 mg
Valsartan (Avapro)	20-40 mg twice	320 mg
Aldosterone antagonists		
Spironolactone (Aldactone)	12.5 mg once	50 mg
Eplerenone (Inspra)	25 mg once	50 mg
β-Adrenergic receptor blockers		
Bisoprolol (Zebeta)	1.25 mg once	10 mg
Carvedilol(Coreg)	3.125 mg twice	50 mg; 100 mg for patients > 85 kg
Metoprolol succinate (Toprol XL) (extended release)	12.5-25 mg once	200 mg

9. Common side effects to be monitored include hypotension (patients should be well hydrated before initiation of ACEIs), dizziness, reduced renal function (increased serum creatinine of 0.5 mg/dL or more requires reassessment), cough, and potassium retention (if potassium levels are high without supplementation, discontinue the ACEI for several days and then try to restart at lower dose).
10. Angioedema is a life-threatening side effect of ACEIs that has been reported to occur in < 1% of patients. It has been reported to occur at a more frequent rate in black patients, and the suspicion of the reaction would justify the avoidance of ACEIs in such patients.

E. ARBs

1. The newest in the class of drugs used to treat HF that has been approved for use in the treatment of mild to moderate hypertension. However, this class of drugs is now considered a reasonable alternative to the use of ACEIs.

2. Currently available agents include candesartan cilexetil (Atacand), eprosartan (Teveten), irbesartan (Avapro), losartan (Cozaar), olmesartan (Benicar), telmisartan (Micardis), and valsartan (Diovan) and initial studies on several of the agents have shown potential benefits for treating HF.
3. Current guidelines suggest that ACEIs should be preferred over the ARBs. However, ARBs may be used in patients who initially responded to ACEIs and are intolerant to them.

F. β-Adrenergic blocking agents

1. Unlike ACEIs, which strictly work by blocking the effects of the renin-angiotensin system, β-adrenergic blockers interfere with the sympathetic nervous system—that is, norepinephrine-induced peripheral vasoconstriction, norepinephrine-induced sodium excretion by the kidney, norepinephrine-induced cardiac hypertrophy, norepinephrine induced arrhythmia generation, norepinephrine-induced hypokalemia, or norepinephrine-induced cell death (apoptosis) through increased stress owing to norepinephrine stimulation.
2. β-Adrenergic blockers, specifically, bisoprolol (Zebeta), sustained-release metoprolol (Toprol XL), and carvedilol (Coreg), have been shown to decrease the risk of death or hospitalization as well as improve the clinical status of HF patients. However, doses for other select β-adrenergic blockers have been included in the current guidelines based on reported experience (Table 42-5).
3. Current guidelines recommend the use of β-adrenergic blockers in all patients with stable HF as a result of left ventricular dysfunction, unless they have a contraindication to their use or are unable to tolerate their effects owing to hypotension, bradycardia, bronchospasm, and the like.
4. β-adrenergic blockers are generally used in conjunction with diuretics, ACEIs, or ARBs. β-Adrenergic blockers should not be taken without diuretics in patients with a current or recent history of fluid retention to avoid its development and to maintain sodium balance.
5. Side effects of β-adrenergic blockers may occur during the early days of therapy but do not generally prevent their long-term use; and progression of the disease may be reduced, even if symptoms of the disease have not responded to β-adrenergic blocker therapy. Therapy should be initiated with low doses and titrated upward slowly as tolerated.
6. Patients should be monitored for signs of fluid retention by having patients weigh themselves daily and report any significant increases, which might warrant increases in diuretic doses or reductions in the dose of the β-adrenergic blocker. In addition, fatigue, hypotension, bradycardia, and heart block are reported sides effects, which should be monitored to ensure appropriate attention and management.
7. Studies support the use of β-adrenergic blockers in patients with stage C heart failure—and not in the acute management of patients, as in an intensive care unit (ICU). Patients should have no or minimal evidence of fluid retention and have no recent evidence for the use of an intravenous inotropic agent. In addition, β-adrenergic blockers should be considered in patients who develop HF post-myocardial infarction if they are able to tolerate the negative inotropic effects.

8. Initiation of β-adrenergic blockers should not be undertaken until the patient is stable without fluid overload or hypotension, and on concomitant medications, which include diuretics and/or ACEIs or ARBs.
9. Patient education is an important aspect for initiating β-adrenergic blockers therapy, and patients need to be informed that they might not see positive effects for several months after obtaining the target dosage of the agent.

G. Diuretics

1. Diuretics should be prescribed for all patients with symptoms of HF who have evidence of or who have experienced fluid retention because these drugs are the only ones that can correct fluid retention. Diuretics are generally best used in conjunction with an ACEI, ARB, and/or β-adrenergic blocker.
2. Diuretics have been shown to cause a reduction in jugular venous pressures, pulmonary congestion, peripheral edema, and body weight in short-term studies and have been shown to improve cardiac function and exercise tolerance in intermediate-term studies.
3. The goal of diuretic therapy is to reduce and eventually eliminate signs and symptoms of fluid retention as assessed by jugular venous distension (JVD), peripheral edema, or both. Slow titration upward in doses may be necessary to minimize hypotension and should be continued until fluid retention is eliminated.
4. Body weight is an effective method of monitoring fluid losses and is best done on a daily basis by the patient.
5. Patients who experience diuretic resistance or tolerance to their effects might need intravenous administration, a combination of two agents with differing mechanisms (furosemide and metolazone) or the addition of agents such as dopamine or dobutamine, which increase renal blood flow. Furthermore, evaluation of patient drug profiles may identify the addition of sodium-retaining agents such as nonsteroidal anti-inflammatory drugs (NSAIDs).
6. All diuretics increase urine volume and sodium excretion but differ in their pharmacological properties.
7. Select Diuretic Classes
a. Thiazide diuretics include chlorothiazide (Diuril), hydrochlorothiazide (HydroDIURIL), chlorthalidone (Hygroton), and indapamide (Lozol). They are effective and commonly used in HF, specifically in patients with hypertension, but they deplete potassium stores in the process. These agents are relatively weak because they are able to increase the fractional excretion of sodium to only 5%-10% of the filtered load. However, they have been shown to lose their effectiveness in HF patients with moderately impaired renal function (creatinine clearance < 30 mL/min).
b. Loop diuretics include furosemide (Lasix), ethacrynic acid (Edecrin), bumetanide (Bumex), and torsemide (Demadex) and have become the preferred diuretics. They have the ability to increase sodium excretion to 20%-25% of the filtered load and to maintain their efficacy until renal function is severely impaired (creatinine clearance

< 5 mL/min) plus have the added advantage of reducing venous return independent of diuresis. In addition, furosemide's action is more intense, making it useful as a rapid-acting intravenous agent in reversing acute pulmonary edema, owing to its direct dilating effects on pulmonary vasculature (see Table 42-5 for dosing).

c. Potassium-sparing diuretics include amiloride (Midamor), spironolactone (Aldactone) and triamterene (Dyrenium) and may help avoid the incidence of hypokalemia. However, they also possess a weaker diuretic effect than the other diuretics. As the number of HF patients receiving ACEIs or ARBs continues to increase, fewer patients may require supplemental potassium therapy.

8. Aldosterone antagonists. Spironolactone (Aldactone), is a potassium-sparing diuretic, but was the first aldosterone antagonist available for clinical use in the United States, when it had been shown to have direct blocking effects on the actions of aldosterone. Results from a large study, the Randomized Aldactone Evaluation Study (RALES), revealed that the addition of low doses (12.5-25 mg daily) of spironolactone to patients with class IV symptoms (NYHA) taking ACEIs reduced the risk of death and hospitalization.

a. Current guidelines recommend that spironolactone be considered in patients with stage C heart failure—as add-on therapy to ACEIs or ARBs and a β-adrenergic blocker—who can be closely monitored for changes in renal function and potassium levels.

b. Patients receiving spironolactone should have serum potassium levels evaluated and reduced to < 5.0 mmol/L along with a serum creatinine level < 2.5 mg/dL before initiation of therapy. Potassium levels should be routinely monitored to prevent the subsequent development of hyperkalemia.

c. Eplerenone (Inspra) was the second aldosterone receptor antagonist introduced and is currently indicated in the treatment of hypertension and in post-MI patients with HF.

H. Vasodilators

1. These agents reduce pulmonary congestion and increase cardiac output by reducing preload and/or afterload. However, at the current time, there are no large-scale trials supporting the use of vasodilators (nitrates or hydralazine) alone in the treatment of HF.

2. Individual agents

a. Nitroprusside (Nipride) is administered intravenously in doses of 0.3-10 μg/kg/min to provide potent dilation of both arteries and veins.

b. Hydralazine (Apresoline). This arteriole dilator decreases afterload and increases cardiac output in patients with HF.

c. Prazosin (Minipress). This α-adrenergic blocker acts as a balanced arteriovenous dilator.

d. Nitrates. Venous dilation by nitrates increases venous pooling, which decreases preload.

(1) Their arterial effects seem to result in decreased afterload with continued therapy.

(2) Nitrates are available in many forms and doses. Because individual reactions to these agents vary widely, dosages have to be adjusted; but, in general, they are higher for HF than for angina. Table 42-6 provides examples of nitrate doses that have been used in HF.

e. Combination therapy. Hydralazine has been used with isosorbide dinitrate (Isordil) to reduce afterload (or with nitroglycerin to reduce preload) for treating chronic HF.

(1) The combination of these two agents—hydralazine and isosorbide dinitrate (BiDil) should not be used as initial therapy over ACEIs, ARBs, or β-adrenergic blockers, but could be considered in patients who have persistent symptoms despite the use of these agents.

(2) A recently completed trial demonstrated that the addition of isosorbide dinitrate and hydralazine to standard medical therapy consisting of ACEIs and β-adrenergic blockers can be effective in black patients with NYHA functional class III or IV heart failure.

(3) Suggested dosing regimens include hydralazine 50-100 mg four times daily and isosorbide dinitrate 10-40 mg three times daily.

I. Digitalis glycosides

1. Digitalis, specifically digoxin, continues to play a role in the treatment of HF, but ongoing evaluations have altered its place in the long-term management of HF. It has been shown to be effective as a short-term therapy in improving symptoms, quality of life, and exercise tolerance in patients with mild to moderate HF. It is now recommended as add-on therapy in conjunction with diuretics, ACEIs or ARBs, and a β-adrenergic blocker to improve the symptoms and clinical status of patients with HF.

Table 42-6. Examples of Nitrates That Have Been Used in Heart Failure

Form of Nitrate	Typical Dose	Dosing Interval
Intravenous nitroglycerin	5-200 μg/min	Continuous infusion
Nitroglycerin buccal tablets	1-3 mg	4-6 hr
Nitroglycerin capsules (sustained release)	6.5-19.5 mg	4-6 hr
Nitroglycerin ointment	1-3 inches	4-6 hr
Sublingual nitroglycerin	0.4 mg	1-2 hr

Oral isosorbide dinitrate	10-60 mg	4-6 hr
Sublingual isosorbide dinitrate	5-10 mg	4 hr

2. Digoxin (Lanoxin) had previously been recommended in patients with HF who had rapid atrial fibrillation to control the ventricular rate. However, β-adrenergic blockers have been shown to improve survival and may be more effective in controlling the rate alone. Current guidelines suggest use of alternative agents for ventricular rate control rather than digoxin.
3. Digoxin can be used early to reduce symptoms in HF patients who have been started on ACEIs or β-adrenergic blockers but have not yet responded to them.
4. Long-term trials of select patients with HF have demonstrated that treatment with digoxin had little effect on short-term mortality but reduced the risk of death and hospitalization.
5. Therapeutic effects
a. Positive inotropic effects were previously felt to provide most of the benefits through increased cardiac output, decreased cardiac filling pressure, decreased venous and capillary pressure, increased renal blood flow, and decreased heart size.
b. Recent evidence suggests that digitalis acts by furthering the activation of neurohormonal systems rather than as a positive inotropic agent. This results in deactivation of renin-angiotensin-aldosterone compensation, which promotes diuresis, reduces fluid volume, decreases renal sodium reabsorption, and diminishes edema.
c. Negative chronotropic effects occur from the effect of digitalis on the sinoatrial (SA) node when given in doses that produce high total body stores (e.g., 15-18 μg/kg).
6. Choice of agent. All of the digitalis glycosides have similar properties; however, digoxin is the most commonly used preparation in the United States.
a. Digoxin is available in tablet, injection, elixir, and capsule forms.
b. Calculation of doses must factor in the differences in systemic availability among these forms. For example, digoxin solution in capsules is more bioavailable than

digoxin tablets; therefore, 0.125-mg tablets are equivalent to 0.1-mg capsules. In the majority of patients, the dosage of digoxin should be the equivalent of 0.125-0.25 mg daily of the tablet formulation.

7. Dosage and administration. The range between therapeutic and toxic doses is extremely narrow. There is no magic threshold level for digoxin therapy, but serum concentrations of 0.8-1.0 ng/mL have been associated with therapeutic response and minimal toxicity.

a. Rapid digitalization. Though not routinely necessary in the treatment of HF, in this method, the effects (and steady-state levels) are achieved within 24 hr, but the actual administration rate is usually slow and delivered in divided doses.

b. Slow digitalization. For the average HF patient, oral administration of maintenance doses should achieve steady-state levels in 7-8 days (3-4 weeks in a patient with renal dysfunction).

8. Precautions and monitoring effects

a. Potassium seems to antagonize digitalis preparations.

(1) Decreased potassium levels favor digoxin binding to cardiac cells and increase its effect, thus increasing the likelihood of digitalis toxicity. This antagonism is particularly significant for the HF patient who is receiving a diuretic (many of which decrease potassium levels).

(2) Conversely, increased potassium levels seem to decrease digoxin binding and decrease its effect. This is likely in patients taking potassium or an ACEI or ARB (which increase potassium reabsorption).

b. Calcium ions act synergistically with digoxin, and increased levels increase the force of myocardial contraction. At excessive levels, arrhythmias and systolic standstill can develop.

c. Magnesium levels are inversely related to digoxin activity. As magnesium levels decrease, the predisposition to toxicity increases and, within reason, vice versa.

d. Serum digoxin levels

(1) In cardiac glycoside therapy, the patient's clinical state is the most practical barometer of a successful regimen. However, should questions arise as to compliance, absorption, or a drug-drug interaction, serum digoxin levels may be helpful.

(2) After oral ingestion of digoxin, serum levels rise rapidly, then drop sharply as the drug enters the myocardium and other tissues. Therefore, a meaningful evaluation requires a determination of the relationship between serum digoxin levels and myocardial tissue levels.

(3) The most meaningful results are obtained if serum samples are taken after steady state has been reached and 6-8 hr after an oral dose (3-4 hr after an intravenous dose).

e. Renal function studies. Because the kidney is the primary metabolic route for **digoxin,** renal function studies such as serum creatinine levels aid the evaluation of elimination kinetics for digoxin.

9. Digitalis toxicity is a fairly common occurrence because of the narrow therapeutic range and can be fatal in a significant percentage of patients experiencing a toxic reaction.

a. Risk of toxicity increases with coadministration of quinidine, verapamil (Calan), itraconazole (Sporanox), erythromycin (Erythrocin), clarithromycin (Biaxin), propafenone (Rythmol), spironolactone (Aldactone), and amiodarone (Cordarone) and is influenced by the electrolyte (hypokalemia, hypomagnesemia) effects described previously.

b. Signs of toxicity include

(1) Anorexia, a common and early sign

(2) Fatigue, headache, and malaise

(3) Nausea and vomiting

(4) Mental confusion and disorientation

(5) Alterations in visual perception (e.g., blurring, yellowing, a halo effect)

(6) Cardiac effects:

(a) Premature ventricular contractions and ventricular tachycardia and fibrillation

(b) SA and atrioventricular (AV) block

(c) Atrial tachycardia with AV block

c. Treatment of toxicity

(1) Digitalis is discontinued immediately, as is any potassium-depleting diuretic.

(2) If the patient is hypokalemic, potassium supplements are administered and serum levels are monitored to avoid hyperkalemia through overcompensation. However, potassium supplements are contraindicated in a patient with severe AV block.

(3) Arrhythmias are treated with lidocaine (Xylocaine) (usually a 100-mg bolus, followed by infusion at 2-4 mg/min) or phenytoin (Dilantin) (as a slow intravenous infusion of 25-50 mg/min, to a maximum of 1.0 g).

(4) Cholestyramine (Questran), which binds to digitalis glycosides, may help prevent absorption and reabsorption of digitalis in the bile.

(5) Patients with very high serum digoxin levels (such as those resulting from a suicidal overdose) may benefit from the use of purified digoxin-specific Fab fragment antibodies (Digibind). One vial (38 mg) will bind 0.6 mg of digitalis. The dosage is calculated based on the estimated total body store of digitalis.

J. Calcium-channel blockers

1. Owing to the lack of evidence supporting efficacy, calcium-channel blockers should not be used for the treatment of HF. Current guidelines list calcium channel blockers as a class III recommendation, which states: “Calcium-channel blocking drugs are not indicated as routine treatment for HF in patients with current or prior symptoms of HF and reduced LVEF.”

2. Calcium channel blockers have been listed as one of three classes of drugs (with antiarrhythmics and NSAIDs) that can exacerbate HF and should be avoided in most patients.

K. Inotropic agents have been used in the emergency treatment of patients with HF. However, long-term oral therapy with these agents has not improved symptoms

or clinical status, and has been reported to increase mortality, especially in patients with advanced HF.

1. Current guidelines provide a class III recommendation, which states: “Long-term use of an infusion of a positive inotropic drug may be harmful and is not recommended for patients with current or prior symptoms of HF and reduced LVEF, except as palliation for patients with end-stage disease who cannot be stabilized with standard medical treatment.”

2. Dopamine (intravenous)

a. Low doses of 2-5 μg/kg/min stimulate specific dopamine receptors within the kidney to increase renal blood flow and thus increase urine output.

b. Moderate doses of 5-10 μg/kg/min increase cardiac output (positive inotropic effect) in HF patients.

c. High doses

(1) As doses are raised above 10 μg/kg/min, α peripheral activity increases, resulting in increased total peripheral resistance and pulmonary pressures.

(2) When the infusion exceeds 8-9 μg/kg/min, the patient should be monitored for tachycardia. If the infusion is slowed or interrupted, the adverse effect should disappear, as dopamine has a very short half-life in plasma.

3. Dobutamine (intravenous)

a. Patients who are unresponsive to, or adversely affected by, dopamine may benefit from dobutamine in doses of 5-20 μg/kg/min.

b. Although dobutamine resembles dopamine chemically, its actions differ somewhat. For example, dobutamine does not directly affect renal receptors and, therefore, does not act as a renal vasodilator. It increases urinary output only through increased cardiac output.

c. Serious arrhythmias are a potential occurrence, although less likely to occur than with dopamine. Slowing or interrupting the infusion usually reverses this effect, as it does for dopamine.

d. Dobutamine and dopamine have been used together to treat cardiogenic shock, but similar use in HF has yet to be accepted.

4. Inamrinone (intravenous) is referred to as nonglycoside, nonsympathomimetic inotropic agents.

a. A bipyridine derivative, inamrinone has both a positive inotropic effect and a vasodilating effect.

b. By inhibiting phosphodiesterase located specifically in the cardiac cells, it increases the amount of cyclic adenosine monophosphate (cAMP).

c. Inamrinone has been used in patients with HF that have been refractory to treatment with other inotropic agents.

d. Effective regimens have used loading intravenous infusions of 0.75 mg/kg over 2-3 min followed by maintenance infusions of 5-10 μg/kg/min.

e. Precautions and monitoring effects

(1) Inamrinone is unstable in dextrose solutions and should be added to saline solutions instead. Because of fluid balance concerns, this can be a potential problem in patients with HF.
(2) Because of the peripheral dilating properties, patients should be monitored for hypotension.
(3) Thrombocytopenia has occurred and is dose dependent and asymptomatic.
(4) Ventricular rates may increase in patients with atrial flutter or fibrillation.
5. Milrinone (Primacor), intravenous, is similar to inamrinone. It possesses both inotropic and vasodilatory properties.
a. This agent has been used as short-term management to treat patients with HF.
b. Most milrinone patients in clinical trials have also been receiving digoxin and diuretics.
c. Effective dosing regimens have used a loading dose of 50 µg/kg administered slowly over 10 minutes intravenously, followed by maintenance doses of 0.375 µg/kg/min by continuous infusion, based on the clinical status of the patient.
d. Precautions and monitoring effects
(1) Renal impairment significantly prolongs the elimination rate of milrinone, and infusions need to be reduced accordingly.
(2) Monitoring is necessary for the potential arrhythmias occurring in HF, which may be increased by drugs such as milrinone and other inotropic agents.
(3) Blood pressure and heart rate should be monitored when administering milrinone, owing to its vasodilatory effects and its potential to induce arrhythmias.
(4) Additional side effects include mild to moderate headache, tremor, and thrombocytopenia.
6. Nesiritide (Natrecor) is a recombinant form of human BNP, which is a naturally occurring hormone secreted by the ventricles. It is the first of this drug class to become available for human use in the United States.
a. Nesiritide is approved for the intravenous treatment of patients with acutely decompensated HF associated with shortness of breath at rest or with minimal activity.
b. Nesiritide binds to natriuretic peptide receptors in blood vessels, resulting in increased production of cyclic guanosine monophosphate (cGMP) in target tissues, which mediates

vasodilation. In HF, nesiritide reduces pulmonary capillary wedge pressure and systemic vascular resistance.
c. Initial treatment involves a bolus dose of 2 µg/kg followed by a continuous intravenous infusion of 0.01 µg/kg/min to a maximum dose of 0.03 µg/kg/min.
d. Monitoring for hypotension, elevated serum creatinine, headache, nausea, and dizziness is the key to successful use. Concomitant use of ACEIs may increase the risk of symptomatic hypotension (systolic blood pressure < 90 mm Hg and syncope).
e. Nesiritide has been shown to improve symptoms in the setting of acute HF, but the effect on morbidity and mortality has not yet been proven. At this point in time,

owing to lack of pivotal studies demonstrating its benefit, nesiritide's use as intermittent or continuous outpatient treatment is not recommended.

L. Patient education

1. Patients should be made aware of the importance of taking their medications exactly as prescribed and should be advised to watch for signs of toxicity.

2. Patients should be educated on the need for lifestyle modifications that will have a positive effect on reducing HF development and reducing HF symptoms, including daily weight monitoring, fluid management, sodium restriction, early intervention if symptoms appear, compliance with the treatment plan, modification of alcohol intake, exercise, and stress reduction.

3. The patient should understand the need for regular checkups and be able to recognize symptoms that require immediate physician notification—for example, an unusually irregular pulse rate, palpitations, shortness of breath, swollen ankles, visual disturbances, or weight gain exceeding 3-5 lb in 1 week.

4. The patient needs to be educated about drugs such as calcium channel blockers; NSAIDs, which may cause a problem in HF by retaining fluid; and sodium. In addition, the patient needs to be informed of the potential dangers of use of over-the-counter medications that might also predispose him or her to HF symptoms and loss of symptom control. A thorough review of all medications (both prescription and over-the-counter) should be carried out as frequently as possible to ensure compliance with the treatment regimen.

STUDY QUESTIONS

Directions for questions 1-8: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following combinations of drugs, when used together, particularly in black patients, reduce both preload and afterload angiotensin-converting enzyme and might provide an alternative to ACEIs in patients who are intolerant of them?

(A) nitroglycerin (Nitrostat) and isosorbide dinitrate (Isordil)

(B) hydralazine (Apresoline) and isosorbide dinitrate

(C) diltiazem (Cardizem) and verapamil (Calan)

(D) prazosin (Minipress) and angiotensin II

(E) hydralazine and methyldopa (Aldomet)

View Answer***1. The answer is B[see].*****2. When spironolactone (Aldactone) is used in a patient with heart failure (HF), it works through what primary mechanism?**

(A) positive inotropic effect

(B) positive chronotropic effect

(C) aldosterone antagonism

(D) negative inotropic effect

(E) angiotensin II blockade

View Answer***2. The answer is C[see].*****For questions 3-4:** A 60-year-old hypertensive woman is currently being treated with nitroglycerin, carvedilol, furosemide, nifedipine (Procardia), ramipril, aspirin, and digoxin. She is admitted with a diagnosis of stage C heart failure.

3. Which agent is most likely to be discontinued in this patient?

(A) nifedipine

(B) carvedilol

(C) aspirin

(D) digoxin

(E) furosemide

View Answer***3. The answer is A[seeand].*****4. Which of the following best represents the goals of therapy for this patient?**

(A) Treat underlying causes such as hypertension, cigarette smoking, lipid disorders.

(B) Discourage the use of alcohol intake, illicit drug use, and dietary salt intake.

(C) Control the metabolic syndrome.

(D) All of the above.

(E) None of the above.

View Answer***4. The answer is D[see].*****5. Because of proven beneficial effects on cardiac remodeling, a particular group of agents is now indicated as first-line therapy in HF patients. Which of the following is a representative of this group of drugs?**

(A) hydrochlorothiazide (HydroDIURIL)

(B) lisinopril (Zestril)

(C) losartan (Cozaar)

(D) carvedilol (Atacand)

(E) furosemide (Lasix)

View Answer***5. The answer is B[see*****6. Which of the following statements is *not* correct, as it relates to the current status of heart failure (HF) in the United States?**

(A) HF is the one cardiovascular disorder that is increasing in incidence and prevalence.

(B) Medication costs for treating HF in the United States approaches $38 billion.

(C) Patients with advanced disease have a 30%-40% risk of death annually.

(D) Current figures reveal approximately 5 million people in the United States who suffer from HF.

(E) Approximately 500,000 people each year are diagnosed with HF in the United States.

View Answer***6. The answer is B[seeand].***P.895

7. If treating a patient with HF, which of the following dosages of dopamine would be used to elicit its positive inotropic effects?

(A) 2.0 µg/kg/min

(B) 5-10 µg/kg/min
(C) 10-20 µg/kg/min
(D) 40 µg/kg/min
(E) 40 mg/kg/min

View Answer***7. The answer is B[see].*****8. The use of angiotensin-converting enzyme inhibitors (ACEIs) in heart failure (HF) centers around what pharmacologic effect?**

(A) direct reduction in renin levels with a resultant decrease in angiotensin II and aldosterone levels
(B) indirect reduction in angiotensin II and aldosterone levels owing to inhibition of angiotensin-converting enzyme
(C) direct reduction in aldosterone secretion and angiotensin I production by inhibiting angiotensin-converting enzyme
(D) increase in afterload owing to an indirect decrease in angiotensin II as well as a decrease in preload owing to an indirect reduction in aldosterone secretion
(E) inhibition of the angiotensin II receptor, which results in reduced angiotensin II levels and reduced secretion of aldosterone

View Answer***8. The answer is B[seeand].*****Directions for questions 9-12:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

9. Which of the following have been shown to be effective in the acute management of digitalis toxicity?

I. cholestyramine resin (Questran)
II. Fab fragment antibody (Digibind)
III. potassium administration

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***9. The answer is E[see].*****10. Situations that predispose a digitalis-treated patient to toxicity include**

I. hypercalcemia.
II. hyperkalemia.
III. hypermagnesemia.

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***10. The answer is A[seeand].*****11. Correct statements about dobutamine include which of the following?**

I. Doses of 5-20 µg**/kg/min have been associated with a positive inotropic effect in treating the patient with heart failure (HF).**

II. Patients receiving dobutamine should be monitored for increases in peripheral vascular resistance.
III. Dobutamine is considered a nonglycoside, nonsympathomimetic-positive inotropic agent.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***11. The answer is A[see].*****12. Which statements accurately describe heart (HF) classification stage A?**
I. Patients have a high risk for HF without structural heart disease or symptoms
II. Patients need to receive ACEIs or ARBs
III. Patients should be treated for any underlying causes that would be responsible for causing HF
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***12. The answer is E[see].***P.896

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* IV.H.2.e*].*
The venous dilating properties of isosorbide dinitrate (preload) in conjunction with the arteriolar dilating effects of hydralazine (afterload) make this combination effective in reducing both preload and afterload. Recent guidelines suggest that the combination of the vasodilators hydralazine and isosorbide dinitrate should not be considered as initial therapy over ACEIs but has been shown to be effective, particularly in black patients when added to standard therapy for HF.
2. The answer is C *[see* IV.G.8*].*
Spironolactone was the first aldosterone antagonist available for clinical use in the United States. In the completed RALES trial, spironolactone, given in 12.5- to 25-mg daily doses to HF patients with class IV symptoms who were taking ACEIs, reduced the risk of death and hospitalization. It is a weak diuretic but also works as a direct antagonist to the actions of aldosterone, which has demonstrated benefit in HF patients with moderately to severe symptoms.
3. The answer is A *[see* IV.J.1 *and* 2*].*
Because they have the potential to produce negative inotropic effects, calcium channel blockers such as nifedipine have been identified as one of three groups of drugs to avoid in most HF patients. Besides calcium channel blockers,

antiarrhythmics, and NSAIDs should be avoided in most HF patients owing to their ability to induce HF symptoms.

4. The answer is D *[see* Table 42-4*].*

The updated classification system was introduced with the newly established guidelines to demonstrate the progressive nature of HF and to provide a continuum of goals and treatment options as it progresses. Stage C represents the first stage in which the patient presents with structural heart disease as well as current or prior symptoms of HF. Initial goals for earlier stages remain important goals for stage C, but the “restriction in dietary salt” is added to all of the previous goals.

5. The answer is B *[see* IV.D.1]

ACEIs have shown an ability to have a positive effect on cardiac remodeling, which is believed to be the underlying change that results in the increased stresses and pathologic events that eventually cause the symptoms associated with HF. Recent studies have shown the positive benefits for each of the ACEIs used in HF patients, and today they represent the initial therapy for HF patients.

6. The answer is B *[see* I.B, C *and* D*].*

The actual costs involved in the treatment of HF, including medical care, home health care, medication costs, and hospitalization costs, reported in 2005 were approximately $27.9 billion. Medication costs alone are a bit less but are still reported to be more than $2.9 billion annually.

7. The answer is B *[see* IV.K.2.b*].*

Dopamine has shown great versatility in its effects. At doses of 2-5 μg/kg/min, it increases renal blood flow through its dopaminergic effects. At doses of 5-10 μg/kg/min, it increases cardiac output through its β-adrenergic stimulating effect. At doses of 10-20 μg/kg/min, it increases peripheral vascular resistance through its β-adrenergic stimulating effects. There is no specific cutoff for any of these effects, so close titration is required to provide for individual response.

8. The answer is B *[see* IV.D.4 *and* 5; Figure 42-2*].*

By directly inhibiting the angiotensin-converting enzyme, production of angiotensin II is reduced, as is angiotensin II-mediated secretion of aldosterone from the adrenal gland. These effects are believed to have a beneficial effect on the prevention of cardiac remodeling, which has been shown to have a detrimental effect on cardiac function.

9. The answer is E (I, II, III) *[see* IV.I.9.c.(5)*].*

Cholestyramine resin has been used in the acute situation to decrease the absorption of digoxin within the gastrointestinal tract. This results in lower digoxin levels if the resin is administered before all the digoxin has been absorbed. Potassium administration has been shown to be effective in protecting the myocardium from the toxic effects of digoxin while toxic levels return to normal. Fab fragment antibody, though expensive, has been shown to be effective in the management of very high serum digoxin levels, by which 40 mg of drug is able to bind 0.6 mg of digitalis.

10. The answer is A (I) *[see* IV.I.8.a, b *and* c*].*
Calcium ions act synergistically with digitalis. Therefore, when hypercalcemia occurs, digitalis exerts an added pharmacological effect on the heart. This may present itself as toxic arrhythmias, cardiac standstill, and even death. Elevated potassium levels or elevated magnesium levels seem to aid in the prevention of digitalis-induced toxicity. There is building evidence that digitalis preparations need calcium ions to work, and consequently low calcium levels may negate the pharmacological potential of digoxin.
11. The answer is A (I) *[see* IV.K.3.a*].*
Dobutamine in doses of 5-20 μg/kg/min is an inotropic agent that is useful in the treatment of HF. Dobutamine does not have the versatility that dopamine offers, lacking comparable effects on renal blood flow and peripheral vascular resistance. Rather, dobutamine has a peripheral dilating effect that offers a benefit to patients who have reduced cardiac output due to elevated peripheral resistance.
12. The answer is E (I, II, III) *[see* Table 42-4*].*
The recent guidelines for the diagnosis and management of chronic heart failure recognize four stages in the progression of HF, and each stage is associated with clinical findings, goals of treatment, and medications that should be considered. Stage A represents patients who are merely at risk for heart failure owing to underlying risk factors such as hypertension, hyperlipidemia, and smoking. ACEIs are recognized for their beneficial effects in cardiac remodeling and have been recommended as first-line therapy for select patients with stage A heart failure.

43

Thromboembolic Diseases

James B. Groce III

I. Definition.

Venous thromboembolic disease (VTED) occurs when one or more of the elements of **Virchow's triad** are present, resulting in deep venous thrombosis (DVT) and/or pulmonary embolism (PE).

A. Vascular injury

B. Venous stasis

C. Hypercoagulable state (i.e., decreased protein C, protein S, or antithrombin)

II. Incidence.

It is estimated that the annual incidence of VTE events exceeds 600,000 and the number of VTE-associated deaths is 296,370 annually.

III. Risk Factors for VTE

A. Patient specific and those associated with medical illness and surgical procedures

1. Surgery

2. Trauma (major or lower extremity)

3. Immobility or paresis

4. Malignancy

5. Cancer therapy (hormonal, chemotherapy or radiotherapy)

6. Previous VTE

7. Increasing age (> 40 years of age)

8. Pregnancy and the postpartum period

9. Estrogen-containing oral contraceptives or hormone-replacement therapy

10. Selective estrogen-receptor modulators

11. Acute medical illness

12. Heart or respiratory failure

13. Inflammatory bowel disease

14. Nephrotic syndrome

15. Myeloproliferative disorders, i.e., diseases in which malignant (cancer) bone marrow cells multiply and spread to the blood.

16. Paroxysmal nocturnal hemoglobinuria

17. Obesity

18. Smoking

19. Varicose veins

20. Central venous catheterization

21. Inherited or acquired thrombophilia (e.g., deficiency of antithrombin, protein C, or protein S, activated protein C resistance, antiphospholipid antibody, lupus anticoagulant)

IV. Prevention and Treatment

A. Nonpharmacologic prevention. Mechanical methods of prophylaxis are recommended, primarily in patients who are at high risk of bleeding, and may include **external pneumatic compression, graduated compression stockings** or **venous foot pumps.** These devices **increase venous outflow and/or reduce stasis** within the leg veins.

B. Pharmacologic prevention. VTED can be prevented by counteracting increased blood coagulability with **unfractionated heparin (UFH)** (see V.A), **oral anticoagulant therapy with a vitamin** K **antagonist such as warfarin** (see V.B), **low molecular weight heparin (LMWH)** (see V.C), or a **synthetic pentasaccharide** (see V.D).

V. Pharmacologic Agents.

New recommendations for treatment of VTED have been promulgated that suggest a hierarchical approach to selection of pharmacologic agents for managing VTED. These recommendations are listed in Table 43-1 and each of the recommended pharmacologic agents are discussed in the following sections.

Table 43-1. Guidelines for Initial Treatment of Venous Thromboembolic Disease

Clinical situation	**Recommended treatment**
Confirmed acute DVT of the leg High suspicion of DVT of the leg	SC LMWH, IV UFH, or SC UFH anticoagulants while awaiting the outcome of diagnostic tests
Selection	**Treatment options**
IV UFH	Continuous infusion Using weight-based dosing protocol, adjust dosage to prolong aPTT to a range that corresponds to a plasma heparin level of 0.3-0.7 units/mL antifactor Xa activity by amidolytic antifactor Xa assay If therapeutic levels of aPTT are not reached despite large daily doses of UFH, measure antifactor Xa levels for dosage guidance
SC UFH	An alternative to IV UFH Initial dose 35,000 units/24 hr, then maintain aPTT within therapeutic range
SC LMWH	Recommended initial treatment once or twice a day over UFH (as outpatient therapy if possible, as inpatient

	therapy if necessary) Routine monitoring with antifactor Xa levels not recommended
Further recommendations	
Once UFH therapy commences, check aPTT or antifactor Xa heparin level at 6 hr for UFH and adjust to maintain aPTT corresponding to therapeutic antifactor Xa heparin level of 0.3-0.7 units/mL	
Antifactor Xa heparin levels not recommended for LMWH therapy	
Platelet count should be checked daily while on UFH or LMWM	
Warfarin therapy should be commenced on day 1; adjust daily dosing based on PT/INR	
Stop unfractionated heparin or LMWH after 5 days overlap with warfarin (minimally), when INR is stable and > 2.0	
Anticoagulate (warfarin) for 6-12 months (depending on patient and disease state)	
aPTT, activated partial thromboplastin time; *INR,* international normalized ratio; *IV,* intravenous; *LMWH,* low molecular weight heparin; *PT,* prothrombin time; *SC,* subcutaneous; *UFH,* unfractionated heparin. Adapted with permission from Buller HR, Agnelli G, Hull R, et al. Antithrombotic therapy for venous thromboembolic disease. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126(Suppl):401s-428s.	

A. Unfractionated heparin

1. Indications. Patients with proven VTED may receive concomitant UFH for acute treatment and warfarin therapy acutely, followed by warfarin therapy for continued prevention of recurrence of VTED (Table 43.1), unless contraindications to warfarin (e.g., pregnancy) are present.

2. Mechanism of action. The major mechanism by which heparin blocks coagulation is by catalyzing the inhibition of thrombin. UFH acts as an anticoagulant by catalyzing the **inactivation of thrombin (factor IIa), activated factor X (factor Xa),** and **activated factor IX (factor IXa) by antithrombin.**

3. Pharmacokinetics. The mechanisms of heparin clearance are complex.

a. Heparin binds to a number of plasma proteins other than antithrombin, which competes with antithrombin heparin binding.

b. UFH is cleared by rapid-phase (cellular) elimination followed by a more gradual (renal) clearance, which can best be explained by a **combination of saturable and nonsaturable first-order kinetic models.**

c. When administered in fixed doses, the anticoagulant response to UFH varies among patients and within the same patient (i.e., interpatient and intrapatient variability). This variability is caused by differences in patients' plasma concentrations of heparin-neutralizing proteins and rates of heparin clearance.

4. Administration and dosage

a. UFH's therapeutic effect is hastened by administration of a **loading dose,** which may be **empirically selected** (e.g., 5000-units bolus given intravenously) or individualized by the patient's **dosing weight.**

(1) The weight-based approach has resulted in the use of loading doses varying from 70 to 100 units/kg.

(2) In some instances, the indication for which heparin therapy is being initiated is considered, with 70 units/kg being used for all thrombotic indications other than suspected or proved pulmonary embolism, for which up to 100 units/kg may be used.

b. Variable approaches to continuous dosing have been employed.

(1) Empiric dosing of 1000 units/hr may be used but may result in subtherapeutic or supratherapeutic outcomes (i.e., an activated partial thromboplastin time below or above the targeted range).

(2) Another approach to continuous dosing includes commencing with a fixed dose (other than the empiric dose of 1000 units/hr). One such approach may see an initial loading dose followed by 32,000 units/24 hr by continuous infusion.

(3) Yet another approach validated in the medical and pharmaceutical literature uses a **weight-based dosing nomogram** for commencing UFH therapy that varies between 15 and 25 units/kg/hr.

(a) Lower doses are used initially for most thrombotic indications other than pulmonary embolism.

(b) Pulmonary embolism requires more aggressive therapy (i.e., up to 25 units/kg/hr) based on the consideration that the clearance of heparin may be increased, thus necessitating an increased dose.

(4) Initial heparin weight-based dosing nomograms and subsequent adjustment protocols have been developed to assist the initial weight-based dosing efforts. Such protocols should be developed for a specific aPTT reagent (Tables 43-2 and 43-3).

5. Monitoring the effects of UFH. The anticoagulant effects of UFH are usually monitored by the **aPTT.** The aPTT should be **obtained at baseline** before commencing therapy and then **monitored 6 hr** after commencing heparin therapy.

Subsequent dosing adjustments are based on the results of this and additional aPTTs.

a. The aPTT ratio used to determine therapeutic effect is measured by dividing the observed aPTT by the mean of the normal laboratory control aPTT.

b. Traditionally, it was taught that for many aPTT reagents, a therapeutic effect was achieved with an **aPTT ratio of 1.5-2.5.**

c. However, because aPTT reagents may vary in their sensitivity, it is **inappropriate to use the same aPTT ratio (i.e., 1.5-2.5) for all reagents.** The therapeutic range for each aPTT reagent should be calibrated to be equivalent to a heparin level of 0.2-0.4 units/mL by whole blood (protamine titration) or to an **antifactor Xa level (i.e., plasma heparin level) of 0.3-0.7 units/**mL **collected at the 6th hr for UFH.**

Table 43-2. Weight-Based Nomogram

aPTT	Dose
Initial dose	80 units/kg bolus, then 18 units/kg/hr
< 35 sec	80 units/kg bolus, then 4 units/kg/hr
35-45 sec	40 units/kg bolus, then 2 units/kg/hr
46-70 sec[a]	No change
71-90 sec	Decrease infusion rate by 2 units/kg/hr
90 sec	Hold infusion 1 hr, then decrease infusion rate by 3 units/kg/hr

[a] This therapeutic range corresponds to antifactor Xa activity of 0.3-0.7 units/mL. The therapeutic range at any institution should be established by correlation with antifactor Xa levels in the range of 0.3-0.7 units/mL.

Adapted with permission from Hirsch J, Raschke R. Heparin and low-molecular-weight heparin. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126(Suppl):188s-203s.

B. Oral anticoagulants—warfarin

1. Indications

a. Warfarin is proven effective in the:

(1) Primary and secondary prevention of VTED

(2) Prevention of systemic arterial embolism in patients with tissue and mechanical prosthetic heart valves or atrial fibrillation

(3) Prevention of acute myocardial infarction (MI) in patients with peripheral arterial disease

(4) Prevention of stroke, recurrent infarction, and death in patients with acute MI

b. Warfarin may also be used in patients with valvular heart disease to prevent systemic arterial embolism, although its effectiveness has never been demonstrated by a randomized clinical trial.

2. Mechanism of action

a. Oral anticoagulants (e.g., warfarin) are vitamin K antagonists, producing their anticoagulant effect by **interfering with the cyclic interconversion of vitamin** K **and its 2,3-epoxide (vitamin** K **epoxide).**

b. Inhibition of this process leads to the depletion of vitamin K_{H2} and **results in the production**

of hemostatically defective, vitamin K-dependent coagulant proteins or clotting factors (prothrombin or factors II, VII, IX, and X).

Table 43-3. Heparin Dosage Adjustment Protocol[a]

Patient's aPTT (sec)[b]	Repeat Bolus Dose (units)	Stop Infusion (min)	Change Rate of Infusion (mL/hr)[c] [units/24 hr]	Timing of Next aPPT
< 50	5000	0	+3 [2880]	6 hr
50-59	0	0	+3 [2880]	6 hr
60-85[d]	0	0	0	Next morning
86-95	0	0	-2 [-1920]	Next morning
96-120	0	30	-2 [-1920]	6 hr
> 120	0	60	-4 [-3840]	6 hr

aPTT, activated partial thromboplastin time.

[a]Starting dose of 5000 units intravenous IV bolus followed by 32,000 units/24 hr as a continuous infusion. First aPTT performed 6 hr after the bolus injection; dosage adjustments are made according to protocol and the aPTT is repeated as indicated in the far-right column.

[b] The normal range for aPTT with Dade Actin FS reagent is 27-35 sec; the range may vary, depending on the sensitivity of the reagent.

[c] Concentration of heparin equal to 40 units/mL.

[d] A therapeutic range of 60-85 sec is equivalent to a heparin level of 0.2-0.4 units/mL by whole blood protamine titration or 0.3-0.7 units/mL as a plasma antifactor Xa level. The therapeutic range varies with the responsiveness of the aPTT reagent to heparin.

Adapted with permission from Hirsch J, Raschke R. Heparin and low-molecular-weight heparin. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126(Suppl):188s-203s.

c. These vitamin K-dependent coagulant proteins or clotting factors (factors VII, IX, X, and II, respectively) decline over 6-96 hr.

3. Pharmacokinetics

a. Warfarin is a **racemic mixture** of roughly equal amounts of two optically active isomers: the **R and S forms.**

b. Warfarin is rapidly absorbed from the gastrointestinal tract and reaches maximal blood concentrations in healthy volunteers in 90 min.

c. Dose response to warfarin is influenced by:

(1) Pharmacokinetic factors (i.e., differences in absorption and metabolic clearance)

(2) Pharmacodynamic factors (i.e., differences in the hemostatic response to given concentrations of warfarin)

(3) Technical factors—for example, inaccuracies in prothrombin time (PT) and international normalized ratio (INR) testing and reporting

(4) Patient-specific factors—for example, diet (increased intake of green, leafy vegetables), poor patient compliance (missed doses, self-medication, alcohol consumption), poor communication between patient and physician (undisclosed use of drugs that may interact with warfarin) (Table 43-4)

4. Administration and dosage

a. Warfarin, a coumarin compound, is the most widely used oral anticoagulant in North America. Although it is primarily **administered orally,** an injectable preparation is available in the United States.

b. Commence oral anticoagulant therapy with the **anticipated daily maintenance dose of warfarin,** which can be variable.

Table 43-4. Factors that May Potentiate or Inhibit Warfarin Effects

Factor	Potentiate Anticoagulant Effect	Inhibit Anticoagulant Effect
Drugs	Phenylbutazone	Cholestyramine
	Metronidazole	Barbiturates
	Sulfinpyrazone	Rifampin
	Trimethoprim-sulfamethoxazole	Griseofulvin
	Disulfiram	Carbamazepine
	Amiodarone	
	Erythromycin	
	Anabolic steroids	
	Clofibrate	
	Cimetidine	
	Omeprazole	
	Thyroxine	
	Ketoconazole	
	Isoniazid	
	Fluconazole	
	Piroxicam	

	Tamoxifen	
	Quinidine	
	Vitamin E (large doses)	
	Phenytoin	
	Penicillin	
Other	Low vitamin K intake	High vitamin K intake
	Reduced vitamin K absorption	Alcohol (acute use)
	Liver disease	
	Hypermetabolic states (e.g., thyrotoxicosis)	
	Alcohol (chronic use)	

Adapted with permission from Ansell J, Hirsh J, Poller L, et al. The pharmacology and management of the vitamin K antagonists. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126:204S-233S.

Table 43-5. Practical Oral Anticoagulation Dosing

Day	Rapid Anticoagulation	Anticoagulation[a]
1	5-10 mg	5 mg
2	5-10 mg	5 mg
3	2.5-7.5 mg (adjust based on INR)[b]	5 mg (adjust based on INR)[b]

[a] Rapid anticoagulation is not required or there is a risk of bleeding.

[b] Adjust dosage based on INR until the INR is stable and therapeutic.

Adapted with permission from Ansell J, Hirsh J, Poller L, et al. The pharmacology and management of the vitamin K antagonists. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126: 204S-233S.

c. The initial dose of warfarin therapy can be flexible. (Table 43-5)

(1) Patient-specific parameters used to determine the initial dose of warfarin include the patient's weight (e.g., obesity, concurrent use of interacting drugs known to inhibit the anticoagulant effect of warfarin, and the desired rapid anticoagulant effect).

(2) Based on these patient-specific parameters, some clinicians may use a larger initial dose of warfarin (e.g., 7.5-10 mg), which should not be misconstrued as a loading dose.

d. The initial dose of warfarin should be **overlapped with UFH, LMWH or a pentasaccharide** for **5-7 days** (Table 43-1).

e. The **duration of warfarin therapy** depends on each patient's indication(s) for use (Table 43-6).

f. Reversal of warfarin effects may be necessary owing to an elevated INR or complications associated with oral anticoagulant therapy (Table 43-7).

5. Monitoring warfarin therapy. PT and INR monitoring are usually performed daily on commencing oral anticoagulant therapy (e.g., warfarin), until such time that the INR has been found to be therapeutic.

a. Laboratory monitoring is performed by measuring the **PT** for calculation of the INR.

(1) The PT is **responsive to depression of three** of the four vitamin K-dependent procoagulant **clotting factors** (**prothrombin** or **factors II, VII, and X**).

(2) The common commercial PT reagents vary markedly in their responsiveness to coumarin-induced reduction in clotting factors; therefore, PT results reported using different reagents are not interchangeable among laboratories.

b. The problem of variability in responsiveness of PT reagents has been overcome by the introduction of a standardized test known as the **INR.**

(1) The INR is equal to:

$$INR = \left(\frac{\text{patient PT}}{\text{mean laboratory control PT}}\right)^{ISI}$$

Table 43-6. Duration of Warfarin Therapy[a]

Duration	Indications
3-6 months	First event with reversible[b] or time-limited risk factor
≥ 6 months	Idiopathic venous thromboembolism, first event
12 months to lifetime	First event[c] with cancer (until resolved), anticardiolipin antibody, antithrombin deficiency
	Recurrent event, idiopathic or with throbophilia

[a] See Table 43-4 for factors that may influence warfarin effects. All recommendations are subject to modification by individual characteristics, including patient preference, age, comorbidity, and likelihood of recurrence.

[b] Reversible or time-limited risk factors: surgery, trauma, immobilization, estrogen use.

[c] Proper duration of therapy is unclear in first event with homozygous factor V Leiden, homocystinemia, deficiency of protein C or S or multiple thrombophilias and in recurrent events with reversible risk factors.

Adapted with permission from Buller HR, Agnelli G, Hull R, et al. Antithrombotic therapy for venous thromboembolic disease. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126(Suppl):401s-28s.

Table 43-7. Guidelines for Reversal of Warfarin Effects

Clinical Situation	Guidelines
INR > therapeutic range but < 5.0; no clinically significant bleeding, rapid reversal not indicated for reasons of surgical intervention	
INR significantly above therapeutic range	Lower the dose or omit the next dose; resume warfarin therapy at a lower dose when the INR approaches desired range
INR minimally above therapeutic range	Dose reduction may not be necessary
INR > 5.0 but < 9.0; no clinically significant bleeding	
No additional risk factors for bleeding	Omit the next dose or two of warfarin; monitor INR more frequently; resume warfarin therapy at a lower does when the INR is in therapeutic range
Increased risk of bleeding	Omit the next dose of warfarin; give vitamin K1 (1.0-2.5 mg orally)
More rapid reversal needed before urgent surgery or dental extraction	Give vitamin K_1 (2-4 mg orally); closely monitor INR; repeat dose of vitamin K_1 if INR not substantially reduced by 24-48 hr
INR > 9.0; no clinically significant bleeding	Give vitamin K_1 (3-5 mg orally); closely monitor INR; repeat dose of vitamin K_1 if INR not substantially reduced by 24-48 hr
INR > 20.0; serious bleeding, major warfarin overdose requiring very rapid reversal of anticoagulant effect	Give vitamin K_1 (10 mg by slow intravenous infusion) with fresh frozen plasma transfusion or prothrombin complex concentrate, depending on urgency; vitamin K_1 injections may be

	needed every 12 hr
Life-threatening bleeding, serious warfarin overdose	Give prothrombin complex concentrate with vitamin K_1 (10 mg by slow intravenous infusion); repeat if necessary, depending on INR
Continuing warfarin therapy indicated after high doses of vitamin K_1	Give heparin until the effects of vitamin K_1 have been reversed and patient is responsive to warfarin

INR, international normalized ratio.

Adapted with permission from Ansell J, Hirsh J, Poller L, et al. The pharmacology and management of the vitamin K antagonists. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126:204S-233S.

where ISI (international sensitivity index) is a measure of the responsiveness of a given thromboplastin to reduction of the vitamin K-dependent coagulation factors. The **lower the ISI,** the **more responsive the reagent** and the closer the derived INR will be to the observed PT ratio.

(2) Guidelines of the American College of Chest Physicians (ACCP) Conference on Antithrombotic and Thrombolytic Therapy recommend two levels of therapeutic intensity: a less-intense range corresponding to an INR of 2.0-3.0, and a more-intense range corresponding to an INR of 2.5-3.5. The range corresponds to the indication (Table 43-8).

(3) Once the desired therapeutic INR has been achieved for 2 consecutive days, (e.g., for concomitant heparin plus warfarin overlap therapy) follow-up INR monitoring can be performed according to the following protocol:

(a) Week 1: monitor INR two or three times

(b) Week 2: monitor INR two times

(c) Weeks 3-6: monitor INR once a week

(d) Weeks 7-14: monitor INR once every 2 weeks

(e) Week 15 to end of therapy: monitor INR once every 4 weeks (if INR dose responsiveness remains stable; if dose adjustment is necessary, a more frequent monitoring schedule is employed until stable dose responsiveness is achieved)

Table 43-8. Recommended Therapeutic Goal and Range for Oral Anticoagulant

Therapy

Indication	INR Goal	INR Range
Prophylaxis of venous thrombosis (high-risk surgery)	2.5	2.0-3.0
Treatment of venous thrombosis	2.5	2.0-3.0
Treatment of pulmonary embolism	2.5	2.0-3.0
Prevention of systemic embolism	2.5	2.0-3.0
Tissue heart valves	2.5	2.0-3.0
Anterior myocardial infarction (to prevent systemic embolism)	2.5	2.0-3.0
Anterior myocardial infarction (to prevent recurrent infarction)	3.0	2.5-3.5
Valvular heart disease	2.5	2.0-3.0
Atrial fibrillation	2.5	2.0-3.0
Mechanical prosthetic valves (high risk)	3.0	2.5-3.5

Adapted with permission from Ansell J, Hirsh J, Poller L, et al. The pharmacology and management of the vitamin K antagonists. Paper presented at the Seventh ACCP Conference on Antithrombotic and Thrombolytic Therapy. Chest 2004;126:204S-233S.

c. Upon commencing oral anticoagulant therapy, **prolongation of the PT/INR** does not occur until depletion of the vitamin K-dependent procoagulant clotting factors occurs. This delay is **variable over 2-4 days.** During this delay, if active venous thrombosis is present, either UFH or LMWH is concomitantly commenced to adequately anticoagulate the patient while awaiting the therapeutic effect of warfarin.

C. Low molecular weight heparin

1. Indications

a. LMWH indications vary by manufacturer.

b. Each of the LMWHs have been evaluated in a large number of randomized clinical trials and have been proven to be safe and efficacious for **the prevention and treatment of venous thromboembolism.**

c. To date, different LMWHs have been evaluated for their role in:

(1) Prevention of venous thrombosis

(2) Treatment of VTED

(3) Management of unstable angina pectoris/non-Q wave MI

2. Chemistry. LMWHs are fragments of standard commercial-grade heparin produced by either chemical or enzymatic depolymerization. LMWHs are approximately one third the size of heparin. Like **heparin,** which has a **mean molecular weight of 15,000 Da** (range 3000-30,000 Da), **LMWHs** are heterogeneous in size with a **mean molecular weight of 4000-5000 Da** (range 1000-10,000 Da).

3. Mechanism of action

a. LMWHs achieve their **major anticoagulant effect by binding to antithrombin** through a unique pentasaccharide sequence that enhances the ability of antithrombin **to inactivate factor IIa (thrombin) and factor Xa.**

(1) Heparin and **LMWHs catalyze the inactivation of factor IIa (thrombin) by binding to antithrombin through the unique pentasaccharide sequence and to thrombin to form a ternary complex.** A minimum chain length of 18 saccharides (including the pentasaccharide sequence) is required for ternary complex formation.

(a) Virtually all heparin molecules contain at least 18 saccharide units.

(b) Only 20%-50% of the different LMWHs contain fragments with 18 or more saccharide units.

(c) Therefore, **compared with heparin, which has an antifactor Xa to antifactor IIa binding affinity ratio of approximately 1:1,** the various commercial **LMWHs have an antifactor Xa to antifactor IIa binding affinity ratio varying from 2:1 up to 4:1,** depending on their molecular size distribution (Table 43-9).

(2) In contrast, inactivation of factor Xa by antithrombin does not require binding of the heparin molecules to the clotting enzyme. Therefore, inactivation of factor Xa is

achieved by small molecular weight heparin fragments provided that they contain the high-affinity pentasaccharide.

Table 43-9. Pharmacokinetic and Pharmacodynamic Parameters of Different Low Molecular Weight Heparins (LMWHs)

LMWH	Brand Name	Average Molecular Weight	Bioavailability	Half-Life	Xa:IIa Binding-Affinity Ratio
Dalteparin	Fragmin	6000 Da	87%	3-5 hr	2.7:1
Enoxaparin	Lovenox	4500 Da	92%	4.5 hr	3.8:1
Tinzaparin	Innohep	6500 Da	87%	3.9 hr	2.8:1

b. The **antithrombotic and hemorrhagic effects** of heparin have been compared with LMWHs in a variety of **experimental animal models.**

(1) When compared on a gravimetric basis, **LMWHs are said to cause decreased** potential for **hemorrhagic episodes.**

(2) These differences in the relative antithrombotic to hemorrhagic ratios among these polysaccharides could be explained by the observation that **LMWHs have less inhibitory effects on platelet function** and vascular permeability.

4. Pharmacokinetics. The plasma recoveries and pharmacokinetics of LMWHs differ from heparin because of differences in the binding properties of the two sulfated polysaccharides to plasma proteins and endothelial cells.

a. LMWHs bind much less avidly to heparin-binding proteins than heparin, a property that contributes to the superior bioavailability of LMWHs at low doses and their more predictable anticoagulation effect.

b. LMWHs do not bind to endothelial cells in culture, a property that could account for their longer plasma half-life and their dose-independent clearance. Principally, the renal route clears LMWHs; therefore, the biologic half-life of LMWHs is increased in patients with renal failure.

5. Administration and dosage

a. Dosing of LMWHs is **disease-state** and **product specific;** different doses are administered based on the indication for use and the manufacturer of the specific LMWH. Table 43-10 shows manufacturer's suggested, U.S. Food and Drug Administration (FDA) approved dosing for specific indications.

D. Synthetic pentasaccharide

1. Indications

a. Synthetic pentasaccharide [fondaparinux (Arixtra)] is indicated for:

(1) Thromboprophylaxis against DVT/PE after

(a) Hip fracture surgery

(b) Hip fracture surgery; extended prophylaxis

(c) Knee-replacement surgery

(d) Hip-replacement surgery

(e) Abdominal surgery

(2) Treatment of

(a) Acute DVT

(b) Acute PE

2. Chemistry. Synthetic pentasaccharide is a selective **factor Xa inhibitor.** The molecular weight of the synthetic pentasaccharide product is 1728 Da.

3. Mechanism of action

a. The antithrombotic activity of fondaparinux is the result of antithrombin-mediated selective inhibition of factor Xa. Neutralization of factor Xa interrupts the blood coagulation cascade and thus inhibits thrombin formation and thrombus development.

b. Fondaparinux does not inactivate thrombin (activated factor II) and has no known effect on platelet function.

4. Pharmacokinetics

a. After subcutaneous administration, the drug is completely bioavailable, and steady-state peak plasma levels are achieved in approximately 3 hr after administration of the dose.

Table 43-10. FDA-Approved Dosing of Low Molecular Weight Heparin (LMWH) Based on Disease State

Approved Labeling and Dosing[a]	Dalteparin	Enoxaparin	Tinzaparin
Hip-replacement surgery prophylaxis	5000 units q.d. for 5-10 days	30 mg every 12 hr, or 40 mg q.d. for 7-10 days	n/a
Extended hip-replacement prophylaxis	n/a	40 mg q.d. for 3 weeks	n/a
Knee-replacement surgery prophylaxis	n/a	30 mg every 12 hr for 7-10 days	n/a
General	2500 units q.d.	40 mg q.d. for 7-10	n/a

surgery prophylaxis	or 5000 units qd (high risk) for 5-10 days	days	
Acute medically ill prophylaxis	5000 units q.d. for 12-14 days	40 mg q.d. for 6-14 days	n/a
Treatment of DVT with or without PE	n/a	As a bridge to warfarin until stable INR: 1 mg/kg every 12 h (outpatient treatment permitted) *or* 1.5 mg/kg every 24 h (inpatient only)	As a bridge to warfarin until stable INR: 175 units/kg every 24 hr
Unstable angina and NSTEMI	120 units/kg every 12 hr for 5-8 days plus aspirin indefinitely	1 mg/kg every 12 hr for 2-8 days plus aspirin indefinitely	n/a

DVT, deep-vein thrombosis; *INR,* international normalized ratio; *n/a,* not applicable; *NSTEMI,* non-ST-segment elevated myocardial infarction; *PE,* pulmonary embolism.

Adapted with permission from Rihn T, Vanscoy GJ. Low molecular weight heparin: Formulary drug class reviews. Pharm Ther 2001:26;486-492.

b. The elimination half-life is 17-21 hr, enabling once-daily dosing.

c. The drug does not seem to be metabolized and appears in the urine in active form and is renally eliminated.

5. Administration and dosage

a. Fondaparinux must not be administered intramuscularly.

b. For prophylaxis against VTE, the drug should not be used in patients with body weight < 50 kg because the incidence of major bleeding was found to double in this patient population during clinical trials.

c. For prophylaxis against VTE a usual **dose of 2.5** mg **subcutaneously once daily for 5-9 days** is recommended for **all prophylaxis indications.** The initial dose should be started 6-8 hr after surgery when hemostasis is established.

d. For treatment of established VTE, administer a once-daily subcutaneous dose as follows:
(1) Patients with body weight between 50 and 100 kg: 7.5 mg
(2) Patients with body weight < 50 kg: 5 mg
(2) Patients with body weight > 100 kg: 10 mg
6. Cautions
a. Contraindications
(1) Severe renal impairment
(2) Patients weighing < 50 kg when used for prophylaxis
(3) Patients with active major bleeding
(4) Bacterial endocarditis
(5) Thrombocytopenia associated with positive in vitro test for antiplatelet antibody in the presence of fondaparinux
(6) Known hypersensitivity to fondaparinux
P.908

b. Precautions
(1) Conditions or procedures that may enhance the risk of severe bleeding (e.g., trauma, hemophilia, gastrointestinal ulceration, concurrent use of antiplatelet agents, history of cerebrovascular hemorrhage, severe uncontrolled hypertension)
(2) Renal impairment
(3) Heparin-induced thrombocytopenia
(4) Neuraxial anesthesia and indwelling epidural catheter use
(5) Elderly patients
(6) Pregnancy category B and lactating (the drug is excreted into breast milk)
(7) Protamine is **ineffective** as an antidote
P.909

STUDY QUESTIONS

Directions for questions 1-4: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.
1. A 67-year-old man who weighs 100 kg (212 lb) and is 60 in. tall presents to his physician after a transatlantic flight complaining of pain and swelling of his right lower extremity. The patient had total knee arthroplasty 2 weeks before his travel. His medical history reveals that he has an ejection fraction of 15%, he is in remission for non-Hodgkin lymphoma, and he has had a previous myocardial infarction. His mother, father, and sister are dead as a result of stroke, pulmonary embolism, and childbirth, respectively. Given this patient's history, he is most likely suffering from which of the following?
(A) ruptured Baker cyst
(B) deep venous thrombosis of the lower extremity

(C) torn medial meniscus
(D) septic arthritis

View Answer***1. The answer is B[seeand].*****2. Prophylaxis against venous thromboembolic disease (VTED) may include**
(A) nonpharmacological prophylaxis.
(B) pharmacological prophylaxis.
(C) nonpharmacological and pharmacological prophylaxis.
(D) neither nonpharmacological and pharmacological prophylaxis

View Answer***2. The answer is C[seeand].*****3. Unfractionated heparin binds to antithrombin III and inactivates clotting factor(s)**
(A) Xa
(B) IXa
(C) IIa
(D) All of the above
(E) None of the above

View Answer***3. The answer is D[see].*****4. Initiation of unfractionated heparin therapy for the patient described in question 1 would best be achieved with**
(A) 5000 U loading dose followed by 1000 U/hr
(B) 5000 U loading dose followed by 1800 U/hr
(C) 8000 U loading dose followed by 1800 U/hr
(D) 1000 U loading dose followed by 1000 U/hr

View Answer***4. The answer is C[see].*****Directions for questions 5-11:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**
Directions for questions 5-10: Upon confirmation of diagnosis, the attending physician asks you, the pharmacist, to commence low molecular weight heparin therapy for the patient described in question 1 above. The following questions pertain to your pharmaceutical care for this patient.
5. When choosing an FDA-approved low molecular weight heparin to treat this patient, you would administer
I. enoxaparin 1 mg**/kg/dose subcutaneously q 12** hr.
II. enoxaparin 1.5 mg**/kg/dose subcutaneously q 24** hr.
III. tinzaparin 175 IU/kg/dose subcutaneously q 24 hr.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***5. The answer is E(I, II, III) [see].*****6. Which of the following tests are used to monitor heparin antithrombotic therapy?**
I. international normalized ratio
II. activated partial thromboplastin time
III. heparin assay
A if **I only** is correct

B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***6. The answer is D(II, III) [seeand].***P.910

7. A patient to be commenced on oral anticoagulant therapy for DVT would be treated with:
I. oral anticoagulant therapy with warfarin for a goal international normalized ratio (INR) of 2-3.
II. oral anticoagulant therapy with warfarin for a goal INR of 2.5-3.5.
III. oral anticoagulant therapy with aspirin for a goal INR of 2-3.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***7. The answer is A(I) [seeand].*****8. A patient on oral anticoagulant therapy is commenced on sulfamethoxazole-trimethoprim, double-strength twice daily. One may expect to see the international normalized ratio**
I. increase.
II. decrease.
III. remain unchanged.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***8. The answer is A(I) [see].*****9. If a patient has an international normalized ratio (INR) > 20 and active bleeding that is clinically significant (i.e., hematuria), the pharmacist should**
I. hold the drug therapy.
II. administer vitamin K.
III. administer fresh frozen plasma.
A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***9. The answer is E(I, II, III) [see].*****10. Compared to unfractionated heparin, low molecular weight heparins have**
I. preferential binding affinity to factor Xa relative to IIa (thrombin).
II. shorter half-lives.

III. dose-dependent renal clearance.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***10. The answer is A(I) [see].independent*****11. An 87-year-old woman who weighs 49.0 kg (108 lb) and is 66 in tall has sustained a hip fracture requiring open reduction with internal fixation (ORIF) surgery. She has a documented serum creatine value recorded in the chart and in the laboratory results as 4.3** mg**%. The orthopedic surgeon asks you, the pharmacist, about the appropriate fondaparinux dosing for this patient to prevent venous thromboembolism after the surgery. Which of the following are contraindications to the use of fondaparinux in this patient?**

I. patient weighs < 50 kg

II. patient has severe renal impairment

III. patient is elderly

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***11. The answer is C(I, II) [seeand].precaution***P.911

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* I.A, B *and* C*].*

The patient has the classic triad of risk factors predisposing him to DVT injury (recent knee arthroplasty), venous stasis (transatlantic travel), and hypercoagulable state (family history of venous thromboembolic disease). The patient has other risk factors as well, including age > 40, recent surgery, oncologic disease (though in remission), congestive heart failure, previous myocardial infarction with low ejection fraction, and obesity.

2. The answer is C *[see* IV.A *and* B*].*

Prophylaxis of VTED can involve a nonpharmacological approach, a pharmacological approach, or a combination of nonpharmacological and pharmacological approaches. The method of prophylaxis used is determined based on the patient's degree of risk. For example, a patient at high to extremely high risk for development of VTED requires nonpharmacological and pharmacological prophylaxis.

3. The answer is D *[see* V.A.2*].*

Unfractionated heparin acts as an anticoagulant by catalyzing the inactivation of factor IIa, factor Xa, and factor IXa by antithrombin III.

4. The answer is C *[see* V.A.4.b.(4)*].*

Several nomograms for dosing continuous infusion unfractionated heparin exist in the medical and pharmaceutical literature. The loading dose is typically 70-100 units/kg. In this case, the patient weighs 100 kg (212 lb) and the loading dose is 80 units/kg. Maintenance doses of 15-25 units/kg/hr are typically used. In this case, the maintenance dose is 18 units/kg/hr.

5. The answer is E *(I, II, III) [see* Table 43-10*].*

Primary literature reveals appropriate randomized prospective trials examining the role of LMWH compared to unfractionated heparin. From these trials, evidence of efficacy and safety for enoxaparin and tinzaparin at the treatment doses listed exists and has been approved by FDA for treatment of established VTE.

6. The answer is D *(II, III) [see* V.A.5.a, b *and* c*].*

Unfractionated heparin may be appropriately monitored by either the activated partial thromboplastin time (aPTT) or heparin assay. Because different laboratories use aPTT reagents with different sensitivities, the aPTT range and its corresponding ratio must be correlated to a heparin level of 0.2-0.4 units/mL by whole-blood (protamine titration) assay or 0.3-0.7 units/mL by plasma-amidolytic assay. The safety and efficacy of LMWH cannot be reliably evaluated by aPTT determinations. LMWH safety and efficacy can be evaluated by heparin assay. Because of the reliability of dose responsiveness seen with LMWH therapy, the need to perform heparin assays is controversial.

7. The answer is A *(I) [see* V.B.5.a *and* b; Table 43-8*].*

Oral anticoagulant therapy is monitored by measuring the PT. The PT is responsive to depression of three of the four vitamin K-dependent procoagulant clotting factors (prothrombin or factors II, VII, and X). These respective clotting factors take approximately 96 hr to be depleted, at which time the PT should be sufficient to arrive at an INR of 2.0-3.0 for patients with DVT (by appropriately converting the PT ratio to the power of the ISI). Patients with mechanical prosthetic heart valves have INRs targeted in the 2.5-3.5 range. Aspirin therapy is not monitored by INR determinations.

8. The answer is A *(I) [see* Table 43-4*].*

Oral anticoagulant therapy with warfarin may be complicated by myriad drug-drug interactions owing to the highly protein-bound state of warfarin. Such drug interactions may potentiate (prolong) PT:INR ratio, inhibit (shorten) the anticoagulant effect of warfarin, or have no effect on the actions of warfarin. Sulfamethoxazole-trimethoprim and other antibiotics have the potential to augment the anticoagulant effect of warfarin by eliminating bacterial flora and, thereby, producing vitamin K deficiency.

9. The answer is E *(I, II, III) [see* Table 43-7*].*

Pharmacists may be called on to offer advice regarding reversal of warfarin therapy or may be empowered using Pharmacy and Therapeutics Committee or Medical Board approved protocols to reverse warfarin's effect. In all instances, the pharmacist must critically and clinically evaluate the situation and communicate with the physician regarding management issues. A need for immediate surgery or invasive procedures will always hasten the urgency of warfarin reversal. In the setting of active bleeding, its clinical significance must be demonstrated by

consultation with the patient's physician. If the INR is > 20 and the patient has active bleeding that is clinically significant, the pharmacist must hold drug therapy, consider the most appropriate dose and route of vitamin K delivery, and administer fresh frozen plasma to replete the vitamin K-dependent clotting factors.
P.912

10. The answer is A *(I) [see* V.C.3.a.(1); V.C.4.b*].*
UFH has an Xa:IIa binding-affinity ratio of approximately 1:1, and the various commercial LMWHs have Xa:IIa binding-affinity ratios of 2:1 up to 4:1, depending on their molecular size distribution. This increased binding affinity for factor Xa relative to factor IIa (thrombin) is said to account for the improved ability of LMWHs to catalyze inactivation of thrombin; the smaller fragments cannot bind to thrombin and, therefore, retain their ability to inactivate factor Xa. LMWHs have longer half-lives than unfractionated heparin. LMWHs are cleared primarily via the kidneys, and their biologic half-life is increased in patients with renal failure *independent* of dose.
11. The answer is C *(I, II) [see* V.D.5.b; V.D.6.a.(1) *and* (2)*].*
The synthetic pentasaccharide fondaparinux is contraindicated in patients who have severe renal impairment and who weigh < 50 kg. Calculation of the patient's estimated creatinine clearance by the Crockcoft-Gault method reveals an estimated clearance of approximately 8.5 mL/min, which would be defined as severe renal impairment. Her stated weight is 49 kg. Thus this patient's severe renal impairment and low weight constitute contraindications to the use of fondaparinux. Fondaparinux is recommended for use with *precaution* in the elderly patient population.

Infectious Diseases

Paul F. Souney
Anthony E. Zimmermann
Linda M. Spooner

I. Principles of Anti-Infective Therapy

A. Definition. Anti-infective agents treat infection by suppressing or destroying the causative microorganisms—bacteria, mycobacteria, fungi, protozoa, or viruses. Anti-infective agents derived from natural substances are called **antibiotics;** those produced from synthetic substances are called **antimicrobials.** These two terms are now used interchangeably.

B. Indications. Confirm the presence of infection by completing a careful history and physical examination, searching for signs and symptoms of infection as well as predisposing factors. Anti-infective agents should be used only when

1. A significant infection has been diagnosed or is strongly suspected

2. An established indication for prophylactic therapy exists

C. Gram stain, microbiological culturing, and **susceptibility tests** should be performed before anti-infective therapy is initiated. Test materials must be obtained by a method that avoids contamination of the specimen by the patient's own flora.

1. Gram stain. Performed on all specimens except blood cultures, the gram stain helps identify the cause of infection immediately. By determining if the causative agent is gram positive or gram negative, the test allows a better choice of drug therapy, particularly when an anti-infective regimen must begin without delay.

a. Gram-positive microorganisms stain **blue** or **purple.**

b. Gram-negative microorganisms stain **red** or **rose-pink.**

c. Fungi may also be identified by gram stain.

2. Microbiological cultures. To identify the specific causative agent, specimens of body fluids or infected tissue are collected for analysis.

3. Susceptibility tests. Different strains of the same pathogenic species may have widely varying susceptibility to a particular anti-infective agent. Susceptibility tests determine microbial susceptibility to a given drug and thus can be used to predict whether the drug will combat the infection effectively.

a. Microdilution method. The drug is diluted serially in various media containing the test microorganism.

(1) The lowest drug concentration that prevents microbial growth after 18-24 hr of incubation is called the **minimum inhibitory concentration (MIC).**

(2) The lowest drug concentration that reduces bacterial density by 99.9% is called the **minimum bactericidal concentration (MBC).**

(3) Breakpoint concentrations of antibiotics are used to characterize antibiotic activity: The interpretive categories are **susceptible, moderately**

susceptible (intermediate), and **resistant.** These concentrations are determined by considering pharmacokinetics, serum and tissue concentrations following normal doses, and the **population distribution** of MICs of a group of bacteria for a given drug.

b. Kirby-Bauer disk diffusion technique. This test is less expensive but less reliable than the microdilution method; however, it provides qualitative susceptibility information.

(1) Filter paper disks impregnated with specific drug quantities are placed on the surface of agar plates streaked with a microorganism culture. After 18 hr, the size of

a clear inhibition zone is determined; drug activity against the test strain is then correlated to zone size.

(2) The Kirby-Bauer technique does not reliably predict therapeutic effectiveness against certain microorganisms (e.g., *Staphylococcus aureus, Shigella*).

D. Choice of agent. An anti-infective agent should be chosen on the basis of its pharmacological properties and spectrum of activity as well as on various host (patient) factors (Figure 44-1).

1. Pharmacological properties include the drug's ability to reach the infection site and to attain a desired level in the target tissue.

2. Spectrum of activity. To treat an infectious disease effectively, an anti-infective drug must be active against the causative pathogen. Susceptibility testing or clinical experience in treating a given infection may suggest the effectiveness of a particular drug.

3. Patient factors. Selection of an anti-infective drug regimen must take various patient factors into account to determine which type of drug should be administered, the correct drug dosage and administration route, and the potential for adverse drug effects.

a. Immunological status. A patient with impaired immune mechanisms may require a drug that rapidly destroys pathogens (i.e., **bactericidal agent**) rather than one that merely suppresses a pathogen's growth or reproduction (i.e., **bacteriostatic agent**).

b. Presence of a foreign body. The effectiveness of anti-infective therapy is reduced in patients who have prosthetic joints or valves, cardiac pacemakers, and various internal shunts.

c. Age. A drug's pharmacokinetic properties may vary widely in patients of different ages. In very young and very old patients, drug metabolism and excretion commonly decrease. Elderly patients also have an increased risk of suffering ototoxicity when receiving certain antibiotics.

d. Underlying disease

(1) Preexisting **kidney** or **liver disease** increases the risk of nephrotoxicity or hepatotoxicity during the administration of some antibacterial drugs.

(2) Patients with **central nervous system (CNS) disorders** may suffer neurotoxicity (motor seizures) during penicillin therapy.
(3) Patients with **neuromuscular disorders** (e.g., myasthenia gravis) are at increased risk for developing neuromuscular blockade during aminoglycoside or polymyxin B therapy.
e. History of drug allergy or adverse drug reactions. Patients who have had previous allergic or other untoward reactions to a particular antibiotic have a higher risk of experiencing the same reaction during subsequent administration of that drug. Except in life-threatening situations, patients who have had serious allergic reactions to penicillin, for example, should not receive the drug again.
f. Pregnancy and lactation. Because drug therapy during pregnancy and lactation can cause unwanted effects, the mother's need for the antibiotic must be weighed against the drug's potential harm.
(1) Pregnancy can increase the risk of adverse drug effects for both mother and fetus. Also, plasma drug concentrations tend to decrease in pregnant women, reducing a drug's therapeutic effectiveness.
(2) Most drugs, including antibiotics, appear in the breast milk of nursing mothers and may cause adverse effects in infants. For example, sulfonamides may lead to toxic bilirubin accumulation in a newborn's brain.
g. Genetic traits
(1) Sulfonamides may cause hemolytic anemia in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency.
(2) Patients who rapidly metabolize drugs (i.e., rapid acetylators) may develop hepatitis when receiving the antitubercular drug isoniazid.
E. Empiric therapy. In serious or life-threatening disease, anti-infective therapy must begin before the infecting organism has been identified. In this case, the choice of drug (or drugs) is based on clinical experience, suggesting that a particular agent is effective in a given setting.

Figure 44-1. Approach to management of infection.

P.916

1. A **broad-spectrum antibiotic** usually is the most appropriate choice until the specific organism has been determined.

2. In all cases, **culture specimens must be obtained** before therapy begins.

F. Multiple antibiotic therapy. A combination of drugs should be given only when clinical experience has shown such therapy to be more effective than single-agent therapy in a particular setting. A multiple-agent regimen can increase the risk of toxic drug effects and, in a few cases, may result in drug antagonism and subsequent therapeutic ineffectiveness. Indications for multiple-agent therapy include

1. Need for increased antibiotic effectiveness. The **synergistic** (intensified) effect of two or more agents may allow a dosage reduction or a faster or enhanced drug effect.

2. Treatment of an infection caused by multiple pathogens (e.g., intra-abdominal infection)

3. Prevention of proliferation of drug-resistant organisms (e.g., during treatment of tuberculosis)

G. Duration of anti-infective therapy. To achieve the therapeutic goal, anti-infective therapy must continue for a sufficient duration.

1. Acute uncomplicated infection. Treatment generally should continue until the patient has been afebrile and asymptomatic for at least 72 hr.

2. Chronic infection (e.g., endocarditis, osteomyelitis). Treatment may require a longer duration (4-6 weeks) with follow-up culture analyses to assess therapeutic effectiveness.

H. Monitoring therapeutic effectiveness. To assess the patient's response to anti-infective therapy, appropriate specimens should be cultured and the following parameters monitored.

1. Fever curve. An important assessment tool, the fever curve may be a reliable indication of response to therapy. Defervescence usually indicates favorable response.

2. White blood cell (WBC) count. In the initial stage of infection, the neutrophil count from a peripheral blood smear may rise above normal (neutrophilia), and immature neutrophil forms (“bands”) may appear (“left shift”). In patients who are elderly, debilitated, or suffering overwhelming infection, the WBC count may be normal or subnormal.

3. Radiographic findings. Small effusions, abscesses, or cavities that appear on radiographs indicate the focus of infection.

4. Pain and **inflammation** (as evidenced by swelling, erythema, and tenderness) may occur when the infection is superficial or within a joint or bone, also indicating a possible focus of infection.

5. Erythrocyte sedimentation rate (ESR or “sed rate”). Large elevations in ESR are associated with acute or chronic infection, particularly endocarditis, chronic osteomyelitis, and intra-abdominal infections. A normal ESR does not exclude infection; more often, ESR is elevated as a result of noninfectious causes such as collagen vascular disease.

6. Serum complement concentrations, particularly the C3 component, are often reduced in serious infections because of consumption during the host defense process.

I. Lack of therapeutic effectiveness. When an antibiotic drug regimen fails, other drugs should not be added indiscriminately or the regimen otherwise changed. Instead, the situation should be reassessed and diagnostic efforts intensified. Causes of therapeutic ineffectiveness include the following:

1. Misdiagnosis. The isolated organism may have been misidentified by the laboratory or may not be the causative agent for infection (e.g., the patient may have an unsuspected infection).

2. Improper drug regimen. The drug dosage, administration route, dosing frequency, or duration of therapy may be inadequate or inappropriate.

3. Inappropriate choice of antibiotic agent. As discussed in I.D, patient factors and the pharmacological properties and spectrum of activity of a given drug must be considered when planning anti-infective drug therapy.

4. Microbial resistance. By acquiring resistance to a specific antibiotic, microorganisms can survive in the drug's presence. Many gonococcal strains, for instance, now resist penicillin. Drug resistance is particularly common in geographical areas in which a specific drug has been used excessively (and perhaps improperly).

5. Unrealistic expectations. Antibiotics are ineffective in certain circumstances.

a. Patients with conditions that require **surgical drainage** frequently cannot be cured by anti-infective drugs until the drain has been removed. For example, the presence of necrotic tissue or pus in patients with pneumonia, empyema, or renal calculi is a common cause of antibiotic failure.

b. Fever should not be treated with anti-infective drugs unless infection has been identified as the cause. Although fever frequently signifies infection, it sometimes stems from noninfectious conditions (e.g., drug reactions, phlebitis, neoplasms, metabolic disorders, arthritis). These conditions do not respond to antibiotics. One exception to this position is neutropenic cancer patients; such patients with no signs or symptoms of infection other than fever are widely treated with antimicrobial agents.

6. Infection by two or more types of microorganisms. If not detected initially, an additional cause of infection may lead to therapeutic failure.

J. Antimicrobial prophylaxis for surgery

1. Definition. Antibiotic prophylaxis is a short course of antibiotic administered before there is clinical evidence of infection.

2. General considerations

a. Timing. The antibiotic should be administered to ensure that appropriate antibiotic levels are available at the site of contamination before the incision. Initiation of prophylaxis is often at induction of anesthesia, within 1 hr or just before the surgical incision. This ensures peak serum and tissue antibiotic levels.

b. Duration. Prophylaxis should be maintained for the duration of surgery. Long surgical procedures (e.g., > 3 hr) may require additional doses. There is little evidence to support continuation of prophylaxis beyond 24 hr.

c. Antibiotic spectrum should be appropriate for the usual pathogens.

(1) In general, **first-generation cephalosporins** (e.g., cefazolin) are the drugs of choice for most procedures and patients. These agents have an appropriate spectrum, a low frequency of side effects, a favorable half-life, and a low cost.

(2) Vancomycin is a suitable alternative in penicillin-sensitive patients and in situations in which methicillin-resistant *S. aureus* is a concern.

d. Route of administration. Intravenous (IV) or intramuscular (IM) routes are preferred to guarantee good serum and tissue levels at the time of incision.

II. Antibacterial Agents

A. Definition and classification. Used to treat infections caused by **bacteria,** antibacterial agents fall into several major categories: **aminoglycosides, carbapenems, cephalosporins, erythromycins, penicillins** (including various subgroups), **sulfonamides, tetracyclines, fluoroquinolones, metronidazole** (see V.C.2.b), **urinary tract antiseptics,** and **miscellaneous anti-infectives** (Table 44-1).

B. Aminoglycosides. These drugs, containing amino sugars, are used primarily in infections caused by gram-negative enterobacteria and in

suspected sepsis. They have little activity against anaerobic and facultative organisms. The toxic potential of these drugs limits their use. Major aminoglycosides include **amikacin (Amikin), gentamicin (Garamycin), kanamycin, neomycin, netilmicin, streptomycin,** and **tobramycin (Nebcin).**

1. Mechanism of action. Aminoglycosides are **bactericidal;** they inhibit bacterial protein synthesis by binding to and impeding the function of the 30S ribosomal subunit. (Some aminoglycosides also bind to the 50S ribosomal subunit.) Their mechanism of action is not fully known.

Table 44-1. Some Important Parameters of Anti-Infective Drugs

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Aminoglycosides				
Amikacin	Renal	2-3 hr	IV, IM	15 mg/kg/day, (once daily dose)
Gentamicin	Renal	2 hr	IV, IM	3 mg/kg/da

					y (standard dose); 6-7 mg/kg/day (once daily dose)
	Kanamycin	Renal	2-4 hr	Oral, IV	15 mg/kg every 8-12 hr
	Neomycin	Renal	2-3 hr	Oral, topical	50-100 mg/kg/day (oral); 10-15 mg/day (topical)
	Netilmicin	Renal	2-7 hr	IV, IM	3-6 mg/kg/day
	Streptomycin	Renal	2-3 hr	IM	15 mg/kg/day[a]
	Tobramycin	Renal	2-5 hr	IV, IM	3 mg/kg/day (standard dose); 6-7 mg/kg/day, (once daily dose)
Carbapenems					
	Doripenem	Renal	1 hr	IV	500 mg every 8 hr

	Imipenem		Renal	1 hr	IV	250 mg-1 g every 6 hr
	Ertapenem		Renal	4 hr	IV, IM	1 g/day
	Meropenem		Renal	1.5 hr	IV, IM	0.5-2 g every 8 hr
Cephalosporins						
	First-generation					
		Cefadroxil	Renal	1.5 hr	Oral	1-2 g/day
		Cefazolin	Renal	1.4-2.2 hr	IV	250 mg-1 g every 8 hr
		Cephalexin	Renal	0.9 1.3 hr	Oral	250-500 mg every 6 hr
		Cephapirin	Renal (H)	0.6-0.8 hr	IV, IM	500 mg-2 g every 4-6 hr
		Cephradine	Renal	1.3 hr	Oral, IV	250-500 mg every 6 hr
	Second-generation					
		Cefaclor	Renal (H)	0.8 hr	Oral	250-500 mg every 8 hr

		Cefmetazole	Renal	72 min	IV	2 g every 6-12 hr
		Cefotetan	Renal	2.8-4.6 hr	IV, IM	1-2 g every 12 hr
		Cefoxitin	Renal	0.8 hr	IV	1-2 g every 6-8 hr
		Cefprozil	Renal	78 min	Oral	250-500 mg every 12-24 hr
		Cefuroxime	Renal	1.5-2.2 hr	IV, IM	750 mg-1.5 g every 8 hr
		Loracarbef	Renal	1 hr	Oral	200 mg every 12 hr or 400 mg/day
	Third-generation					
		Cefixime	Renal	3-4 hr	Oral	400 mg/day
		Cefdinir	Renal	1.7-1.8 hr	Oral	300 mg every 12 hr
		Cefoperazone	Hepatic	1.6-2.4 hr	IV	2-4 g every 12 hr
		Cefotaxime	Renal (H)	1.5 hr	IV	1-2 g every 6-8

						hr
		Cefpodoxime	Renal	2.5 hr	Oral	100-400 mg every 12 hr
		Ceftazidime	Renal	1.8 hr	IV, IM	1-2 g every 8-12 hr
		Ceftibuten	Renal	2.5 hr	Oral	400 mg/day
		Ceftizoxime	Renal	1.7 hr	IV	1-2 g every 8-12 hr
		Ceftriaxone	Renal	8 hr	IV, IM	1-2 g/day
	Fourth-generation					
		Cefepime	Renal	2-2.3 hr	IV, IM	1-2 g every 8-12 hr
Erythromycins and other macrolides						
	Azithromycin		Hepatic	68 hr	Oral	250 mg/day
	Clarithromycin		Renal	3-7 hr	Oral	250-500 mg every 12 hr
	Dirithromycin		Hepatic	8 hr	Oral	500 mg/day

	Erythromycin base estolate, ethylsuccinate, and stearate	Hepatic	1.2-2.6 hr	Oral	250-500 mg every 6 hr
	Erythromycin gluceptate and lactobionate			IV	0.5-2 g every 6 hr
Natural penicillins					
	Penicillin G	Renal (H)	0.5 hr	Oral, IV, IM	200,000-500,000 U every 6-8 hr
	Penicillin V	Renal	1 hr	Oral	500 mg-2 g/day
	Penicillin G procaine	Renal	24-60 hr	IM	300,000-600,000 U/day
	Penicillin G benzathine	Renal	24-60 hr	IM	300,000-600,000 U/day
Penicillinase-resistant penicillins					
	Cloxacillin	Renal (H)	0.5 hr	Oral	250-500 mg every 6 hr
	Dicloxacillin	Renal (H)	0.5-0.9 hr	Oral	500 mg-1 g/day
	Methicillin	Renal (H)	0.5-1 hr	IV, IM	1-2 g every 4-6 hr

	Nafcillin	Hepatic (R)	0.5 hr	Oral, IV, IM	0.25-2 g every 6 hr
	Oxacillin	Renal (H)	0.5 hr	Oral, IV, IM	500 mg-2 g every 4-6 hr 500-875 mg every 12 hr
Aminopenicillins					
	Amoxicillin	Renal (H)	0.9-2.3 hr	Oral	250-500 mg every 8 hr
	Amoxicillin/clavulanic acid	Renal	1 hr	Oral	250-500 mg every 8 hr
	Ampicillin	Renal (H)	0.8-1.5 hr	Oral, IV, IM	250 mg-2 g every 4-6 hr
	Ampicillin/sulbactam	Renal	1-1.8 hr	IV, IM	1.5-3 g every 6 hr
Extended-spectrum penicillins					
	Mezlocillin	Renal (H)	0.6-1.2 hr	IV, IM	1-3 g every 4-6 hr
	Piperacillin	Renal (H)	0.8-1.4 hr	IV, IM	1-1.5 mg/kg every 6-12 hr
	Piperacillin/tazobact	Renal	0.7-1.2	IV	3.375 g

	am		hr		every 6 hr
	Ticarcillin	Renal	0.9-1.5 hr	IV, IM	1-3 g every 4-6 hr
	Ticarcillin/clavulanic acid	Renal	1-1.5 hr	IV	3.1 g every 4-6 hr
Sulfonamides					
	Sulfacytine	Renal	4-4.5 hr	Oral	250 mg every 6 hr
	Sulfadiazine	Renal (H)	6 hr	Oral, IV	2-4 g/day
	Sulfamethoxazole	Hepatic (R)	9-11 hr	Oral	1-3 g/day
	Sulfisoxazole	Renal (H)	3-7 hr	Oral, IV	2-8 g/day
	Sulfamethizole	Renal	—	Oral	0.5-1 g every 6-8 hr
Tetracyclines					
	Demeclocycline	Renal	10-17 hr	Oral	300 mg-1 g/day
	Doxycycline	Hepatic	14-25 hr	Oral, IV	100-200 mg every 12 hr

	Minocycline	Hepatic	12-15 hr	Oral, IV	100-200 mg every 12 hr
	Oxytetracycline	Renal	6-12 hr	Oral, IM	250-500 mg every 6 hr 250-500 mg q.i.d. or 300 mg/day in 1 or 2 divided doses
	Tetracycline[b]	Renal	6-12 hr	Oral, IV, IM	1-2 g/day
Fluoroquinolones					
	Ciprofloxacin	Renal (H)	5-6 hr	IV	200-600 mg every 12 hr
	Enoxacin	Renal (H)	3-6 hr	Oral	200 mg/day-400 mg every 12 hr
	Gemifloxacin	Fecal (R)	4-12 hr	Oral	320 mg once daily
	Lomefloxacin	Renal	6.35-7.77 hr	Oral	400 mg/day
	Levofloxacin	Renal	8 hr	IV, Oral	250-500 mg every 24 hr

	Moxifloxacin	Hepatic	12 hr	Oral	400 mg once daily
	Ofloxacin	Renal	5-7.5 hr	Oral	100 mg/day-400 mg
Urinary tract antiseptics					
	Cinoxacin	Renal	1-1.5 hr	Oral	250 mg every 6 hr or 500 mg every 12 hr
	Fosfomycin	Renal/fecal	5.7 hr	Oral	One packet (3 g) in 90-120 mL water × 1 dose
	Methenamine hippurate and mandelate	Renal	1-3 hr	Oral	0.5-2 g q.i.d.
	Nalidixic acid	Renal	8 hr	Oral	4 g/day
	Nitrofurantoin	Renal	0.3-1 hr	Oral	5-7 mg/kg/day
	Norfloxacin	Hepatic	3-4 hr	Oral	400 b.i.d.
Miscellaneous anti-infectives					
	Atovaquone	Fecal	50-84 hr	Oral	750 mg b.i.d. × 21 days

	Aztreonam	Renal	1.7 hr	Oral, IV	50-100 mg/kg/day
	Clindamycin	Hepatic	2-4 hr	Oral, IM, IV	300-900 mg every 6-8 hr
	Clofazimine	Hepatic	70 days	Oral	50-100 mg/day
	Dapsone	Hepatic (R)	28 hr	Oral	50-100 mg/day
	Daptomycin	Renal	8 hr	IV	4 mg/kg/day
	Lincomycin	Hepatic (R)	4.4-6.4 hr	IV, IM	600 mg-1 g every 8-12 hr
	Linezolid	Renal	4-6 hr	Oral, IV	600 mg every 12 hr
	Mupirocin	Renal	19-35 min	Topical	Apply every 8-12 hr
	Quinupristin/dalfopristin	Hepatic	1 hr/0.4-0.5 hr	IV	7.5 mg/kg every 8 hr
	Rifaximin	Fecal	6 hrs	Oral	200 mg t.i.d.
	Spectinomycin	Renal	1.2-2.8 hr	IM	2-4 g (single

					dose)
	Telithromycin	Hepatic (R)	10 hr	Oral	800 mg/day
	Tigecycline	Biliary (R)	42 hr	IV	100 mg load, 50 mg every 12 hr
	Trimethoprim	Renal (H)	8-15 hr	Oral	100-200 mg/day
	Vancomycin	Renal	6-8 hr	Oral, IV	500 mg every 6 hr
Antifungal agents					
	Amphotericin B	Unknown	24 hr	IV	1-1.5 mg/kg/day
	Anidulafungin	Fecal (R)	40-50 hr	IV	Candidemia: 200 mg day 1, then 100 mg/day
					Esophageal candidiasis: 100 mg day 1, then 50 mg/day
	Caspofungin	Hepatic	9-11 hr	IV	70 mg on day 1, then 50 mg q.d.

	Fluconazole	Renal	22-37 hr	IV, Oral	100-800 mg/day
	Flucytosine	Renal	6 hr	Oral	50-150 mg/kg/day
	Griseofulvin	Hepatic (R)	9-24 hr	Oral	300-375 mg/day
	Itraconazole	Hepatic	24-42 hr	Oral	200-600 mg/day
	Ketoconazole	Hepatic/fecal	3.3 hr	Oral	200-400 mg/day b.i.d
	Micafungin	Hepatic	11-17 hr	IV	Esophageal candidiasis: 150 mg/day
					HSCT prophylasis: 50 mg/day
	Miconazole	Hepatic	20-24 hr	Oral	200-400 mg/day
	Nystatin	Fecal	—	Oral	500,000-1,000,000 U t.i.d.
	Posaconazole	Fecal/renal	35 hrs	Oral	200 mg t.i.d.
	Terbinafine	Hepatic	11-16	Oral	250

		(R)	hr		mg/day
	Voriconazole	Hepatic	6 hr	IV, Oral	IV: 6 mg/kg every 12 hr × 2 doses, then 4 mg/kg every 12 h; oral: 200 mg every 12 h for > 40 kg, 100 mg every 12 h for < 40 kg
Antiprotozoal agents					
	Atovaquone	Hepatic	67 hr	Oral	750 mg b.i.d.
	Chloroquine	Renal/fecal	72-120 hr	IM, Oral	Depends on disease
	Diloxanide	Renal	—	IM	500 mg t.i.d.
	Eflornithine	Renal	3 hr	IV	100 mg/kg/dose every 6 hr
	Fansidar	Renal	100-231 hr	Oral	1 tablet every week
	Halofantrine	Hepatic	3-4	Oral	500 mg

			days		every 6 hr × 3 doses; repeat in 7 days
		Renal	72-120 hr	Oral	310 mg every week
	Hydroxychloroquine				
	Iodoquinol	Fecal	—	Oral	650 mg t.i.d. for 20 days
	Mefloquine	Hepatic	15-33 days	Oral	1250 mg single dose
	Metronidazole	Hepatic (R)	6-14 hr	Oral, IV	250-500 mg every 6-8 hr
	Nitazoxanide	Hepatic	1-1.6 hr	Oral	100-200 mg b.i.d. based on age
	Paromomycin	Fecal	—	Oral	25-35 mg/kg/day
	Pentamidine	Renal	6-9 hr	IM, IV, inhalation	IV, IM: 3-4 mg/kg every day; inhalation: 300 mg every 4

					weeks
	Primaquine	Hepatic	3.7-9.6 hr	Oral	15 mg (base)/day
	Pyrimethamine	Renal	111 hr	Oral	25 mg every week
	Quinacrine		5 days	Oral	100 mg/day
	Quinine	Renal	12 hr	Oral	325 mg b.i.d.
	Tinidazole	Hepatic (R)	13.2 hr	Oral	2 g q.d. × 1-3 days
Antitubercular agents					
	Aminosalicylic acid	Renal	1 hr	Oral	150 mg/kg daily (maximum 12 g/day)
	Capreomycin	Renal	4-6 hr	IM	15 mg/kg/day to 1 g/day maximum
	Cycloserine	Renal	10 hr	Oral	15-20 mg/kg (maximum 1 g/day)

	Ethambutol	Hepatic	3.3 hr	Oral	15-25 mg/kg/day
	Ethionamide	Hepatic	3 hr	Oral	500 mg-1 g/day
	Isoniazid	Hepatic	1-4 hr	Oral, IV	5-10 mg/kg daily (maximum dose = 300 mg)
	Pyrazinamide	Hepatic	9-10 hr	Oral	15-30 mg/kg daily (maximum 2 g/day)
	Rifampin	Hepatic	2-3 hr	Oral, IV	10 mg/kg (up to 600 mg) q.d.
	Rifabutin	Hepatic	45 hr	Oral	300 mg q.d.
	Rifepentine	Hepatic	13.9 hr (active metabolite \13.4 hr)	Oral	600 mg every 3 days
Antiviral agents					
	Abacavir	Hepatic	1.5 hr	Oral	300 mg b.i.d. or 600 mg

					every day
	Adefovir	Renal	7.5 hr	Oral	10 mg every day
	Acyclovir	Renal	2.2 hr	Oral, IV, topical	IV: 5-10 mg/kg every 8 hr; oral: 200-800 mg 3-5 × daily (depending upon indication)
	Amantadine	Renal	17 hr	Oral	100 mg b.i.d. or 200 mg every day
	Amprenavir	Hepatic	7-10 hr	Oral	1200 mg b.i.d. (caps)
	Atazanavir	Hepatic	7 hr	Oral	400 mg every day
	Cidofovir	Renal	6.5 hr	IV	5 mg/kg week × 2 (induction); 5 mg/kg every 2 weeks (maintenance)
	Darunavir	Hepatic	15 hr	Oral	600 mg plus 100

					mg ritonavir b.i.d.
	Delavirdine	Hepatic (R)	2-11 hr	Oral	400 mg t.i.d.
	Didanosine	Renal	1.5 hr	Oral	≥ 60 kg: 400 mg every day (EC caps); < 60 kg: 250 mg every day (EC caps)
	Emtricitabine	Renal	10 hr	Oral	200 mg every day (caps)
	Enfuvirtide	n/a	3.8 hr	SC	90 mg b.i.d.
	Entecavir	Renal	128-149 hr	Oral	0.5 mg every day, or 1 mg every day in patients with lamivudine resistance
	Efavirenz	Hepatic	40-55 hr	Oral	600 mg at bedtime
	Famciclovir	Renal	2-2.3 hr	Oral	250-500 mg every 8-12 hr

	Fosamprenavir	Hepatic	7.7 hr	Oral	1400 mg b.i.d.
	Foscarnet	Renal	3-6 hr	IV	90 mg/kg every 12 hr × 14-21 days (CMV induction); 90 mg/kg every day (CMV maintenance)
	Ganciclovir	Renal	2.9 hr	IV	5 mg/kg every 12 hr (induction) × 14-21 days; 5 mg/kg every day (maintenance)
			4.8 hr	Oral	1000 mg t.i.d. (after induction)
	Indinavir	Hepatic	1.4-2.2 hr	Oral	800 mg every 8 hr
	Lamivudine	Renal	3-7 hr	Oral	150 mg b.i.d. or 300 mg daily
	Lopinavir/ritonavir	Hepatic	4.4-6.1 hr	Oral	200 mg/50 mg

					per tab (2 tablets b.i.d.)
	Maraviroc	Hepatic	14-18 hr	Oral	150-600 mg b.i.d., depending upon concomitant medications
	Nelfinavir	Hepatic	3.5-5 hr	Oral	1250 mg b.i.d.
	Nevirapine	Renal (H)	25-30 hr	Oral	200 mg every day × 14 days, then 200 mg b.i.d.
	Oseltamivir	Renal	6-10 hr	Oral	75 mg b.i.d. (treatment); 75 mg every day (prophylaxis)
	Raeltegravir	Hepatic	9 hr	Oral	400 mg b.i.d.
	Ribavirin	Renal	298 hr	Oral	800-1200 mg daily, divided into 2 doses
	Rimantadine	Renal	25 hr	Oral	100 mg

					b.i.d.
	Ritonavir	Hepatic	3-5 hr	Oral	100-400 mg daily, divided in 1 or 2 doses (as booster agent with other PIs)
	Saquinavir	Hepatic	13 hr	Oral	1000 mg (Invirase) plus 100 mg ritonavir b.i.d.
	Stavudine	Renal	1.5 hr	Oral	≥ 60 kg: 40 mg every 12 hr; < 60 kg: 30 mg every 12 hr
	Telbivudine	Renal	40-49 hr	Oral	600 mg every day
	Tenofovir	Renal	10-14 hr	Oral	300 mg daily
	Tipranavir	Hepatic	6 hr	Oral	500 mg plus 200 mg ritonavir b.i.d.
	Valacyclovir	Renal	2.5-3.6 hr	Oral	0.5-1 g every day

					or b.i.d. or t.i.d.
	Valganciclovir	Renal	4 hr	Oral	900 mg b.i.d. × 21 days (induction), 900 mg every day (maintenance)
	Zalcitabine	Renal	1-3 hr	Oral	0.75 mg t.i.d.
	Zanamivir	Renal	2.5-5.1 hr	Inhalation (Diskhaler)	2 inhalations (10 mg) b.i.d. (treatment); 10 mg every day (prophylaxis)
	Zidovudine	Renal (H)	1.5-3.1 hr	Oral	300 mg b.i.d.
				IV	2 mg/kg over 1 hr, then 1 mg/kg/hr until cord clamping (intrapartum perinatal prophylaxis for pregnant women)

Anthelmintics				
Albendazole	Hepatic	8-12 hr	Oral	400-800 mg daily
Diethylcarbamazine	Renal	8 hr	Oral	25 mg/day for 3 days, then 50 mg/day for 5 days, then 100 mg/day for 3 days, then 150 mg/day for 12 days
Ivermectin	Hepatic	16-35 hr	Oral	150-200 mcg/kg × 1 dose
Mebendazole	Hepatic	8 hr	Oral	100 mg b.i.d. × 3 consecutive days
Praziquantel	Hepatic	0.8-3 hr	Oral	60-75 mg/kg in 3 divided doses on the same day
Pyrantel	Hepatic	—	Oral	11 mg/kg (maximum = 1 g) as a

					single dose
	Thiabendazole	Hepatic	—	Oral	Dose based upon weight chart in prescribing information, 100 lb: 1 g b.i.d. 125 lb: 1.25 g b.i.d. > 150 lb: 1.5 g b.i.d.

CMV, cytomegalovirus; *EC cap,* enteric-coated capsule; *H,* additional significant hepatic elimination; HSCT, hematopoietic stem cell transplant; *IM*, intramuscular; *IV,* intravenous; *PIs,* protease inhibitors *R,* additional significant renal elimination; *SC,* subcutaneous.

[a] Dosage applies to infections other than tuberculosis; for tuberculosis, dosage is 1 g/day.

[b] Intravenous agent withdrawn from U.S. market.

2. Spectrum of activity

a. Streptomycin is active against both gram-positive and gram-negative bacteria. However, widespread resistance to this drug has restricted its use to the organisms that cause plague and tularemia, gram-positive streptococci (given in combination with penicillin), and *Mycobacterium tuberculosis* (given in combination with other antitubercular agents, as described in VI.C.2).

b. Amikacin, kanamycin, gentamicin, tobramycin, neomycin, and **netilmicin** are active against many gram-negative bacteria (e.g., *Proteus, Serratia,* and *Pseudomonas* organisms).

(1) Gentamicin is active against some *Staphylococcus* strains; it is more active than tobramycin against *Serratia* organisms.
(2) Amikacin is the broadest spectrum aminoglycoside with activity against most aerobic gram-negative bacilli as well as many anaerobic gram-negative bacterial strains that resist gentamicin and tobramycin. It is also active against *M. tuberculosis* and *Mycobacterium avium-intracellulare* (MAI).
(3) Tobramycin may be more active against *Pseudomonas aeruginosa* than gentamicin.
(4) Netilmicin may be active against gentamicin-resistant organisms; it appears to be less ototoxic than other aminoglycosides.
(5) Neomycin, in addition to its activity against such gram-negative organisms as *Escherichia coli* and *Klebsiella pneumoniae,* is active against several gram-positive organisms (e.g., *S. aureus*). *P. aeruginosa* and most streptococci are now neomycin resistant.
3. Therapeutic uses
a. Streptomycin is used to treat plague, tularemia, acute brucellosis (given in combination with tetracycline), bacterial endocarditis caused by *Streptococcus viridans* (given in combination with penicillin), and tuberculosis (given in combination with other antitubercular agents, as described in VI.C.2).
b. Gentamicin, tobramycin, amikacin, and **netilmicin** are therapeutic for serious gram-negative bacillary infections (e.g., those caused by *Enterobacter, Serratia, Klebsiella,* and *P. aeruginosa*), pneumonia (given in combination with a cephalosporin or penicillin), meningitis, complicated urinary tract infections, osteomyelitis, bacteremia, and peritonitis.
c. Neomycin is used for preoperative bowel sterilization; hepatic coma (as adjunctive therapy); and, in topical form, for skin and mucous membrane infections (e.g., burns).
4. Precautions and monitoring effects. Aminoglycosides can cause serious adverse effects. To prevent or minimize such problems, blood drug concentrations and blood urea nitrogen (BUN) and serum creatinine levels should be monitored during therapy.
a. Ototoxicity. Aminoglycosides can cause vestibular or auditory damage. The relative ototoxicity is as follows:
streptomycin = kanamycin > amikacin = gentamicin = tobramycin > netilmicin
(1) Gentamicin and streptomycin cause primarily **vestibular** damage (manifested by tinnitus, vertigo, and ataxia). Such damage may be bilateral and irreversible.
(2) Amikacin, kanamycin, and neomycin cause mainly **auditory** damage (hearing loss).
(3) Tobramycin can result in both vestibular and auditory damage.
b. Nephrotoxicity. Because aminoglycosides accumulate in the proximal tubule, mild renal dysfunction develops in up to 25% of patients receiving

these drugs for several days or more. Usually, this adverse effect is reversible. Use of once-daily administration (ODA) has been reported in the literature to be as effective and less nephrotoxic than traditional dosing.
(1) Neomycin is the most nephrotoxic aminoglycoside; streptomycin is the least nephrotoxic. Gentamicin and tobramycin are nephrotoxic to approximately the same degree.
(2) Risk factors for increased nephrotoxic effects include the following:
(a) Preexisting renal disease
(b) Previous or prolonged aminoglycoside therapy
(c) Concurrent administration of another nephrotoxic drug
(d) Impaired renal flow unrelated to renal disease (e.g., from hypotension, severe hepatic disease)

(3) Trough levels > 2 µg/mL for gentamicin and tobramycin and > 10 µg/mL for amikacin are associated with nephrotoxicity.
c. Neuromuscular blockade. This problem may arise in patients receiving high-dose aminoglycoside therapy.
(1) Risk factors for neuromuscular blockade include the following:
(a) Concurrent administration of a neuromuscular blocking agent or an anesthetic
(b) Preexisting hypocalcemia or myasthenia gravis
(c) Intraperitoneal or rapid IV drug administration
(2) Apnea and respiratory depression may be reversed with administration of calcium or an anticholinesterase.
d. Hypersensitivity and **local reactions** are rare adverse effects of aminoglycosides.
e. Therapeutic levels
(1) Gentamicin and tobramycin peak at 6-10 µg/mL for traditional dosing; when using the ODA method, the peak is 16-20 µg/mL or 8-10 times the MIC of targeted bacteria. Their trough level is 0.5-1.5 µg/mL for traditional or once-daily regimens.
(2) Amikacin peaks at 25-30 µg/mL. The trough level is 5-8 µg/mL.
5. Significant interactions
a. IV loop diuretics can result in increased ototoxicity.
b. Other aminoglycosides, cephalothin, cisplatin, amphotericin B, and **methoxyflurane** can cause increased nephrotoxicity when given concurrently with streptomycin.
C. Carbapenems. These agents are β-lactams that contain a fused β-lactam ring and a 5-membered ring system that differs from penicillins in being unsaturated and containing a carbon atom instead of a sulfur atom. The class has a broader spectrum of activity than do most β-lactams. Formerly known as thienamycin, **imipenem (Primaxin)** was the first carbapenem compound introduced in the United States, followed by

meropenem (Merrem) and, most recently, **ertapenem (Invanz)** and **doripenem (Doribax).** Because it is inhibited by renal dipeptidases, imipenem must be combined with **cilastatin** sodium, a dipeptidase inhibitor (cilastatin is not required with the others because these are not sensitive to renal dipeptidase).

1. Mechanism of action. Carbapenems are **bactericidal,** inhibiting bacterial cell wall synthesis.

2. Spectrum of activity. These drugs have the broadest spectrum of all β-lactam antibiotics. The group is active against most gram-positive cocci (including many enterococci), gram-negative rods (including many *P. aeruginosa* strains), and anaerobes. This class has good activity against many bacterial strains that resist other antibiotics. Ertapenem has a narrower spectrum of activity than the other carbapenems. It has little or no activity against *P. aeruginosa* and *Acinetobacter.* These β-lactam antibiotics resist destruction by most β-lactamases.

3. Therapeutic uses. Carbapenems are most valued in the treatment of severe infections caused by drug-resistant organisms susceptible to these agents. These agents are effective against urinary tract and lower respiratory infections, intra-abdominal and gynecological infections, and skin, soft-tissue, bone, and joint infections.

4. Precautions and monitoring effects

a. Carbapenems may cause nausea, vomiting, diarrhea, and pseudomembranous colitis.

b. Seizures, dizziness, and hypotension may develop; seizures appear less frequently with meropenem or ertapenem (1.5% of patients receiving imipenem versus 0.5% of those receiving meropenem or ertapenem).

c. Patients who are allergic to penicillin or cephalosporins may suffer cross-sensitivity reactions during carbapenem therapy.

D. Cephalosporins. These agents are known as **β-lactam antibiotics** because their chemical structure consists of a β-lactam ring adjoined to a thiazolidine ring. Cephalosporins generally are classified in four major groups based mainly on their spectrum of activity (Table 44-2).

1. Mechanism of action. Cephalosporins are **bactericidal;** they inhibit bacterial cell wall synthesis, reducing cell wall stability and thus causing membrane lysis.

Table 44-2. Classification of Cephalosporins

First Generation	Second Generation	Third Generation	Fourth Generation
Cefadroxil (Duricef, Ultracef)[a] Cefazolin (Ancef, Kefzol) Cephalexin (Keflex)[a] Cephapirin (Cefadyl) Cephradine (Anspor, Velosef)[a]	Cefaclor (Ceclor)[a] Cefmetazole (Zefazone) Cefotetan (Cefotan)[b] Cefoxitin (Mefoxin) Cefuroxime(Zinacef) Cefuroxime axetil (Ceftin)[a] Cefprozil (Cefzil)[a] Loracarbef (Lorabid)[a]	Cefdinir (Omnicef)[a] Cefixime (Suprax)[a] Cefoperazone (Cefobid) Cefotaxime (Claforan) Cefpodoxime proxetil (Vantin)[a] Ceftazidime (Fortex, Tazicef, Tazidime) Ceftibuten (Cedax)[a] Ceftizoxime (Cefizox) Ceftriaxone (Rocephin) Cefditoren (Spectracef)[a]	Cefepime (Maxipime)

[a] Oral agent.

[b] Discontinued in the U.S. market 2005.

2. Spectrum of activity

a. First-generation cephalosporins are active against most gram-positive cocci (except enterococci) as well as enteric aerobic gram-negative bacilli (e.g., *E. coli, K. pneumoniae, Proteus mirabilis*).

b. Second-generation cephalosporins are active against the organisms covered by first-generation cephalosporins and have extended gram-negative coverage, including β-lactamase-producing strains of *Haemophilus influenzae*.

c. Third-generation cephalosporins have wider activity against most gram-negative bacteria, for example, *Enterobacter, Citrobacter, Serratia, Providencia, Neisseria,* and *Haemophilus* organisms, including β-lactamase-producing strains.

d. Fourth-generation cephalosporins include **cefepime (Maxipime),** which is the first member of this group to be marketed. However, its designation as a fourth-generation cephalosporin is debatable. Cefepime is highly

resistant to β-lactamases and has a low propensity for selection of β-lactam-resistant mutant strains. It shows evidence of greater activity versus gram-positive cocci, *Enterobacteriaceae,* and *Pseudomonas* than third-generation cephalosporins.

e. Each generation of cephalosporin has shifted toward increased gram-negative activity but has lost activity toward gram-positive organisms. Fourth-generation agents have improved activity toward gram-positive organisms over third-generation agents.

3. Therapeutic uses

a. First-generation cephalosporins commonly are administered to treat serious *Klebsiella* infections and gram-positive and some gram-negative infections in patients with mild penicillin allergy. These agents also are used widely in perioperative prophylaxis. For most other indications, they are not the preferred drugs.

b. Second-generation cephalosporins are valuable in the treatment of urinary tract infections resulting from *E. coli* organisms, acute otitis media, sinusitis, and gonococcal disease caused by organisms that resist other agents.

(1) Cefaclor (Ceclor) is useful in otitis media and sinusitis in patients who are allergic to ampicillin and amoxicillin. **Cefprozil (Cefzil)** and **loracarbef (Lorabid)** are second-generation cephalosporins that can be administered twice daily but offer no important spectrum differences.

(2) Cefoxitin (Mefoxin) is therapeutic for mixed aerobic-anaerobic infections, such as intra-abdominal infection. The **cefotetan (Cefotan)** spectrum is similar but this agent can be given twice daily.

(3) Cefuroxime (Zinacef) is commonly administered for outpatient community-acquired pneumonia.

c. Third-generation cephalosporins penetrate the cerebrospinal fluid (CSF) and thus are valuable in the treatment of meningitis caused by such organisms as meningococci, pneumococci, *H. influenzae,* and enteric gram-negative bacilli.

(1) These agents also are used to treat sepsis of unknown origin in immunosuppressed patients and to treat fever in neutropenic immunosuppressed patients (given in combination with an aminoglycoside).

(2) Third-generation cephalosporins are useful in infections caused by many organisms resistant to older cephalosporins.

(3) These agents are frequently administered as empiric therapy for life-threatening infection in which resistant organisms are the most likely cause.

(4) Initial therapy of mixed bacterial infections (e.g., sepsis) commonly involves third-generation cephalosporins.

d. The **fourth-generation** agent, cefepime, is approved for treatment of urinary tract infections, uncomplicated skin and skin structure infections,

pneumonia, and empiric use in febrile neutropenic patients. Cefepime has a spectrum of activity similar to third-generation agents but is more resistant to some β-lactamases.

4. Precautions and monitoring effects

a. Because all cephalosporins (except cefoperazone) are eliminated renally, doses must be adjusted for patients with renal impairment.

b. Cross-sensitivity with penicillin has been reported in up to 10% of patients receiving cephalosporins. More recent information indicates that true cross-reactivity is rare.

c. Cephalosporins can cause hypersensitivity reactions similar to those resulting from penicillin (see II.E.1.e.(1)). Manifestations include fever, maculopapular rash, anaphylaxis, and hemolytic anemia.

d. Other adverse effects include nausea, vomiting, diarrhea, superinfection, nephrotoxicity, and *Clostridium difficile*-induced colitis; with cefoperazone, cefmetazole, and cefotetan (and formerly moxalactam and cefamandole), bleeding diatheses may occur. Bleeding can be reversed by vitamin K administration.

e. Cephalosporins may cause false-positive glycosuria results on tests using the copperreduction method.

f. Ceftriaxone now contraindicated in newborns receiving concurrent administration of calcium-containing solutions or products due to risk of fatal precipitation in lungs and kidneys. New warning added also stating that ceftriaxone and IV calcium-containing solutions should not be administered within 48 hours of each other.

5. Significant interactions

a. Probenecid may impair the excretion of cephalosporins (except ceftazidime), causing increased cephalosporin levels and possible toxicity.

b. Alcohol consumption may result in a disulfiram-type reaction in patients receiving cefmetazole, cefotetan, and cefoperazone.

c. Aminoglycosides or loop diuretics may cause additive toxicity when administered with cephalothin.

d. Plasma concentrations of cefaclor extended-release tablets, cefdinir, and cefpodoxime may be reduced by coadministration with **antacids.**

e. H_2-antagonists may reduce plasma levels of cefpodoxime and cefuroxime.

f. Iron supplements and **iron-fortified foods** reduce absorption of cefdinir by 80% and 30%, respectively.

E. Erythromycins. The chemical structure of these macrolide antibiotics is characterized by a lactone ring to which sugars are attached. Erythromycin base and the estolate, ethylsuccinate, and stearate salts are given orally; erythromycin lactobionate and gluceptate are given parenterally.

1. Mechanism of action. Erythromycins may be **bactericidal** or **bacteriostatic;** they bind to the 50S ribosomal subunit, inhibiting bacterial protein synthesis.

2. Spectrum of activity. Erythromycins are active against many gram-positive organisms, including streptococci (e.g., *Streptococcus pneumoniae*), and *Corynebacterium* and *Neisseria* species as well as some strains of *Mycoplasma, Legionella, Treponema,* and *Bordetella.* Some *S. aureus* strains that resist penicillin G are susceptible to erythromycins.

3. Therapeutic uses

a. Erythromycins are the preferred drugs for the treatment of *Mycoplasma pneumoniae* and *Campylobacter* infections, Legionnaires disease, chlamydial infections, diphtheria, and pertussis.

b. In patients with penicillin allergy, erythromycins are important alternatives in the treatment of pneumococcal pneumonia, *S. aureus* infections, syphilis, and gonorrhea.

c. Erythromycins may be given prophylactically before dental procedures to prevent bacterial endocarditis.

4. Precautions and monitoring parameters

a. Gastrointestinal (GI) distress (e.g., nausea, vomiting, diarrhea, epigastric discomfort) may occur with all erythromycin forms and are the most common adverse effects.

b. Allergic reactions (rare) may present as skin eruptions, fever, and eosinophilia.

c. Cholestatic hepatitis may arise in patients treated for 1 week or longer with erythromycin estolate; symptoms usually disappear within a few days after drug therapy ends. There have been infrequent reports of hepatotoxicity with other salts of erythromycin.

d. IM injections of more than 100 mg produce severe pain persisting for hours.

e. Transient hearing impairment may develop with high-dose erythromycin therapy.

5. Significant interactions

a. Erythromycin inhibits the hepatic metabolism of **theophylline,** resulting in toxic accumulation.

b. Erythromycin interferes with the metabolism of **digoxin, corticosteroids, carbamazepine, cyclosporin,** and **lovastatin,** possibly potentiating the effect and toxicity of these drugs.

c. Clarithromycin (Biaxin) may potentiate **oral anticoagulants** (monitor prothrombin time), increase **cyclosporine** levels with increased toxicity, and increase **digoxin** and **theophylline** levels.

d. Co-administration of clarithromycin and **cisapride** may increase risk of serious cardiac arrhythmias; coadministration is contraindicated.

e. Sudden deaths have been reported when clarithromycin was added to ongoing **pimozide** therapy; co-administration is contraindicated.

6. Alternatives to erythromycin

a. Clarithromycin, azithromycin (Zithromax), and **dirithromycin (Dynabac)** are semisynthetic macrolide antibiotics. These expensive but well-tolerated alternatives to erythromycin are administered once daily.

(1) Clarithromycin

(a) Spectrum of activity. Clarithromycin is more active than erythromycin against staphylococci and streptococci. In addition to activity against other organisms covered by erythromycin, it is also active in vitro against MAI, *Toxoplasma gondii,* and *Cryptosporidium* spp.

(b) Therapeutic uses. This agent is indicated for the prevention of *Mycobacterium avium* complex (MAC) infection and is useful in otitis media, sinusitis, mycoplasmal pneumonia, and pharyngitis. Clarithromycin is also used with proton pump inhibitors (PPIs) for *Helicobacter pylori* eradication.

(2) Azithromycin

(a) Spectrum of activity. Azithromycin is less active than erythromycin against gram-positive cocci but more active against *H. influenzae* and other gram-negative organisms. Azithromycin concentrates within cells, and tissue levels are higher than serum levels.

(b) Therapeutic uses. This agent is useful in nongonococcal urethritis caused by chlamydia, lower respiratory tract infections, (MAC) infection and prophylaxis, pharyngitis, pelvic inflammatory disease, and legionnaires' disease. Azithromycin is also indicated for pediatric use.

(3) Dirithromycin is indicated for the treatment of acute exacerbations of chronic bronchitis, pharyngitis and tonsillitis caused by *Streptococcus pyogenes,* and uncomplicated skin and skin structure infections caused by *S. aureus.*

F. Penicillins

1. Natural penicillins. As with cephalosporins and all other penicillins, natural penicillins are β-lactam antibiotics. Among the most important antibiotics, natural penicillins are the preferred drugs in the treatment of many infectious diseases.

a. Available agents

(1) Penicillin G sodium and potassium salts can be administered orally, intravenously, or intramuscularly.

(2) Penicillin V (Pen-Vee K), a soluble drug form, is administered orally.

(3) Penicillin G procaine and **penicillin G benzathine** are repository drug forms. Administered intramuscularly, these insoluble salts allow slow drug absorption from the injection site and thus have a longer duration of action (12-24 hr).

b. Mechanism of action. Penicillins are **bactericidal;** they inhibit bacterial cell wall synthesis in a manner similar to that of the cephalosporins.

c. Spectrum of activity

(1) Natural penicillins are highly active against gram-positive cocci and against some gram-negative cocci.
(2) Penicillin G is 5-10 times more active than penicillin V against gram-negative organisms and some anaerobic organisms.
(3) Because natural penicillins are readily hydrolyzed by penicillinases (β-lactamases), they are ineffective against *S. aureus* and other organisms that resist penicillin.

d. Therapeutic uses

(1) Penicillin G is the preferred agent for all infections caused by penicillin-susceptible *S. pneumoniae* organisms, including
(a) Pneumonia
(b) Arthritis
(c) Meningitis
(d) Peritonitis
(e) Pericarditis
(f) Osteomyelitis
(g) Mastoiditis
(2) Penicillins G and V are highly effective against other streptococcal infections, such as pharyngitis, otitis media, sinusitis, and bacteremia.
(3) Penicillin G is the preferred agent in gonococcal infections, syphilis, anthrax, actinomycosis, gas gangrene, and *Listeria* infections.
(4) Administered when an oral penicillin is needed, penicillin V is most useful in skin, soft-tissue, and mild respiratory infections.
(5) Penicillin G procaine is effective against syphilis and uncomplicated gonorrhea.
(6) Used to treat syphilis infections outside the CNS, penicillin G benzathine also is effective against group Aβ-hemolytic streptococcal infections.
(7) Penicillins G and V may be used prophylactically to prevent streptococcal infection, rheumatic fever, and neonatal gonorrhea ophthalmia. Patients with valvular heart disease may receive these drugs preoperatively.
(8) There is emerging resistance to penicillin G by *S. pneumoniae* in some areas of the United States. The alternative therapy is vancomycin.

e. Precautions and monitoring effects

(1) Hypersensitivity reactions. These occur in up to 10% of patients receiving penicillin. Manifestations range from mild rash to anaphylaxis.
(a) The rash may be urticarial, vesicular, bullous, scarlatiniform, or maculopapular. Rarely, thrombopenic purpura develops.
(b) Anaphylaxis is a life-threatening reaction that most commonly occurs with parenteral administration. Signs and symptoms include severe hypotension, bronchoconstriction, nausea, vomiting, abdominal pain, and extreme weakness.
(c) Other manifestations of hypersensitivity reactions include fever, eosinophilia, angioedema, and serum sickness.

(d) Before penicillin therapy begins, the patient's history should be evaluated for reactions to penicillin. A positive history places the patient at heightened risk for a subsequent reaction. In most cases, such patients should receive a substitute antibiotic. (However, hypersensitivity reactions may occur even in patients with a negative history.)

(2) Other adverse effects of natural penicillins include GI distress (e.g., nausea, diarrhea), bone marrow suppression (e.g., impaired platelet aggregation, agranulocytosis), and superinfection. With high-dose therapy, seizures may occur, particularly in patients with renal impairment.

f. Significant interactions

(1) Probenecid increases blood levels of natural penicillins and may be given concurrently for this purpose.

(2) Antibiotic antagonism occurs when **erythromycins, tetracyclines,** or **chloramphenicol** is given within 1 hr of the administration of penicillin. The clinical significance of such antagonism is not clear.

(3) With penicillin G procaine and benzathine, precaution must be used in patients with a history of hypersensitivity reactions to penicillins because prolonged reactions may occur. Intravascular injection should be avoided. Procaine hypersensitivity is a contraindication to the use of procaine penicillin G.

(4) Parenteral products contain either potassium (1.7 mEq/million units) or sodium (2 mEq/million units).

2. Penicillinase-resistant penicillins. These penicillins are not hydrolyzed by staphylococcal penicillinases (β-lactamases). These agents include **methicillin, nafcillin,** and the **isoxazolyl penicillins—cloxacillin, dicloxacillin (Dynapen),** and **oxacillin.**

a. Mechanism of action (see II.E.1.b)

b. Spectrum of activity. Because these penicillins resist penicillinases, they are active against staphylococci that produce these enzymes.

c. Therapeutic uses

(1) Penicillinase-resistant penicillins are used solely in staphylococcal infections resulting from organisms that resist natural penicillins.

(2) These agents are less potent than natural penicillins against organisms susceptible to natural penicillins and thus make poor substitutes in the treatment of infections caused by these organisms.

(3) Nafcillin is excreted by the liver and thus may be useful in treating staphylococcal infections in patients with renal impairment.

(4) Oxacillin, cloxacillin, and **dicloxacillin** are most valuable in long-term therapy of serious staphylococcal infections (e.g., endocarditis, osteomyelitis) and in the treatment of minor staphylococcal infections of the skin and soft tissues.

d. Precautions and monitoring effects

(1) As with all penicillins, the penicillinase-resistant group can cause hypersensitivity reactions (see II.E.1.e.(1)).
(2) Methicillin may cause nephrotoxicity and interstitial nephritis.
(3) Oxacillin may be hepatotoxic.
(4) Complete cross-resistance exists among the penicillinase-resistant penicillins.
e. Significant interactions. Probenecid increases blood levels of these penicillins and may be given concurrently for that purpose.
3. Aminopenicillins. This penicillin group includes the semisynthetic agents **ampicillin** and **amoxicillin (Amoxil).** Because of their wider antibacterial spectrum, these drugs are also known as **broad-spectrum penicillins.**
a. Mechanism of action (see II.E.1.b)
b. Spectrum of activity. Aminopenicillins have a spectrum that is similar to but broader than that of the natural and penicillinase-resistant penicillins. Easily destroyed by staphylococcal penicillinases, aminopenicillins are ineffective against most staphylococcal organisms. Against most bacteria sensitive to penicillin G, aminopenicillins are slightly less effective than this agent.
c. Therapeutic uses. Aminopenicillins are used to treat gonococcal infections, upper respiratory infections, uncomplicated urinary tract infections, and otitis media caused by susceptible organisms.
(1) For infections resulting from penicillin-resistant organisms, **ampicillin** may be given in combination with sulbactam (**Unasyn**).
(2) Amoxicillin is less effective than ampicillin against shigellosis.
(3) Amoxicillin is more effective against *S. aureus, Klebsiella,* and *Bacteroides fragilis* infections when administered in combination with clavulanic acid—amoxicillin/potassium clavulanate (**Augmentin**) because clavulanic acid inactivates penicillinases.
d. Precautions and monitoring effects
(1) Hypersensitivity reactions may occur (see II.E.1.e.(1)).
(2) Diarrhea is most common with ampicillin.
(3) In addition to the urticarial hypersensitivity rash seen with all penicillins, ampicillin and amoxicillin frequently cause a generalized erythematous, maculopapular rash. (This occurs in 5%-10% of patients receiving ampicillin.)
e. Significant interactions (see II.E.2.e)

4. Extended-spectrum penicillins. These agents have the widest antibacterial spectrum of all penicillins. Also called **antipseudomonal penicillins,** this group includes the **carboxypenicillin** (e.g., **ticarcillin**) and the **ureidopenicillins** (e.g., **mezlocillin, piperacillin**).
a. Mechanism of action (see II.E.1.b)

b. Spectrum of activity. These drugs have a spectrum similar to that of the aminopenicillins but also are effective against *Klebsiella* and *Enterobacter* spp., some *B. fragilis* organisms, and indole-positive *Proteus* and *Pseudomonas* organisms.

(1) Ticarcillin is active against *P. aeruginosa.* Combined with clavulanic acid (**Timentin**), ticarcillin has enhanced activity against organisms that resist ticarcillin alone.

(2) Piperacillin is more active than ticarcillin against *Pseudomonas* organisms.

(3) Piperacillin and tazobactam (Zosyn). Tazobactam is a β-lactamase inhibitor that expands the spectrum of activity to include some organisms not sensitive to piperacillin alone (if resistance is the result of β-lactamase production), including strains of staphylococci, *Haemophilus, Bacteroides,* and *Enterobacteriaceae.* Generally, tazobactam does not enhance activity against *Pseudomonas.*

c. Therapeutic uses. Extended-spectrum penicillins are used mainly to treat serious infections caused by gram-negative organisms (e.g., sepsis; pneumonia; infections of the abdomen, bone, and soft tissues). Piperacillin/tazobactam is effective in the treatment of nosocomial pneumonia.

d. Precautions and monitoring effects

(1) Hypersensitivity reactions may occur (see II.E.1.e.(1)).

(2) Ticarcillin may cause hypokalemia.

(3) The high sodium content of ticarcillin may pose a danger to patients with heart failure (HF).

(4) All inhibit platelet aggregation, which may result in bleeding.

e. Significant interactions (see II.E.2.e)

G. Sulfonamides. Derivatives of sulfanilamide, these agents were the first drugs to prevent and cure human bacterial infection successfully. Although their current usefulness is limited by the introduction of more effective antibiotics and the emergence of resistant bacterial strains, sulfonamides remain the drugs of choice for certain infections. The major sulfonamides are **sulfadiazine, sulfamethoxazole, sulfisoxazole,** and **sulfamethizole.**

1. Mechanism of action. Sulfonamides are **bacteriostatic;** they suppress bacterial growth by triggering a mechanism that blocks folic acid synthesis, thereby forcing bacteria to synthesize their own folic acid.

2. Spectrum of activity. Sulfonamides are broad-spectrum agents with activity against many gram-positive organisms (e.g., *S. pyogenes, S. pneumoniae*) and certain gram-negative organisms (e.g., *H. influenzae, E. coli, P. mirabilis*). They also are effective against certain strains of *Chlamydia trachomatis, Nocardia, Actinomyces,* and *Bacillus anthracis.*

3. Therapeutic uses

a. Sulfonamides most often are used to treat urinary tract infections caused by *E. coli,* including acute and chronic cystitis, and chronic upper urinary tract infections.

b. These agents have value in the treatment of nocardiosis, trachoma and inclusion conjunctivitis, and dermatitis herpetiformis.
c. Sulfadiazine may be administered in combination with pyrimethamine to treat toxoplasmosis.
d. Sulfamethoxazole may be given in combination with trimethoprim (**Bactrim**) to treat such infections as *Pneumocystis carinii* pneumonia, *Shigella* enteritis, *Serratia* sepsis, urinary tract infections, respiratory infections, and gonococcal urethritis (see II.J.7.c). It is the drug of choice in the treatment of *Stenotrophomonas maltophilia.*
e. Sulfisoxazole is sometimes used in combination with erythromycin ethylsuccinate to treat acute otitis media caused by *H. influenzae* organisms. For the initial treatment of uncomplicated urinary tract infections, sulfisoxazole may be given in combination with phenazopyridine for relief of symptoms of pain, burning, or urgency.
f. Prophylactic sulfonamide therapy has been used successfully to prevent streptococcal infections and rheumatic fever recurrences.
4. Precautions and monitoring effects
a. Sulfonamides may cause blood dyscrasias (e.g., hemolytic anemia—particularly in patients with G6PD deficiency, aplastic anemia, thrombocytopenia, agranulocytosis, and eosinophilia).

b. Hypersensitivity reactions to sulfonamides probably result from sensitization and most commonly involve the skin and mucous membranes. Manifestations include various types of skin rash, exfoliative dermatitis, and photosensitivity. Drug fever and serum sickness also may develop.
c. Crystalluria and hematuria may occur, possibly leading to urinary tract obstruction. (Adequate fluid intake and urine alkalinization can prevent or minimize this risk.) Sulfonamides should be used cautiously in patients with renal impairment.
d. Life-threatening hepatitis caused by drug toxicity or sensitization is a rare adverse effect. Signs and symptoms include headache, nausea, vomiting, and jaundice.
e. AIDS patients have increased frequency of cutaneous hypersensitivity reactions to sulfamethoxazole.
5. Significant interactions. Sulfonamides may potentiate the effects of **phenytoin, oral anticoagulants,** and **sulfonylureas.**
H. Tetracyclines. These broad-spectrum agents are effective against certain bacterial strains that resist other antibiotics. Nonetheless, they are the preferred drugs in only a few situations. The major tetracyclines include **demeclocycline (Declomycin), doxycycline (Vibramycin), minocycline (Minocin),** and **chlortetracycline.**
1. Mechanism of action. Tetracyclines are **bacteriostatic;** they inhibit bacterial protein synthesis by binding to the 30S ribosomal subunit.

2. Spectrum of activity. Tetracyclines are active against gram-negative and gram-positive organisms, spirochetes, *Mycoplasma* and *Chlamydia* organisms, rickettsial species, and certain protozoa.

a. *Pseudomonas* and *Proteus* organisms are now resistant to tetracyclines. Many coliform bacteria, pneumococci, staphylococci, streptococci, and *Shigella* strains are increasingly resistant.

b. Cross-resistance within the tetracycline group is extensive.

3. Therapeutic uses

a. Tetracyclines are the agents of choice in rickettsial (Rocky Mountain spotted fever), chlamydial, and mycoplasmal infections; amebiasis; and bacillary infections (e.g., cholera, brucellosis, tularemia, some *Salmonella* and *Shigella* infections).

b. Tetracyclines are useful alternatives to penicillin in the treatment of anthrax, syphilis, gonorrhea, Lyme disease, nocardiosis, and *H. influenzae* respiratory infections.

c. Oral or topical tetracycline may be administered as a treatment for acne.

d. Doxycycline is highly effective in the prophylaxis of “traveler's diarrhea” (commonly caused by *E. coli*). Because the drug is excreted mainly in the feces, it is the safest tetracycline for the treatment of extrarenal infections in patients with renal impairment.

e. Demeclocycline is used commonly as an adjunctive agent to treat the **syndrome of inappropriate antidiuretic hormone (SIADH)** secretion.

4. Precautions and monitoring effects

a. GI distress (e.g., diarrhea, abdominal discomfort, nausea, anorexia) is a common adverse effect of tetracyclines. This problem can be minimized by administering the drug with food or temporarily decreasing the dosage.

b. Skin rash, urticaria, and generalized exfoliative dermatitis signify a hypersensitivity reaction. Rarely, angioedema and anaphylaxis occur.

c. Cross-sensitivity within the tetracycline group is common.

d. Phototoxic reactions (severe skin lesions) can develop with exposure to sunlight. This reaction is most common with demeclocycline and doxycycline.

e. Tetracyclines may cause hepatotoxicity, particularly in pregnant women. Manifestations include jaundice, acidosis, and fatty liver infiltration.

f. Renally impaired patients may experience a significant increase in BUN secondary to catabolic effects of tetracyclines.

g. Tetracyclines may induce permanent tooth discoloration, tooth enamel defects, and retarded bone growth in infants and children.

h. Use of outdated and degraded tetracyclines can lead to renal tubular dysfunction, possibly resulting in renal failure.

i. Minocycline can cause vestibular toxicity (e.g., ataxia, dizziness, nausea, vomiting).

j. IV tetracyclines are irritating and may cause phlebitis.

5. Significant interactions

a. Dairy products and other foods, **iron preparations,** and **antacids** and **laxatives** containing aluminum, calcium, or magnesium can cause reduced tetracycline absorption. Absorption of doxycycline is not inhibited by these factors.

b. Methoxyflurane may exacerbate the tetracyclines' nephrotoxic effects.

c. Barbiturates and **phenytoin** decrease the antibiotic effectiveness of tetracyclines.

d. Demeclocycline antagonizes the action of **antidiuretic hormone (ADH)** and may be given as a diuretic in patients with SIADH.

I. Fluoroquinolones are agents related to nalidixic acid—see II.I.1.c; II.2.c.(1); II.4.c.(1)—and include **ciprofloxacin (Cipro), enoxacin (Penetrex), lomefloxacin (Maxaquin), norfloxacin (Noroxin), ofloxacin (Floxin), moxifloxacin (Avelox), levofloxacin (Levaquin),** and **gemifloxacin (Factive).** They are bactericidal for growing bacteria.

1. Mechanism of action. Fluoroquinolones inhibit DNA gyrase.

2. Spectrum of activity. Fluoroquinolones are highly active against enteric gram-negative bacilli, *Salmonella, Shigella, Campylobacter, Haemophilus,* and *Neisseria.*

a. Ciprofloxacin has activity against *P. aeruginosa,* but the fluoroquinolones as a group have variable activity against non-*P. aeruginosa.* Ciprofloxacin is active against some anaerobes; it has moderate activity against *M. tuberculosis.*

b. Gram-positive organisms are less susceptible than gram-negative organisms but usually are sensitive, except for *Enterococcus faecalis* and methicillin-resistant staphylococci.

c. Ofloxacin has the greatest activity against *Chlamydia.*

3. Therapeutic uses (Table 44-3)

a. Norfloxacin is indicated for the oral treatment of urinary tract infections, uncomplicated gonococcal infections, and prostatitis.

b. Ciprofloxacin, ofloxacin, and levofloxacin are available orally and intravenously. Ciprofloxacin is approved for use in urinary tract infections; lower respiratory infections; sinusitis; bone, joint, and skin structure infections; empiric use in febrile neutropenic patients; typhoid fever; urethral and cervical gonococcal infections; and infectious diarrhea. Ofloxacin is approved for use in lower respiratory infections, uncomplicated gonococcal and chlamydial cervicitis and urethritis, skin and skin structure infections, prostatitis, and urinary tract infections.

c. Lomefloxacin, levofloxacin, and enoxacin are approved for the treatment of urinary tract infections. Lomefloxacin, moxifloxacin, and levofloxacin are also used in lower respiratory infections.

d. Moxifloxacin is approved for the treatment of complicated intra-abdominal infections but should not be used for urinary tract infections.

4. Precautions and monitoring effects

a. Occasional adverse effects include nausea, dyspepsia, headache, dizziness, insomnia, cardiac QT prolongation, arthropathy, tendonitis, CNS effects, photosensitivity, and hypoglycemia.

Table 44-3. Quinolone Agents Classified by Generation

	Agent	Spectrum of Coverage	Site of Infection
First-generation	Cinoxacin (Cinoxacin, Cinobac)	Gram negatives	Urinary tract
	Enoxacin (Penetrex)		
	Nalidixic acid (NegGram)		
	Norfloxacin (Noroxin)		
Second-generation	Lomefloxacin (Maxaquin)	Gram negatives	Urinary tract
	Ciprofloxacin (Cipro)		Systemic, urinary tract
	Ofloxacin (Floxin)		Systemic, urinary tract
Third-generation	Levofloxacin (Levaquin)	Gram negatives	Systemic, urinary tract
	Moxifloxacin (Avelox)	Atypicals	Systemic only

b. Infrequent adverse effects include rash, urticaria, leukopenia, and elevated liver enzymes. Crystalluria occurs with high doses at alkaline pH.

c. The FDA has added a black box warning about the increased risk of developing tendinitis and tendon rupture in patients taking this class of medications.

5. Significant interactions

a. Ciprofloxacin has been shown to increase **theophylline** levels. Variable effects on theophylline levels have been reported from other members of the group. In patients requiring fluoroquinolones, theophylline levels should be monitored.

b. Antacids and **sucralfate** and divalent or trivalent cations such as iron significantly decrease the absorption of fluoroquinolones.

c. Fluoroquinolones may increase prothrombin times in patients receiving **warfarin.**

d. Concurrent use with **nonsteroidal anti-inflammatory drugs** (NSAIDs) may increase the risk of CNS stimulation (seizures).

e. Fluoroquinolones may produce prolonged QT interval when administered with **cisapride** and **antiarrhythmic agents.** Some fluoroquinolones (i.e., gatifloxacin, moxifloxacin) should be avoided in patients with known prolongation of the QTC interval, with uncorrected hypocalcemia, or who are receiving class IA or class III antiarrhythmic drugs.

f. Some fluoroquinolones have been reported to enhance the effects of oral anticoagulants.

g. Hyperglycemia and hypoglycemia have been reported in patients receiving quinolones and an antidiabetic agent. Blood glucose monitoring is recommended in such patients.

h. Didanosine should be administered at least 4 hr after gatifloxacin.

J. Urinary tract antiseptics. Concentrating in the renal tubules and bladder, these agents exert local antibacterial effects; most do not achieve blood levels high enough to treat systemic infections. However, some new quinolone derivatives, such as ciprofloxacin and ofloxacin, are valuable in the treatment of certain infections outside the urinary tract (see II.H.3.b).

1. Mechanism of action

a. Methenamine is hydrolyzed to ammonia and formaldehyde in acidic urine; formaldehyde is antibacterial against gram-positive and gram-negative organisms. Mandelic and hippuric acids, with which methenamine is combined, provide supplementary antibacterial action.

b. Nitrofurantoin is **bacteriostatic;** in high concentrations, it may be **bactericidal.** Presumably, it disrupts bacterial enzyme systems.

c. Quinolones. Nalidixic acid and its analogs and derivatives—**oxolinic acid, norfloxacin, cinoxacin, ciprofloxacin,** and others—interfere with DNA gyrase and inhibit DNA synthesis during bacterial replication.

d. Fosfomycin tromethamine is bactericidal in the urine at therapeutic doses. The bactericidal action is because of its inactivation of the enzyme enolpyruvyl transferase, thereby blocking the condensation of uridine diphosphate-*N*-acetylglucosamine with p-enolpyruvate, one of the first steps in bacterial cell wall synthesis.

2. Spectrum of activity

a. Methenamine is active against both gram-positive and gram-negative organisms (e.g., *Enterobacter, Klebsiella, Proteus, P. aeruginosa, S. aureus*).

b. Nitrofurantoin is active against many gram-positive and gram-negative organisms, including some strains of *E. coli, S. aureus, Proteus, Enterobacter,* and *Klebsiella.*

c. Quinolones (see II.H)

(1) Nalidixic acid and **oxolinic acid** are active against most gram-negative organisms that cause urinary tract infections, including *P. mirabilis, E. coli, Klebsiella,* and *Enterobacter* organisms. These drugs are not effective against *Pseudomonas* organisms.

(2) Norfloxacin is active against *E. coli, Enterobacter, Klebsiella, Proteus, P. aeruginosa, S. aureus, Citrobacter,* and some *Streptococcus* organisms.

(3) Cinoxacin is active against *E. coli, Klebsiella, P. mirabilis, Proteus vulgaris, Proteus morganii, Serratia,* and *Citrobacter* organisms.

3. Therapeutic uses

a. Methenamine and **nitrofurantoin** are used to prevent and treat urinary tract infections.

b. Quinolones are administered to treat urinary tract infections; some also are used in such diseases as osteomyelitis and respiratory tract infections.

c. Fosfomycin is indicated for treatment of uncomplicated urinary tract infection (acute cystitis) in women caused by susceptible strains of *E. coli* or *E. faecalis.*

4. Precautions and monitoring effects

a. Methenamine may cause nausea, vomiting, and diarrhea; in high doses, it may lead to urinary tract irritation (e.g., dysuria, frequency, hematuria, albuminuria). Skin rash also may develop.

b. Nitrofurantoin may cause various adverse effects.

(1) GI distress (e.g., nausea, vomiting, diarrhea) is relatively common.

(2) Hypersensitivity reactions to nitrofurantoin may involve the skin, lungs, blood, or liver; manifestations include fever, chills, hepatitis, jaundice, leukopenia, hemolytic anemia, granulocytopenia, and pneumonitis.

(3) Adverse CNS effects include headache, vertigo, and dizziness. Polyneuropathy may develop with high doses or in patients with renal impairment.

c. Quinolones

(1) Nalidixic acid and **oxolinic acid** may cause nausea, vomiting, abdominal pain, urticaria, pruritus, skin rash, fever, eosinophilia, and CNS effects, such as headache, dizziness, confusion, vertigo, drowsiness, and weakness.

(2) Cinoxacin may induce nausea, vomiting, diarrhea, headache, insomnia, skin rash, pruritus, and urticaria.

5. Significant interactions

a. The effects of methenamine are inhibited by **alkalinizing agents** and are antagonized by **acetazolamide.**

b. Nitrofurantoin absorption is decreased by **magnesium-containing antacids.** Nitrofurantoin blood levels are increased and urine levels decreased by **sulfinpyrazone** and **probenecid,** leading to increased toxicity and reduced therapeutic effectiveness.

c. Quinolones

(1) Cinoxacin urine levels are decreased by **probenecid,** reducing therapeutic effectiveness.

(2) Norfloxacin is rendered less effective by **antacids.**

K. Miscellaneous antibacterial agents

1. Aztreonam (Azactam). This agent was the first commercially available monobactam (monocyclic β-lactam compound). It resembles the aminoglycosides in its efficacy against many gram-negative organisms but does not cause nephrotoxicity or ototoxicity. Other advantages of this drug include its ability to preserve the body's normal gram-positive and anaerobic flora, activity against many gentamicin-resistant organisms, and lack of cross-allergenicity with penicillin.

a. Mechanism of action. Aztreonam is **bactericidal;** it inhibits bacterial cell wall synthesis.

b. Spectrum of activity. This drug is active against many gram-negative organisms, including *Enterobacter* and *P. aeruginosa*.

c. Therapeutic uses. Aztreonam is therapeutic for urinary tract infections, septicemia, skin infections, lower respiratory tract infections, and intra-abdominal infections resulting from gram-negative organisms. Increased incidence of *P. aeruginosa* resistant to aztreonam have been reported.

d. Precautions and monitoring effects

(1) Aztreonam sometimes causes nausea, vomiting, and diarrhea.

(2) Liver enzymes may increase transiently during aztreonam therapy.

(3) This drug may induce skin rash.

2. Chloramphenicol. A nitrobenzene derivative, this drug has broad activity against rickettsia as well as many gram-positive and gram-negative organisms. It also is effective against many ampicillin-resistant strains of *H. influenzae*.

a. Mechanism of action. Chloramphenicol is primarily **bacteriostatic,** although it may be bactericidal against a few bacterial strains.

b. Spectrum of activity. This agent is active against rickettsia and a wide range of bacteria, including *H. influenzae, Salmonella typhi, Neisseria meningitidis, Bordetella pertussis, Clostridium, B. fragilis, S. pyogenes,* and *S. pneumoniae*.

c. Therapeutic uses. Because of its toxic side effects, chloramphenicol is used only to suppress infections that cannot be treated effectively with other antibiotics. Such infections typically include

(1) Typhoid fever

(2) Meningococcal infections in cephalosporin-allergic patients

(3) Serious *H. influenzae* infections, particularly in cephalosporin-allergic patients

(4) Anaerobic infections (e.g., those originating in the pelvis or intestines)

(5) Anaerobic or mixed infections of the CNS

(6) Rickettsial infections in pregnant patients, tetracycline-allergic patients, and renally impaired patients

d. Precautions and monitoring effects

(1) Chloramphenicol can cause bone marrow suppression (dose-related) with resulting pancytopenia; rarely, the drug leads to aplastic anemia (not related to dose).

(2) Hypersensitivity reactions may include skin rash and, in extremely rare cases, angioedema or anaphylaxis.

(3) Chloramphenicol therapy may lead to gray baby syndrome in neonates (especially premature infants). This dangerous reaction, which stems partly from inadequate liver detoxification of the drug, is manifested by vomiting, gray cyanosis, rapid and irregular respirations, vasomotor collapse, and in some cases death.

e. Significant interactions

(1) Chloramphenicol inhibits the metabolism of **phenytoin, tolbutamide, chlorpropamide,** and **dicumarol,** leading to prolonged action and intensified effect of these drugs.

(2) Phenobarbital shortens chloramphenicol's half-life, thereby reducing its therapeutic effectiveness.

(3) Penicillins can cause antibiotic antagonism.

(4) Acetaminophen elevates chloramphenicol levels and may cause toxicity.

3. Clindamycin (Cleocin). This agent has essentially replaced lincomycin, the drug from which it is derived. It is used to treat skin, respiratory tract, and soft-tissue infections caused by staphylococci, pneumococci, and streptococci.

a. Mechanism of action. Clindamycin is **bacteriostatic;** it binds to the 50S ribosomal subunit, thereby suppressing bacterial protein synthesis.

b. Spectrum of activity. This agent is active against most gram-positive and many anaerobic organisms, including *B. fragilis.*

c. Therapeutic uses. Because of its marked toxicity, clindamycin is used only against infections for which it has proven to be the most effective drug. Typically, such infections include abdominal and female genitourinary tract infections caused by *B. fragilis.*

d. Precautions and monitoring effects

(1) Clindamycin may cause rash, nausea, vomiting, diarrhea, and pseudomembranous colitis as evidenced by fever, abdominal pain, and bloody stools.

(2) Blood dyscrasias (e.g., eosinophilia, thrombocytopenia, leukopenia) may occur.

e. Significant interactions. Clindamycin may potentiate the effects of **neuromuscular blocking agents.**

4. Dapsone. A member of the sulfone class, this drug is the primary agent in the treatment of all forms of leprosy.

a. Mechanism of action. Dapsone is **bacteriostatic** for *Mycobacterium leprae;* its mechanism of action probably resembles that of the sulfonamides.

b. Spectrum of activity. This drug is active against *M. leprae;* however, drug resistance develops in up to 40% of patients. Dapsone also has some activity against *P. carinii* organisms and the malarial parasite *Plasmodium.*

c. Therapeutic uses

(1) Dapsone is the drug of choice for treating leprosy.

(2) This agent may be used to treat dermatitis herpetiformis, a skin disorder.

(3) Maloprim, a dapsone-pyrimethamine product, is valuable in the prophylaxis and treatment of malaria.

(4) Dapsone, with or without trimethoprim, is used for prophylaxis of *P. carinii* pneumonia in patients with AIDS.

d. Precautions and monitoring effects

(1) Hemolytic anemia can occur with daily doses > 200 mg. Other adverse hematological effects include methemoglobinemia and leukopenia.

(2) Nausea, vomiting, and anorexia may develop.

(3) Adverse CNS effects include headache, dizziness, nervousness, lethargy, paresthesias, and psychosis.

(4) Dapsone occasionally results in a potentially lethal mononucleosis-like syndrome.

(5) Paradoxically, this drug sometimes exacerbates leprosy.

(6) Other adverse effects include skin rash, peripheral neuropathy, blurred vision, tinnitus, hepatitis, and cholestatic jaundice.

e. Significant interactions. Probenecid elevates blood levels of dapsone, possibly resulting in toxicity.

5. Clofazimine is phenazine dye with antimycobacterial and anti-inflammatory activity.

a. Mechanism of action. Clofazimine appears to bind preferentially to mycobacterial DNA, inhibiting replication and growth. It is **bactericidal** against *M. leprae,* and it appears to be **bacteriostatic** against MAI.

b. Spectrum of activity. Clofazimine is active against various mycobacteria, including *M. leprae, M. tuberculosis,* and MAI.

c. Therapeutic uses. Clofazimine is used to treat leprosy and a variety of atypical *Mycobacterium* infections.

d. Precautions and monitoring effects

(1) Pigmentation (pink to brownish) occurs in 75%-100% of patients within a few weeks. This skin discoloration has led to severe depression (and suicide).

(2) Urine, sweat, and other body fluids may be discolored.

(3) Other effects include ichthyosis and dryness of skin (8%-28%), rash and pruritus (1%-5%), and GI intolerance (e.g., abdominal/epigastric pain, diarrhea, nausea, vomiting) in 40%-50% of patients. Clofazimine should be taken with food.

6. Daptomycin (Cubicin) is a unique lipopeptide antibiotic with clinical activity in the treatment of resistant gram-positive infections.

a. Mechanism of action. Daptomycin is bactericidal; unlike other antibiotics, it binds to the bacterial cell membrane, causing depolarization of the membrane potential leading to inhibition of RNA, DNA, and protein synthesis.

b. Spectrum of activity. This drug is active against vancomycin-susceptible *E. faecium* and *S. aureus* (including methicillin-resistant strains) as well as other aerobic gram-positive bacteria.

c. Therapeutic uses. Daptomycin is indicated for the treatment of complicated skin and skin structure infections and S. aureus bacteremia. It is *not* indicated for the treatment of pneumonia.

d. Precautions and monitoring effects

(1) Reported side effects are generally mild and self-limiting and include constipation, abnormal liver function tests, and renal failure.

(2) Cases of myalgia and/or muscle weakness, exacerbations of myasthenia gravis, and increases in creatine phosphokinase (CPK) have been reported.

7. Linezolid (Zyvox) is a synthetic oxazolidinone that has clinical use in the treatment of infections caused by aerobic gram-positive bacteria.

a. Mechanism of action. Linezolid is bacteriostatic against *Enterococci* and *Staphylococci,* and bactericidal against *Streptococci.* Linezolid binds to the 23S ribosomal RNA of the 50S subunit and thus inhibits protein synthesis.

b. Spectrum of activity. The drug is active against vancomycin-resistant *Enterococcus faecium* and *S. aureus* (methicillin-susceptible and -resistant strains) as well as other aerobic gram-positive bacteria.

c. Therapeutic uses. Linezolid is indicated for treatment of infections caused by vanco-mycin-resistant *E. faecium,* nosocomial pneumonia caused by methicillin-susceptible and -resistant strains of *S. aureus,* community-acquired pneumonia caused by penicillin-susceptible strains of *S. pneumoniae,* and skin and skin structure infections owing to these organisms.

d. Precautions and monitoring effects

(1) Safety data are limited. Adverse effects generally are minor (e.g., gastrointestinal complaints, headache, rash).
(2) Thrombocytopenia or a significant reduction in platelet count has been reported (2.4%) and is related to duration of therapy. Monitor platelets in patients with risk of bleeding, preexisting thrombocytopenia, platelet disorders (including those

caused by concurrent medications) and in patients receiving linezolid lasting longer than 2 weeks.
(3) Myelosuppression owing to direct bone marrow suppression has been reported rarely.
e. Significant interactions. Patients receiving concomitant therapy with adrenergic or serotonergic agents or consuming more than 100 mg of tyramine a day may experience an enhancement of the drug's effect or serotonin syndrome.
8. Quinupristin/dalfopristin (Synercid) is an intravenous streptogramin antibiotic composed of two chemically distinct compounds.
a. Mechanism of action. Quinupristin binds to the 50S subunit, and dalfopristin binds tightly to the 70S ribosomal particle.
b. Spectrum of activity. Synercid has activity against *Staphylococci* spp., including resistant strains. This combination has better activity against *E. faecium* than *Enterococcus faecalis* and is also active against some gram-negative organisms and anaerobes; activity has not been shown against *Enterobacteriaceae.*
c. Therapeutic uses. It is used for treatment of vancomycin-resistant *E. faecium* (VREF) bacteremia and skin and skin structure infections caused by *S. aureus* and *S. pyogenes.*
d. Precautions and monitoring effects
(1) Reported side effects are generally mild and infusion related: pain, erythema, or itching at the infusion site; increases in pulse and diastolic pressure; headache; nausea or vomiting; and diarrhea. It may increase liver function tests slightly.
(2) Drug interactions are a result of cytochrome P450 3A4 inhibition. Potential drug interactions include **cyclosporin, nifedipine,** and **midazolam.**
(3) Concomitant use of medications that may prolong QTc interval should be avoided.
(4) Mild to life-threatening pseudomembranous colitis has been reported.
9. Rifaximin. Is a semi-synthetic antibiotic that is structurally related to rifamycin.
a. Mechanism of action. It inhibits bacterial RNA synthesis by binding to the beta-subunit of bacterial DNA-dependent RNA polymerase.

b. Spectrum of activity. This non-systemically absorbed drug has activity against both enterotoxigenic and enteroaggregative strains of *Escherichia coli.*

c. Therapeutic uses. Rifaximin is used in the treatment of Traveler's diarrhea with noninvasive strains of *E. coli.* High resistance rates have been reported after 5 days of treatment.

d. Precautions and monitoring effects. Because of its limited systemic absorption, adverse effects are few but include constipation, vomiting, flatulence and headache.

10. Spectinomycin. An aminocyclitol agent related to the aminoglycosides, this antibiotic is useful against penicillin-resistant strains of gonorrhea.

a. Mechanism of action. Spectinomycin is **bacteriostatic;** it selectively inhibits protein synthesis by binding to the 30S ribosomal subunit.

b. Spectrum of activity. This agent is active against various gram-negative organisms.

c. Therapeutic uses. Spectinomycin is used only to treat gonococcal infections in patients with penicillin allergy or when such infection stems from penicillinase-producing gonococci (PPNG).

d. Precautions and monitoring effects. Because spectinomycin is given only as a single-dose IM injection, it causes few adverse effects. Nausea, vomiting, urticaria, chills, dizziness, and insomnia occur rarely.

11. Telithromycin (Ketek) is the first of a new class of antimicrobials called the ketolides. It is an oral semisynthetic derivative of erythromycin.

a. Mechanism of action. Telithromycin may be bactericidal or bacteriostatic; it inhibits bacterial protein synthesis.

b. Spectrum of activity. This drug is active against many aerobic and anaerobic gram-positive organisms, including multidrug- resistant *S. pneumoniae,* some gram-negative organisms as well as atypical pathogens.

c. Therapeutic uses. Telithromycin is indicated for the treatment of mild to moderate community-acquired pneumonia only. The FDA removed the previous 2 approved indications and added a black box warning.

d. Precautions and monitoring effects

(1) GI effects (including diarrhea, nausea, and vomiting) were the most common side effects followed by dizziness and visual disturbances (such as diplopia and blurred and abnormal vision); serious liver toxicity has been reported.

(2) Cross-sensitivity with the other macrolides occurs.

(3) Concomitant use of drugs or conditions that may prolong the QTc interval should be avoided.

(4) Contraindicated in patients with myasthenia gravis, hepatitis, or jaundice.

e. Significant interactions

(1) Co-administration of telithromycin with either cisapride or pimozide is contraindicated.
(2) Concomitant administration of drugs metabolized by cytochrome P450 3A4 in patients with telithromycin should be closely monitored.
(3) Patients on bepridil, mesoridazine, terfenadine, thioridazine, or ziprasidone should not be prescribed telithromycin owing to the high potential for toxicity.
(4) This agent has a high potential to interact with many drugs. Check product information for the most current interaction information.
12. Tigecycline (Tygacil). An intravenous glycylcycline antibiotic developed as a semisynthetic analogue of tetracycline with a broad spectrum of activity.
a. Mechanism of action. Tigecycline is bacteriostatic; it inhibits bacterial protein synthesis by reversibly binding to the 30S ribosome subunit.
b. Spectrum of activity. The drug is active against vancomycin-susceptible *E. faecalis,* methicillin-resistant *S. epidermidis,* and *S. aureus* (methicillin-susceptible and -resistant strains) as well as some gram-negative aerobes and anaerobes.
c. Therapeutic uses. Tigecycline is indicated for the treatment of complicated intra-abdominal infections caused by *E. coli,* vancomycin-susceptible *E. faecalis, S. aureus* (methicillin-susceptible strains only) and *B. fragilis.* Also indicated for the treatment of complicated skin and skin structure infections caused by *E. faecalis* (vancomycin-susceptible strains), *S. pyogenes* and *S. aureus* (methicillin-susceptible and -resistant strains).
d. Precautions and monitoring effects.
(1) Safety data are limited. Side effects are generally mild with GI disturbances—for example, nausea (22%-35%) and vomiting (13%-19%)—the most commonly reported. The mechanism of these reactions is uncertain.
(2) May cause permanent discoloration of the teeth similar to the tetracyclines.
(3) Caution in patients with a history of hypersensitivity reactions to tetracyclines.
(4) Phototoxic reactions, pancreatitis, and increases in BUN may occur.
e. Significant interactions. Closely monitor the prothrombin time or international sensitivity index (INR) in patients on warfarin during concomitant administration of tigecycline.
13. Trimethoprim. A substituted pyrimidine, trimethoprim is most commonly combined with sulfamethoxazole (a sulfonamide discussed in II.F) in a preparation called cotrimoxazole. However, it may be used alone for certain urinary tract infections.
a. Mechanism of action. Trimethoprim inhibits dihydrofolate reductase, thus blocking bacterial synthesis of folic acid.
b. Spectrum of activity

(1) Trimethoprim is active against most gram-negative and gram-positive organisms. However, drug resistance may develop when this drug is used alone.
(2) Trimethoprim-sulfamethoxazole is active against a variety of organisms, including *S. pneumoniae, N. meningitidis,* and *Corynebacterium diphtheriae;* some strains of *S. aureus, Staphylococcus epidermidis, P. mirabilis, Enterobacter, Salmonella, Shigella, Serratia,* and *Klebsiella* spp.; and *E. coli.*
(3) The trimethoprim-sulfamethoxazole combination is synergistic; many organisms resistant to one component are susceptible to the combination.
c. Therapeutic uses
(1) Trimethoprim may be used alone or in combination with sulfamethoxazole to treat uncomplicated urinary tract infections caused by *E. coli, P. mirabilis,* and *Klebsiella* and *Enterobacter* organisms.
(2) Trimethoprim-sulfamethoxazole is therapeutic for acute gonococcal urethritis, acute exacerbation of chronic bronchitis, shigellosis, and *Salmonella* infections.

(3) Trimethoprim-sulfamethoxazole may be given as prophylactic or suppressive therapy in *P. carinii* pneumonia. It is the drug of choice for the treatment of *Stenotrophomonas maltophilia* infections.
d. Precautions and monitoring effects
(1) Most adverse effects involve the skin (possibly from sensitization). These include rash, pruritus, and exfoliative dermatitis.
(2) Rarely, trimethoprim-sulfamethoxazole causes blood dyscrasias (e.g., acute hemolytic anemia, leukopenia, thrombocytopenia, methemoglobinemia, agranulocytosis, aplastic anemia).
(3) Adverse GI effects including nausea, vomiting, and epigastric distress glossitis may occur.
(4) Neonates may develop kernicterus.
(5) Patients with AIDS sometimes suffer fever, rash, malaise, and pancytopenia during trimethoprim therapy.
14. Vancomycin. This glycopeptide destroys most gram-positive organisms.
a. Mechanism of action. Vancomycin is **bactericidal;** it inhibits bacterial cell wall synthesis.
b. Spectrum of activity. This drug is active against most gram-positive organisms, including methicillin-resistant strains of *S. aureus and Enterococci.*
c. Therapeutic uses. Vancomycin usually is reserved for serious infections, especially those caused by methicillin-resistant staphylococci. It is particularly useful in patients who are allergic to penicillin or cephalosporins. Typical uses include endocarditis, osteomyelitis, and staphylococcal pneumonia.

(1) Oral vancomycin is valuable in the treatment of antibiotic-induced pseudomembranous colitis caused by *C. difficile* or *S. aureus* enterocolitis. Because vancomycin is not absorbed after oral administration, it is not useful for systemic infections. Because of resistance, the Centers for Disease Control and Prevention (CDC) recommend vancomycin as the second choice to metronidazole for *C. difficile* infections.
(2) Because 1 g provides adequate blood levels for 7-10 days, IV vancomycin is particularly useful in the treatment of anephric patients with gram-positive bacterial infections.

d. Precautions and monitoring effects

(1) Ototoxicity may arise; nephrotoxicity is rare but can occur with high doses.
(2) Vancomycin may cause hypersensitivity reactions, manifested by such symptoms as anaphylaxis and skin rash.
(3) Therapeutic levels peak at 20-40 µg/mL. The trough is < 15 µg/mL.
(4) Red man's syndrome may occur. This is facial flushing and hypotension owing to too rapid infusion of the drug. Infusion should be over a minimum of 60 min for a 1-g dose.
(5) IV solutions are very irritating to the vein.

e. Vancomycin-resistant enterococci. A few strains of vancomycin-resistant enterococci are susceptible to teicoplanin (investigational by Hoechst Marion Roussel), linezolid (Zyvox), or quinupristin/dalfopristin (Synercid). These agents may be useful for multiple-drug-resistant *E. faecium.*

III. Systemic Antifungal Agents

A. Definition. These agents treat systemic and local fungal (mycotic) infections—diseases that resist treatment with antibacterial drugs.

B. Amphotericin B (Fungizone). This polyene antifungal antibiotic is therapeutic for various fungal infections that frequently proved fatal before the drug became available. It is used increasingly in the empiric treatment of severely immunocompromised patients in certain clinical situations.

1. Mechanism of action. Amphotericin B is both **fungistatic** in clinically obtained concentrations and may be fungicidal in the presence of susceptible organisms. It binds to sterols in the fungal cell membrane, thereby increasing membrane permeability and permitting leakage of intracellular contents. Other mechanisms may be involved as well.

2. Spectrum of activity. Amphotericin B is a broad-spectrum antifungal agent with activity against *Aspergillus, Blastomyces, Candida* spp. *(albicans, krusei tropicalis,* and *glabrata), Cryptococcus, Coccidioides, Histoplasma, Paracoccidioides, Phycomycetes* (*mucor*), and *Sporothrix.* It is

also useful against some protozoa such as *Leishmania, Naegleria,* and *Acanthamoeba.*

3. Therapeutic uses. Amphotericin B is the most effective antifungal agent in the treatment of systemic fungal infections, especially in immunocompromised patients.

a. It is the treatment of choice for pulmonary *Aspergillus* infections; *Blastomyces* infections, which are life-threatening with AIDS or CNS involvement; deep-organ infections with *Candida; Coccidioides* infections with severe pulmonary involvement or with disseminated nonmeningeal immunocompetent or immunocompromised patients; all *Cryptococcus* infections; disseminated *Histoplasma* infections involving CNS or immunosuppressed patients; *Malassezia furfur* fungemia; pulmonary and extrapulmonary *Phycomycetes* (mucormycosis); *Penicillium marneffei;* and extracutaneous *Sporothrix.*

b. This agent may be used to treat coccidioidal arthritis.

c. Topical preparations are given to eradicate cutaneous and mucocutaneous candidiasis.

d. It may be used as empiric therapy in febrile, neutropenic patients.

e. It is used as secondary prophylaxis of fungal infections in HIV-positive patients, guarding against recurrence of infection.

f. It may be used prophylactically in neutropenic cancer patients and bone marrow transplant or solid-organ transplant patients to reduce the incidence of *Aspergillus* and *Candida* infections.

4. Precautions and monitoring effects. Because amphotericin B can cause many serious adverse effects, it should be administered in a hospital setting—at least during the initial therapeutic stage. The adverse effects are divided into infusion reactions and others.

a. Infusion reactions occur while the drug is being administered and include fever, shaking chills, hypotension, anorexia, nausea, vomiting, headache, dyspnea, and tachypnea. Premedication with acetaminophen and diphenhydramine has been helpful in prophylaxing against infusion reactions. In addition, hydrocortisone 10-50 mg may be added to the infusion as prophylaxis against infusion-related reactions. Meperidine 25-50 mg IV is effective treatment of active shaking chills/rigors. Meperidine is also effective in prophylaxis of rigors.

b. Nephrotoxicity frequently occurs. Dosage adjustment or drug discontinuation or changing to a liposomal amphotericin B product may be necessary as renal impairment progresses.

c. Electrolyte abnormalities, including hypokalemia, hypomagnesemia, and hypocalcemia, are common. Monitor and replace electrolytes as needed.

d. Normocytic, normochromic anemia will develop over long-term use (10 weeks). Monitor hematocrit periodically.

e. Bronchospasm, wheezing, and anaphylaxis or anaphylactoid reactions have occurred. A test dose of 1 mg of amphotericin B is often administered before infusion of large quantities of the drug.

f. Phlebitis or thrombophlebitis is reported with conventional amphotericin B. Heparin (500-1000 U) can be added to the infusion to aid in prevention.
g. CNS effects include headache, peripheral neuropathy, malaise, depression, seizure, myasthenia, and hallucinations.
h. Elevated liver transaminases, aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, bilirubin, γ-glutamyltransferase (GGT), and lactate dehydrogenase (LDH) may occur.
i. Amphotericin B parenteral use should be mixed only in dextrose 5% in water (D5W) and should be protected from light.
5. Significant interactions. Other nephrotoxic drugs (aminoglycosides, capreomycin, colistin, cisplatin, cyclosporine, methoxyflurane, pentamidine, polymyxin B, and vancomycin) may cause additive nephrotoxicity.
6. Amphotericin B lipid complex (Abelcet), amphotericin B cholesterol sulfate complex (Amphotec), and liposomal amphotericin B (AmBisome) offer alternative formulations of amphotericin B for the treatment of severe fungal infections in patients who are intolerant of or whose disease is refractory to conventional treatment.

C. Echinocandins. Three echinocandins are approved in the US: capsofungin (Cancidas), micafungin (Mycamine) and anidulafungin (Eraxis). These agents have a broad spectrum of activity against *Candida* species with micafungin and anidulafungin having similar MICs that are generally lower than the MIC of capsofungin.
1. Mechanism of action. Caspofungin works by causing fungal cell wall lysis. By being a noncompetitive inhibitor of β (1,3) synthase, which is an essential component of fungal cell wall synthesis, it causes osmotic instability within the fungus and fungal cell wall lysis.
2. Spectrum of activity. Echinocandins have fungicidal activity against Candida species and fungistatic activity against *Aspergillus* species. All three agents in this class appear to have good activity in vitro for most isolates of Candida species, including those that are either Amphotericin-B or fluconazole and itraconazole-resistant, such as *C. glabrata.*
3. Therapeutic uses. All three agents are indicated for the treatment of esophageal candidiasis
a. Caspofunfin and anidulafungin are also indicated for the treatment of candidemia and other infections caused by *Candida* species, including intrabdominal abscesses and peritonitis.
b. Caspofungin may also be used for the treatment of candidal pleural space infections, empiric treatment of presumed fungal infections in neutropenic patients, and treatment of invasive aspergillosis in patients refractory to or intolerant of other antifungals (i.e., amphotericin B, itraconazole).

c. Micafungin is indicated for the prophylaxis of candidal infections in patients indergoing hematopoietic stem cell transplantation (HSCT).

4. Precautions and monitoring effects. Although this class has adverse events associated with its use, the overall toxicity profile is significantly better than that of amphotericin B.

a. Infusion vein complications (not defined by manufacturer) and thrombophlebitis have been seen on infusion of caspofungin.

b. Hematological decreases in hemoglobin and hematocrit may occur; however, the incidence does not differ from that of having a fungal disease.

c. Headache may occur.

d. Slight decreases in serum potassium may occur, but nowhere near the magnitude of that caused by amphotericin B.

e. Anorexia, nausea, vomiting, and diarrhea have occurred.

f. Rare increases in serum creatinine; however, there have been no reported cases of nephrotoxicity.

g. Possible slight increases in serum aminotransferases

h. Allergic reactions occur in < 5% of patients and anaphylaxis in < 2% of patients.

i. Pregnancy category C embryotoxic reactions have occurred in animals.

5. Significant interactions

a. When cyclosporine is combined with caspofungin, clinically significant rises in ALT were observed. Serum transaminases should be monitored, and this combination should be avoided in patients with preexisting liver disease.

b. When used in combination, carbamazepine, nelfinavir, nevirapine, phenytoin, and rifampin increases the clearance of caspofungin. Higher doses of caspofungin (70 mg every day) should be considered when this combination is administered.

c. Tacrolimus clearance will be increased when the combination is used; monitor tacrolimus serum levels closely.

D. Flucytosine (Ancobon). This fluorinated pyrimidine usually is given in combination with amphotericin B.

1. Mechanism of action. Flucytosine penetrates fungal cells and is converted to fluorouracil, a metabolic antagonist. Incorporated into the RNA of the fungal cell, flucytosine causes defective protein synthesis. It is either **fungistatic** or **fungicidal,** depending on the concentration of the drug.

2. Spectrum of activity. This drug is primarily active against *Cryptococcus* and *Candida.* It is most commonly used in conjunction with amphotericin B. Fungal resistance against flucytosine alone has been well documented. Flucytosine may also possess some activity against chromomycosis and some strains of *Aspergillus* (in vitro testing only).

3. Therapeutic uses. Flucytosine is adjunctively used with amphotericin B for severe systemic infections (e.g., septicemia, endocarditis, pulmonary and urinary tract infections, meningitis). Use of flucytosine alone is not recommended.

4. Precautions and monitoring effects

a. Frequent adverse effects include GI intolerance with nausea, vomiting, and diarrhea.

b. Occasional adverse reactions are more severe and include marrow suppression with leukopenia or thrombocytopenia (dose related, especially with renal failure or concurrent amphotericin B use). Confusion, rash, hepatitis, enterocolitis, headache, and photosensitivity reactions can also occur.

c. Rare reactions include hallucinations, blood dyscrasias with agranulocytosis and pancytopenia, fatal hepatitis, anaphylaxis, and anemia.

d. Flucytosine may cause a markedly false elevation of serum creatinine if an Ektachem analyzer is used.

5. Significant interactions. Beneficial drug interactions occur with flucytosine. Flucytosine has demonstrated synergy with **amphotericin B** and **fluconazole** against *Cryptococcus* and *Candida* spp.

E. Griseofulvin (Fulvicin). Produced from *Penicillium griseofulvin Dierckx,* this drug is deposited in the skin, bound to keratin.

1. Mechanism of action. This agent is **fungistatic;** it inhibits fungal cell activity by interfering with mitotic spindle structure. Its mechanism of action is similar to colchicine.

2. Spectrum of activity. Griseofulvin is active against various strains of *Microsporum, Epidermophyton,* and *Trichophyton.*

3. Therapeutic uses. Griseofulvin is effective in tinea infections of the skin, hair, and nails (including athlete's foot, jock itch, and ringworm) caused by *Microsporum, Epidermophyton,* and *Trichophyton.*

a. Generally, this agent is given only for infections that do not respond to topical antifungal agents.

b. Griseofulvin is available only in oral form.

c. It possesses vasodilatory activity and may be used in Raynaud disease.

d. It may be used to treat gout.

4. Precautions and monitoring effects

a. Griseofulvin rarely results in serious adverse effects. However, the following problems have been reported.

(1) *Common:* headache, fatigue, confusion, impaired performance, syncope, and lethargy, which generally resolve with continued use

(2) *Occasional:* leukopenia, neutropenia, and granulocytopenia

(3) *Rare:* serum sickness, angioedema, urticaria, erythema, and hepatotoxicity

b. The dosage depends on the particle size of the product: 250 mg of ultramicrosize (Fulvicin P/G) is equivalent in therapeutic effects to 500 mg of microsize (Fulvicin U/F).

5. Significant interactions

a. Griseofulvin may increase the metabolism of **warfarin,** leading to decreased prothrombin time.

b. Barbiturates may reduce griseofulvin absorption.

c. Alcohol consumption may cause tachycardia and flushing.

d. Oral contraceptives may cause amenorrhea or increased breakthrough bleeding.

F. Imidazoles. The substituted imidazole derivatives **ketoconazole (Nizoral), miconazole (Monistat), fluconazole (Diflucan), itraconazole (Sporanox), voriconazole (Vfend)** and **posaconazole (Noxafil)** are valuable in the treatment of a wide range of systemic fungal infections.

1. Mechanism of action. Imidazoles inhibit sterol synthesis in fungal cell membranes and increase cell wall permeability; this, in turn, makes the cell more vulnerable to osmotic pressure. These agents are **fungistatic.**

2. Spectrum of activity. These agents are active against many fungi, including yeasts, dermatophytes, actinomycetes, and some *Phycomycetes.*

P.944

3. Therapeutic uses

a. Ketoconazole, an oral agent, successfully treats many fungal infections that previously yielded only to parenteral agents.

(1) It is therapeutic for systemic and vaginal candidiasis, mucocandidiasis, candiduria, oral thrush, histoplasmosis, coccidioidomycosis, chromomycosis, dermatophytosis (tinea), and paracoccidioidomycosis.

(2) Because ketoconazole is slow acting and requires a long duration of therapy (up to 6 months for some chronic infections), it is less effective than other antifungal agents for the treatment of severe and acute systemic infections.

b. Miconazole, primarily administered as a topical agent, The parenteral form has been discontinued in the United States. It was a relatively toxic formulation which has been replaced by other members of this class (e.g., fluconazole).

(1) Topical miconazole is highly effective in vulvovaginal candidiasis, ringworm, and other skin infections.

c. Fluconazole. Available in oral and parenteral forms, fluconazole can be used against systemic and CNS infections involving *Cryptococcus* and *Candida. Candida* oropharyngeal infection and esophagitis may also be treated with fluconazole. *Aspergillus, Coccidioides,* and *Histoplasma* have demonstrated in vitro sensitivity.

d. Itraconazole is available as an oral agent with activity against systemic and invasive pulmonary aspergillosis without the hematological toxicity of amphotericin B. Other deep mycotic infections susceptible to itraconazole include blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis.

e. Voriconazole. Voriconazole is available as both an intravenous and an oral agent for the treatment of fungal infections involving invasive aspergillosis, *Scedosporium apiospermum,* and *Fusarium* spp., including those species that are refractory to other therapy.

f. Posaconazole. Available as an oral suspension indicated for the prevention of invasive infections caused by *Aspergillus* and *Candida* species in patients receiving HSCT or with neutropenis. Posaconazole may also be used to treat invasive fungal infections in patients who have previously failed or are intolerant to other antifungals.

4. Precautions and monitoring effects

a. Ketoconazole may cause nausea, vomiting, diarrhea, abdominal pain, and constipation. Rarely, it leads to headache, dizziness, gynecomastia, and fatal hepatotoxicity.

b. Fluconazole commonly causes GI disturbances (e.g., nausea, vomiting, epigastric pain, diarrhea). Reversible elevations in serum aminotransferase, exfoliative skin reactions, and headaches have been reported.

c. Itraconazole may cause nausea, vomiting, hypertriglyceridemia, hypokalemia, rash, and elevations in liver enzymes.

d. Voriconazole. Visual disturbances, fever, rash, vomiting, nausea, diarrhea, headache, sepsis, peripheral edema, abdominal pain, and respiratory disorders rarely occurred. Liver function test abnormalities have occurred.

e. Posaconazole. Most common adverse events have been nausea and headache. Rash, dry skin, taste disturbances, abdominal pain, dizziness, hypokalemia, thrombocytopenia, and flushing can occur. Posaconazole can cause abnormalities in liver function and has been associated with prolongation of the QT interval.

5. Significant interactions

a. Both **ketoconazole** and **miconazole** may enhance the anticoagulant effect of **warfarin.**

b. Ketoconazole may antagonize the antibiotic effects of **amphotericin B.**

c. Fluconazole has been shown to elevate serum levels of **phenytoin, cyclosporine, warfarin,** and **sulfonylureas.** Concurrent hepatic enzyme inducers, such as **rifampin,** have resulted in increased elimination of both fluconazole and itraconazole.

d. Coadministration of **itraconazole** or **ketoconazole** with **astemizole** or **terfenadine** may result in increased astemizole or terfenadine levels, possibly leading to life-threatening dysrhythmias and death.

e. Both **ketoconazole** and **itraconazole** need the presence of stomach acid for adequate absorption. Use with antacids, H_2-blockers, or proton pump inhibitors is contraindicated.

f. Concomitant use of imidazole antifungal agents with **cisapride** may result in increased concentrations of cisapride, which has been associated with adverse cardiac events such as torsades de pointes leading to sudden death.

g. Voriconazole. Cytochrome P450 2C19 is the major enzyme involved in metabolism. Voriconazole inhibits cytochrome P450 2C19, 2C9, and 3A4. Any medication that is metabolized via these routes may be affected, and monitoring of blood levels (if appropriate) or clinical signs and symptoms is necessary when taking concomitant medications.

h. Posaconazole serum levels are reduced by concurrent administration with cimetidine, phenytoin or rifbutin; avoid concommitant use if possible. Posaconazole may increase concentrations of cyclosporine, tacrolimus, rifabutin, midazolam, and phenytoin; dosage adjustments may be required.

(1) Food increases the oral bioavailability; take posaconazole with a full meal or liquid nutritional supplement

G. Nystatin (Mycostatin). A polyene antibiotic, nystatin has a chemical structure similar to that of amphotericin B.

1. Mechanism of action. Nystatin is **fungicidal** and **fungistatic;** binding to sterols in the fungal cell membrane, it increases membrane permeability and permits leakage of intracellular contents.

2. Spectrum of activity. Nystatin is active primarily against *Candida* spp.

3. Therapeutic uses

a. This drug is used primarily as a topical agent in vaginal and oral *Candida* infections.

b. Oral nystatin is therapeutic for *Candida* infections of the GI tract, especially oral and esophageal infections; because the drug is not readily absorbed, it maintains good local activity.

4. Precautions and monitoring effects. Oral nystatin occasionally causes GI distress (e.g., nausea, vomiting, diarrhea). Rarely, hypersensitivity reactions occur.

H. Terbinafine (Lamisil) is a synthetic allylamine with structure and activity related to naftifine.

1. Mechanism of action. Terbinafine inhibits squalene monooxygenase, leading to an interruption of fungal sterol biosynthesis. Terbinafine may be **fungicidal** or **fungistatic,** depending on drug concentration and species.

2. Spectrum of activity. Terbinafine has activity against dermatophytic fungi (*Trichophyton, Microsporum,* and *Epidermophyton*), filamentous fungi (*Aspergillus*), and dimorphic fungi (*Blastomyces*). It may also possess some activity against yeasts.

3. Therapeutic uses

a. Oral terbinafine is useful against infections of the toenail and fingernail (onychomycosis, tinea unguium). Time to cure is reduced over imidazole antifungals for these indications. It is useful in patients who may not tolerate the adverse effect profile of imidazole antifungals.

b. It is also used in tinea capitis and tinea corporis infections.

4. Precautions and monitoring effects. Adverse effects include taste or ocular disturbances, symptomatic hepatobiliary dysfunction, decrease in lymphocyte count and neutropenia, and serious skin reactions.

IV. Topical Antifungal Agents

A. Definition. These agents are for topical use for fungal infections.

B. Amphotericin B (Fungizone) is available as a 3% cream or lotion or an oral suspension that is not absorbed through the GI tract.

1. Mechanism of action. See III.B.1.

2. Spectrum of activity. See III.B.2.

3. Therapeutic uses. Amphotericin B is used for oropharyngeal candidiasis, cutaneous and mucocutaneous candidal infections, or as a local irrigant for the bladder and intrapleural or intraperitoneal areas.

4. Precautions and monitoring effects. Compared with systemic administration, the topical formulations have relatively low toxicity.

a. Dry skin and local irritation with erythema, pruritus, or burning, along with mild skin discoloration, has occurred with the lotion and cream.

b. Rash and GI effects (e.g., nausea, vomiting, steatorrhea, diarrhea) tend to occur with the suspension. In addition, there have been case reports of urticaria, angioedema, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

C. Butenafine (Mentax) is a synthetic benzylamine related to the allylamine antifungal agents (naftifine, terbinafine).

1. Mechanism of action. Butenafine alters fungal membrane permeability and growth inhibition, interferes with sterol biosynthesis by allowing squalene to accumulate within the cell, and may be fungicidal in certain concentrations against susceptible organisms such as the dermatophytes.

2. Spectrum of activity. Butenafine is active against *Trichophyton rubrum, Trichophyton mentagrophytes, Microsporum canis, Sporothrix schenckii,* and yeasts including *Candida parapsilosis* and *C. albicans.*

3. Therapeutic uses. The 1% cream is used in dermatophytoses, including tinea corporis, tinea cruris, and tinea pedis.

4. Precautions and monitoring effects. If clinical improvement of fungal infection does not improve after the treatment period, the diagnosis should be reevaluated.

D. Butoconazole (Mycelex) is an azole antifungal cream available for vaginal use.

1. Mechanism of action. Butoconazole has fungistatic activity against susceptible organisms. The drug interferes with membrane permeability, secondary metabolic effects, and growth inhibition. Butoconazole contains antibacterial effects against some gram-positive organisms.

2. Spectrum of activity. Butoconazole is active against dermatophytes (*Trichophyton concentricum, T. mentagrophytes, T. rubrum, Trichophyton tonsurans, Epidermophyton floccosum, M. canis, Microsporum gypseum*), yeasts (*C. albicans, C. glabrata*), and some gram-positive organisms (S. *aureus, E. faecalis,* and *S. pyogenes*).

3. Therapeutic uses. A 2% cream is used for vulvovaginal candidiasis and complicated, recurrent vulvovaginal candidiasis.

4. Precautions and monitoring effects

a. Vulvovaginal burning and itching are the most common; however, their incidence is low. Headache; itching of fingers; urinary frequency and burning; and vulvovaginal discharge, irritation, soreness, stinging, odor, and swelling rarely occur.

b. Butoconazole may damage birth-control devices such as condoms and diaphragms, leading to inadequate protection. Consider alternative methods of birth control.

c. Tampon use should be avoided with the use of butoconazole.

E. Ciclopirox (Loprox) is a synthetic antifungal agent that is chemically unrelated to any other antifungal agent. The ethanolamine contained in ciclopirox appears to enhance epidermal penetration.

1. Mechanism of action. Ciclopirox causes intracellular depletion of amino acids and ions necessary for normal cellular function.

2. Spectrum of activity. Ciclopirox is active against dermatophytes, yeasts, some gram-positive and gram-negative bacteria, *Mycoplasma,* and *Trichomonas vaginalis.* Specifically, ciclopirox has activity against *T. mentagrophytes, T. rubrum, E. floccosum, M. canis, M. furfur,* and *C. albicans.*

3. Therapeutic uses. Ciclopirox is used topically for the treatment of tinea pedis, tinea cruris, tinea corporis, tinea versicolor (from *Malassezia*), and cutaneous candidiasis (moniliasis) from *C. albicans.*

4. Precautions and monitoring effects. Local irritation manifested by erythema, pruritus, burning, blistering, swelling, and oozing has occurred. If this occurs, ciclopirox should be discontinued.

F. Clioquinol (formerly iodochlorhydroxyquin) is a topical antifungal in a 3% ointment that can be used alone or in combination with hydrocortisone.

1. Mechanism of action. Unknown

2. Spectrum of activity. It is active against dermatophytic fungi.

3. Therapeutic uses. It is used topically against the following:

a. Tinea pedis and tinea cruris (ringworm infections)

b. Previously used to treat diaper rash; however, it is no longer recommended, and use in children < 2 years of age is contraindicated

4. Precautions and monitoring effects

a. Local irritation, rash, and sensitivity reactions are common.

b. Systemic absorption after topical application may occur.
c. High doses of clioquinol over long periods of time have been associated with oculotoxic/neurotoxic effects, including optic neuritis, optic atrophy, and subacute myelooptic neuropathy.
G. Clotrimazole (Lotrimin) is an azole antifungal agent that is an imidazole derivative. It is related to other azole antifungal agents such as **butoconazole, econazole, ketoconazole, miconazole, oxiconazole, sulconazole,** and **tioconazole.**
1. Mechanism of action. Clotrimazole alters fungal cell membrane permeability by binding with phospholipids in the membrane.
2. Spectrum of activity. It is active against yeasts, dermatophytes (*T. rubrum, T. mentagrophytes, E. floccosum, M. canis),* and some gram-positive bacteria. At higher concentrations, clotrimazole inhibits *M. furfur, Aspergillus fumigatus, C. albicans,* and some strains of *S. aureus, S. pyogenes, Proteus vulgaris,* and *Salmonella.* At very high concentrations, clotrimazole has an effect on *Sporothrix, Cryptococcus, Cephalosporium, Fusarium,* and *T. vaginalis.*
3. Therapeutic uses
a. The lozenges, which are administered 5 times per day, are useful in treating oropharyngeal candidiasis. Lozenges are also used for primary prophylaxis of mucocutaneous candidiasis in HIV-infected infants or children with severe immunosuppression.
b. The cream, lotion, or solution is used to treat dermatophytoses, superficial mycoses, and cutaneous candidiasis.
c. Intravaginal dosage forms are useful in treating vulvovaginal candidiasis.
4. Precautions and monitoring effects
a. Cutaneous reactions with topical administration may include blistering, erythema, edema, pruritus, burning, stinging, peeling, skin fissures, and general irritation.
b. The vaginal tablets are associated with mild burning, skin rash, itching, vulval irritation, lower abdominal cramps, bloating, slight cramping, vaginal soreness during intercourse, and an increase in urinary frequency.
c. Cross-sensitization occurs with imidazole; however, it is unpredictable.
d. Abnormal liver function tests (elevated AST) have occurred in patients taking the lozenges.
H. Econazole (Spectazole) is an azole antifungal agent that is an imidazole derivative.
1. Mechanism of action. Econazole alters cell membranes and increases permeability (like many other azole agents).
2. Spectrum of activity. Econazole is active against dermatophytes, yeasts, some gram-positive bacteria, and *T. vaginalis.*
3. Therapeutic uses
a. The 1% topical cream, lotion, or solution is useful in treating dermatophytoses and cutaneous candidiasis (tinea corporis and tinea cruris).

b. Econazole is also used to treat pityriasis (tinea) versicolor (*M. furfur*).

4. Precautions and monitoring effects. In general, there is a low incidence of toxicity. Topically, a patient may experience burning, stinging sensations, pruritus, and erythema (after 2-4 days).

I. Gentian violet is a dye that possesses the ability to kill fungi, yeasts, and some gram-positive bacteria.

1. Mechanism of action. None known

2. Spectrum of activity. Gentian violet is active against *Candida, Epidermophyton, Cryptococcus, Trichophyton,* and some *Staphylococcus* spp.

3. Therapeutic uses. It is used to treat cutaneous *C. albicans* infections (monilia or thrush).

4. Precautions and monitoring effects

a. Gentian violet may cause irritation or sensitivity reactions or possibly ulceration of the mucous membranes. If the solution is swallowed, esophagitis, laryngitis, or tracheitis may occur.

b. Skin tattooing may occur if gentian violet is applied to granulation tissue.

c. Gentian violet should not be used in areas of extensive ulceration.

d. This drug is a dye and will stain clothing.

J. Ketoconazole (Nizoral) is an imidazole-derived antifungal drug that is available topically as a cream and a shampoo.

1. Mechanism of action. See III.E.1.

2. Spectrum of activity. See III.E.2.

3. Therapeutic uses

a. The 2% topical cream is used in treating tinea corporis, tinea cruris, and tinea pedis caused by the dermatophytes (*E. floccosum, T. mentagrophytes,* and *T. rubrum*).

b. It is used for cutaneous candidiasis.

c. The 2% topical cream or 2% shampoo may be used in treating tinea versicolor (*M. furfur*). Selenium-based shampoos may also be useful in this area.

d. The 2% topical cream is useful against seborrheic dermatitis. The 2% shampoo is useful in reducing scaling caused by dandruff.

e. When combined with a steroid, ketoconazole is useful in treating the following: atopic dermatitis, diaper rash, eczema, folliculitis, impetigo, intertrigo, lichenoid dermatitis, and psoriasis.

f. An ophthalmic suspension can be extemporaneously prepared to treat fungal keratitis.

4. Precautions and monitoring effects

a. Reactions from the 2% topical cream include local irritation, pruritus, and stinging. Contact dermatitis is possible and occurs with other imidazole derivatives.

b. The 2% shampoo may lead to increased hair loss, irritation, abnormal hair texture, scalp pustules, dry skin, pruritus, and oiliness or dryness of hair and scalp. It may in addition straighten otherwise curly hair.

K. Miconazole (Monistat) is an imidazole-derived antifungal drug that is available topically as a 2% aerosol, 2% aerosol powder, 2% cream, a kit, 2% powder and 2% tincture, 2% vaginal cream, and 100 mg and 200 mg vaginal suppositories.

1. Mechanism of action. See III.E.1.

2. Spectrum of activity. See III.E.2.

3. Therapeutic uses. Miconazole is advantageous over other agents such as nystatin and tolnaftate in that its activity covers dermatophytes as well as *Candida.*

a. Topical use is effective against tinea pedis, tinea cruris, and tinea corporis caused by dermatophytes (*T. mentagrophytes, T. rubrum,* and *E. floccosum*).

b. It is also effective against tinea versicolor from *M. furfur.*

c. Like other imidazole derivatives, it is useful in treating cutaneous fungal infections.

d. The vaginal cream and vaginal suppositories are effective in treating vulvovaginal candidiasis.

4. Precautions and monitoring parameters

a. Topical creams have caused local irritation and burning.

b. Vaginal preparations have led to vulvovaginal burning, itching, irritation, pelvic cramps, vaginal burning, headache, hives, and skin rash.

c. If vulvovaginal candidiasis persists for longer than 3 days, seek further medical attention.

d. Tampons should be avoided in patients using vaginal suppositories or cream; sanitary pads should be substituted.

e. Vaginal suppositories are manufactured from a vegetable oil base that may interact with latex products. Avoid using diaphragms or condoms concurrently with suppositories. Seek an alternative form of birth control.

L. Naftifine (Naftin) is a synthetic allylamine similar to terbinafine. It is available as a 1% topical cream and a 1% topical gel.

1. Mechanism of action. Naftifine is **fungistatic** and interferes with sterol biosynthesis by accumulating squalene in the fungal cell. Naftifine also possesses some local anti-inflammatory activity.

2. Spectrum of activity

a. Naftifine is active against *T. mentagrophytes, T. rubrum, T. tonsurans, Trichophyton verrucosum, Trichophyton violaceum, E. floccosum, Microsporum audouinii, M. canis,* and *M. gypseum.*

b. *C. albicans, Candida krusei, Candida parapsilosis,* and *Candida tropicalis* are affected by naftifine; however, the concentrations of naftifine vary for *Candida* killing, depending on the species.
c. In vitro activity has been demonstrated against *Aspergillus flavus* and *Aspergillus fumigatus.* Others include *Sporothrix schenckii, Cryptococcus neoformans, Petriellidium boydii, Blastomyces dermatitidis,* and *Histoplasma capsulatum.*
3. Therapeutic uses. Naftifine is active against dermatophytoses and cutaneous candidiasis.
a. It is also used to treat tinea cruris, tinea pedis, tinea corporis, and tinea manus (*T. mentagrophytes, T. rubrum, T. verrucosum, T. violaceum, E. floccosum,* or *M. canis*).
b. It is also useful in treating tinea unguium (onychomycosis).
4. Precautions and monitoring effects. Transient burning and stinging
M. Nystatin (Mycostatin). A polyene antibiotic, nystatin has a chemical structure similar to that of amphotericin B. It is available as an oral suspension, tablet, lozenge, topical cream, ointment, topical powder, and vaginal tablet.
1. Mechanism of action. Nystatin is **fungicidal** and **fungistatic;** binding to sterols in the fungal cell membrane, it increases membrane permeability and permits leakage of intracellular contents.
2. Spectrum of activity. Nystatin is active primarily against *Candida* spp.
3. Therapeutic uses. This drug is used primarily as a topical agent in vaginal and oral *Candida* infections.
4. Precautions and monitoring effects. Irritation has occurred in extremely rare instances.
N. Oxiconazole (Oxistat) is an imidazole-derived antifungal drug that is available as a 1% topical cream or 1% topical lotion.
1. Mechanism of action. See III.E.1.
2. Spectrum of activity. See III.E.2.
3. Therapeutic uses
a. The 1% cream or lotion is useful in treating tinea cruris, tinea corporis, tinea manus, and tinea pedis from dermatophytes.
b. Oxiconazole is also effective against tinea versicolor caused by *M. furfur.*
4. Precautions and monitoring effects. Adverse effects are rare and are confined to local irritation.

O. Sulconazole (Exelderm) is an imidazole-derived antifungal drug that is available as a 1% topical cream and a 1% topical solution.
1. Mechanism of action (see III.E.1). The antibacterial effects exerted by sulconazole are thought to be the result of a direct physicochemical effect

on the destruction of unsaturated fatty acids present in bacterial cell membranes.

2. Spectrum of activity

a. Sulconazole has activity against dermatophytes, including *E. floccosum, M. audouinii, M. canis, M. gypseum, T. mentagrophytes, T. rubrum, T. tonsurans,* and *T. violaceum.* It also has activity against *M. furfur.*

b. Sulconazole also has activity against selected gram-positive aerobes (*S. aureus, S. epidermidis, Staphylococcus saprophyticus, E. faecalis, Micrococcus luteus,* and *Bacillus subtilis*) and anaerobes (*Clostridium* and *Propionibacterium acnes, Clostridium perfringens, Clostridium tetani,* and *Clostridium botulinum*).

3. Therapeutic uses

a. The 1% topical cream or 1% topical solution is useful in treating tinea corporis and tinea cruris.

b. The 1% topical cream has been studied for use against tinea pedis; the solution has not been evaluated for this indication.

c. The 1% cream is useful against tinea versicolor (*M. furfur*).

d. There is not an approved indication for cutaneous candidiasis; however, sulconazole 1% is as effective as miconazole 2% or clotrimazole 1% in treating cutaneous candidiasis.

e. Sulconazole is useful in treating infections caused by bacteria such as impetigo (*S. pyogenes*) and ecthyma (*S. aureus*).

4. Precautions and monitoring effects. Adverse reactions include local effects such as burning and irritation, skin edema, dryness, scaling, fissuring, cracking, generalized red papules, and severe eczema.

P. Terbinafine (Lamisil AT) is a synthetic allylamine available as a 1% cream with structure and activity related to naftifine.

1. Mechanism of action. Terbinafine inhibits squalene monooxygenase, leading to an interruption of fungal sterol biosynthesis. Terbinafine may be **fungicidal** or **fungistatic,** depending on drug concentration and species.

2. Spectrum of activity. Terbinafine has activity against dermatophytic fungi (*Trichophyton, Microsporum,* and *Epidermophyton*), filamentous fungi (*Aspergillus*), and dimorphic fungi (*Blastomyces*). It may also possess some activity against yeasts.

3. Therapeutic uses. It is useful for tinea pedis, tinea corporis, and tinea cruris.

4. Precautions and monitoring effects. It can cause local irritation.

Q. Terconazole (Terazol-7) is an imidazole-derived antifungal drug that is available as a 0.4% and 0.8% vaginal cream and an 80-mg vaginal suppository.

1. Mechanism of action. It is **fungicidal** against *C. albicans.* Like other imidazole agents, terconazole alters cellular membranes, resulting in increased membrane permeability.

2. Spectrum of activity. It is active against dermatophytes; yeasts; and, at high concentrations, gram-positive and gram-negative bacteria.

3. Therapeutic uses are for complicated and uncomplicated vulvovaginal candidiasis.

4. Precautions and monitoring effects. Adverse reactions include burning, pruritus, irritation, headache, body pain, and pain of female genitalia.

R. Tioconazole (Vagistat-1) is an imidazole-derived antifungal drug that is available as a 6.5% vaginal ointment.

1. Mechanism of action. Tioconazole is **fungicidal** against *C. albicans.* Like other imidazole agents, tioconazole alters cellular membranes, resulting in increased membrane permeability.

2. Spectrum of activity

a. Activity against fungi includes most strains of *Candida* and the dermatophytes. There is also activity against *Aspergillus* and *C. neoformans.*

b. Tioconazole is active against the following aerobic gram-positive bacteria: *Gardnerella vaginalis, Corynebacterium minutissimum, E. faecalis, S. aureus, S. epidermidis,* and some *Streptococci* spp. Gram-negative bacteria: it is active against *H. pylori, Haemophilus ducreyi, Moraxella catarrhalis, Neisseria gonorrhoeae,* and *N. meningitidis.*

c. Other organisms that tioconazole has activity against are *T. vaginalis, Lymphogranuloma venereum,* and *Chlamydia trachomatis.*

3. Therapeutic uses. Tioconazole is used for simple and complicated vulvovaginal candidiasis. Other uses have been explored; however, topical creams for use in those scenarios are not available in the United States.

4. Precautions and monitoring effects. Local irritation has been manifested as vulvovaginal burning, vaginitis, and pruritus.

S. Tolnaftate (Tinactin) is available topically as a 1% aerosol, 1% powder, 1% cream, and 1% solution.

1. Mechanism of action. It may distort hyphae and stunt mycelial growth in susceptible fungi.

2. Spectrum of activity. Tolnaftate may be either **fungistatic** or **fungicidal** to the following organisms: *M. gypseum, M. canis, M. audouinii, Microsporum japonicum, T. rubrum, T. mentagrophytes, Trichophyton schoenleinii, T. tonsurans, E. floccosum, Aspergillus niger, C. albicans, C. neoformans,* and *A. fumigatus.*

3. Therapeutic uses. Tolnaftate is used for dermatophytoses and tinea versicolor.

4. Precautions and monitoring effects. There may be slight local irritation.

V. Antiprotozoal Agents

A. Classification. These drugs fall into two main categories: **antimalarial agents,** used to treat malaria infection, and **amebicides** and **trichomonacides,** used to treat amebic and trichomonal infections.

B. Antimalarial agents. Still a leading cause of illness and death in tropical and subtropical countries, malaria results from infection by any of four species of the protozoal genus *Plasmodium.* Antimalarial agents are selectively active during different phases of the protozoan life cycle. Major antimalarial drugs include **chloroquine (Aralen), halofantrine (Halfan), hydroxychloroquine (Plaquenil), primaquine, pyrimethamine (Daraprim), quinine,** and **mefloquine (Lariam).** In addition, two combination brands are available: sulfadoxine plus pyrimethamine (Fansidar) and atovaquone plus proguanil (Malarone).

1. Mechanism of action

a. Chloroquine and **hydroxychloroquine** bind to and alter the properties of microbial and mammalian DNA.

b. The mechanism of action of **primaquine, quinine, Fansidar,** and **mefloquine** is unknown.

c. Pyrimethamine impedes folic acid reduction by inhibiting the enzyme dihydrofolate reductase.

2. Spectrum of activity

a. Chloroquine and **hydroxychloroquine** are suppressive blood **schizonticidal** agents and are active against the asexual erythrocyte forms of *Plasmodium vivax* and *Plasmodium falciparum* and gametocytes of *P. vivax, Plasmodium malariae,* and *Plasmodium ovale.*

b. Primaquine, a curative agent, is active against liver forms of *P. vivax* and *P. ovale* and the primary exoerythrocyte forms of *P. falciparum.*

c. Pyrimethamine is active against chloroquine-resistant strains of *P. falciparum* and some strains of *P. vivax.*

d. Quinine, a generalized protoplasmic poison, is toxic to a wide range of organisms. In malaria, this drug has both suppressive and curative action against chloroquine-resistant strains.

e. Fansidar (sulfadoxine plus pyrimethamine) is a blood **schizonticidal** agent that is active against the erythrocytic forms of susceptible plasmodia. It is also activeagainst *T. gondii.*

f. Malarone (atovaquone plus proguanil) is active against the erythrocytic and exoerythrocytic forms of *Plasmodium* spp.

g. Mefloquine is a blood **schizonticidal** agent that is active against *P. falciparum* (both chloroquine-susceptible and -resistant strains) and *P. vivax.*

h. Halofantrine is a blood schizonticidal agent active against *P. falciparum* and *P. vivax.*

3. Therapeutic uses

a. Chloroquine is the preferred agent used to suppress malaria symptoms and to terminate acute malaria attacks resulting from *P. falciparum* and *P. malariae* infections.

(1) It is more potent and less toxic than quinine.

(2) Except where drug-resistant *P. falciparum* strains are prevalent, chloroquine is the most useful antimalarial agent.

b. Hydroxychloroquine is used as an alternative to chloroquine in patients who cannot tolerate chloroquine or when chloroquine is unavailable.

c. Primaquine is used to cure relapses of *P. vivax* and *P. ovale* malaria and to prevent malaria in exposed persons returning from regions where malaria is endemic.

d. Pyrimethamine is effective in the prevention and treatment of chloroquine-resistant strains of *P. falciparum.* It is now used almost exclusively in combination with a sulfonamide or sulfone.

e. Quinine

(1) Quinine sulfate, an oral form, is therapeutic for acute malaria caused by chloroquine-resistant strains.

(2) Quinine dihydrochloride, a parenteral form, is used in severe cases of chloroquine-resistant malaria. (It is available only from the CDC.)

(3) Quinine is almost always given in combination with another antimalarial agent.

f. Fansidar

(1) Fansidar is used for the suppression or prophylaxis of chloroquine-resistant *P. falciparum* malaria.

(2) It has been used for the prophylaxis of *P. carinii* infections in AIDS patients unable to tolerate cotrimoxazole (trimethoprim-sulfamethoxazole).

g. Mefloquine is indicated for the treatment of acute malaria and the prevention of *P. falciparum* and *P. vivax* infections.

h. Halofantrine is indicated for treatment of malaria in adults who can tolerate oral medication and who have mild to moderate malaria (≥ 100,000 parasites/mm^3) caused by *P. falciparum* or *P. vivax.*

i. Malarone

(1) Prophylaxis of *P. falciparum* malaria, including areas where chloroquine resistance has been reported.

(2) Treatment of acute, uncomplicated *P. falciparum* malaria. This combination has been shown to be effective in regions where the drugs chloroquine, halofantrine, mefloquine, and amodiaquine may have unacceptable failure rates, presumably because of drug resistance.

4. Precautions and monitoring effects

a. Chloroquine and hydroxychloroquine

(1) Because these drugs concentrate in the liver, they should be used cautiously in patients with hepatic disease.

(2) Chloroquine must be administered with extreme caution in patients with neurological, hematological, or severe GI disorders.

(3) Visual disturbances, headache, skin rash, and GI distress have been reported.

b. Primaquine

(1) This agent is contraindicated in patients with rheumatoid arthritis and lupus erythematosus and in those receiving other potentially hemolytic drugs or bone marrow suppressants.

(2) Primaquine may cause agranulocytosis, granulocytopenia, and mild anemia. In patients with G6PD deficiency, it may cause hemolytic anemia.

(3) Abdominal cramps, nausea, vomiting, and epigastric distress sometimes occur.

c. Pyrimethamine

(1) In high doses, this drug may cause agranulocytosis, megaloblastic anemia, aplastic anemia, and thrombocytopenia.

(2) Erythema multiforme (Stevens-Johnson syndrome), nausea, vomiting, and anorexia may develop during pyrimethamine therapy.

d. Quinine

(1) Quinine is contraindicated in patients with G6PD deficiency, tinnitus, and optic neuritis.

(2) Quinine overdose or hypersensitivity reactions may be fatal. Manifestations of quinine poisoning include visual and hearing disturbances; GI symptoms (e.g., nausea, vomiting); hot, flushed skin; headache; fever; syncope; confusion; shallow, then depressed, respirations; and cardiovascular collapse.

(3) Quinine must be used cautiously in patients with atrial fibrillation.

(4) Renal damage and anuria have been reported.

e. Fansidar

(1) Severe, sometimes fatal, hypersensitivity reactions have occurred. In most cases, death resulted from severe cutaneous reactions, including erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

(2) Adverse hematological and hepatic effects as seen with sulfonamides have been reported.

f. Mefloquine

(1) Concomitant use of mefloquine with quinine, quinidine, or β-adrenergic blockade may produce electrocardiographic abnormalities or cardiac arrest.

(2) Concomitant use of mefloquine and quinine or chloroquine may increase the risk of convulsions.

g. Halofantrine

(1) Do not administer with drugs known to prolong the QTc interval; interaction with mefloquine further prolongs the QTc interval.

(2) A sevenfold increase in peak plasma level and threefold increase in the area under the curve (AUC) occurred when given with high-fat food. Similar

increases occur when doses are administered 2 hr after a meal. Administer halofantrine on an empty stomach.

h. Malarone

(1) Concomitant administration with tetracycline has been associated with 40% reduction in plasma concentrations of atovaquone. Similarly, concurrent rifampin is known to reduce atovaquone levels by 50%.

(2) Take malarone with food or milk.

C. Amebicides and trichomonacides. These agents are crucial in the treatment of amebiasis, giardiasis, and trichomoniases—the most common protozoal infections in the United States. The major amebicides include **diloxanide, iodoquinol (Yodoxin), metronidazole (Flagyl), nitazoxanide (Alinia), paromomycin (Humatin), quinacrine,** and **tinidazole (Tindamax).**

1. Mechanism of action

a. Diloxanide, a dichloroacetamide derivative, is **amebicidal;** its mechanism of action is unknown. (Not available commercially but can be compounded by Panorama Compounding Pharmacy, Van Nuys, CA—per Medical Letter 8/04.)

b. Metronidazole is a synthetic compound with direct **amebicidal** and **trichomonacidal** action; it works at both intestinal and extraintestinal sites. Its mechanism of action involves disruption of the helical structure of DNA.

c. Nitazoxanide is designated by the U.S. Food and Drug Administration (FDA) as an orphan drug. Its antiprotozoal activity is believed to be the result of interference with the pyruvate: ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reaction essential for energy metabolism.

d. Quinacrine is an acridine derivative that inhibits DNA metabolism.

e. Iodoquinol is a luminal or contact amebicide that is effective against the trophozoites of *Entamoeba histolytica* located in the lumen of the large intestine.

f. Paromomycin is a poorly absorbed amebicidal aminoglycoside whose mechanism of action parallels other aminoglycosides (i.e., protein synthesis inhibitor). It is also effective against enteric bacteria *Salmonella* and *Shigella.*

g. Tinidazole precise mechanism of action is unknown.

2. Spectrum of activity and therapeutic uses

a. Diloxanide

(1) This drug is used to treat asymptomatic carriers of amebic and *Giardia* cysts.

(2) Diloxanide is therapeutic for invasive and extraintestinal amebiasis (given in combination with a systemic or mixed amebicide).

(3) Diloxanide is not effective as single-agent therapy for extraintestinal amebiasis.

b. Metronidazole

(1) This agent is the preferred drug in amebic dysentery, giardiasis, and trichomoniasis.

(2) Metronidazole also is active against all anaerobic cocci and gram-negative anaerobic bacilli.

(3) This agent is the treatment of choice by the CDC for the treatment of *C. difficile* colitis infections owing to the emerging use of broad-spectrum antibiotics. This therapy is cost-effective.

c. Quinacrine is useful in the treatment of giardiasis and tapeworms (see VIII.H.2).

d. Iodoquinol is indicated for treatment of intestinal amebiasis. It is active against the protozoa *E. histolytica.*

e. Nitazoxanide is indicated for treatment of diarrhea caused by *Cryptosporidium parvum* and *Giardia lamblia* in children.

f. Paromomycin is indicated for acute and chronic intestinal amebiasis; it is not useful for extraintestinal amebiasis because it is not absorbed. Paromomycin has been used for *Dientamoeba fragilis, Taenia saginata, Dipylidium caninum,* and *Hymenolepis nana.*

g. Tinidazole is a second-generation synthetic nitroimidazole active against trichomoniasis, *Giardia duodenalis/G. lamblia, and E. histolytica.*

3. Precautions and monitoring effects

a. Diloxanide rarely causes serious adverse effects. Vomiting, flatulence, and pruritus have been reported.

b. Metronidazole

(1) The most common adverse effects of this drug are nausea, epigastric distress, and diarrhea.

(2) Metronidazole is carcinogenic in mice and should not be used unnecessarily.

(3) Headache, vomiting, metallic taste, and stomatitis have been reported.

(4) Occasionally, neurological reactions (e.g., ataxia, peripheral neuropathy, seizures) develop.

(5) A disulfiram-type reaction may occur with concurrent ethanol use.

c. Quinacrine. See VIII.H.4.

(1) This drug frequently causes dizziness, headache, nausea, and vomiting. Nervousness and seizures also have been reported.

(2) Quinacrine should not be taken in combination with primaquine because this may increase primaquine toxicity.

(3) Quinacrine should be administered with extreme caution in patients with psoriasis because it may cause marked exacerbation of this disease.

d. Iodoquinol may produce optic neuritis or atrophy or peripheral neuropathy with high-dose, long-term use. Protein-bound iodine levels may be increased during treatment and may interfere with the results of thyroid tests for 6 months after treatment. Iodoquinol should not be used in patients who are hypersensitive to 8-hydroxy-quinolone (e.g., iodoquinol,

iodochlorhydroxyquin) or iodine-containing agents or in patients with hepatic disorders.

e. Paromomycin may cause nausea, cramping, and diarrhea at high doses (> 3 g/day). Inadvertent absorption through ulcerative bowel lesions may result in ototoxicity or renal damage.

f. Nitazoxanide may cause abdominal pain, diarrhea, vomiting, headache, flatulence, fever, eye discoloration, rhinitis, and discolored urine.

g. Tinidazole may produce metallic taste, nausea, anorexia, dyspepsia, vomiting, weakness, dizziness, and headache.

D. Pentamidine isethionate (Pentam 300) is an aromatic diamide antiprotozoal agent. It can be administered intramuscularly, intravenously, or by inhalation.

1. Mechanism of action is not fully understood, but in vitro studies indicate interference with nuclear metabolism and inhibition of DNA, RNA, phospholipid, and protein synthesis.

2. Therapeutic uses

a. Pentamidine is indicated for the prevention and treatment of infections caused by *P. carinii.*

b. Unlabeled uses include treatment of trypanosomiasis, visceral leishmaniasis, and babesiosis.

3. Precautions and monitoring effects

a. Nephrotoxicity, bronchospasm, and cough are the most common effects produced by intravenous or inhaled pentamidine.

b. Severe hypotension may occur after a parenteral dose of pentamidine. Cardiorespiratory arrest can occur after a single rapid infusion of the drug.

c. Pain, erythema, and tenderness may occur after an IM administration of the drug. This can be minimized by using the Z-track technique of drug administration. Phlebitis may occur following IV administration.

d. Hypoglycemia may occur with initial administration of drug via the IV, IM, or inhalational route. After the patient has been on the drug for a period of time, hyperglycemia will result. The effect of the drug may actually induce a reversible insulin-dependent diabetes mellitus.

e. Leukopenia and thrombocytopenia, which can be severe, occur occasionally.

f. Pentamidine may result in elevated liver function tests, AST, and ALT.

g. GI effects can also occur, including nausea, vomiting, abdominal discomfort, pain, diarrhea, and dysgeusia.

h. Neurological effects can occur with parenteral administration and may include dizziness, tremors, confusion, anxiety, insomnia, and seizures.

i. Hypocalcemia and fever have also been reported and may be severe at times.

E. Atovaquone (Mepron) is a hydroxynaphthoquinone initially synthesized as an antimalarial drug.

1. Mechanism of action. Atovaquone blocks mitochondrial electron transport at complex III of the respiratory chain of protozoa, resulting in inhibition of pyrimidine synthesis.

2. Spectrum of activity. It is active against *P. carinii, T. gondii, C. parvum, P. falciparum, Isosporidia,* and *Microsporidia.*

3. Therapeutic uses. Atovaquone is used for second-line treatment of mild to moderate *P. carinii* pneumonia in patients intolerant of cotrimoxazole or other sulfonamides or who are nonresponsive to cotrimoxazole.

4. Precautions and monitoring effects

a. Oral absorption significantly increases when administered with food (especially a high-fat meal).

b. Rash, nausea, diarrhea, headache, fever, abdominal pain, dizziness, and elevated liver function tests commonly are reported.

5. Significant interactions. Atovaquone is highly bound to plasma protein. It should be used with caution when administered with other highly protein-bound drugs with a narrow therapeutic range.

F. Eflornithine HCl (Ornidyl). This is an IV antiprotozoal agent. Its activity has been attributed to the inhibition of the enzyme ornithine decarboxylase.

1. Mechanism of action. This is a specific, enzyme-activated, irreversible inhibitor of ornithine decarboxylase.

2. Spectrum of activity and therapeutic uses. Eflornithine is active in the treatment of the meningoencephalitic stage of *Trypanosoma brucei gambiense* (sleeping sickness).

3. Precautions and monitoring effects

a. Myelosuppression is the most frequent serious side effect.

b. Seizures occur in about 8% of treated patients.

c. Cases of hearing impairment have been reported.

VI. Antitubercular Agents

A. Definition and classification. Drugs used to treat tuberculosis suppress or kill the slow-growing mycobacteria that cause this disease. Antitubercular agents fall into two main categories: first-line

and second-line drugs. Because the causative organisms tend to develop resistance to any single drug, combination drug therapy has become standard in the treatment of tuberculosis.

1. The **incidence** of tuberculosis in the United States is increasing owing to shifts in populations considered to be endemic for tuberculosis, the rise in HIV-positive patients, and drug resistance.

2. Agents chosen for **therapy** must eradicate mycobacterium. First-line agents available include isoniazid, ethambutol, pyrazinamide, rifampin, rifabutin, and rifapentine. **Combination chemotherapy** is essential. Agents

showing the lowest incidence of resistance (isoniazid, rifampin) are usually used in combination with pyrazinamide or ethambutol.

3. Choice of therapy depends on many patient and disease factors (e.g., duration of therapy needed, likelihood of drug resistance, and HIV status).

4. Treatment choices based on CDC recommendations (Table 44-4).

B. First-line. These drugs, isoniazid, ethambutol, rifampin, rifabutin, rifapentine, and pyrazinamide usually offer the greatest effectiveness with the least toxicity; they are successful in most tuberculosis patients. At least three to four drug combinations are recommended. The CDC recommends daily treatment with isoniazid, rifampin, pyrazinamide, and ethambutol for the initial phase of 2 months, followed by a continuation phase of isoniazid and rifampin for 4-5 months (Table 44-4).

1. Ethambutol (Myambutol) is a synthetic water-based compound.

a. Mechanism of action. This drug is **bacteriostatic.** Its precise mechanism of action is unknown; however, it has demonstrated activity only against susceptible bacteria actively undergoing cell division.

b. Spectrum of activity and therapeutic uses. Ethambutol is active against many *M. tuberculosis* strains as well as many other mycobacterial species. However, drug resistance develops fairly rapidly when it is used alone. In most cases, ethambutol is given adjunctively in combination with isoniazid or rifampin for tuberculosis. It is also useful in combination with other agents such as clarithromycin or azithromycin and rifabutin in treating MAC.

Table 44-4. Treatment for Active Tuberculosis

		Initial Phase	Continuation Phase	
Rank	**Agent**	**Dosage**	**Agent**	**Dosage**
1	INH	7 days a week × 8 weeks	INH/RIF	7 days a week × 18 weeks
	RIF	*or*		*or*
	PZA	5 days a week × 8 weeks		5 days a week × 18 weeks
	EMB			
2	INH RIF	7 days a week × 2 weeks, *then* 2 times a week × 6 weeks	INH/RIF	2 times a week × 18 weeks

	PZA	*or*		
	EMP	5 days a week × 2 weeks, *then* 2 times a week × 6 weeks		
3	INH	3 times a week × 8 weeks	INH/RIF	3 times a week × 19 weeks
	RIF			
	PZA			
	EMB			
4	INH	7 days a week × 8 weeks	INH/RIF	7 days a week × 31 weeks
	RIF	*or*		*or*
	EMP	5 days a week × 8 weeks		5 days a week × 31 weeks
				or
				2 times a week × 31 weeks

EMB, ethambutol; *INH,* isoniazid; *PZA,* pyrazinamide; *RIF,* rifampin.

Adapted with permission from CDC guidelines for treatment of tuberculosis 2003. MMWR 2003; 52 (RR11); 1-77.

c. Precautions and monitoring effects. Rarely, ethambutol causes such adverse effects as reversible dose-related (= 15 mg/kg/day) optic neuritis, drug fever, abdominal pain, headache, dizziness, and confusion. Liver function tests should be periodically monitored. Visual testing and renal function (reduce dose with impairment) should also be monitored.

2. Isoniazid (Nydrazid) is a hydrazide of isonicotinic acid. The mainstay of antitubercular therapy, this drug should be included (if tolerated) in all therapeutic regimens.

a. Mechanism of action. Isoniazid is **bacteriostatic** for resting bacilli and **bactericidal** for rapidly dividing organisms. Its mechanism of action is not fully known; the drug probably disrupts bacterial cell wall synthesis by inhibiting mycolic acid synthesis.

b. Spectrum of activity. Isoniazid has activity only against organisms in the genus *Mycobacterium.* More specifically, it has demonstrated activity against *M. tuberculosis, Mycobacterium bovis,* and select strains of *Mycobacterium kansasii.*

c. Therapeutic uses

(1) The most widely used antitubercular agent, isoniazid should be given in combination with other antitubercular drugs (such as rifampin, ethambutol, and pyrazinamide) to prevent drug resistance in tuberculosis.

(2) Treatment of latent infection (previously referred to as preventive therapy of chemoprophylaxis). Isoniazid may be administered alone for up to 1 year in adults or children who have a positive tuberculin test result but lack active lesions.

d. Precautions and monitoring effects

(1) The most common adverse effects of isoniazid are skin rash, fever, jaundice, and peripheral neuritis.

(2) Hepatitis, an occasional reaction, can be severe and, in some cases, fatal. The risk of hepatitis increases with the patient's age and rises with alcohol abuse. Monitor liver function tests.

(3) Blood dyscrasias (e.g., agranulocytosis, aplastic or hemolytic anemia, thrombocytopenia) may occur. Monitor complete blood count (CBC) routinely.

(4) Adverse GI effects include nausea, vomiting, and epigastric distress.

(5) CNS toxicity may result from pyridoxine deficiency. Signs and symptoms include insomnia, restlessness, hyperreflexia, and convulsions. Pyridoxine 15-50 mg/day should be administered to patients taking isoniazid to minimize the peripheral neuropathy associated with its use (especially in patients with diabetes, HIV, uremia, alcoholism, malnutrition, pregnancy, or seizure disorder).

e. Significant interactions

(1) With concurrent **phenytoin** therapy, blood levels of both phenytoin and isoniazid may increase, possibly causing toxicity.

(2) Aluminum-containing antacids may reduce isoniazid absorption.

(3) Concurrent **carbamazepine** therapy may increase the risk of hepatitis.

(4) Use of isoniazid with other antitubercular agents, such as cycloserine or ethionamide, may cause additive nervous system effects.
(5) There is the potential for the serotonin syndrome to exist when isoniazid is used in combination with selective serotonin reuptake inhibitors or in patients taking meperidine. Isoniazid has been shown to have some monoamine oxidase (MAO) inhibiting activity.
3. Rifampin (Rimactane) is a complex macrocyclic agent.
a. Mechanism of action. This drug is **bactericidal;** it impairs bacterial RNA synthesis by binding to DNA-dependent RNA polymerase.
b. Spectrum of activity. Rifampin has activity against most mycobacterial strains. In addition, rifampin has activity against many other organisms, including *N. meningitidis, S. aureus, H. influenzae, Legionella pneumophila,* and *C. trachomatis.*
c. Therapeutic uses
(1) In recommended combinations for treatment of active tuberculosis
(2) Prophylactic rifampin is effective when administered to carriers of *N. meningitidis* disease and chemoprophylaxis of patients with *H. influenzae* type b organisms.
(3) Rifampin may be used in combination with dapsone for the treatment of leprosy.
d. Precautions and monitoring effects
(1) Serious hepatotoxicity may result from rifampin therapy. Liver function tests should be routinely conducted.

(2) In rare cases, this drug induces an influenza-like syndrome.
(3) Other adverse effects include skin rash, drowsiness, headache, fatigue, confusion, nausea, vomiting, and abdominal pain.
(4) Rifampin colors urine, sweat, tears, saliva, and feces orange red.
e. Significant interactions
(1) Rifampin induces hepatic microsomal cytochrome P450 isoenzymes and thus may decrease the therapeutic effectiveness of **corticosteroids, warfarin, oral contraceptives, quinidine, digitoxin, protease inhibitors (PIs), nonnucleoside reverse transcriptase inhibitors, ketoconazole, verapamil, methadone, oral antidiabetic agents, cyclosporine, dapsone, chloramphenicol,** and **barbiturates.**
(2) Probenecid may increase blood levels of rifampin.
(3) Aminosalicylic acid may impair absorption of rifampin secondary to bentonite, an excipient used in preparation of aminosalicylic granules.
f. The newer rifamycins, **rifabutin (Mycobutin)** and **rifapentine (Priftin)** may be substituted for rifampin in special situations, e.g., intolerance or serious drug interactions.

4. Rifabutin (Mycobutin) is an antimycobacterial agent that is similar to rifampin, with activity against both tubercular and nontubercular mycobacterial, and offers no clear advantage over rifampin.

a. Mechanism of action. In addition to its antimycobacterial activity against tubercular and nontubercular mycobacterial, rifabutin has been reported to inhibit reverse transcriptase and block the in vitro infectivity and replication of HIV.

b. Therapeutic uses. Rifabutin is indicated for the prevention of disseminated MAI complex disease in patients with advanced HIV infections.

c. Precautions and monitoring effects. The use of rifabutin has resulted in mild elevation of liver enzymes and thrombocytopenia.

d. Significant interactions

(1) Rifabutin antagonizes and potentially negates the immune response mediated by the bacillus Calmette-Guérin (BCG) vaccine.

(2) Rifabutin may increase the clearance of drugs by inducing hepatic microsomal enzymes, but does so to a lesser extent than rifampin. The concentrations of the following drugs may be reduced while taking rifabutin: **cyclosporine, zidovudine, prednisone, digitoxin, quinidine, ketoconazole, protease inhibitors, propranolol, phenytoin, sulfonylureas,** and **warfarin.** Serum cyclosporine levels should be monitored in patients receiving both agents.

5. Rifapentine (Priftin) is a long-acting rifamycin-derivative and has a similar profile of microbiological activity to rifampin. It is usually administered once or twice weekly.

a. Mechanism of action. Rifapentine is bactericidal against intracellular and extracellular *M. tuberculosis* at therapeutic levels.

b. Spectrum of activity and therapeutic uses. Indicated for treatment of primary tuberculosis. Rifapentine should always be used in conjunction with ≥ 1 other antituberculosis drug to which the isolate is susceptible.

c. Precautions and monitoring effects. Rifapentine induces cytochrome P450 isoenzymes 3A4 and 2C8/9 responsible for inactivation of certain calcium channel blocking agents (verapamil, diltiazem, nifedipine), antifungals (ketoconazole, fluconazole, itraconazole), sulfonylurea antidiabetic agents, methadone, corticosteroids, cardiac glycosides, certain antiarrhythmic agents (disopyramide, mexiletine, quinidine, tocainide), quinine, dapsone, chloramphenicol, clarithromycin, doxycycline, fluoroquinolones, transcriptase inhibitor cyclosporin, tacrolimus, and warfarin. Concomitant use of rifapentine with these drugs may decrease plasma concentrations and dosage adjustments may be required.

6. Pyrazinamide is a pyrazine analog of nicotinamide.

a. Mechanism of action. This drug is **bactericidal** and/or **bacteriostatic,** depending on the cell concentration achieved.

b. Spectrum of activity and therapeutic uses. Pyrazinamide is a highly specific agent and has activity only against *M. tuberculosis.* Pyrazinamide

is used as a primary agent with isoniazid and rifampin for at least 2 months, followed by isoniazid and rifampin.

c. Precautions and monitoring effects. This agent may result in hepatotoxicity and, rarely, hepatic necrosis resulting in death. Anorexia, nausea, vomiting, malaise, and fever have

been reported. Hyperuricemia may result in gouty exacerbations. Both liver function tests and uric acid levels should routinely be monitored.

C. Second-line agents. These agents include aminosalicylic acid **(Paser),** capreomycin **(Capastat),** cycloserine **(Seromycin),** ethionamide **(Trecator-SC),** quinolones (ciprofloxacin, ofloxacin, levofloxacin, sparfloxacin), streptomycin and kanamycin. Second-line drugs are mainly substituted or added to preferred therapy owing to intolerance or drug resistance. These agents are less effective, more toxic, and are used in combination with primary agents.

1. Mechanism of action

a. Aminosalicylic acid is **bacteriostatic;** it probably inhibits the enzymes responsible for folic acid synthesis.

b. Cycloserine can be **bacteriostatic** or **bactericidal,** depending on its concentration at the infection site; it impairs amino acid use, thereby inhibiting bacterial cell wall synthesis.

c. The mechanism of action of capreomycin (**bacteriostatic**), ethionamide (**bactericidal**), and pyrazinamide (**bactericidal**) is unknown.

2. Spectrum of activity and therapeutic uses. Second-line antitubercular agents are active against various microorganisms, including *M. tuberculosis.* These agents generally are reserved for patients with extensive extrapulmonary or drug-resistant disease or for patients who need retreatment. These drugs are almost always administered in combination.

3. Precautions and monitoring effects

a. Adverse effects of **aminosalicylic acid** include leukopenia, agranulocytopenia, thrombocytopenia, hemolytic anemia, mononucleosis-like syndrome, malaise, joint pain, fever, and skin rash.

b. Capreomycin and **streptomycin** are ototoxic and nephrotoxic; they should not be administered together.

c. Cycloserine may cause adverse CNS effects, including headache, suicidal and psychotic tendencies, hyperirritability, confusion, paranoia, and nervousness.

d. Ethionamide may induce nausea, vomiting, orthostatic hypotension, metallic taste, epigastric distress, and peripheral neuropathy.

e. Streptomycin. See II.B.3.

D. Alternative agents

1. Rifater. A combination of rifampin 120 mg, isoniazid 50 mg, and pyrazinamide 300 mg in one tablet is used in patients expected to have low

compliance with tuberculosis drug therapy. One **disadvantage** is that many patients are required to take as many as 5-6 tablets daily, which may reduce compliance.

2. Quinolones. Ciprofloxacin and levofloxacin are used in tuberculosis therapy. Levofloxacin is preferred owing to increased serum concentrations. Levofloxacin is usually used in combination with other tuberculosis agents for active treatment. For prophylaxis, levofloxacin is combined with pyrazinamide.

3. Macrolides. Clarithromycin and azithromycin have shown limited activity against *M. tuberculosis*.

VII. Antiviral Agents

A. Definition. These drugs treat viral infections by affecting viral replication. Because viruses lack independent metabolic activity and can replicate only within living host cells, antiviral agents tend to injure host as well as viral cells. Although most antiviral drugs are active against either DNA or RNA viruses, some (e.g., adefovir, ribavirin) are active against both.

B. DNA viruses. Currently approved antiviral therapies against the *Herpesviridae* family of DNA viruses—herpes simplex virus 1 and 2 (HSV-1, HSV-2), varicella-zoster virus (VZV), cytomegalovirus (CMV)—are **virustatic** and arrest DNA synthesis by inhibiting viral DNA polymerase. Many of these agents are prodrugs and require viral and host cellular enzymes (e.g., thymidine, deoxyguanosine kinase) to phosphorylate them into the active triphosphate form before exerting their antiviral activity. Hence, a common mechanism of resistance is a deficiency or

structural alteration in viral thymidine kinase (Table 44-5). Some of these agents also demonstrate activity against RNA viruses, including hepatitis C and HIV.

Table 44-5. Activity of Various Anti-DNA Viral Agents

Agent	HSV-1	HSV-2	VZV	CMV	Influenza A	Influenza B
Acyclovir[a]	+	+	+	—	—	—
Amantadine	—	—	—	—	+	—
Cidofovir	—	—	—	+	—	—
Famciclovir	+	+	+	—	—	—
Foscarnet	+	+	+	+	—	—
Ganciclovir[a]	—	—	—	+	—	—
Oseltamivir	—	—	—	—	+	+
Rimantadine	—	—	—	—	+	—
Valacyclovir[a]	+	+	+	—	—	—
Valganciclovir[a]	—	—	—	+	—	—
Zanamivir	—	—	—	—	+	+

HSV, herpes simplex virus, *VZV,* varicella-zoster virus; *CMV,* cytomegalovirus.

[a] Requires activation into triphosphate form.

1. Acyclovir (Zovirax) is a synthetic acyclic analog of guanosine with activity against various herpes viruses.

a. Mechanism of action. Acyclovir monophosphate is phosphorylated to the triphosphate, where it becomes incorporated into viral DNA and inhibits viral replication.

b. Spectrum of activity. This agent is active against herpes viruses, particularly HSV-1, HSV-2, VZV, and chickenpox (varicella).

c. Therapeutic uses

(1) Acyclovir is used to treat initial and recurrent HSV-1 and HSV-2 infections and for acute treatment of herpes zoster (shingles) and chickenpox. It is also used orally for long-term suppression of genital HSV infections.
(2) This agent is available in topical, oral, and IV forms. Topical acyclovir is applied directly on herpes lesions in recurrent herpes labialis (cold sores). It is not recommended for use on genital herpes lesions due to poor efficacy.
(3) Acyclovir may be administered intravenously in the treatment of initial and recurrent mucocutaneous HSV infection and VZV infection in immunocompromised patients, as well as in the treatment of HSV infections that are disseminated or affect the central nervous system.

d. Precautions and monitoring effects

(1) Oral acyclovir may induce nausea, vomiting, diarrhea, and headache.
(2) IV administration may cause dose-dependent renal impairment, crystalline nephropathy, neurological effects (e.g., lethargy, confusion, tremors, agitation, seizures, coma, obtundation), hypotension, rash, itching, and phlebitis at the injection site.
(3) Local discomfort and pruritus may result from topical administration.
(4) Acyclovir is removed by hemodialysis. Doses should be adjusted in renal impairment and hemodialysis.

e. Significant interactions. Probenecid reduces the renal clearance of acyclovir, resulting in increases in acyclovir half-life and serum concentration.

2. Adefovir dipivoxil (Hepsera) is a phosphonate nucleotide analog with activity against various DNA and RNA viruses.

a. Mechanism of action. Adefovir is phosphorylated to the active diphosphate form by cellular kinases. It is then incorporated into viral DNA, resulting in termination of replication.

b. Spectrum of activity and therapeutic uses

(1) Adefovir is active against hepatitis B virus (including lamivudine-resistant strains), herpes viruses, and HIV.
(2) However, adefovir is approved for use only for treatment of chronic hepatitis B infection in adults with evidence of active viral replication with persistently elevated liver function tests or histologically active disease.

c. Precautions and monitoring effects

(1) Severe acute hepatitis exacerbations have occurred in patients who discontinue therapy (**black box warning**). If therapy is discontinued, liver function tests must be monitored closely.
(2) Nephrotoxicity has been reported with adefovir, especially in patients with underlying renal dysfunction or those taking concomitant nephrotoxins (**black box warning**).

(3) Other adverse effects include rash, GI disturbances, headache, and weakness.
(4) Dose adjustment is required for renal insufficiency.
3. Amantadine (Symmetrel) is a synthetic tricyclic amine with a unique chemical structure similar to rimantadine. It is effective against influenza A viral infection.
a. Mechanism of action. Amantadine inhibits replication of the influenza A virus by interfering with viral attachment and uncoating.
b. Spectrum of activity and therapeutic uses
(1) Due to increasing rates of resistance, amantadine is no longer recommended for prophylaxis or treatment of influenza A virus.
(2) This drug may also be used to treat parkinsonism as well as drug-induced extrapyramidal symptoms.
c. Precautions and monitoring effects
(1) The most pronounced adverse effects of amantadine are ataxia, nightmares, and insomnia. Other CNS effects include depression, confusion, dizziness, fatigue, anxiety, and headache. Elderly patients may be at increased risk of CNS adverse reactions. Patients with a history of seizures or psychiatric disorders should be monitored closely during therapy.
(2) Anticholinergic reactions (e.g., dry mouth, blurred vision) have been reported.
(3) Dosage adjustment is needed for patients with impaired renal function.
4. Cidofovir (Vistide) is a synthetic acyclic purine nucleoside phosphonate derivative.
a. Mechanism of action. Cidofovir diphosphate suppresses CMV replication by selective inhibition of viral DNA synthesis.
b. Spectrum of activity. In vitro activity has been demonstrated against CMV, VZV, Epstein-Barr virus (EBV), and HSV-1 and HSV-2. Controlled clinical studies are limited to patients with AIDS and CMV retinitis.
c. Therapeutic use includes the treatment, but not the cure of, CMV retinitis in patients with AIDS.
d. Precautions and monitoring effects
(1) Avoid using this drug in patients with serum creatinine > 1.5 mg/dL or creatinine clearance (CrCl) ≤ 55 mL/min or in patients who are receiving (or have received in the past 7 days) nephrotoxic agents.
(2) Cidofovir is contraindicated in patients with a history of severe hypersensitivity to probenecid or sulfa-containing medications.
(3) The dose-limiting toxicity of cidofovir is **nephrotoxicity;** neutropenia, peripheral neuropathy, and diarrhea are common adverse effects.
(4) Probenecid must be administered before and after each cidofovir dose. The patient must be hydrated with 1 L of normal saline before infusing. Cidofovir is available only in IV form.
5. Entecavir (Baraclude) is a carbocyclic analog of guanosine used for treatment of chronic hepatitis B infection.

a. Mechanism of action. Once phosphorylated to the active triphosphate form, entecavir inhibits hepatitis B viral polymerase and ultimately halts hepatitis B DNA synthesis.

b. Spectrum of activity. Entecavir exhibits activity against hepatitis B virus, including lamivudine-resistant strains. Development of HIV resistance to nucleoside reverse transcriptase inhibitors is possible if entecavir is used without antiretroviral treatment in HIV and hepatitis B virus co-infection.

c. Therapeutic uses

(1) Entecavir is approved for treatment of chronic hepatitis B infection in adults with evidence of active viral replication and persistent elevations in liver function tests or histologically active disease.

(2) It is effective for patients who have failed treatment with lamivudine owing to resistance development.

(3) Entecavir is not recommended for use in patients with hepatitis B virus infection who are co-infected with HIV and are not receiving antiretroviral therapy.

d. Precautions and monitoring effects

(1) Severe acute exacerbations of hepatitis B have been observed in patients who discontinue therapy, necessitating close monitoring (**black box warning**).

(2) Common adverse effects include dizziness, fatigue, headache, and nausea.

(3) Dose adjustment is required for renal insufficiency.

(4) Counsel patients to take entecavir on an empty stomach.

6. Famciclovir (Famvir) is a prodrug of the antiviral agent penciclovir.

a. Mechanism of action. Famciclovir is rapidly phosphorylated in virus-infected cells by viral thymidine kinase to penciclovir monophosphate. Penciclovir is a competitive inhibitor of viral DNA polymerase and prevents viral replication by inhibition of herpes virus DNA synthesis.

b. Spectrum of activity and therapeutic uses

(1) Famciclovir has activity against HSV-1, HSV-2, and VZV. The drug is indicated for management of acute herpes zoster (shingles) and oral and genital herpes.

(2) Therapy must be promptly initiated as soon as herpes zoster is diagnosed (within 48-72 hr), at a dose of 500 mg every 8 hr for 7 days.

c. Precautions and monitoring effects

(1) Common adverse events include fatigue, GI complaints (nausea, diarrhea, vomiting, constipation), and anorexia. Headache is also commonly reported.

(2) Dose adjustment is necessary in patients with renal dysfunction. Famciclovir is removed by hemodialysis.

7. Foscarnet (Foscavir) is a synthetic pyrophosphate analog that directly inhibits enzymes involved in viral DNA synthesis without incorporation into viral DNA. It is a broad-spectrum antiviral agent and is an option in cases of acyclovir or ganciclovir resistance.

a. Mechanism of action

(1) Viral DNA replication requires the addition of deoxynucleoside triphosphates at the end of the DNA strand by DNA polymerase and the subsequent cleavage of pyrophosphate from the newly attached nucleotide. Foscarnet binds noncompetitively to DNA polymerase to form an inactive complex and prevents pyrophosphate cleavage. Viral DNA chain elongation is thus terminated.

(2) Foscarnet is also active against HIV. It is a noncompetitive, reversible inhibitor of HIV reverse transcriptase, the enzyme responsible for converting viral RNA to viral DNA.

b. Spectrum of activity and therapeutic uses. Foscarnet has in vitro activity against HSV-1 and HSV-2, CMV, VZV, EBV DNA polymerases, influenza polymerase, and HIV reverse transcriptase. Therapeutically, the drug is used to treat CMV disease as well as acyclovir-resistant HSV and VZV infections.

(1) Foscarnet is an alternative to ganciclovir and valganciclovir for treatment of CMV infection in immunocompromised patients. Foscarnet causes less hematologic toxicity than ganciclovir in patients who have received allogeneic stem cell transplants. An initial induction therapy lasts 2-3 weeks. Maintenance therapy is needed to prevent relapse.

(2) Foscarnet is indicated for the treatment of acyclovir-resistant mucocutaneous HSV in immunocompromised patients. It is not, however, a cure for HSV infections.

(3) Foscarnet is able to cross the blood-brain barrier.

c. Precautions and monitoring effects

(1) IV foscarnet is highly **nephrotoxic,** causing acute tubular necrosis. The incidence of acute renal failure can be markedly reduced if adequate hydration and daily monitoring of serum creatinine and BUN are maintained throughout therapy.

(2) Other common adverse effects include electrolyte abnormalities (e.g., hypocalcemia, hypomagnesemia, hypophosphatemia and hyperphosphatemia, hypokalemia), anemia, fever, headache, and seizures.

(3) Dose adjustment for renal dysfunction is required. Foscarnet is removed by hemodialysis.

(4) Foscarnet must be administered using an infusion pump over at least 1.5-2 hr. Do not administer the drug as an IV bolus.

d. Significant interactions

(1) Concomitant nephrotoxins (aminoglycosides, amphotericin B, etc.) increase the risk of renal toxicity.
(2) Foscarnet is exclusively eliminated by glomerular filtration; concurrent nephrotoxic agents should be avoided whenever possible.

8. Ganciclovir (Cytovene) is a synthetic purine nucleoside analog that is approved for the treatment and prophylaxis of CMV infections in immunocompromised patients (e.g., HIV-positive patients, transplant recipients).

a. Mechanism of action. After conversion to ganciclovir triphosphate, ganciclovir is incorporated into viral DNA, which inhibits viral DNA polymerase, thereby terminating viral replication.

b. Spectrum of activity. Ganciclovir has in vitro activity against HSV-1 and HSV-2, VZV, EBV, and CMV (owing to its enhanced ability to penetrate host cells).

c. Therapeutic uses. It is indicated for treatment of CMV retinitis in patients with HIV/AIDS. It is also used for prophylaxis of CMV infection in HIV-positive patients (secondary prophylaxis) and transplant recipients at risk for CMV disease.
(1) Conversion into the triphosphate form is greater in infected host cells, even though drug penetration occurs in both uninfected and infected cells.
(2) Inhibitory concentrations for the viral DNA polymerase are lower than those for the host cellular polymerase.
(3) It is available in oral and IV formulations as well as an intraocular implant. Although the oral formulation is approved for prevention and maintenance treatment of CMV, its poor bioavailability has limited its use. Valganciclovir has become the drug of choice for these indications, owing to its markedly improved bioavailability.

d. Precautions and monitoring effects
(1) Ganciclovir has a **black box warning** concerning increased potential for neutropenia, anemia, and thrombocytopenia. It is also teratogenic, carcinogenic, and mutagenic.
(2) Adverse effects commonly include fever, rash, and GI disturbances. Phlebitis and pain may occur at the site of infusion.
(3) Because ganciclovir is cleared by glomerular filtration and tubular secretion, renal function and adequate hydration should be monitored. Doses should be adjusted in cases of renal impairment and hemodialysis.
(4) Solutions of ganciclovir are extremely alkaline. Avoid direct contact with skin.

e. Significant interactions
(1) Probenecid may increase ganciclovir concentrations and possibly toxicity.
(2) Use of **zidovudine, azathioprine,** or **mycophenolate mofetil** in combination with ganciclovir may result in neutropenia; careful monitoring of neutrophil count is required when these are taken concurrently with ganciclovir.

(3) Imipenem-cilastatin in combination with ganciclovir may increase the potential for seizures.

9. Oseltamivir (Tamiflu) is pharmacologically similar to zanamivir but structurally different. Both of these agents are in a class known as the neuraminidase inhibitors and have a unique mechanism of action.

a. Mechanism of action. Oseltamivir is a prodrug that must be hydrolyzed to oseltamivir carboxylate in vivo to exert its antiviral activity. It is a potent selective inhibitor of the influenza virus enzyme, neuraminidase. Inhibition of this enzyme prevents viral replication and spread to other host cells.

b. Spectrum of activity. This agent is active against both influenza A and B viruses.

c. Therapeutic uses

(1) It is approved for the symptomatic treatment of influenza A and B infections in patients 1 year of age and older who present with symptoms within 48 hr.

(2) Oseltamivir has been shown to decrease the duration of symptoms by 1-2 days if taken within 48 hr of onset of viral symptoms.

(3) It is also approved for the prophylaxis of influenza infections in patients 1 year of age and older. *Note:* The influenza virus vaccine is still the gold standard for prophylaxis.

(4) Oseltamivir demonstrates some activity against strains of avian influenza, making it a possible option for treatment and prophylaxis.

d. Precautions and monitoring effects

(1) The most common adverse effects are nausea and vomiting. There have been post marketing reports of self-injury and delirium (mostly in Japan) among pediatric patients. Close monitoring for abnormal behavior is recommended.

(2) Dosage adjustments are required for patients with impaired renal function.

(3) Cross-resistance between oseltamivir and zanamivir has been reported.

10. Ribavirin (Rebetol, Copegus) is a synthetic nucleoside analog.

a. Mechanism of action. Ribavirin may inhibit RNA and DNA synthesis by depleting intracellular nucleotide reserves.

b. Spectrum of activity. This agent is active in vitro against a broad spectrum of DNA and RNA viruses, including influenza A and B, RSV, herpes simplex, and hepatitis C virus.

c. Therapeutic uses. The aerosolized form of ribavirin is no longer recommended for treatment of RSV in infants and children, owing to inconsistent clinical benefits observed in clinical trials. Combination therapy with oral ribavirin and subcutaneous interferon-α is effective in treatment of chronic hepatitis C.

d. Precautions and monitoring effects

(1) Common adverse effects of oral ribavirin include hemolytic anemia and GI disturbances. Hemoglobin and hematocrit should be monitored carefully, especially during the first 4 weeks of treatment.
(2) Ribavirin is teratogenic; its use is contraindicated in pregnancy.
(3) Ribavirin should be avoided in patients with a CrCl < 50 mL/min.
(4) Ribavirin should never be used as monotherapy in treatment of chronic hepatitis C.

11. Rimantadine (Flumadine) is a synthetic antiviral agent and an α-methyl derivative of amantadine that blocks the early step in the replication of the influenza A virus.

a. Mechanism of action. Rimantadine inhibits the early viral replication cycle, possibly inhibiting the uncoating of the virus. It has the same mechanism of action and spectrum of activity as amantadine.

b. Spectrum of activity and therapeutic uses

(1) Due to increasing rates of resistance, rimantadine is no longer recommended for prophylaxis or treatment of influenza A virus.
(2) Influenza vaccination is the method of choice for prevention of influenza infection.

c. Precautions and monitoring effects

(1) Rimantadine may increase the incidence of seizure in patients with seizure disorder.
(2) The most frequent adverse reactions include GI disturbance (e.g., nausea, vomiting, anorexia) and CNS toxicity (e.g., insomnia, dizziness, headache), which are less than those observed with amantadine.
(3) Dose reductions are recommended in patients with hepatic or renal dysfunction.

12. Telbivudine (Tyzeka) is a synthetic thymidine nucleoside analog used for treatment of chronic hepatitis B infection.

a. Mechanism of action. Telbivudine is phosphorylated into the active triphosphate form that inhibits hepatitis B viral DNA polymerase, with ultimate termination of the DNA chain and inhibition of viral replication.

b. Spectrum of activity.

(1) Telbivudine exhibits activity against hepatitis B virus but not HIV.
(2) There is a high incidence of cross-resistance between lamivudine-resistant hepatitis B virus and telbivudine.

c. Therapeutic uses.

(1) Telbivudine is indicated for treatment of chronic hepatitis B infection in adults with active viral replication and persistent elevations in liver function tests or histologically active disease.
(2) When compared with lamivudine, telbivudine produced a greater virologic response in controlled clinical trials.

d. Precautions and monitoring effects.

(1) There is a **black box warning** regarding severe exacerbations of hepatitis B in patients discontinuing therapy, requiring close monitoring.

(2) Common adverse effects include elevations in creatine phosphokinase, headache, fatigue, nausea, and vomiting.
(3) Dosage adjustment is required in patients with renal insufficiency.
(4) May be taken without regard to meals.

13. Valacyclovir (Valtrex) is the L-valyl ester prodrug of the antiviral agent acyclovir.

a. Mechanism of action. Valacyclovir is rapidly converted to acyclovir. Acyclovir is selective for the thymidine kinase enzyme, beginning the conversion of acyclovir to acyclovir triphosphate, stopping the replication of herpes viral DNA.

b. Spectrum of activity and therapeutic uses

(1) Valacyclovir is active against HSV-1, HSV-2, and VZV.
(2) This agent is used for the acute treatment of herpes zoster (shingles), herpes labialis (cold sores), and genital herpes in immunocompetent adults. It is also effective for suppression of recurrent episodes of genital herpes in immunocompetent and HIV-infected people as well as reduction of transmission of genital herpes.
(3) Advantages over acyclovir include oral dosing of only once to three times daily and attainment of higher plasma concentrations than oral acyclovir. A disadvantage is that there is no IV form available.

c. Precautions and monitoring effects

(1) Valacyclovir has caused thrombotic thrombocytopenic purpura/hemolytic uremic syndrome in immunocompromised individuals, including those with advanced HIV and transplant recipients.
(2) Begin therapy within 72 hr of herpes zoster rash onset.
(3) Most commonly reported adverse reactions are mild and include nausea, headache, and vomiting. Dosage adjustment is needed in patients with renal dysfunction.

14. Valganciclovir (Valcyte) is the L-valyl ester prodrug of the antiviral agent ganciclovir.

a. Mechanism of action. Valganciclovir is converted in vivo to ganciclovir. After conversion to the active form, ganciclovir triphosphate, ganciclovir is incorporated into viral DNA, which inhibits viral DNA polymerase, thereby terminating viral replication.

b. Spectrum of activity and therapeutic uses

(1) For in vitro activity, see VII.B.8.b.
(2) Valganciclovir is indicated for the treatment of CMV retinitis in patients with AIDS and for prevention of CMV after transplantation of kidney, heart, and kidneypancreas. It is not indicated for liver transplant recipients, due to an increased risk of tissue-invasive CMV as compared with ganciclovir.
(3) The markedly improved bioavailability of valganciclovir over oral ganciclovir has resulted in the widespread use of valganciclovir for treatment and prevention of CMV disease.

c. Precautions and monitoring effects

(1) Same **black box warnings** as for ganciclovir.

(2) Doses should be adjusted in cases of renal impairment. Do not use in hemodialysis patients; ganciclovir must be used.

(3) Only available orally. Do not substitute doses of oral valganciclovir 1:1 for oral ganciclovir; they are not equivalent.

(4) A potential carcinogen and teratogen; common adverse effects are the same as for ganciclovir.

(5) If the tablet is broken, avoid contact with skin owing to teratogenic and carcinogenic potential.

(6) Be aware of the potential for errors as a result of the look-alike and sound-alike names of valganciclovir and valacyclovir.

d. Significant interactions. Same as for ganciclovir; see VII.B.8.e.

15. Zanamivir (Relenza) is the first of a class of antiviral agents called neuraminidase inhibitors approved by the FDA for the treatment of influenza A and B infections in adults and children at least 7 years of age. It is also indicated for prevention of influenza in adults and children at least 5 years of age.

a. Mechanism of action. Zanamivir inhibits replication of the influenza A and B viruses by selective inhibition of the influenza virus neuraminidase enzyme.

b. Spectrum of activity. This agent is active against both the influenza A and B viruses. It demonstrates activity against avian influenza in animal studies.

c. Therapeutic uses

(1) It is approved for the treatment of uncomplicated influenza A and B infection for patients who have been symptomatic for < 48 hr. It is also indicated for influenza prophylaxis.

(2) Zanamivir is approved for oral inhalation use only, using the Diskhaler device provided by the manufacturer.

(3) Zanamivir may be considered for prevention or treatment of avian influenza.

(4) Shown to decrease duration of symptoms by approximately 1.5 days if taken within 48 hr of onset of viral symptoms.

d. Precautions and monitoring effects

(1) The use of zanamivir is generally not recommended in patients with a history of asthma or chronic obstructive pulmonary disease, owing to the risk of bronchospasm and acute decline in lung function.

(2) The most common adverse effects were mild and included diarrhea, nausea, and vomiting. The incidence of these was no different than placebo.

(3) Do not puncture the Rotadisk blister until immediately before administering the dose to ensure full dosage. Manual dexterity required for this device.

C. RNA viruses (HIV)

1. Currently, six classes of antiretroviral agents are approved. These drugs are active against HIV and include the nucleoside reverse transcriptase inhibitors (NRTIs) **abacavir, didanosine, emtricitabine, lamivudine, stavudine, zalcitabine,** and **zidovudine;** the nucleotide reverse transcriptase inhibitor (NtRTI) **tenofovir disoproxil fumarate;** the nonnucleoside reverse transcriptase inhibitors (NNRTIs) **delavirdine, efavirenz, nevirapine** and **etravirine;** and the protease inhibitors (PIs) **amprenavir, atazanavir, darunavir, fosamprenavir, indinavir, lopinavir/ritonavir, nelfinavir, ritonavir, saquinavir,** and **tipranavir;** the fusion inhibitor **enfuvirtide;** the entry inhibitor **maraviroc;** and the integrase inhibitor **raltegravir.**

2. These agents are virustatic and require lifelong therapy. They are currently approved for use in various combinations known as potent combination antiretroviral therapy.

a. Appropriate combinations include those that have demonstrated efficacy and safety in controlled clinical trials (Table 44-6).

b. Monotherapy with any single antiretroviral agent is unacceptable in the treatment of HIV infection owing to rapid development of viral resistance.

c. Before designing a treatment plan, a minimum of two $CD4^+$ cell counts and one HIV RNA level (viral load) should be obtained to confirm the initial measurements and determine if treatment should be initiated. After starting therapy, repeat these measurements in 2-8 weeks, followed by every 3-4 months thereafter.

d. A minimum of 1.0-$\log_{10}$ copies/mL decline in HIV RNA levels should be seen after the first 2-8 weeks of therapy for clinical response; a subsequent decrease to undetectable levels should be achieved by 16-24 weeks.

3. Reverse transcriptase inhibitors are classified as either nucleosides or nucleotides. These agents are competitive inhibitors of reverse transcriptase, which leads to chain termination when incorporated into the viral DNA chain. They are inactive until phosphorylated by human cellular kinases into the active triphosphate metabolite. Each agent has a corresponding three-letter acronym as well as a brand name. With the exception of abacavir, each agent in this class of antiretrovirals requires dosage adjustment in patients with renal dysfunction. **All agents in this class have a black box warning concerning the potential for development of lactic acidosis and severe hepatomegaly with steatosis.**

a. Abacavir (ABC; Ziagen) is a synthetic carbocyclic nucleoside analog indicated for the treatment of both adult and pediatric patients with HIV.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Abacavir is approved for use in adults and children ≥ 3 months of age only in combination with other antiretroviral agents.

(a) Abacavir is available alone or co-formulated as a combination tablet with lamivudine and zidovudine (Trizivir) which is dosed twice daily.

(b) Abacavir is also available in a combination tablet with lamivudine (Epzicom) which is dosed once daily.

(3) Precautions and monitoring effects. Abacavir has a **black box warning** for a life-threatening hypersensitivity reaction that can lead to death. It occurs in approximately 5% of patients taking this drug, typically within the first 6 weeks of therapy. This reaction involves respiratory symptoms, fever, rash, and GI complaints. Reexposure following these symptoms can mimic anaphylaxis and may result in death. Therefore, rechallenge is contraindicated. A Medication Guide describing this reaction should be dispensed with each new prescription and refill of abacavir-containing products. The HLA-B*5701 screening test should be used prior to initiating therapy to reduce the risk of this reaction.

Table 44-6. Department of Health and Human Services Guidelines for the Use of Antiviral Agents in HIV-1-Infected Adults and Adolescents

When to begin treatment
Treat any patient with history of AIDS defining illness
Treat any patients with $CD4^+$ cell count < 200/mm^3 or between 200-350/mm^3
Treat patients who are pregnant, have HIV-associated nephropathy or those co-infected with hepatitis B virus (when treatment for hepatitis B is indicated).
Note: The optimal time to start treatment in patients with $CD4^+$ cell count > 350/mm^3 is not well defined.
Regimen selection
Selection of a treatment regimen should be individualized for each patient based on adverse effect profiles, drug interactions, comorbidities, pill burden, etc. Preferred and alternative treatment regimens in previously

untreated patients are as follows:					
To select an antiretroviral regimen, select one component from Column A and one from Column B:					
Column A (NNRTI or PI Options)				**Column B (Dual NRTI Options)**	
Preferred Components	NNRTI Efavirenz[a]	or	PI Atazanavir or ritonavir Fosamprenavir + ritonavir (b.i.d.) Lopinavir/ritonavir (b.i.d.)	Preferred Components	Tenofovir/emtricitabine or abacavir/lamivudine
Alternative to Preferred Components	NNRTI Nevirapine[b]	or	PI Atazanavir Fosamprenavir Fosamprenavir/ritonavir (once daily) Lopinavir/ritonavir (once daily) Saquinavir + ritonavir	Alternative to Preferred Components	Zidovudine/lamivudine or didanosine + (emtricitabine or lamivudine)
Agents or combinations that should not be offered at any time					
All monotherapies					
2-NRTI regimens					
Abacavir + tenofovir + lamivudine as a triple NRTI regimen					
Tenofovir + didanosine + lamivudine as a triple NRTI regimen					

Saquinavir as the sole PI in a PI-based regimen
Zidovudine + stavudine
Didanosine + stavudine
Lamivudine + emtricitabine
Atazanavir + indinavir
2-NNRTI combination
Monitoring
Before initiating drug therapy, must obtain $CD4^+$ cell count and plasma HIV RNA levels plus complete blood count, chemistry, lipid profile, liver enzymes, and genotypic resistance testing
If HIV RNA does not reach undetectable levels (< 50 copies/mL) by 16-24 weeks, perform resistance testing, compliance assessment, and consider a regimen change
NNRTI, nonnucleoside reverse transcriptase inhibitor; *NRTI,* nucleoside reverse transcriptase inhibitor; *PI,* protease inhibitor.
[a] Cannot be used in the first trimester of pregnancy or in women who wish to conceive or are not using effective contraception. [b] Should not be initiated in women with pre-nevirapine $CD4^+$ cell counts > $250/mm^3$ or men with pre-nevirapine $CD4^+$ cell counts > $400/mm^3$ owing to high incidence of hepatic adverse effects.

(4) Significant interactions. Alcohol increases abacavir's AUC by 41%.

b. Didanosine (ddI; Videx), a synthetic purine analog, inhibits HIV replication and has a longer intracellular half-life (> 20 hr) than zidovudine (7 hr).

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Didanosine is approved for the treatment of adults and children only in combination with other antiretroviral agents.

(3) Precautions and monitoring effects

(a) Didanosine can cause reversible peripheral neuropathy and acute, potentially lethal pancreatitis (**black box warning**). Serum triglycerides should be monitored, and didanosine should be withheld when initiating potential pancreatitis-inducing agents (e.g., IV pentamidine, sulfonamides). Transiently elevated serum amylase may not reflect pancreatitis.

(b) Other adverse effects include headaches, diarrhea, nausea, and hyperuricemia (because didanosine is catalyzed to uric acid).

(c) Didanosine is available in an enteric coated capsule or buffered oral tablet formulation to prevent degradation at acidic pH. It must be taken on an empty stomach.

(d) Do not use in combination with stavudine or zalcitabine because of additive potential for toxicity.

(e) Do not use the combination regimen of didanosine and tenofovir in treatmentnaïve patients, owing to high rates of early virologic failure.

(4) Significant interactions. Pancreatitis-inducing drugs, **alcohol,** and **those known to cause peripheral neuropathy** should not be used with didanosine. Ribavirin should not be co-administered with didanosine.

c. Emtricitabine (FTC; Emtriva) is a synthetic nucleoside analog structurally related to lamivudine with activity against HIV infection.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Emtricitabine is indicated for use in HIV-infected adults and children in combination with other antiretroviral agents. It is available by itself or as a combination tablet with tenofovir (Truvada) and as a combination tablet with tenofovir and efavirenz (Atripla). Although it demonstrates activity against hepatitis B virus, it is not approved for use in treatment of this infection.

(3) Precautions and monitoring effects

(a) Adverse effects most commonly observed in clinical trials were mild-moderate and include headache, rash, diarrhea, and nausea. Hyperpigmentation of the palms or soles may occur.

(b) Serious acute exacerbations of hepatitis B have been documented in HIV/hepatitis B co-infected patients who discontinued therapy with emtricitabine (**black box warning**); therefore, liver function tests should be monitored for several months after discontinuation.

(4) Significant interactions. None have been identified.

d. Lamivudine (3TC; Epivir) is a synthetic nucleoside analog with activity against HIV and hepatitis B virus.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Lamivudine is indicated for use in HIV-positive adults and children > 3 months of age in combination

with other antiretroviral agents. It is also used in a lower dosage for the treatment of chronic hepatitis B in patients with active liver inflammation and evidence of hepatitis B viral replication.

(a) Lamivudine is available alone or within a twice daily combination tablet containing lamivudine, zidovudine and abacavir (Trizivir).

(b) Lamivudine is also available as a combination tablet with abacavir (Epzicom) and zidovudine (Combivir).

(3) Precautions and monitoring effects

(a) Reported adverse reactions are minor and include headache, fatigue, and GI reactions such as nausea, vomiting, and diarrhea. CNS toxicity includes neuropathy, dizziness, and insomnia. Lab test abnormalities such as neutropenia and elevations in liver enzymes have also been reported.

(b) Do not use in combination with zalcitabine owing to antagonism of effects.

(c) Lamivudine has the same **black box warning** regarding acute exacerbations of hepatitis B as emtricitabine (see VII.C.3.c).

(4) Significant interactions. Co-administration with **cotrimoxazole** results in increased lamivudine levels. No dose adjustment is required.

e. Stavudine (d4T; Zerit) is a synthetic thymidine nucleoside analog that is active against HIV.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Stavudine is indicated for use in combination with other antiretroviral agents in adults and children of all ages.

(3) Precautions and monitoring effects

(a) The major toxicity with stavudine is a dose related but reversible peripheral neuropathy occurring in up to 21% of patients.

(b) Other adverse effects include headache, rash, diarrhea, nausea, and vomiting.

(c) Fatal episodes of pancreatitis have been reported.

(4) Significant interactions. Do not use in combination with zidovudine or zalcitabine.

f. Tenofovir disoproxil fumarate (TDF; Viread) is an acyclic nucleoside phosphonate diester analog (**nucleotide**) with antiviral activity against HIV and hepatitis B virus.

(1) Mechanism of action. Tenofovir (a prodrug) is rapidly hydrolyzed by plasma esterases to tenofovir, with subsequent conversion to the active tenofovir diphosphate. *Note:* NtRTIs are active as the diphosphate, unlike the NRTIs, which require conversion to the triphosphate.

(2) Spectrum of activity and therapeutic uses. Tenofovir is approved for use in combination with other antiretroviral agents for the treatment of HIV in adults. It is also available as a once daily combination tablet containing

tenofovir and emtricitabine (Truvada) and tenofovir, emtricitabine, and efavirenz (Atripla).

(3) Precautions and monitoring effects

(a) Minor adverse effects have been reported in clinical trials. These include complaints of diarrhea, vomiting, and nausea.

(b) Additional adverse effects observed during postmarketing surveillance include acute renal failure and decreases in bone mineral density.

(c) Tenofovir has the same **black box warning** that emtricitabine has for patients with concomitant hepatitis B (see VII.C.3.c).

(d) Dose adjustment is required for renal insufficiency.

(4) Significant interactions

(a) Tenofovir increases **didanosine** serum concentrations, necessitating a dose reduction of didanosine.

(b) Tenofovir decreases serum concentrations of **atazanavir.** When these 2 agents are used together, ritonavir must be added to the regimen.

g. Zalcitabine (ddC; Hivid) is a synthetic pyrimidine nucleoside analogue that is active against HIV.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Zalcitabine is no longer recommended as a component of initial combination therapy of HIV owing to its severe adverse effect profile. The manufacturer discontinued its production in 2006.

(3) Precautions and monitoring effects

(a) The major clinical toxicity of zalcitabine is peripheral neuropathy, which occurs in up to 35% of patients and may be potentially disabling.

(b) Other adverse effects include pancreatitis, stomatitis, cardiomyopathy, and hypersensitivity reactions.

(c) Do not use in combination with lamivudine, stavudine, or zidovudine.

(4) Significant interactions

(a) Drugs that have the potential to cause peripheral neuropathy should be avoided. These include **chloramphenicol, cisplatin, dapsone, didanosine, disulfiram, hydralazine, isoniazid, metronidazole, nitrofurantoin, phenytoin, ribavirin,** and **vincristine.**

(b) Zalcitabine treatment should be interrupted when a drug with the potential to cause pancreatitis is initiated (i.e., **pentamidine**).

(c) Do not take with magnesium-, calcium-, or aluminum-containing antacids.

(d) Cimetidine and **probenecid** may increase zalcitabine levels, causing increased zalcitabine toxicity.

h. Zidovudine (AZT; Retrovir) is a synthetic thymidine analog. This agent was the first available drug for the treatment of HIV infection.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses

(a) Zidovudine is indicated in the treatment of adults and children > 6 weeks of age for the treatment of HIV.

(b) It is indicated for the prevention of maternal-fetal HIV transmission.

(c) Zidovudine is available as oral capsules, tablets, and solution as well as an IV solution.

(d) Oral zidovudine is also available as a co-formulation with lamivudine (Combivir) and with lamivudine and abacavir (Trizivir).

(3) Precautions and monitoring effects

(a) Zidovudine can cause severe bone marrow suppression, including macrocytic anemia and neutropenia after the first few weeks to months of therapy. The risk is increased in patients with preexisting bone marrow suppression or who are taking concomitant medications that cause bone marrow suppression.

(b) Erythropoietin can be considered as an adjunctive therapy in patients with zidovudine-induced anemia, in cases for which it cannot be discontinued.

(c) Other adverse effects include headache, malaise, seizures, anxiety, fever, and rash.

(d) Prolonged use may lead to symptomatic myopathy.

(4) Significant interactions

(a) Cotrimoxazole, atovaquone, valproic acid, methadone, and **probenecid** may increase zidovudine concentrations, causing increased risk of zidovudine toxicity.

(b) Other **cytotoxic drugs,** such as **ganciclovir, dapsone,** and **interferon-α,** can cause additive bone marrow suppression.

(c) Ribavirin, rifabutin, and rifampin may decrease levels of zidovudine.

4. Nonnucleoside reverse transcriptase inhibitors. The NNRTI class binds directly to and produces a noncompetitive inhibition of the HIV reverse transcriptase, leading to chain termination. These agents are indicated for use in adults and pediatric patients in combination with either NRTIs or possibly PIs. Efavirenz is considered a preferred NNRTI, whereas the others are currently recommended as alternatives. NNRTI-based regimens provide potent antiviral activity with less pill burden than many PI-based regimens. All NNRTIs may cause **rash and hepatotoxicity;** patients should be monitored closely for these adverse effects.

a. Delavirdine (Rescriptor)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Delavirdine is approved for use in adults in the treatment of HIV in combination with other antiretroviral agents. Its use has fallen out of favor owing to its three times daily dosing schedule.

(3) Precautions and monitoring effects

(a) In clinical trials, 4.3% of patients discontinued delavirdine because of rash. Cases of Stevens-Johnson syndrome have been reported.

(b) Other adverse effects include headache and nausea.

(4) Significant interactions

(a) The concentrations of the following medications are greatly increased by delavirdine and must be avoided: **alprazolam, midazolam, triazolam, simvastatin, lovastatin, rifabutin,** and **cisapride.**

(b) Decreased delavirdine concentrations result when it is administered with **St. John's wort, carbamazepine, phenobarbital, phenytoin,** or **rifampin.** Concomitant use should be avoided.

(c) Because delavirdine requires an acidic GI tract for optimal absorption, its use is contraindicated with **proton pump inhibitors** and **H_2-receptor antagonists.**

b. Efavirenz (Sustiva)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Efavirenz is approved for use in combination with other antiretroviral agents for the treatment of HIV infection in adults and pediatric patients (≥ 3 years of age). Its advantage over other NNRTIs is once-daily dosing. It is available alone or as a combination tablet with tenofovir and emtricitabine (Atripla).

(3) Precautions and monitoring effects

(a) Most common adverse effects are CNS-related (52%), including insomnia, dizziness, drowsiness, nightmares, and hallucinations, necessitating bedtime dosing to minimize these effects. These effects typically subside after 2-4 weeks of treatment.

(b) Owing to its teratogenic effects, efavirenz should be avoided in the first trimester of pregnancy and in women of childbearing potential who wish to conceive.

(c) Other adverse effects include rash, increased transaminases, and GI disturbances.

(4) Significant interactions

(a) Efavirenz induces and inhibits the cytochrome P450 3A4 isoenzyme system. It should not be used concomitantly with **cisapride, midazolam, triazolam,** or **ergot derivatives.**

(b) St. John's wort decreases efavirenz concentrations and should be avoided.

(c) Efavirenz decreases **methadone** concentrations by 60%; patients should be monitored for opiate withdrawal and have their doses titrated accordingly.

c. Etravirine (Intelence)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Etravirine is indicated for use in combination with at least two additional antiretroviral agents in treatment-experienced adults who demonstrate viral replication and

documented resistance to other NNRTIs. It is not for use in treatment-naïve patients.

(3) Precautions and monitoring effects.

(a) Adverse effects include nausea and rash.

(b) Since food increases the absorption of etravirine by 50%, it should be taken following a meal.

(4) Significant interactions.

(a) Etravirine induces and inhibits a variety of cytochrome P450 isoenzymes. It should not be used concomitantly with **carbamazepine, phenobarbital, phenytoin, unboosted PIs, atazanavir/ritonavir, fosamprenavir/ritonavir, tipranavir/ritonavir,** or **other NNRTIs.**

(b) St. John's wort and **rifampin** decrease etravirine concentrations and should be avoided.

(c) Etravirine may decrease serum concentrations of **methadone;** patients should be monitored closely.

d. Nevirapine (Viramune) was the first NNRTI approved for use by the FDA for the treatment of HIV infection.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Nevirapine is indicated in combination with other antiretrovirals in adult and pediatric (≥ 2 months old) HIV patients.

(3) Precautions and monitoring effects

(a) Nevirapine has the highest incidence of Stevens-Johnson syndrome of all NNRTIs.

(b) Symptomatic hepatitis, including fatal hepatic necrosis, has been observed with nevirapine (**black box warning**). The frequency of this adverse effect is increased in women with pre-nevirapine $CD4^+$ **counts > 250 cells/mm^3 and men with $CD4^+$ counts > 400 cells/mm^3. Nevirapine should not be initiated in these patients.**

(c) Other adverse effects include fever, nausea, and headache.

(d) To decrease the frequency of adverse effects, a 2-week dose escalation is required.

(4) Significant interactions

(a) Nevirapine induces cytochrome P450 3A4, resulting in decreased concentrations of **caspofungin, ketoconazole, itraconazole, oral contraceptives,** and **protease inhibitors.**

(b) Use of **rifampin** and **St. John's wort** should be avoided, as they decrease the serum concentrations of nevirapine.

(c) Methadone concentrations decrease significantly with nevirapine, often necessitating a dose increase.

5. Protease inhibitors. The PIs competitively inhibit the viral protease enzyme, preventing the enzyme from cleaving the gag and gag-pol

polyproteins necessary for virion production. PIs are used in combination with other antiretroviral agents, including other PIs, to suppress HIV replication. All of the PIs are cytochrome P450 inhibitors; ritonavir is the most potent inhibitor. All PIs are contraindicated with numerous drugs, including **simvastatin, lovastatin, rifampin, cisapride, pimozide, midazolam, triazolam, ergots,** and **St. John's wort.** Concomitant therapy with antiepileptic drugs, erectile dysfunction drugs, and azole antifungals must be undertaken with caution. Owing to the wide array of drug interactions with PIs, always assess medication profiles carefully for drug interactions before initiation.

a. Amprenavir (Agenerase)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Amprenavir is no longer recommended for use in treatment regimens for HIV due to its discontinuation in late 2007.

(3) Precautions and monitoring effects.

(a) Use of the oral solution in pregnant women, children < 4 years old, and patients with hepatic or renal insufficiency is contraindicated owing to the propylene glycol vehicle (**black box warning**).

(b) Because amprenavir is a sulfonamide, the potential for cross-sensitivity to other sulfonamides exists.

(c) Adverse effects include hyperlipidemia, hyperglycemia, fat maldistribution, rash, and GI disturbances.

(d) Dosage adjustment is required for hepatic insufficiency.

(4) Significant interactions (see VII.C.5). Amprenavir decreases **methadone** concentrations, possibly requiring a methadone dose increase to prevent withdrawal.

b. Atazanavir (Reyataz)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Atazanavir is a component of preferred and alternative PI-based regimens for HIV. It is dosed once daily.

(3) Precautions and monitoring effects.

(a) Atazanavir may prolong the PR interval and possibly cause first-degree AV block. Electrocardiogram (ECG) should be monitored.

(b) Other adverse effects include fat maldistribution, hyperglycemia, and indirect hyperbilirubinemia. In contrast to the other PIs, atazanavir appears to be devoid of effects on lipids.

(c) Dose adjustment is required for hepatic insufficiency.

(4) Significant interactions (see VII.C.5). Atazanavir is the most problematic of all PIs in terms of drug interactions.

(a) If used in combination with **efavirenz or tenofovir,** low-dose ritonavir must be administered concomitantly.

(b) Because atazanavir requires an acidic GI tract for optimal absorption, concomitant use of **proton pump inhibitors** is contraindicated. If other acid

suppressants are used with atazanavir, the doses must be separated by as much time as possible (up to 12 hr apart).

c. Darunavir (Prezista)

(1) Mechanism of action. See VII.C.5

(2) Spectrum of activity and therapeutic uses. Darunavir is the newest PI to receive FDA approval for the treatment of HIV. Its use is limited to highly treatment-experienced patients or patients with HIV resistance mutations.

(3) Precautions and monitoring effects

(a) Darunavir must be co-administered with ritonavir

(b) Because darunavir contains a sulfonamide moiety, cross-reactivity may occur in sulfa-allergic patients.

(c) Adverse effects include nausea, increased amylase, hepatotoxicity, hyperlipidemia, hyperglycemia, and rash.

(4) Significant interactions. See VII.C.5.

d. Fosamprenavir (Lexiva)

(1) Mechanism of action. See VII.C.5. Fosamprenavir is the prodrug of amprenavir.

(2) Spectrum of activity and therapeutic uses. Fosamprenavir has largely replaced amprenavir because of its improved dosing convenience. It is recommended as one of the preferred components in PI-based regimens for initial treatment of HIV.

(3) Precautions and monitoring effects

(a) Fosamprenavir may be dosed once daily in treatment naïve patients. PI-experienced patients require twice daily dosing. In most cases, fosamprenavir is administered with low dose ritonavir.

(b) Adverse effects are the same as those with amprenavir (see VII.C.5.a.(3). b, c and d).

(4) Significant interactions (see VII.C.3). If used in combination with **efavirenz,** fosamprenavir must be administered with a booster dose of ritonavir.

e. Indinavir (Crixivan)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Indinavir, in combination with ritonavir, is no longer recommended as part of regimen for patients receiving initial treatment for HIV due to a high incidence of nephrolithiasis.

(3) Precautions and monitoring effects

(a) Because indinavir may cause **nephrolithiasis** (kidney stones), patients should be instructed to drink at least 1.5 L of water daily to prevent this adverse effect.

(b) Indinavir can cause **indirect hyperbilirubinemia.** Combination therapy with atazanavir is not recommended owing to the potential for additive effects.

(c) Other adverse effects include hyperglycemia, hyperlipidemia, fat maldistribution, headache, and GI intolerance.
(d) Dose adjustment is required for hepatic insufficiency.
(4) Significant interactions (see VII.C.5). Vitamin C in doses > 1 g daily decreases indinavir concentrations. Caution patients not to exceed the recommended daily allowance for vitamin C.

f. Lopinavir/ritonavir (Kaletra)

(1) Mechanism of action. See VII.C.5.
(2) Spectrum of activity and therapeutic uses. This product is available as a co-formulation of lopinavir with a "booster" dose of ritonavir, which inhibits lopinavir metabolism and results in higher serum concentrations. Lopinavir/ritonavir is a preferred PI used in initial PI-based regimens owing to its potency and convenient dosing.
(3) Precautions and monitoring effects
(a) Lopinavir/ritonavir was recently reformulated as a film-coated tablet that does not require refrigeration. It is also available as an oral solution containing 42% alcohol.
(b) Adverse effects include GI intolerance, hyperlipidemia, hyperglycemia, fat maldistribution, and pancreatitis.
(4) Significant interactions. See VII.C.5.
(a) Lopinavir/ritonavir decreases **methadone** concentrations, possibly necessitating a methadone dose increase to prevent opiate withdrawal.
(b) Concomitant administration with **voriconazole** is contraindicated because of the risk of decreased voriconazole efficacy.
(c) Dosing varies due to drug interactions with concomitant use of efavirenz, nevirapine, fosamprenavir, or nelfinavir. Be sure to check appropriate references for proper dosing.

g. Nelfinavir (Viracept)

(1) Mechanism of action. See VII.C.5.
(2) Spectrum of activity and therapeutic uses. Nelfinavir is a possible component of an alternative PI-based regimen for initial treatment of adults with HIV infection. Unlike the other PIs, it is never used in combination with ritonavir. It is not generally recommended due to inferior virologic efficacy.
(3) Precautions and monitoring effects
(a) Diarrhea is commonly reported with nelfinavir. This can often be managed with antidiarrheals.
(b) Other adverse effects are similar to those with lopinavir/ritonavir.
(c) Use caution with look-alike, sound-alike names (nelfinavir and nevirapine).
(4) Significant interactions (see VII.C.5.) Nelfinavir decreases **methadone** concentrations, necessitating increased monitoring and dose adjustment if indicated.

h. Ritonavir (Norvir)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Ritonavir is rarely used as the sole PI in a PI-based regimen owing to its poor tolerability and high pill burden when administered in full doses. Alternatively, it is used in low doses as a pharmacokinetic boosting agent with other PIs. Because it is such a potent cytochrome 450 enzyme inhibitor, ritonavir markedly increases the serum concentrations of other PIs, resulting in higher concentrations with improved viral suppression.

(3) Precautions and monitoring effects

(a) Capsules should be refrigerated before dispensing. Capsules then may be stored at room temperature for up to 30 days.

(b) Oral solution should **not** be refrigerated.

(c) Adverse effects include GI intolerance, circumoral paresthesias, hyperlipidemia, hyperglycemia, fat maldistribution, increased liver function tests, and taste perversion.

(4) Significant interactions (see VII.C.5). Many drug interactions occur with ritonavir because it is such a potent inhibitor of so many cytochrome P450 isoenzymes. Always refer to proper resources to assess for drug interactions.

i. Saquinavir (Invirase)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Use of saquinavir without booster doses of ritonavir is not recommended because of the poor bioavailability of saquinavir.

(3) Precautions and monitoring effects

(a) Saquinavir is available as a hard gel capsule and tablet (Invirase) and was previously available as a soft gel capsule (Fortovase). The various dosage forms are **not bioequivalent** and cannot be used interchangeably.

(b) The soft gel capsule formulation is no longer manufactured (effective February 2006).

(c) Adverse effects are similar to lopinavir/ritonavir.

(4) Significant interactions. See VII.C.5.

j. Tipranavir (Aptivus)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. The use of tipranavir is limited to highly treatment-experienced patients with HIV who are resistant to other PIs as well as to other classes of antiretrovirals.

(3) Precautions and monitoring effects.

(a) Owing to the poor bioavailability of tipranavir, it must be co-administered with ritonavir.

(b) Capsules must be refrigerated. Once dispensed, they are stable at room temperature for up to 60 days.

(c) Tipranavir has been associated with clinical hepatitis and fatal hepatic decompensation (**black box warning**). Liver function tests should be monitored closely, especially in patients with underlying liver disease.
(d) Rarely, there have been reports of fatal and nonfatal intracranial hemorrhage with tipranavir (**black box warning**).
(e) Because the structure of tipranavir contains a **sulfonamide** moiety, cross-reactivity may occur in sulfa-allergic patients.
(f) Other adverse effects include rash, hyperlipidemia, hyperglycemia, and fat maldistribution.
(4) Significant interactions (see VII.C.5). Loperamide may decrease tipranavir concentrations.
6. Fusion inhibitors. Enfuvirtide (T-20; Fuzeon) is the first and only member of this class of antiretrovirals.
a. Mechanism of action. Enfuvirtide inhibits the entry of HIV into $CD4^+$ **cells by interfering with the fusion of viral and cellular membranes.**
b. Spectrum of activity and therapeutic uses. Enfuvirtide is primarily used in highly treatment-experienced patients with extensive viral resistance. It is not recommended for use as initial therapy in treatment-naive patients, as it has not been studied in this population.
c. Precautions and monitoring effects
(1) Enfuvirtide is injected subcutaneously twice daily. Local injection site reactions occur in almost all patients, including pain, redness, pruritus, and nodules.

(2) Other adverse effects include hypersensitivity reactions and increased rate of bacterial pneumonia.
(3) No dose adjustment is necessary for renal impairment.
d. Significant interactions. There are no significant drug interactions with enfuvirtide.
7. Entry inhibitor. Maraviroc (Selzentry) is the first and only member of this class of antiretroviral therapy.
a. Mechanism of action. Maraviroc is a chemokine receptor 5 (CCR5) coreceptor antagonist. It binds to the CCR5 receptor on the CD4 cell membrane, preventing entry of the virus into the cell.
b. Spectrum of activity and therapeutic uses. Maraviroc is used along with other antiretrovirals only in highly treatment-experienced adult patients who are infected with HIV that binds to the CCR5 receptor.
c. Precautions and monitoring effects.
(1) Hepatotoxicity was observed during clinical trials with maraviroc (**black box warning**). This may be preceded by a systemic allergic reaction. Patients should be evaluated immediately if either occurs.
(2) Use caution in patients with liver disease or cardiovascular risk factors.

(3) Adverse effects include cough, rash, fever, musculoskeletal symptoms, dizziness, and abdominal pain.
(4) Not recommended for use in patients with renal insufficiency unless no alternative option is available.
d. Significant interactions.
(1) Dosing for maraviroc varies depending upon concomitant medications that interact:
(a) When used with cytochrome P450 inhibitors, such as **PIs (except tipranavir/ritonavir), delavirdine, ketoconazole, itraconazole, and clarithromycin,** administer maraviroc 150 mg twice daily.
(b) When used with cytochrome P450 inducers (such as **carbamazepine, phenobarbital, phenytoin, efavirenz, and rifampin**) without a strong cytochrome P450 inhibitor, administer maraviroc 600 mg twice daily.
(c) When used with other medications, including tipranavir/ritonavir, nevirapine, NRTIs, and enfuvirtide, administer maraviroc 300 mg twice daily.
(2) Concomitant administration with **St. John's wort** is not recommended due to reduction in maraviroc serum concentrations.
8. Integrase inhibitor. Raltegravir (Isentress) is the first and only member of this class of antiretroviral therapy.
a. Mechanism of action. Raltegravir inhibits the viral enzyme integrase, thereby preventing the insertion of HIV genetic material into the CD4 cell genome and halting the viral replication process.
b. Spectrum of activity and therapeutic uses. Raltegravir is used along with other antiretrovirals only in treatment-experienced adult patients who demonstrate resistant strains of HIV.
c. Precautions and monitoring effects.
(1) Since elevations in creatine kinase, along with myopathy and rhabdomyolysis, may occur with raltegravir, use with caution in patients who are receiving concomitant medications that may cause these adverse effects.
(2) The most common adverse effects include nausea, diarrhea, headache, and fever.
d. Significant interactions. Rifampin decreases the serum concentration of raltegravir and should be used with caution.

VIII. Anthelmintics

A. Definition. These drugs are used to rid the body of worms (**helminths**). These agents may act locally to rid the GI tract of worms or work systemically to eradicate worms that are invading organs or tissues.
B. Mebendazole (Vermox) is a synthetic benzimidazole-derivative anthelmintic.
1. Mechanism of action. Mebendazole interferes with reproduction and survival of helminths by inhibiting the formation of microtubules and

irreversibly blocking glucose uptake, thereby depleting glycogen stores in the helminth.

2. Spectrum of activity. Mebendazole is active against various nematodes that are pathogenic to humans, including *Ancylostoma duodenale* (common hookworm), *Ascaris lumbricoides*

(roundworm), *Capillaria philippinensis* (Philippine threadworm), *Enterobius vermicularis* (pinworm), *Necator americanus* (American hookworm), and *Trichuris trichiura* (whipworm).

3. Therapeutic uses. Mebendazole is used for the treatment of single or mixed infections with the helminths listed in VIII.B.2. Immobilization and subsequent death of helminths are slow, with complete GI clearance up to 3 days after therapy.

4. Precautions and monitoring effects

a. In cases of massive infection, abdominal pain, nausea, and diarrhea associated with expulsion of organisms may result.

b. Myelosuppression (neutropenia and thrombocytopenia) can occur with high doses (40-50 mg/kg/day).

c. If the patient is not cured in 3 weeks, retreatment is necessary.

5. Significant interactions. Agents that may reduce the serum concentrations and subsequent efficacy of mebendazole include carbamazepine and phenytoin.

C. Albendazole (Albenza) is a synthetic benzimidazole-derivative anthelmintic.

1. Mechanism of action. See VIII.B.1.

2. Spectrum of activity. Albendazole is active against *Taenia solium* (pork tapeworm) and *Echinococcus granulosus* (dog tapeworm).

3. Therapeutic uses. Albendazole is used to treat parenchymal neurocysticercosis in combination with corticosteroids as well as cystic hydatid disease (before and after surgical removal of the disease).

4. Precautions and monitoring effects

a. The drug should be administered with a fatty meal to achieve optimal absorption.

b. Hepatotoxicity occurs in 16% of patients; liver function tests every 2 weeks are recommended while taking albendazole.

c. Rarely, leukopenia, thrombocytopenia, granulocytopenia, pancytopenia, and agranulocytosis occur. A CBC should be checked every 2 weeks while taking albendazole.

D. Diethylcarbamazine citrate (Hetrazan)

1. Mechanism of action. Diethylcarbamazine citrate is a synthetic organic compound highly specific for several common parasites.

2. Spectrum of activity. This agent is active against *Wuchereria bancrofti, Onchocerca volvulus, Brugia malayi, Mansonella perstans, Mansonella ozzardi, Ascaris lumbricoides,* and *Loa loa.*

3. Therapeutic uses. Diethylcarbamazine citrate is used for the treatment of Bancroft's filariasis, onchocerciasis, ascariasis, and loiasis. It is available directly from the manufacturer for compassionate use only.

4. Precautions and monitoring effects

a. Patients treated for *W. bancrofti* infection often present with headache and general malaise. Severe allergic phenomena in conjunction with a skin rash have been reported.

b. Patients treated for onchocerciasis present with pruritus, facial edema, and systemic symptoms secondary to the inflammatory response caused by pathogen death (known as a **Mazzotti reaction**). Severe reactions may be noted after a single dose. For this reason, ivermectin is used to treat onchocerciasis.

c. Children who are undernourished or are suffering from debilitating ascariasis infection may experience giddiness, malaise, nausea, and vomiting after treatment. Other drugs are available to treat *Ascaris* (mebendazole and albendazole).

E. Pyrantel (Pin-Rid) is a pyrimidine-derivative anthelmintic.

1. Mechanism of action. Pyrantel is a depolarizing neuromuscular blocking agent that causes a spastic paralysis of the helminth.

2. Spectrum of activity. Pyrantel is active against *A. lumbricoides* (roundworm), *E. vermicularis* (pinworm), *A. duodenale* (hookworm), *N. americanus* (hookworm), and *Trichostrongylus orientalis* (hairworm).

3. Therapeutic uses. Pyrantel is used for the treatment of roundworm, pinworm, and hookworm infections.

4. Precautions and monitoring effects

a. Most commonly reported reactions include anorexia, nausea, vomiting, diarrhea, headache, and rash.

b. A single dose may be mixed with food, milk, juice, or taken on an empty stomach.

F. Thiabendazole (Mintezol), a pyrazinoisoquinoline derivative, is a synthetic heterocyclic anthelmintic.

1. Mechanism of action is not known precisely. Thiabendazole is shown to inhibit the helminth-specific enzyme, fumarate reductase. Thiabendazole also demonstrates anti-inflammatory, antipyretic, and analgesic effects.

2. Spectrum of activity. It is active against most intestinal nematodes, including *Ancylostoma braziliense* (dog and cat hookworm), *A. duodenale* (hookworm), *A. lumbricoides* (roundworm), *E. vermicularis* (pinworm), *N. americanus* (hookworm), *Strongyloides stercoralis* (threadworm), *T. trichiura* (whipworm), *T. spiralis,* and *Toxocara canis* and *Toxocara cati* (dog and cat roundworms).

3. Therapeutic uses. Thiabendazole is used for the treatment of strongyloidiasis (threadworm infection), cutaneous larva migrans (creeping

eruption), and visceral larva migrans. It is used for the treatment of uncinariasis (hookworm), *N. americanus, A. duodenale,* trichuriasis (whipworm), and ascariasis (large roundworm) when more specific therapy is unavailable or further treatment is required with a second agent.

4. Precautions and monitoring effects

a. Adverse effects of thiabendazole are usually mild and transient, occurring 3-4 hr after the drug has been administered and lasting for 2-8 hr.

b. Most common reactions include anorexia, nausea, vomiting, and dizziness.

c. Giddiness, seizures, vertigo, paresthesias, and psychic disturbances may also occur, but less frequently.

d. If hypersensitivity develops, the drug should be discontinued. Erythema multiforme (including Stevens-Johnson syndrome) has been reported.

5. Significant interactions. Serum **xanthine** levels (theophylline and caffeine) may increase.

G. Ivermectin (Stromectol)

1. Mechanism of action. Ivermectin potentiates the inhibitory effects of γ-aminobutyric acid (GABA) in various nematodes and arthropods, resulting in paralysis and death of the organisms.

2. Spectrum of activity. This agent is active against *S. stercoralis* (intestinal forms only) and *O. volvulus* (immature forms only). It is also useful for treatment of infections with *A. lumbricoides, E. vermicularis, M. ozzardi, T. trichiura,* and *W. bancrofti.*

3. Therapeutic uses

a. Ivermectin is useful for treatment of infections with the parasites listed in VIII.G.2.

b. Two studies demonstrated that ivermectin was more effective than albendazole for treatment of strongyloidiasis.

c. Ivermectin is often favored over diethylcarbamazine citrate owing to its less severe adverse effect profile.

4. Precautions and monitoring effects,

a. May cause a **Mazzotti reaction** (see VIII.D.4.b) that is less severe than with diethylcarbamazine citrate.

b. Reports of serious and possibly fatal encephalopathy have occurred in patients with concomitant *L. loa* infection

c. Other adverse effects include edema, dizziness, headache, rash, and GI disturbances.

d. Counsel patients to take ivermectin with water.

H. Praziquantel (Biltricide)

1. Mechanism of action. Praziquantel increases cell membrane permeability in susceptible helminths, with loss of intracellular calcium and paralysis of their musculature. Vacuolization and disintegration of the schistosome tegument result, followed by attachment of phagocytes to the parasite and death.

2. Spectrum of activity. Praziquantel is active against trematodes (flukes), including all *Schistosoma* spp. and *Clonorchis sinensis, Opisthorchis viverrini, Fasciola hepatica* (liver flukes), *Paragonimus uterobilateralis, Paragonimus westermani* (lung flukes), *Metagonimus yokogawai, Fasciolopsis buski,* and *Heterophyes heterophyes* (intestinal flukes).

3. Therapeutic uses. Praziquantel is active in treating all types of schistosomiasis that are pathogenic to humans; clonorchiasis and opisthorchiasis (Chinese and southeast Asian liver flukes); many other types of infections involving intestinal, liver, and lung flukes; and cestodiasis (tapeworm) infections.

4. Precautions and monitoring effects

a. Treatment of ocular cysticercosis is contraindicated because parasite destruction within the eyes may cause irreparable lesions.

b. In general, adverse effects are generally mild and well tolerated. It is difficult to differentiate between effects caused by the praziquantel versus effects demonstrated by dying parasites.

c. The most common side effects are transient and may include malaise, headache, dizziness, and abdominal discomfort.

d. Praziquantel may impair activities that require mental alertness.

STUDY QUESTIONS

Directions for questions 1-12: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Isoniazid is a primary antitubercular agent that

(A) requires pyridoxine supplementation.

(B) may discolor the tears, saliva, urine, or feces orange red.

(C) causes ocular complications that are reversible if the drug is discontinued.

(D) may be ototoxic and nephrotoxic.

(E) should never be used because of hepatotoxic potential.

View Answer***1. The answer is A[see V.B.2.d.(5)].*****2. All of the following factors may increase the risk of nephrotoxicity from gentamicin therapy *except* which one?**

(A) age > 70 years

(B) prolonged courses of gentamicin therapy

(C) concurrent amphotericin B therapy

(D) trough gentamicin levels < 2 mg/mL

(E) concurrent cisplatin therapy

View Answer***2. The answer is D[see].*****3. In which of the following groups do all four drugs warrant careful monitoring for drug-related seizures in high-risk patients?**

(A) penicillin G, imipenem, amphotericin B, metronidazole

(B) penicillin G, chloramphenicol, tetracycline, vancomycin

(C) imipenem, tetracycline, vancomycin, sulfadiazine

(D) cycloserine, metronidazole, vancomycin, sulfadiazine

(E) metronidazole, imipenem, doxycycline, erythromycin

View Answer***3. The answer is A[see II.E.1.e.(2); II.J.5.d.(2);].*****4. AC is a 34-year-old male admitted with a diagnosis of peritonitis. Cultures are positive for *Bacteroides fragilis, Enterococcus faecalis,* and *Staphylococcus aureus.* Which of the following would be the best initial therapy to recommend?**

(A) telithromycin

(B) quinupristin/dalfopristin

(C) tigecycline

(D) trimethoprim/sulfamethoxazole

(E) kanamycin

View Answer***4. The answer is C[see].*****5. TJ is a 45-year-old female presenting with an *Enterobacter aerogenes* bacteremia with a low-grade fever (101.6°F). The most appropriate management of her fever would be to**

(A) give acetaminophen 1000 mg orally every 6 hr.

(B) give aspirin 650 mg orally every 4 hr.

(C) give alternating doses of aspirin and acetaminophen every 4 hr.

(D) withhold antipyretics and use the fever curve to monitor her response to antibiotic therapy.

(E) use tepid water baths to reduce the fever.

View Answer***5. The answer is D[see].*****6. BC has an upper respiratory infection. Two years ago, she experienced an episode of bronchospasm after penicillin therapy. Current cultures are positive for a strain of *Streptococcus pneumoniae* that is sensitive to all of the following drugs. Which of these drugs would be the best choice for this patient?**

(A) amoxicillin/clavulanate

(B) telithromycin

(C) ampicillin

(D) cefaclor

(E) loracarbef

View Answer***6. The answer is B[see II.K. 12].*****7. All of the following drugs are appropriate therapies for a lower urinary tract infection owing to *Pseudomonas aeruginosa except***

(A) norfloxacin.

(B) trimethoprim-sulfamethoxazole.

(C) ciprofloxacin.

(D) tobramycin.

(E) methenamine mandelate.

View Answer***7. The answer is B[seeand].P. aeruginosa.*****8. BT is a 43-year-old female seen by her primary-care physician for a mild staphylococcal cellulitis on the arm. Which of the following regimens would be appropriate oral therapy?**

(A) dicloxacillin 125 mg every 6 hr

(B) vancomycin 250 mg every 6 hr

(C) methicillin 500 mg every 6 hr

(D) cefazolin 1 g every 8 hr

(E) penicillin V 500 mg every 6 hr

View Answer***8. The answer is A[see].***P.980

9. RC is a 33-year-old male with a history of HIV for 10 years who now presents with *Mycobacterium avium-intracellulare* (MAI). Which of the following drugs has demonstrated in vitro activity against MAI?

(A) daptomycin

(B) clarithromycin

(C) erythromycin base

(D) cloxacillin

(E) minocycline

View Answer***9. The answer is B[see II.D.6.a-b].Toxoplasma gondiiCryptosporidium*****10. All of the following statements regarding pentamidine isethionate are true *except* which one?**

(A) It is indicated for treatment or prophylaxis of infection owing to *Pneumocystis carinii.*

(B) It may be administered intramuscularly, intravenously, or by inhalation.

(C) It has no clinically significant effect on serum glucose.

(D) It is effective in the treatment of leishmaniasis.

View Answer***10. The answer is C[see].P. carinii.*****11. RE is a 23-year-old male with a history of influenza A infections. An outbreak of influenza A has just been reported in his community, and he is exhibiting initial symptoms of the infection. Which agent would be the most useful to treat RE?**

(A) cidofovir

(B) famciclovir

(C) oseltamivir

(D) foscarnet

(E) ribavirin

View Answer***11. The answer is C[see].*****12. Dr. Jones requests your help in prescribing a protease inhibitor for his patient. He has heard that not all agents are the same and asks for your recommendation as**

to which agent would be least likely to cause the patient's cholesterol to increase. Which agent would you recommend?

(A) saquinavir

(B) ritonavir

(C) indinavir

(D) nelfinavir

(E) atazanavir

View Answer***12. The answer is E[see].*****Directions for questions 13-14:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

13. Drugs usually active against penicillinase-producing *Staphylococcus aureus* include which of the following?

(I) piperacillin-tazobactam

(II) amoxicillin-clavulanate

(III) nafcillin

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***13. The answer is E(I, II, III) [seeand].S. aureus*****14. Antiviral agents that are active against cytomegalovirus (CMV) include which of the following?**

(I) ganciclovir

(II) foscarnet

(III) acyclovir

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***14. The answer is C(I and II) [seeand].*****Directions for questions 15-17:** Each description listed in this section is most closely associated with **one** of the following drugs. The drugs may be used more than once or not at all. Choose the **best** answer, **A-E.**

15. It may be administered once per day for the treatment of urinary tract infections.

A clofazimine

B itraconazole

C lomefloxacin

D neomycin

View Answer***15. The answer is C[see].*****16. It may cause pink to brownish skin pigmentation within a few weeks of initiation of therapy.**

A clofazimine

B itraconazole

C lomefloxacin

D neomycin

View Answer***16. The answer is A[see II.J. 9].Mycobacterium*17. Co-administration with astemizole or terfenadine may lead to life-threatening cardiac dysrhythmias.**

A clofazimine

B itraconazole

C lomefloxacin

D neomycin

View Answer***17. The answer is B[see].***P.981

ANSWERS AND EXPLANATIONS

1. The answer is A *[see V.B.2.d.(5)].*

Isoniazid increases the excretion of pyridoxine, which can lead to peripheral neuritis, particularly in poorly nourished patients. Pyridoxine (a form of vitamin B_6) deficiency may cause convulsions as well as the neuritis, involving synovial tenderness and swelling. Treatment with the vitamin can reverse the neuritis and prevent or cure the seizures.

2. The answer is D *[see* II.B.4.b*].*

Trough serum levels < 2 mg/mL are considered appropriate for gentamicin and are recommended to minimize the risk of toxicity from this aminoglycoside. Because aminoglycosides accumulate in the proximal tubule of the kidney, nephrotoxicity can occur.

3. The answer is A *[see II.E.1.e.(2); II.J.5.d.(2);* III.B.4.b; IV.C.3.c*].*

Seizures have been attributed to the use of penicillin G, imipenem, amphotericin B, and metronidazole. Seizures are especially likely with high doses in patients with a history of seizures and in patients with impaired drug elimination.

4. The answer is C *[see* II.K.13*].*

Although active against various gram-positive and negative organisms, tigecycline is only agent approved for the treatment of intra-abdominal infections caused by these organisms.

5. The answer is D *[see I.H. 1].*

The fever curve is useful for monitoring a patient's response to antimicrobial therapy. Antipyretics can be used to reduce high fever in patients at risk for complications (e.g., seizures) or, in some cases, to make the patient more comfortable.

6. The answer is B *[see* II.K. 12*].*

Amoxicillin and ampicillin are all penicillins and should be avoided in patients with histories of hypersensitivity to other penicillin compounds. Although the risk of cross-reactivity with cephalosporins (e.g., cefaclor, loracarbef) is now considered low, most clinicians avoid the use of these agents in patients with histories of type I hypersensitivity reactions (e.g., anaphylaxis, bronchospasm, giant hives).

7. The answer is B *[see* II.E.4; II.H.3.a *and* b; II.I.2.a; II.I.3.a; II.J.7*].*
Norfloxacin, ciprofloxacin, tobramycin, and methenamine mandelate achieve urine concentrations high enough to treat urinary tract infections caused by *P. aeruginosa.* Trimethoprim-sulfamethoxazole is not useful for treating infection caused by this organism, although the combination is useful for treating certain other urinary tract infections.
8. The answer is A *[see* II.C; II.E. 1.c.(3); II.E.2.b; II.J.8*].*
Although vancomycin, methicillin, and cefazolin have excellent activity against staphylococci, they are not effective orally for systemic infections. Vancomycin is prescribed orally for infections limited to the gastrointestinal tract, but because it is poorly absorbed orally, it is not effective for systemic infections. Most hospital- and community-acquired staphylococci are currently resistant to penicillin. Thus of the drugs listed, the most appropriate drug for oral therapy of staphylococcal cellulitis is dicloxacillin.
9. The answer is B *[see II.D.6.a-b].*
Clarithromycin, an alternative to erythromycin, has demonstrated in vitro activity against MAI. Clarithromycin is also used against *Toxoplasma gondii* and *Cryptosporidium* spp., and it is more active than erythromycin against staphylococci and streptococci. Vancomycin and cloxacillin are used to treat staphylococci and streptococci, but has no demonstrated activity versus MAI.
10. The answer is C *[see* IV.D*].*
Pentamidine isethionate is indicated for both treatment and prophylaxis of infection from *P. carinii.* It can be administered intramuscularly, intravenously, or by inhalation. Inhalation may produce bronchospasm. Blood glucose should be carefully monitored because pentamidine may produce either hyperglycemia or hypoglycemia.

11. The answer is C *[see* VII.B.9*].*
Cidofovir, famciclovir, and foscarnet have little or no in vivo activity against influenza A. Ribavirin has some activity but is a second-line agent for influenza A and is mainly indicated for treatment of hepatitis C in combination with interferon. Oseltamivir is an agent that demonstrates activity against influenza A and B. It is indicated for the prophylaxis and treatment of influenza infections.
12. The answer is E *[see* VII.C.5.b.(3).(b)*].*
The majority of protease inhibitors cause hyperlipidemia. Atazanavir does not cause this adverse effect and may be preferred in certain clinical situations.
13. The answer is E *(I, II, III) [see* II.E.2, 3 *and* 4*].*
Piperacillin and amoxicillin each include a β-lactamase inhibitor. These combinations offer activity against *S. aureus* similar to that of the penicillinase-resistant penicillins, such as nafcillin.
14. The answer is C *(I and II) [see VII.B. 1;* VII.B.7 *and* 8*].*
Only ganciclovir and foscarnet are active against CMV infections. These agents are virustatic and arrest DNA synthesis by inhibiting viral DNA polymerase. Foscarnet is

a broad-spectrum antiviral agent and is used in patients with ganciclovir resistance. Acyclovir is not clinically useful for the treatment of CMV infections because CMV is relatively resistant to acyclovir in vitro.

15. The answer is C *[see* II.H.3.c*].*

Lomefloxacin may be administered daily for treating urinary tract infections. Enoxacin is another fluoroquinolone used to treat urinary tract infections. Compared to other fluoroquinolones, neither lomefloxacin nor enoxacin improves the spectrum of activity.

16. The answer is A *[see II.J. 9].*

Because clofazimine contains phenazine dye, it can cause pink to brown skin pigmentation. This change in pigmentation occurs in 75%-100% of patients taking clofazimine, and it occurs within a few weeks of the initiation of therapy. The discoloration of skin has reportedly led to severe depression and even suicide in some patients. Clofazimine is used in the treatment of leprosy and several atypical *Mycobacterium* infections.

17. The answer is B *[see* III.E.5.d*].*

Administration of itraconazole or ketoconazole with astemizole or terfenadine may increase the level of astemizole or terfenadine, which can lead to life-threatening dysrhythmias and death. Itraconazole, which is an imidazole, is a fungistatic agent. Specifically, itraconazole can be taken orally to treat aspergillosis infections and other deep fungal infections, such as blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis.

Infectious Diseases

Paul F. Souney

Anthony E. Zimmermann

Linda M. Spooner

I. Principles of Anti-Infective Therapy

A. Definition. Anti-infective agents treat infection by suppressing or destroying the causative microorganisms—bacteria, mycobacteria, fungi, protozoa, or viruses. Anti-infective agents derived from natural substances are called antibiotics; those produced from synthetic substances are called antimicrobials. These two terms are now used interchangeably.

B. Indications. Confirm the presence of infection by completing a careful history and physical examination, searching for signs and symptoms of infection as well as predisposing factors. Anti-infective agents should be used only when

1. A significant infection has been diagnosed or is strongly suspected
2. An established indication for prophylactic therapy exists

C. Gram stain, microbiological culturing, and susceptibility tests should be performed before anti-infective therapy is initiated. Test materials must be obtained by a method that avoids contamination of the specimen by the patient's own flora.

1. Gram stain. Performed on all specimens except blood cultures, the gram stain helps identify the cause of infection immediately. By determining if the causative agent is gram positive or gram negative, the test allows a better choice of drug therapy, particularly when an anti-infective regimen must begin without delay.

a. Gram-positive microorganisms stain blue or purple.

b. Gram-negative microorganisms stain red or rose-pink.

c. Fungi may also be identified by gram stain.

2. Microbiological cultures. To identify the specific causative agent, specimens of body fluids or infected tissue are collected for analysis.

3. Susceptibility tests. Different strains of the same pathogenic species may have widely varying susceptibility to a particular anti-infective agent. Susceptibility tests determine microbial susceptibility to a given drug and thus can be used to predict whether the drug will combat the infection effectively.

a. Microdilution method. The drug is diluted serially in various media containing the test microorganism.

(1) The lowest drug concentration that prevents microbial growth after 18-24 hr of incubation is called the minimum inhibitory concentration (MIC).

(2) The lowest drug concentration that reduces bacterial density by 99.9% is called the minimum bactericidal concentration (MBC).

(3) Breakpoint concentrations of antibiotics are used to characterize antibiotic activity: The interpretive categories are susceptible, moderately susceptible (intermediate), and resistant. These concentrations are determined by considering pharmacokinetics, serum and tissue concentrations following normal doses, and the population distribution of MICs of a group of bacteria for a given drug.

b. Kirby-Bauer disk diffusion technique. This test is less expensive but less reliable than the microdilution method; however, it provides qualitative susceptibility information.

(1) Filter paper disks impregnated with specific drug quantities are placed on the surface of agar plates streaked with a microorganism culture. After 18 hr, the size of

a clear inhibition zone is determined; drug activity against the test strain is then correlated to zone size.

(2) The Kirby-Bauer technique does not reliably predict therapeutic effectiveness against certain microorganisms (e.g., Staphylococcus aureus, Shigella).

D. Choice of agent. An anti-infective agent should be chosen on the basis of its pharmacological properties and spectrum of activity as well as on various host (patient) factors (Figure 44-1).

1. Pharmacological properties include the drug's ability to reach the infection site and to attain a desired level in the target tissue.

2. Spectrum of activity. To treat an infectious disease effectively, an anti-infective drug must be active against the causative pathogen. Susceptibility testing or clinical experience in treating a given infection may suggest the effectiveness of a particular drug.

3. Patient factors. Selection of an anti-infective drug regimen must take various patient factors into account to determine which type of drug should be administered, the correct drug dosage and administration route, and the potential for adverse drug effects.

a. Immunological status. A patient with impaired immune mechanisms may require a drug that rapidly destroys pathogens (i.e., bactericidal agent) rather than one that merely suppresses a pathogen's growth or reproduction (i.e., bacteriostatic agent).

b. Presence of a foreign body. The effectiveness of anti-infective therapy is reduced in patients who have prosthetic joints or valves, cardiac pacemakers, and various internal shunts.

c. Age. A drug's pharmacokinetic properties may vary widely in patients of different ages. In very young and very old patients, drug metabolism and excretion commonly decrease. Elderly patients also have an increased risk of suffering ototoxicity when receiving certain antibiotics.

d. Underlying disease

(1) Preexisting kidney or liver disease increases the risk of nephrotoxicity or hepatotoxicity during the administration of some antibacterial drugs.
(2) Patients with central nervous system (CNS) disorders may suffer neurotoxicity (motor seizures) during penicillin therapy.
(3) Patients with neuromuscular disorders (e.g., myasthenia gravis) are at increased risk for developing neuromuscular blockade during aminoglycoside or polymyxin B therapy.
e. History of drug allergy or adverse drug reactions. Patients who have had previous allergic or other untoward reactions to a particular antibiotic have a higher risk of experiencing the same reaction during subsequent administration of that drug. Except in life-threatening situations, patients who have had serious allergic reactions to penicillin, for example, should not receive the drug again.
f. Pregnancy and lactation. Because drug therapy during pregnancy and lactation can cause unwanted effects, the mother's need for the antibiotic must be weighed against the drug's potential harm.
(1) Pregnancy can increase the risk of adverse drug effects for both mother and fetus. Also, plasma drug concentrations tend to decrease in pregnant women, reducing a drug's therapeutic effectiveness.
(2) Most drugs, including antibiotics, appear in the breast milk of nursing mothers and may cause adverse effects in infants. For example, sulfonamides may lead to toxic bilirubin accumulation in a newborn's brain.
g. Genetic traits
(1) Sulfonamides may cause hemolytic anemia in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency.
(2) Patients who rapidly metabolize drugs (i.e., rapid acetylators) may develop hepatitis when receiving the antitubercular drug isoniazid.
E. Empiric therapy. In serious or life-threatening disease, anti-infective therapy must begin before the infecting organism has been identified. In this case, the choice of drug (or drugs) is based on clinical experience, suggesting that a particular agent is effective in a given setting.

Figure 44-1. Approach to management of infection.

1. A broad-spectrum antibiotic usually is the most appropriate choice until the specific organism has been determined.
2. In all cases, culture specimens must be obtained before therapy begins.

F. Multiple antibiotic therapy. A combination of drugs should be given only when clinical experience has shown such therapy to be more effective than single-agent therapy in a particular setting. A multiple-agent regimen can increase the risk of toxic drug effects and, in a few cases, may result in drug antagonism and subsequent therapeutic ineffectiveness. Indications for multiple-agent therapy include

1. Need for increased antibiotic effectiveness. The synergistic (intensified) effect of two or more agents may allow a dosage reduction or a faster or enhanced drug effect.
2. Treatment of an infection caused by multiple pathogens (e.g., intra-abdominal infection)
3. Prevention of proliferation of drug-resistant organisms (e.g., during treatment of tuberculosis)

G. Duration of anti-infective therapy. To achieve the therapeutic goal, anti-infective therapy must continue for a sufficient duration.

1. Acute uncomplicated infection. Treatment generally should continue until the patient has been afebrile and asymptomatic for at least 72 hr.
2. Chronic infection (e.g., endocarditis, osteomyelitis). Treatment may require a longer duration (4-6 weeks) with follow-up culture analyses to assess therapeutic effectiveness.

H. Monitoring therapeutic effectiveness. To assess the patient's response to anti-infective therapy, appropriate specimens should be cultured and the following parameters monitored.

1. Fever curve. An important assessment tool, the fever curve may be a reliable indication of response to therapy. Defervescence usually indicates favorable response.
2. White blood cell (WBC) count. In the initial stage of infection, the neutrophil count from a peripheral blood smear may rise above normal (neutrophilia), and immature neutrophil forms (“bands”) may appear (“left shift”). In patients who are elderly, debilitated, or suffering overwhelming infection, the WBC count may be normal or subnormal.
3. Radiographic findings. Small effusions, abscesses, or cavities that appear on radiographs indicate the focus of infection.
4. Pain and inflammation (as evidenced by swelling, erythema, and tenderness) may occur when the infection is superficial or within a joint or bone, also indicating a possible focus of infection.
5. Erythrocyte sedimentation rate (ESR or “sed rate”). Large elevations in ESR are associated with acute or chronic infection, particularly endocarditis, chronic osteomyelitis, and intra-abdominal infections. A normal ESR does not exclude infection; more often, ESR is elevated as a result of noninfectious causes such as collagen vascular disease.
6. Serum complement concentrations, particularly the C3 component, are often reduced in serious infections because of consumption during the host defense process.
I. Lack of therapeutic effectiveness. When an antibiotic drug regimen fails, other drugs should not be added indiscriminately or the regimen otherwise changed. Instead, the situation should be reassessed and diagnostic efforts intensified. Causes of therapeutic ineffectiveness include the following:
1. Misdiagnosis. The isolated organism may have been misidentified by the laboratory or may not be the causative agent for infection (e.g., the patient may have an unsuspected infection).
2. Improper drug regimen. The drug dosage, administration route, dosing frequency, or duration of therapy may be inadequate or inappropriate.
3. Inappropriate choice of antibiotic agent. As discussed in I.D, patient factors and the pharmacological properties and spectrum of activity of a given drug must be considered when planning anti-infective drug therapy.

4. Microbial resistance. By acquiring resistance to a specific antibiotic, microorganisms can survive in the drug's presence. Many gonococcal strains, for instance, now resist penicillin. Drug resistance is particularly common in geographical areas in which a specific drug has been used excessively (and perhaps improperly).
5. Unrealistic expectations. Antibiotics are ineffective in certain circumstances.
a. Patients with conditions that require surgical drainage frequently cannot be cured by anti-infective drugs until the drain has been removed. For

example, the presence of necrotic tissue or pus in patients with pneumonia, empyema, or renal calculi is a common cause of antibiotic failure.

b. Fever should not be treated with anti-infective drugs unless infection has been identified as the cause. Although fever frequently signifies infection, it sometimes stems from noninfectious conditions (e.g., drug reactions, phlebitis, neoplasms, metabolic disorders, arthritis). These conditions do not respond to antibiotics. One exception to this position is neutropenic cancer patients; such patients with no signs or symptoms of infection other than fever are widely treated with antimicrobial agents.

6. Infection by two or more types of microorganisms. If not detected initially, an additional cause of infection may lead to therapeutic failure.

J. Antimicrobial prophylaxis for surgery

1. Definition. Antibiotic prophylaxis is a short course of antibiotic administered before there is clinical evidence of infection.

2. General considerations

a. Timing. The antibiotic should be administered to ensure that appropriate antibiotic levels are available at the site of contamination before the incision. Initiation of prophylaxis is often at induction of anesthesia, within 1 hr or just before the surgical incision. This ensures peak serum and tissue antibiotic levels.

b. Duration. Prophylaxis should be maintained for the duration of surgery. Long surgical procedures (e.g., > 3 hr) may require additional doses. There is little evidence to support continuation of prophylaxis beyond 24 hr.

c. Antibiotic spectrum should be appropriate for the usual pathogens.

(1) In general, first-generation cephalosporins (e.g., cefazolin) are the drugs of choice for most procedures and patients. These agents have an appropriate spectrum, a low frequency of side effects, a favorable half-life, and a low cost.

(2) Vancomycin is a suitable alternative in penicillin-sensitive patients and in situations in which methicillin-resistant S. aureus is a concern.

d. Route of administration. Intravenous (IV) or intramuscular (IM) routes are preferred to guarantee good serum and tissue levels at the time of incision.

II. Antibacterial Agents

A. Definition and classification. Used to treat infections caused by bacteria, antibacterial agents fall into several major categories: aminoglycosides, carbapenems, cephalosporins, erythromycins, penicillins (including various subgroups), sulfonamides, tetracyclines, fluoroquinolones, metronidazole (see V.C.2.b), urinary tract antiseptics, and miscellaneous anti-infectives (Table 44-1).

B. Aminoglycosides. These drugs, containing amino sugars, are used primarily in infections caused by gram-negative enterobacteria and in suspected sepsis. They have little activity against anaerobic and facultative organisms. The toxic potential of these drugs limits their use. Major

aminoglycosides include amikacin (Amikin), gentamicin (Garamycin), kanamycin, neomycin, netilmicin, streptomycin, and tobramycin (Nebcin).

1. Mechanism of action. Aminoglycosides are bactericidal; they inhibit bacterial protein synthesis by binding to and impeding the function of the 30S ribosomal subunit. (Some aminoglycosides also bind to the 50S ribosomal subunit.) Their mechanism of action is not fully known.

Table 44-1. **Some Important Parameters of Anti-Infective Drugs**

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Aminoglycosides				
Amikacin	Renal	2-3 hr	IV, IM	15 mg/kg/day, (once daily dose)
Gentamicin	Renal	2 hr	IV, IM	3 mg/kg/day (standard dose); 6-7

					mg/kg/day (once daily dose)
	Kanamycin	Renal	2-4 hr	Oral, IV	15 mg/kg every 8-12 hr
	Neomycin	Renal	2-3 hr	Oral, topical	50-100 mg/kg/day (oral); 10-15 mg/day (topical)
	Netilmicin	Renal	2-7 hr	IV, IM	3-6 mg/kg/day
	Streptomycin	Renal	2-3 hr	IM	15 mg/kg/day[a]
	Tobramycin	Renal	2-5 hr	IV, IM	3 mg/kg/day (standard dose); 6-7 mg/kg/day, (once daily dose)
Carbapenems					
	Doripenem	Renal	1 hr	IV	500 mg every 8 hr
	Imipenem	Renal	1 hr	IV	250 mg-1

					g every 6 hr
	Ertapenem	Renal	4 hr	IV, IM	1 g/day
	Meropenem	Renal	1.5 hr	IV, IM	0.5-2 g every 8 hr
Cephalosporins					
	First-generation				
		Cefadroxil	Renal	1.5 hr	Oral	1-2 g/day
		Cefazolin	Renal	1.4-2.2 hr	IV	250 mg-1 g every 8 hr
		Cephalexin	Renal	0.9 1.3 hr	Oral	250-500 mg every 6 hr
		Cephapirin	Renal (H)	0.6-0.8 hr	IV, IM	500 mg-2 g every 4-6 hr
		Cephradine	Renal	1.3 hr	Oral, IV	250-500 mg every 6 hr
	Second-generation				
		Cefaclor	Renal (H)	0.8 hr	Oral	250-500 mg every 8 hr
		Cefmetazo	Renal	72 min	IV	2 g every

		le				6-12 hr
		Cefotetan	Renal	2.8-4.6 hr	IV, IM	1-2 g every 12 hr
		Cefoxitin	Renal	0.8 hr	IV	1-2 g every 6-8 hr
		Cefprozil	Renal	78 min	Oral	250-500 mg every 12-24 hr
		Cefuroxime	Renal	1.5-2.2 hr	IV, IM	750 mg-1.5 g every 8 hr
		Loracarbef	Renal	1 hr	Oral	200 mg every 12 hr or 400 mg/day
	Third-generation					
		Cefixime	Renal	3-4 hr	Oral	400 mg/day
		Cefdinir	Renal	1.7-1.8 hr	Oral	300 mg every 12 hr
		Cefoperazone	Hepatic	1.6-2.4 hr	IV	2-4 g every 12 hr
		Cefotaxime	Renal (H)	1.5 hr	IV	1-2 g every 6-8 hr

		Cefpodoxime	Renal	2.5 hr	Oral	100-400 mg every 12 hr
		Ceftazidime	Renal	1.8 hr	IV, IM	1-2 g every 8-12 hr
		Ceftibuten	Renal	2.5 hr	Oral	400 mg/day
		Ceftizoxime	Renal	1.7 hr	IV	1-2 g every 8-12 hr
		Ceftriaxone	Renal	8 hr	IV, IM	1-2 g/day
	Fourth-generation					
		Cefepime	Renal	2-2.3 hr	IV, IM	1-2 g every 8-12 hr
Erythromycins and other macrolides						
	Azithromycin		Hepatic	68 hr	Oral	250 mg/day
	Clarithromycin		Renal	3-7 hr	Oral	250-500 mg every 12 hr
	Dirithromycin		Hepatic	8 hr	Oral	500 mg/day
	Erythromycin base estolate,		Hepatic	1.2-2.6 hr	Oral	250-500 mg every

	ethylsuccinate, and stearate				6 hr
	Erythromycin gluceptate and lactobionate			IV	0.5-2 g every 6 hr
Natural penicillins					
	Penicillin G	Renal (H)	0.5 hr	Oral, IV, IM	200,000-500,000 U every 6-8 hr
	Penicillin V	Renal	1 hr	Oral	500 mg-2 g/day
	Penicillin G procaine	Renal	24-60 hr	IM	300,000-600,000 U/day
	Penicillin G benzathine	Renal	24-60 hr	IM	300,000-600,000 U/day
Penicillinase-resistant penicillins					
	Cloxacillin	Renal (H)	0.5 hr	Oral	250-500 mg every 6 hr
	Dicloxacillin	Renal (H)	0.5-0.9 hr	Oral	500 mg-1 g/day
	Methicillin	Renal (H)	0.5-1 hr	IV, IM	1-2 g every 4-6 hr

	Nafcillin	Hepatic (R)	0.5 hr	Oral, IV, IM	0.25-2 g every 6 hr
	Oxacillin	Renal (H)	0.5 hr	Oral, IV, IM	500 mg-2 g every 4-6 hr 500-875 mg every 12 hr
Aminopenicillins					
	Amoxicillin	Renal (H)	0.9-2.3 hr	Oral	250-500 mg every 8 hr
	Amoxicillin/clavulanic acid	Renal	1 hr	Oral	250-500 mg every 8 hr
	Ampicillin	Renal (H)	0.8-1.5 hr	Oral, IV, IM	250 mg-2 g every 4-6 hr
	Ampicillin/sulbactam	Renal	1-1.8 hr	IV, IM	1.5-3 g every 6 hr
Extended-spectrum penicillins					
	Mezlocillin	Renal (H)	0.6-1.2 hr	IV, IM	1-3 g every 4-6 hr
	Piperacillin	Renal (H)	0.8-1.4 hr	IV, IM	1-1.5 mg/kg every 6-12 hr
	Piperacillin/tazobact	Renal	0.7-1.2	IV	3.375 g

	am		hr		every 6 hr
	Ticarcillin	Renal	0.9-1.5 hr	IV, IM	1-3 g every 4-6 hr
	Ticarcillin/clavulanic acid	Renal	1-1.5 hr	IV	3.1 g every 4-6 hr
Sulfonamides					
	Sulfacytine	Renal	4-4.5 hr	Oral	250 mg every 6 hr
	Sulfadiazine	Renal (H)	6 hr	Oral, IV	2-4 g/day
	Sulfamethoxazole	Hepatic (R)	9-11 hr	Oral	1-3 g/day
	Sulfisoxazole	Renal (H)	3-7 hr	Oral, IV	2-8 g/day
	Sulfamethizole	Renal	—	Oral	0.5-1 g every 6-8 hr
Tetracyclines					
	Demeclocycline	Renal	10-17 hr	Oral	300 mg-1 g/day
	Doxycycline	Hepatic	14-25 hr	Oral, IV	100-200 mg every 12 hr

	Minocycline	Hepatic	12-15 hr	Oral, IV	100-200 mg every 12 hr
	Oxytetracycline	Renal	6-12 hr	Oral, IM	250-500 mg every 6 hr 250-500 mg q.i.d. or 300 mg/day in 1 or 2 divided doses
	Tetracycline[b]	Renal	6-12 hr	Oral, IV, IM	1-2 g/day
Fluoroquinolones					
	Ciprofloxacin	Renal (H)	5-6 hr	IV	200-600 mg every 12 hr
	Enoxacin	Renal (H)	3-6 hr	Oral	200 mg/day-400 mg every 12 hr
	Gemifloxacin	Fecal (R)	4-12 hr	Oral	320 mg once daily
	Lomefloxacin	Renal	6.35-7.77 hr	Oral	400 mg/day
	Levofloxacin	Renal	8 hr	IV, Oral	250-500 mg every 24 hr

	Moxifloxacin	Hepatic	12 hr	Oral	400 mg once daily
	Ofloxacin	Renal	5-7.5 hr	Oral	100 mg/day-400 mg
Urinary tract antiseptics					
	Cinoxacin	Renal	1-1.5 hr	Oral	250 mg every 6 hr or 500 mg every 12 hr
	Fosfomycin	Renal/fecal	5.7 hr	Oral	One packet (3 g) in 90-120 mL water × 1 dose
	Methenamine hippurate and mandelate	Renal	1-3 hr	Oral	0.5-2 g q.i.d.
	Nalidixic acid	Renal	8 hr	Oral	4 g/day
	Nitrofurantoin	Renal	0.3-1 hr	Oral	5-7 mg/kg/day
	Norfloxacin	Hepatic	3-4 hr	Oral	400 b.i.d.
Miscellaneous anti-infectives					
	Atovaquone	Fecal	50-84 hr	Oral	750 mg b.i.d. × 21 days

	Aztreonam	Renal	1.7 hr	Oral, IV	50-100 mg/kg/day
	Clindamycin	Hepatic	2-4 hr	Oral, IM, IV	300-900 mg every 6-8 hr
	Clofazimine	Hepatic	70 days	Oral	50-100 mg/day
	Dapsone	Hepatic (R)	28 hr	Oral	50-100 mg/day
	Daptomycin	Renal	8 hr	IV	4 mg/kg/day
	Lincomycin	Hepatic (R)	4.4-6.4 hr	IV, IM	600 mg-1 g every 8-12 hr
	Linezolid	Renal	4-6 hr	Oral, IV	600 mg every 12 hr
	Mupirocin	Renal	19-35 min	Topical	Apply every 8-12 hr
	Quinupristin/dalfopristin	Hepatic	1 hr/0.4-0.5 hr	IV	7.5 mg/kg every 8 hr
	Rifaximin	Fecal	6 hrs	Oral	200 mg t.i.d.
	Spectinomycin	Renal	1.2-2.8 hr	IM	2-4 g (single

					dose)
	Telithromycin	Hepatic (R)	10 hr	Oral	800 mg/day
	Tigecycline	Biliary (R)	42 hr	IV	100 mg load, 50 mg every 12 hr
	Trimethoprim	Renal (H)	8-15 hr	Oral	100-200 mg/day
	Vancomycin	Renal	6-8 hr	Oral, IV	500 mg every 6 hr
Antifungal agents					
	Amphotericin B	Unknown	24 hr	IV	1-1.5 mg/kg/day
	Anidulafungin	Fecal (R)	40-50 hr	IV	Candidemia: 200 mg day 1, then 100 mg/day
					Esophageal candidiasis: 100 mg day 1, then 50 mg/day
	Caspofungin	Hepatic	9-11 hr	IV	70 mg on day 1, then 50 mg q.d.

	Fluconazole	Renal	22-37 hr	IV, Oral	100-800 mg/day
	Flucytosine	Renal	6 hr	Oral	50-150 mg/kg/day
	Griseofulvin	Hepatic (R)	9-24 hr	Oral	300-375 mg/day
	Itraconazole	Hepatic	24-42 hr	Oral	200-600 mg/day
	Ketoconazole	Hepatic/fecal	3.3 hr	Oral	200-400 mg/day b.i.d
	Micafungin	Hepatic	11-17 hr	IV	Esophageal candidiasis: 150 mg/day
					HSCT prophylasis: 50 mg/day
	Miconazole	Hepatic	20-24 hr	Oral	200-400 mg/day
	Nystatin	Fecal	—	Oral	500,000-1,000,000 U t.i.d.
	Posaconazole	Fecal/renal	35 hrs	Oral	200 mg t.i.d.
	Terbinafine	Hepatic	11-16	Oral	250

		(R)	hr		mg/day
	Voriconazole	Hepatic	6 hr	IV, Oral	IV: 6 mg/kg every 12 hr × 2 doses, then 4 mg/kg every 12 h; oral: 200 mg every 12 h for > 40 kg, 100 mg every 12 h for < 40 kg
Antiprotozoal agents					
	Atovaquone	Hepatic	67 hr	Oral	750 mg b.i.d.
	Chloroquine	Renal/fecal	72-120 hr	IM, Oral	Depends on disease
	Diloxanide	Renal	—	IM	500 mg t.i.d.
	Eflornithine	Renal	3 hr	IV	100 mg/kg/dose every 6 hr
	Fansidar	Renal	100-231 hr	Oral	1 tablet every week
	Halofantrine	Hepatic	3-4	Oral	500 mg

			days		every 6 hr × 3 doses; repeat in 7 days
		Renal	72-120 hr	Oral	310 mg every week
	Hydroxychloroquine				
	Iodoquinol	Fecal	—	Oral	650 mg t.i.d. for 20 days
	Mefloquine	Hepatic	15-33 days	Oral	1250 mg single dose
	Metronidazole	Hepatic (R)	6-14 hr	Oral, IV	250-500 mg every 6-8 hr
	Nitazoxanide	Hepatic	1-1.6 hr	Oral	100-200 mg b.i.d. based on age
	Paromomycin	Fecal	—	Oral	25-35 mg/kg/day
	Pentamidine	Renal	6-9 hr	IM, IV, inhalation	IV, IM: 3-4 mg/kg every day; inhalation: 300 mg every 4

					weeks
	Primaquine	Hepatic	3.7-9.6 hr	Oral	15 mg (base)/day
	Pyrimethamine	Renal	111 hr	Oral	25 mg every week
	Quinacrine		5 days	Oral	100 mg/day
	Quinine	Renal	12 hr	Oral	325 mg b.i.d.
	Tinidazole	Hepatic (R)	13.2 hr	Oral	2 g q.d. × 1-3 days
Antitubercular agents					
	Aminosalicylic acid	Renal	1 hr	Oral	150 mg/kg daily (maximum 12 g/day)
	Capreomycin	Renal	4-6 hr	IM	15 mg/kg/day to 1 g/day maximum
	Cycloserine	Renal	10 hr	Oral	15-20 mg/kg (maximum 1 g/day)

	Ethambutol	Hepatic	3.3 hr	Oral	15-25 mg/kg/day
	Ethionamide	Hepatic	3 hr	Oral	500 mg-1 g/day
	Isoniazid	Hepatic	1-4 hr	Oral, IV	5-10 mg/kg daily (maximum dose = 300 mg)
	Pyrazinamide	Hepatic	9-10 hr	Oral	15-30 mg/kg daily (maximum 2 g/day)
	Rifampin	Hepatic	2-3 hr	Oral, IV	10 mg/kg (up to 600 mg) q.d.
	Rifabutin	Hepatic	45 hr	Oral	300 mg q.d.
	Rifepentine	Hepatic	13.9 hr (active metabolite \13.4 hr)	Oral	600 mg every 3 days
Antiviral agents					
	Abacavir	Hepatic	1.5 hr	Oral	300 mg b.i.d. or 600 mg

					every day
	Adefovir	Renal	7.5 hr	Oral	10 mg every day
	Acyclovir	Renal	2.2 hr	Oral, IV, topical	IV: 5-10 mg/kg every 8 hr; oral: 200-800 mg 3-5 × daily (depending upon indication)
	Amantadine	Renal	17 hr	Oral	100 mg b.i.d. or 200 mg every day
	Amprenavir	Hepatic	7-10 hr	Oral	1200 mg b.i.d. (caps)
	Atazanavir	Hepatic	7 hr	Oral	400 mg every day
	Cidofovir	Renal	6.5 hr	IV	5 mg/kg week × 2 (induction); 5 mg/kg every 2 weeks (maintenance)
	Darunavir	Hepatic	15 hr	Oral	600 mg plus 100

					mg ritonavir b.i.d.
	Delavirdine	Hepatic (R)	2-11 hr	Oral	400 mg t.i.d.
	Didanosine	Renal	1.5 hr	Oral	≥ 60 kg: 400 mg every day (EC caps); < 60 kg: 250 mg every day (EC caps)
	Emtricitabine	Renal	10 hr	Oral	200 mg every day (caps)
	Enfuvirtide	n/a	3.8 hr	SC	90 mg b.i.d.
	Entecavir	Renal	128-149 hr	Oral	0.5 mg every day, or 1 mg every day in patients with lamivudine resistance
	Efavirenz	Hepatic	40-55 hr	Oral	600 mg at bedtime
	Famciclovir	Renal	2-2.3 hr	Oral	250-500 mg every 8-12 hr

	Fosamprenavir	Hepatic	7.7 hr	Oral	1400 mg b.i.d.
	Foscarnet	Renal	3-6 hr	IV	90 mg/kg every 12 hr × 14-21 days (CMV induction); 90 mg/kg every day (CMV maintenance)
	Ganciclovir	Renal	2.9 hr	IV	5 mg/kg every 12 hr (induction) × 14-21 days; 5 mg/kg every day (maintenance)
			4.8 hr	Oral	1000 mg t.i.d. (after induction)
	Indinavir	Hepatic	1.4-2.2 hr	Oral	800 mg every 8 hr
	Lamivudine	Renal	3-7 hr	Oral	150 mg b.i.d. or 300 mg daily
	Lopinavir/ritonavir	Hepatic	4.4-6.1 hr	Oral	200 mg/50 mg

					per tab (2 tablets b.i.d.)
	Maraviroc	Hepatic	14-18 hr	Oral	150-600 mg b.i.d., depending upon concomitant medications
	Nelfinavir	Hepatic	3.5-5 hr	Oral	1250 mg b.i.d.
	Nevirapine	Renal (H)	25-30 hr	Oral	200 mg every day × 14 days, then 200 mg b.i.d.
	Oseltamivir	Renal	6-10 hr	Oral	75 mg b.i.d. (treatment); 75 mg every day (prophylaxis)
	Raeltegravir	Hepatic	9 hr	Oral	400 mg b.i.d.
	Ribavirin	Renal	298 hr	Oral	800-1200 mg daily, divided into 2 doses
	Rimantadine	Renal	25 hr	Oral	100 mg

					b.i.d.
	Ritonavir	Hepatic	3-5 hr	Oral	100-400 mg daily, divided in 1 or 2 doses (as booster agent with other PIs)
	Saquinavir	Hepatic	13 hr	Oral	1000 mg (Invirase) plus 100 mg ritonavir b.i.d.
	Stavudine	Renal	1.5 hr	Oral	≥ 60 kg: 40 mg every 12 hr; < 60 kg: 30 mg every 12 hr
	Telbivudine	Renal	40-49 hr	Oral	600 mg every day
	Tenofovir	Renal	10-14 hr	Oral	300 mg daily
	Tipranavir	Hepatic	6 hr	Oral	500 mg plus 200 mg ritonavir b.i.d.
	Valacyclovir	Renal	2.5-3.6 hr	Oral	0.5-1 g every day

					or b.i.d. or t.i.d.
	Valganciclovir	Renal	4 hr	Oral	900 mg b.i.d. × 21 days (induction), 900 mg every day (maintenance)
	Zalcitabine	Renal	1-3 hr	Oral	0.75 mg t.i.d.
	Zanamivir	Renal	2.5-5.1 hr	Inhalation (Diskhaler)	2 inhalations (10 mg) b.i.d. (treatment); 10 mg every day (prophylaxis)
	Zidovudine	Renal (H)	1.5-3.1 hr	Oral	300 mg b.i.d.
				IV	2 mg/kg over 1 hr, then 1 mg/kg/hr until cord clamping (intrapartum perinatal prophylaxis for pregnant women)

Anthelmintics				
Albendazole	Hepatic	8-12 hr	Oral	400-800 mg daily
Diethylcarbamazine	Renal	8 hr	Oral	25 mg/day for 3 days, then 50 mg/day for 5 days, then 100 mg/day for 3 days, then 150 mg/day for 12 days
Ivermectin	Hepatic	16-35 hr	Oral	150-200 mcg/kg × 1 dose
Mebendazole	Hepatic	8 hr	Oral	100 mg b.i.d. × 3 consecutive days
Praziquantel	Hepatic	0.8-3 hr	Oral	60-75 mg/kg in 3 divided doses on the same day
Pyrantel	Hepatic	—	Oral	11 mg/kg (maximum = 1 g) as a

					single dose
	Thiabendazole	Hepatic	—	Oral	Dose based upon weight chart in prescribing information, 100 lb: 1 g b.i.d. 125 lb: 1.25 g b.i.d. > 150 lb: 1.5 g b.i.d.

CMV, cytomegalovirus; *EC cap,* enteric-coated capsule; *H,* additional significant hepatic elimination; HSCT, hematopoietic stem cell transplant; *IM*, intramuscular; *IV,* intravenous; *PIs,* protease inhibitors *R,* additional significant renal elimination; *SC,* subcutaneous.

[a] Dosage applies to infections other than tuberculosis; for tuberculosis, dosage is 1 g/day.

[b] Intravenous agent withdrawn from U.S. market.

2. Spectrum of activity

a. Streptomycin is active against both gram-positive and gram-negative bacteria. However, widespread resistance to this drug has restricted its use to the organisms that cause plague and tularemia, gram-positive streptococci (given in combination with penicillin), and Mycobacterium tuberculosis (given in combination with other antitubercular agents, as described in VI.C.2).

b. Amikacin, kanamycin, gentamicin, tobramycin, neomycin, and netilmicin are active against many gram-negative bacteria (e.g., Proteus, Serratia, and Pseudomonas organisms).

(1) Gentamicin is active against some Staphylococcus strains; it is more active than tobramycin against Serratia organisms.
(2) Amikacin is the broadest spectrum aminoglycoside with activity against most aerobic gram-negative bacilli as well as many anaerobic gram-negative bacterial strains that resist gentamicin and tobramycin. It is also active against M. tuberculosis and Mycobacterium avium-intracellulare (MAI).
(3) Tobramycin may be more active against Pseudomonas aeruginosa than gentamicin.
(4) Netilmicin may be active against gentamicin-resistant organisms; it appears to be less ototoxic than other aminoglycosides.
(5) Neomycin, in addition to its activity against such gram-negative organisms as Escherichia coli and Klebsiella pneumoniae, is active against several gram-positive organisms (e.g., S. aureus). P. aeruginosa and most streptococci are now neomycin resistant.
3. Therapeutic uses
a. Streptomycin is used to treat plague, tularemia, acute brucellosis (given in combination with tetracycline), bacterial endocarditis caused by Streptococcus viridans (given in combination with penicillin), and tuberculosis (given in combination with other antitubercular agents, as described in VI.C.2).
b. Gentamicin, tobramycin, amikacin, and netilmicin are therapeutic for serious gram-negative bacillary infections (e.g., those caused by Enterobacter, Serratia, Klebsiella, and P. aeruginosa), pneumonia (given in combination with a cephalosporin or penicillin), meningitis, complicated urinary tract infections, osteomyelitis, bacteremia, and peritonitis.
c. Neomycin is used for preoperative bowel sterilization; hepatic coma (as adjunctive therapy); and, in topical form, for skin and mucous membrane infections (e.g., burns).
4. Precautions and monitoring effects. Aminoglycosides can cause serious adverse effects. To prevent or minimize such problems, blood drug concentrations and blood urea nitrogen (BUN) and serum creatinine levels should be monitored during therapy.
a. Ototoxicity. Aminoglycosides can cause vestibular or auditory damage. The relative ototoxicity is as follows:
streptomycin = kanamycin > amikacin = gentamicin = tobramycin > netilmicin
(1) Gentamicin and streptomycin cause primarily vestibular damage (manifested by tinnitus, vertigo, and ataxia). Such damage may be bilateral and irreversible.
(2) Amikacin, kanamycin, and neomycin cause mainly auditory damage (hearing loss).
(3) Tobramycin can result in both vestibular and auditory damage.
b. Nephrotoxicity. Because aminoglycosides accumulate in the proximal tubule, mild renal dysfunction develops in up to 25% of patients receiving

these drugs for several days or more. Usually, this adverse effect is reversible. Use of once-daily administration (ODA) has been reported in the literature to be as effective and less nephrotoxic than traditional dosing.
(1) Neomycin is the most nephrotoxic aminoglycoside; streptomycin is the least nephrotoxic. Gentamicin and tobramycin are nephrotoxic to approximately the same degree.
(2) Risk factors for increased nephrotoxic effects include the following:
(a) Preexisting renal disease
(b) Previous or prolonged aminoglycoside therapy
(c) Concurrent administration of another nephrotoxic drug
(d) Impaired renal flow unrelated to renal disease (e.g., from hypotension, severe hepatic disease)

(3) Trough levels > 2 μg/mL for gentamicin and tobramycin and > 10 μg/mL for amikacin are associated with nephrotoxicity.
c. Neuromuscular blockade. This problem may arise in patients receiving high-dose aminoglycoside therapy.
(1) Risk factors for neuromuscular blockade include the following:
(a) Concurrent administration of a neuromuscular blocking agent or an anesthetic
(b) Preexisting hypocalcemia or myasthenia gravis
(c) Intraperitoneal or rapid IV drug administration
(2) Apnea and respiratory depression may be reversed with administration of calcium or an anticholinesterase.
d. Hypersensitivity and local reactions are rare adverse effects of aminoglycosides.
e. Therapeutic levels
(1) Gentamicin and tobramycin peak at 6-10 μg/mL for traditional dosing; when using the ODA method, the peak is 16-20 μg/mL or 8-10 times the MIC of targeted bacteria. Their trough level is 0.5-1.5 μg/mL for traditional or once-daily regimens.
(2) Amikacin peaks at 25-30 μg/mL. The trough level is 5-8 μg/mL.
5. Significant interactions
a. IV loop diuretics can result in increased ototoxicity.
b. Other aminoglycosides, cephalothin, cisplatin, amphotericin B, and methoxyflurane can cause increased nephrotoxicity when given concurrently with streptomycin.
C. Carbapenems. These agents are β-lactams that contain a fused β-lactam ring and a 5-membered ring system that differs from penicillins in being unsaturated and containing a carbon atom instead of a sulfur atom. The class has a broader spectrum of activity than do most β-lactams. Formerly known as thienamycin, imipenem (Primaxin) was the first carbapenem compound introduced in the United States, followed by meropenem

(Merrem) and, most recently, ertapenem (Invanz) and doripenem (Doribax). Because it is inhibited by renal dipeptidases, imipenem must be combined with cilastatin sodium, a dipeptidase inhibitor (cilastatin is not required with the others because these are not sensitive to renal dipeptidase).

1. Mechanism of action. Carbapenems are bactericidal, inhibiting bacterial cell wall synthesis.

2. Spectrum of activity. These drugs have the broadest spectrum of all β-lactam antibiotics. The group is active against most gram-positive cocci (including many enterococci), gram-negative rods (including many P. aeruginosa strains), and anaerobes. This class has good activity against many bacterial strains that resist other antibiotics. Ertapenem has a narrower spectrum of activity than the other carbapenems. It has little or no activity against P. aeruginosa and Acinetobacter. These β-lactam antibiotics resist destruction by most β-lactamases.

3. Therapeutic uses. Carbapenems are most valued in the treatment of severe infections caused by drug-resistant organisms susceptible to these agents. These agents are effective against urinary tract and lower respiratory infections, intra-abdominal and gynecological infections, and skin, soft-tissue, bone, and joint infections.

4. Precautions and monitoring effects

a. Carbapenems may cause nausea, vomiting, diarrhea, and pseudomembranous colitis.

b. Seizures, dizziness, and hypotension may develop; seizures appear less frequently with meropenem or ertapenem (1.5% of patients receiving imipenem versus 0.5% of those receiving meropenem or ertapenem).

c. Patients who are allergic to penicillin or cephalosporins may suffer cross-sensitivity reactions during carbapenem therapy.

D. Cephalosporins. These agents are known as β-lactam antibiotics because their chemical structure consists of a β-lactam ring adjoined to a thiazolidine ring. Cephalosporins generally are classified in four major groups based mainly on their spectrum of activity (Table 44-2).

1. Mechanism of action. Cephalosporins are bactericidal; they inhibit bacterial cell wall synthesis, reducing cell wall stability and thus causing membrane lysis.

Table 44-2. **Classification of Cephalosporins**

First Generation	Second Generation	Third Generation	Fourth Generation
Cefadroxil (Duricef, Ultracef)[a] Cefazolin (Ancef, Kefzol) Cephalexin (Keflex)[a] Cephapirin (Cefadyl) Cephradine (Anspor, Velosef)[a]	Cefaclor (Ceclor)[a] Cefmetazole (Zefazone) Cefotetan (Cefotan)[b] Cefoxitin (Mefoxin) Cefuroxime(Zinacef) Cefuroxime axetil (Ceftin)[a] Cefprozil (Cefzil)[a] Loracarbef (Lorabid)[a]	Cefdinir (Omnicef)[a] Cefixime (Suprax)[a] Cefoperazone (Cefobid) Cefotaxime (Claforan) Cefpodoxime proxetil (Vantin)[a] Ceftazidime (Fortex, Tazicef, Tazidime) Ceftibuten (Cedax)[a] Ceftizoxime (Cefizox) Ceftriaxone (Rocephin) Cefditoren (Spectracef)[a]	Cefepime (Maxipime)

[a] Oral agent.

[b] Discontinued in the U.S. market 2005.

2. Spectrum of activity

a. First-generation cephalosporins are active against most gram-positive cocci (except enterococci) as well as enteric aerobic gram-negative bacilli (e.g., E. coli, K. pneumoniae, Proteus mirabilis).

b. Second-generation cephalosporins are active against the organisms covered by first-generation cephalosporins and have extended gram-negative coverage, including β-lactamase-producing strains of Haemophilus influenzae.

c. Third-generation cephalosporins have wider activity against most gram-negative bacteria, for example, Enterobacter, Citrobacter, Serratia, Providencia, Neisseria, and Haemophilus organisms, including β-lactamase-producing strains.

d. Fourth-generation cephalosporins include cefepime (Maxipime), which is the first member of this group to be marketed. However, its designation as a fourth-generation cephalosporin is debatable. Cefepime is highly resistant

to β-lactamases and has a low propensity for selection of β-lactam-resistant mutant strains. It shows evidence of greater activity versus gram-positive cocci, Enterobacteriaceae, and Pseudomonas than third-generation cephalosporins.

e. Each generation of cephalosporin has shifted toward increased gram-negative activity but has lost activity toward gram-positive organisms. Fourth-generation agents have improved activity toward gram-positive organisms over third-generation agents.

3. Therapeutic uses

a. First-generation cephalosporins commonly are administered to treat serious Klebsiella infections and gram-positive and some gram-negative infections in patients with mild penicillin allergy. These agents also are used widely in perioperative prophylaxis. For most other indications, they are not the preferred drugs.

b. Second-generation cephalosporins are valuable in the treatment of urinary tract infections resulting from E. coli organisms, acute otitis media, sinusitis, and gonococcal disease caused by organisms that resist other agents.

(1) Cefaclor (Ceclor) is useful in otitis media and sinusitis in patients who are allergic to ampicillin and amoxicillin. Cefprozil (Cefzil) and loracarbef (Lorabid) are second-generation cephalosporins that can be administered twice daily but offer no important spectrum differences.

(2) Cefoxitin (Mefoxin) is therapeutic for mixed aerobic-anaerobic infections, such as intra-abdominal infection. The cefotetan (Cefotan) spectrum is similar but this agent can be given twice daily.

(3) Cefuroxime (Zinacef) is commonly administered for outpatient community-acquired pneumonia.

c. Third-generation cephalosporins penetrate the cerebrospinal fluid (CSF) and thus are valuable in the treatment of meningitis caused by such organisms as meningococci, pneumococci, H. influenzae, and enteric gram-negative bacilli.

(1) These agents also are used to treat sepsis of unknown origin in immunosuppressed patients and to treat fever in neutropenic immunosuppressed patients (given in combination with an aminoglycoside).

(2) Third-generation cephalosporins are useful in infections caused by many organisms resistant to older cephalosporins.

(3) These agents are frequently administered as empiric therapy for life-threatening infection in which resistant organisms are the most likely cause.

(4) Initial therapy of mixed bacterial infections (e.g., sepsis) commonly involves third-generation cephalosporins.

d. The fourth-generation agent, cefepime, is approved for treatment of urinary tract infections, uncomplicated skin and skin structure infections,

pneumonia, and empiric use in febrile neutropenic patients. Cefepime has a spectrum of activity similar to third-generation agents but is more resistant to some β-lactamases.

4. Precautions and monitoring effects

a. Because all cephalosporins (except cefoperazone) are eliminated renally, doses must be adjusted for patients with renal impairment.

b. Cross-sensitivity with penicillin has been reported in up to 10% of patients receiving cephalosporins. More recent information indicates that true cross-reactivity is rare.

c. Cephalosporins can cause hypersensitivity reactions similar to those resulting from penicillin (see II.E.1.e.(1)). Manifestations include fever, maculopapular rash, anaphylaxis, and hemolytic anemia.

d. Other adverse effects include nausea, vomiting, diarrhea, superinfection, nephrotoxicity, and Clostridium difficile-induced colitis; with cefoperazone, cefmetazole, and cefotetan (and formerly moxalactam and cefamandole), bleeding diatheses may occur. Bleeding can be reversed by vitamin K administration.

e. Cephalosporins may cause false-positive glycosuria results on tests using the copperreduction method.

f. Ceftriaxone now contraindicated in newborns receiving concurrent administration of calcium-containing solutions or products due to risk of fatal precipitation in lungs and kidneys. New warning added also stating that ceftriaxone and IV calcium-containing solutions should not be administered within 48 hours of each other.

5. Significant interactions

a. Probenecid may impair the excretion of cephalosporins (except ceftazidime), causing increased cephalosporin levels and possible toxicity.

b. Alcohol consumption may result in a disulfiram-type reaction in patients receiving cefmetazole, cefotetan, and cefoperazone.

c. Aminoglycosides or loop diuretics may cause additive toxicity when administered with cephalothin.

d. Plasma concentrations of cefaclor extended-release tablets, cefdinir, and cefpodoxime may be reduced by coadministration with antacids.

e. H_2-antagonists may reduce plasma levels of cefpodoxime and cefuroxime.

f. Iron supplements and iron-fortified foods reduce absorption of cefdinir by 80% and 30%, respectively.

E. Erythromycins. The chemical structure of these macrolide antibiotics is characterized by a lactone ring to which sugars are attached. Erythromycin base and the estolate, ethylsuccinate, and stearate salts are given orally; erythromycin lactobionate and gluceptate are given parenterally.

1. Mechanism of action. Erythromycins may be bactericidal or bacteriostatic; they bind to the 50S ribosomal subunit, inhibiting bacterial protein synthesis.

2. Spectrum of activity. Erythromycins are active against many gram-positive organisms, including streptococci (e.g., Streptococcus pneumoniae), and Corynebacterium and Neisseria species as well as some strains of Mycoplasma, Legionella, Treponema, and Bordetella. Some S. aureus strains that resist penicillin G are susceptible to erythromycins.
3. Therapeutic uses
a. Erythromycins are the preferred drugs for the treatment of Mycoplasma pneumoniae and Campylobacter infections, Legionnaires disease, chlamydial infections, diphtheria, and pertussis.

b. In patients with penicillin allergy, erythromycins are important alternatives in the treatment of pneumococcal pneumonia, S. aureus infections, syphilis, and gonorrhea.
c. Erythromycins may be given prophylactically before dental procedures to prevent bacterial endocarditis.
4. Precautions and monitoring parameters
a. Gastrointestinal (GI) distress (e.g., nausea, vomiting, diarrhea, epigastric discomfort) may occur with all erythromycin forms and are the most common adverse effects.
b. Allergic reactions (rare) may present as skin eruptions, fever, and eosinophilia.
c. Cholestatic hepatitis may arise in patients treated for 1 week or longer with erythromycin estolate; symptoms usually disappear within a few days after drug therapy ends. There have been infrequent reports of hepatotoxicity with other salts of erythromycin.
d. IM injections of more than 100 mg produce severe pain persisting for hours.
e. Transient hearing impairment may develop with high-dose erythromycin therapy.
5. Significant interactions
a. Erythromycin inhibits the hepatic metabolism of theophylline, resulting in toxic accumulation.
b. Erythromycin interferes with the metabolism of digoxin, corticosteroids, carbamazepine, cyclosporin, and lovastatin, possibly potentiating the effect and toxicity of these drugs.
c. Clarithromycin (Biaxin) may potentiate oral anticoagulants (monitor prothrombin time), increase cyclosporine levels with increased toxicity, and increase digoxin and theophylline levels.
d. Co-administration of clarithromycin and cisapride may increase risk of serious cardiac arrhythmias; coadministration is contraindicated.
e. Sudden deaths have been reported when clarithromycin was added to ongoing pimozide therapy; co-administration is contraindicated.
6. Alternatives to erythromycin

a. Clarithromycin, azithromycin (Zithromax), and dirithromycin (Dynabac) are semisynthetic macrolide antibiotics. These expensive but well-tolerated alternatives to erythromycin are administered once daily.

(1) Clarithromycin

(a) Spectrum of activity. Clarithromycin is more active than erythromycin against staphylococci and streptococci. In addition to activity against other organisms covered by erythromycin, it is also active in vitro against MAI, Toxoplasma gondii, and Cryptosporidium spp.

(b) Therapeutic uses. This agent is indicated for the prevention of Mycobacterium avium complex (MAC) infection and is useful in otitis media, sinusitis, mycoplasmal pneumonia, and pharyngitis. Clarithromycin is also used with proton pump inhibitors (PPIs) for Helicobacter pylori eradication.

(2) Azithromycin

(a) Spectrum of activity. Azithromycin is less active than erythromycin against gram-positive cocci but more active against H. influenzae and other gram-negative organisms. Azithromycin concentrates within cells, and tissue levels are higher than serum levels.

(b) Therapeutic uses. This agent is useful in nongonococcal urethritis caused by chlamydia, lower respiratory tract infections, (MAC) infection and prophylaxis, pharyngitis, pelvic inflammatory disease, and legionnaires' disease. Azithromycin is also indicated for pediatric use.

(3) Dirithromycin is indicated for the treatment of acute exacerbations of chronic bronchitis, pharyngitis and tonsillitis caused by Streptococcus pyogenes, and uncomplicated skin and skin structure infections caused by S. aureus.

F. Penicillins

1. Natural penicillins. As with cephalosporins and all other penicillins, natural penicillins are β-lactam antibiotics. Among the most important antibiotics, natural penicillins are the preferred drugs in the treatment of many infectious diseases.

a. Available agents

(1) Penicillin G sodium and potassium salts can be administered orally, intravenously, or intramuscularly.

(2) Penicillin V (Pen-Vee K), a soluble drug form, is administered orally.

(3) Penicillin G procaine and penicillin G benzathine are repository drug forms. Administered intramuscularly, these insoluble salts allow slow drug absorption from the injection site and thus have a longer duration of action (12-24 hr).

b. Mechanism of action. Penicillins are bactericidal; they inhibit bacterial cell wall synthesis in a manner similar to that of the cephalosporins.

c. Spectrum of activity

(1) Natural penicillins are highly active against gram-positive cocci and against some gram-negative cocci.
(2) Penicillin G is 5-10 times more active than penicillin V against gram-negative organisms and some anaerobic organisms.
(3) Because natural penicillins are readily hydrolyzed by penicillinases (β-lactamases), they are ineffective against S. aureus and other organisms that resist penicillin.
d. Therapeutic uses
(1) Penicillin G is the preferred agent for all infections caused by penicillin-susceptible S. pneumoniae organisms, including
(a) Pneumonia
(b) Arthritis
(c) Meningitis
(d) Peritonitis
(e) Pericarditis
(f) Osteomyelitis
(g) Mastoiditis
(2) Penicillins G and V are highly effective against other streptococcal infections, such as pharyngitis, otitis media, sinusitis, and bacteremia.
(3) Penicillin G is the preferred agent in gonococcal infections, syphilis, anthrax, actinomycosis, gas gangrene, and Listeria infections.
(4) Administered when an oral penicillin is needed, penicillin V is most useful in skin, soft-tissue, and mild respiratory infections.
(5) Penicillin G procaine is effective against syphilis and uncomplicated gonorrhea.
(6) Used to treat syphilis infections outside the CNS, penicillin G benzathine also is effective against group Aβ-hemolytic streptococcal infections.
(7) Penicillins G and V may be used prophylactically to prevent streptococcal infection, rheumatic fever, and neonatal gonorrhea ophthalmia. Patients with valvular heart disease may receive these drugs preoperatively.
(8) There is emerging resistance to penicillin G by S. pneumoniae in some areas of the United States. The alternative therapy is vancomycin.
e. Precautions and monitoring effects
(1) Hypersensitivity reactions. These occur in up to 10% of patients receiving penicillin. Manifestations range from mild rash to anaphylaxis.
(a) The rash may be urticarial, vesicular, bullous, scarlatiniform, or maculopapular. Rarely, thrombopenic purpura develops.
(b) Anaphylaxis is a life-threatening reaction that most commonly occurs with parenteral administration. Signs and symptoms include severe hypotension, bronchoconstriction, nausea, vomiting, abdominal pain, and extreme weakness.
(c) Other manifestations of hypersensitivity reactions include fever, eosinophilia, angioedema, and serum sickness.

(d) Before penicillin therapy begins, the patient's history should be evaluated for reactions to penicillin. A positive history places the patient at heightened risk for a subsequent reaction. In most cases, such patients should receive a substitute antibiotic. (However, hypersensitivity reactions may occur even in patients with a negative history.)
(2) Other adverse effects of natural penicillins include GI distress (e.g., nausea, diarrhea), bone marrow suppression (e.g., impaired platelet aggregation, agranulocytosis), and superinfection. With high-dose therapy, seizures may occur, particularly in patients with renal impairment.
f. Significant interactions
(1) Probenecid increases blood levels of natural penicillins and may be given concurrently for this purpose.

(2) Antibiotic antagonism occurs when erythromycins, tetracyclines, or chloramphenicol is given within 1 hr of the administration of penicillin. The clinical significance of such antagonism is not clear.
(3) With penicillin G procaine and benzathine, precaution must be used in patients with a history of hypersensitivity reactions to penicillins because prolonged reactions may occur. Intravascular injection should be avoided. Procaine hypersensitivity is a contraindication to the use of procaine penicillin G.
(4) Parenteral products contain either potassium (1.7 mEq/million units) or sodium (2 mEq/million units).
2. Penicillinase-resistant penicillins. These penicillins are not hydrolyzed by staphylococcal penicillinases (β-lactamases). These agents include methicillin, nafcillin, and the isoxazolyl penicillins—cloxacillin, dicloxacillin (Dynapen), and oxacillin.
a. Mechanism of action (see II.E.1.b)
b. Spectrum of activity. Because these penicillins resist penicillinases, they are active against staphylococci that produce these enzymes.
c. Therapeutic uses
(1) Penicillinase-resistant penicillins are used solely in staphylococcal infections resulting from organisms that resist natural penicillins.
(2) These agents are less potent than natural penicillins against organisms susceptible to natural penicillins and thus make poor substitutes in the treatment of infections caused by these organisms.
(3) Nafcillin is excreted by the liver and thus may be useful in treating staphylococcal infections in patients with renal impairment.
(4) Oxacillin, cloxacillin, and dicloxacillin are most valuable in long-term therapy of serious staphylococcal infections (e.g., endocarditis, osteomyelitis) and in the treatment of minor staphylococcal infections of the skin and soft tissues.
d. Precautions and monitoring effects

(1) As with all penicillins, the penicillinase-resistant group can cause hypersensitivity reactions (see II.E.1.e.(1)).
(2) Methicillin may cause nephrotoxicity and interstitial nephritis.
(3) Oxacillin may be hepatotoxic.
(4) Complete cross-resistance exists among the penicillinase-resistant penicillins.
e. Significant interactions. Probenecid increases blood levels of these penicillins and may be given concurrently for that purpose.
3. Aminopenicillins. This penicillin group includes the semisynthetic agents ampicillin and amoxicillin (Amoxil). Because of their wider antibacterial spectrum, these drugs are also known as broad-spectrum penicillins.
a. Mechanism of action (see II.E.1.b)
b. Spectrum of activity. Aminopenicillins have a spectrum that is similar to but broader than that of the natural and penicillinase-resistant penicillins. Easily destroyed by staphylococcal penicillinases, aminopenicillins are ineffective against most staphylococcal organisms. Against most bacteria sensitive to penicillin G, aminopenicillins are slightly less effective than this agent.
c. Therapeutic uses. Aminopenicillins are used to treat gonococcal infections, upper respiratory infections, uncomplicated urinary tract infections, and otitis media caused by susceptible organisms.
(1) For infections resulting from penicillin-resistant organisms, ampicillin may be given in combination with sulbactam (Unasyn).
(2) Amoxicillin is less effective than ampicillin against shigellosis.
(3) Amoxicillin is more effective against S. aureus, Klebsiella, and Bacteroides fragilis infections when administered in combination with clavulanic acid—amoxicillin/potassium clavulanate (Augmentin) because clavulanic acid inactivates penicillinases.
d. Precautions and monitoring effects
(1) Hypersensitivity reactions may occur (see II.E.1.e.(1)).
(2) Diarrhea is most common with ampicillin.
(3) In addition to the urticarial hypersensitivity rash seen with all penicillins, ampicillin and amoxicillin frequently cause a generalized erythematous, maculopapular rash. (This occurs in 5%-10% of patients receiving ampicillin.)
e. Significant interactions (see II.E.2.e)

4. Extended-spectrum penicillins. These agents have the widest antibacterial spectrum of all penicillins. Also called antipseudomonal penicillins, this group includes the carboxypenicillin (e.g., ticarcillin) and the ureidopenicillins (e.g., mezlocillin, piperacillin).
a. Mechanism of action (see II.E.1.b)

b. Spectrum of activity. These drugs have a spectrum similar to that of the aminopenicillins but also are effective against Klebsiella and Enterobacter spp., some B. fragilis organisms, and indole-positive Proteus and Pseudomonas organisms.

(1) Ticarcillin is active against P. aeruginosa. Combined with clavulanic acid (Timentin), ticarcillin has enhanced activity against organisms that resist ticarcillin alone.

(2) Piperacillin is more active than ticarcillin against Pseudomonas organisms.

(3) Piperacillin and tazobactam (Zosyn). Tazobactam is a β-lactamase inhibitor that expands the spectrum of activity to include some organisms not sensitive to piperacillin alone (if resistance is the result of β-lactamase production), including strains of staphylococci, Haemophilus, Bacteroides, and Enterobacteriaceae. Generally, tazobactam does not enhance activity against Pseudomonas.

c. Therapeutic uses. Extended-spectrum penicillins are used mainly to treat serious infections caused by gram-negative organisms (e.g., sepsis; pneumonia; infections of the abdomen, bone, and soft tissues). Piperacillin/tazobactam is effective in the treatment of nosocomial pneumonia.

d. Precautions and monitoring effects

(1) Hypersensitivity reactions may occur (see II.E.1.e.(1)).

(2) Ticarcillin may cause hypokalemia.

(3) The high sodium content of ticarcillin may pose a danger to patients with heart failure (HF).

(4) All inhibit platelet aggregation, which may result in bleeding.

e. Significant interactions (see II.E.2.e)

G. Sulfonamides. Derivatives of sulfanilamide, these agents were the first drugs to prevent and cure human bacterial infection successfully. Although their current usefulness is limited by the introduction of more effective antibiotics and the emergence of resistant bacterial strains, sulfonamides remain the drugs of choice for certain infections. The major sulfonamides are sulfadiazine, sulfamethoxazole, sulfisoxazole, and sulfamethizole.

1. Mechanism of action. Sulfonamides are bacteriostatic; they suppress bacterial growth by triggering a mechanism that blocks folic acid synthesis, thereby forcing bacteria to synthesize their own folic acid.

2. Spectrum of activity. Sulfonamides are broad-spectrum agents with activity against many gram-positive organisms (e.g., S. pyogenes, S. pneumoniae) and certain gram-negative organisms (e.g., H. influenzae, E. coli, P. mirabilis). They also are effective against certain strains of Chlamydia trachomatis, Nocardia, Actinomyces, and Bacillus anthracis.

3. Therapeutic uses

a. Sulfonamides most often are used to treat urinary tract infections caused by E. coli, including acute and chronic cystitis, and chronic upper urinary tract infections.

b. These agents have value in the treatment of nocardiosis, trachoma and inclusion conjunctivitis, and dermatitis herpetiformis.
c. Sulfadiazine may be administered in combination with pyrimethamine to treat toxoplasmosis.
d. Sulfamethoxazole may be given in combination with trimethoprim (Bactrim) to treat such infections as Pneumocystis carinii pneumonia, Shigella enteritis, Serratia sepsis, urinary tract infections, respiratory infections, and gonococcal urethritis (see II.J.7.c). It is the drug of choice in the treatment of Stenotrophomonas maltophilia.
e. Sulfisoxazole is sometimes used in combination with erythromycin ethylsuccinate to treat acute otitis media caused by H. influenzae organisms. For the initial treatment of uncomplicated urinary tract infections, sulfisoxazole may be given in combination with phenazopyridine for relief of symptoms of pain, burning, or urgency.
f. Prophylactic sulfonamide therapy has been used successfully to prevent streptococcal infections and rheumatic fever recurrences.
4. Precautions and monitoring effects
a. Sulfonamides may cause blood dyscrasias (e.g., hemolytic anemia—particularly in patients with G6PD deficiency, aplastic anemia, thrombocytopenia, agranulocytosis, and eosinophilia).

b. Hypersensitivity reactions to sulfonamides probably result from sensitization and most commonly involve the skin and mucous membranes. Manifestations include various types of skin rash, exfoliative dermatitis, and photosensitivity. Drug fever and serum sickness also may develop.
c. Crystalluria and hematuria may occur, possibly leading to urinary tract obstruction. (Adequate fluid intake and urine alkalinization can prevent or minimize this risk.) Sulfonamides should be used cautiously in patients with renal impairment.
d. Life-threatening hepatitis caused by drug toxicity or sensitization is a rare adverse effect. Signs and symptoms include headache, nausea, vomiting, and jaundice.
e. AIDS patients have increased frequency of cutaneous hypersensitivity reactions to sulfamethoxazole.
5. Significant interactions. Sulfonamides may potentiate the effects of phenytoin, oral anticoagulants, and sulfonylureas.
H. Tetracyclines. These broad-spectrum agents are effective against certain bacterial strains that resist other antibiotics. Nonetheless, they are the preferred drugs in only a few situations. The major tetracyclines include demeclocycline (Declomycin), doxycycline (Vibramycin), minocycline (Minocin), and chlortetracycline.
1. Mechanism of action. Tetracyclines are bacteriostatic; they inhibit bacterial protein synthesis by binding to the 30S ribosomal subunit.

2. Spectrum of activity. Tetracyclines are active against gram-negative and gram-positive organisms, spirochetes, Mycoplasma and Chlamydia organisms, rickettsial species, and certain protozoa.

a. Pseudomonas and Proteus organisms are now resistant to tetracyclines. Many coliform bacteria, pneumococci, staphylococci, streptococci, and Shigella strains are increasingly resistant.

b. Cross-resistance within the tetracycline group is extensive.

3. Therapeutic uses

a. Tetracyclines are the agents of choice in rickettsial (Rocky Mountain spotted fever), chlamydial, and mycoplasmal infections; amebiasis; and bacillary infections (e.g., cholera, brucellosis, tularemia, some Salmonella and Shigella infections).

b. Tetracyclines are useful alternatives to penicillin in the treatment of anthrax, syphilis, gonorrhea, Lyme disease, nocardiosis, and H. influenzae respiratory infections.

c. Oral or topical tetracycline may be administered as a treatment for acne.

d. Doxycycline is highly effective in the prophylaxis of “traveler's diarrhea” (commonly caused by E. coli). Because the drug is excreted mainly in the feces, it is the safest tetracycline for the treatment of extrarenal infections in patients with renal impairment.

e. Demeclocycline is used commonly as an adjunctive agent to treat the syndrome of inappropriate antidiuretic hormone (SIADH) secretion.

4. Precautions and monitoring effects

a. GI distress (e.g., diarrhea, abdominal discomfort, nausea, anorexia) is a common adverse effect of tetracyclines. This problem can be minimized by administering the drug with food or temporarily decreasing the dosage.

b. Skin rash, urticaria, and generalized exfoliative dermatitis signify a hypersensitivity reaction. Rarely, angioedema and anaphylaxis occur.

c. Cross-sensitivity within the tetracycline group is common.

d. Phototoxic reactions (severe skin lesions) can develop with exposure to sunlight. This reaction is most common with demeclocycline and doxycycline.

e. Tetracyclines may cause hepatotoxicity, particularly in pregnant women. Manifestations include jaundice, acidosis, and fatty liver infiltration.

f. Renally impaired patients may experience a significant increase in BUN secondary to catabolic effects of tetracyclines.

g. Tetracyclines may induce permanent tooth discoloration, tooth enamel defects, and retarded bone growth in infants and children.

h. Use of outdated and degraded tetracyclines can lead to renal tubular dysfunction, possibly resulting in renal failure.

i. Minocycline can cause vestibular toxicity (e.g., ataxia, dizziness, nausea, vomiting).

j. IV tetracyclines are irritating and may cause phlebitis.

5. Significant interactions

a. Dairy products and other foods, iron preparations, and antacids and laxatives containing aluminum, calcium, or magnesium can cause reduced tetracycline absorption. Absorption of doxycycline is not inhibited by these factors.

b. Methoxyflurane may exacerbate the tetracyclines' nephrotoxic effects.

c. Barbiturates and phenytoin decrease the antibiotic effectiveness of tetracyclines.

d. Demeclocycline antagonizes the action of antidiuretic hormone (ADH) and may be given as a diuretic in patients with SIADH.

I. Fluoroquinolones are agents related to nalidixic acid—see II.I.1.c; II.2.c.(1); II.4.c.(1)—and include ciprofloxacin (Cipro), enoxacin (Penetrex), lomefloxacin (Maxaquin), norfloxacin (Noroxin), ofloxacin (Floxin), moxifloxacin (Avelox), levofloxacin (Levaquin), and gemifloxacin (Factive). They are bactericidal for growing bacteria.

1. Mechanism of action. Fluoroquinolones inhibit DNA gyrase.

2. Spectrum of activity. Fluoroquinolones are highly active against enteric gram-negative bacilli, Salmonella, Shigella, Campylobacter, Haemophilus, and Neisseria.

a. Ciprofloxacin has activity against P. aeruginosa, but the fluoroquinolones as a group have variable activity against non-P. aeruginosa. Ciprofloxacin is active against some anaerobes; it has moderate activity against M. tuberculosis.

b. Gram-positive organisms are less susceptible than gram-negative organisms but usually are sensitive, except for Enterococcus faecalis and methicillin-resistant staphylococci.

c. Ofloxacin has the greatest activity against Chlamydia.

3. Therapeutic uses (Table 44-3)

a. Norfloxacin is indicated for the oral treatment of urinary tract infections, uncomplicated gonococcal infections, and prostatitis.

b. Ciprofloxacin, ofloxacin, and levofloxacin are available orally and intravenously. Ciprofloxacin is approved for use in urinary tract infections; lower respiratory infections; sinusitis; bone, joint, and skin structure infections; empiric use in febrile neutropenic patients; typhoid fever; urethral and cervical gonococcal infections; and infectious diarrhea. Ofloxacin is approved for use in lower respiratory infections, uncomplicated gonococcal and chlamydial cervicitis and urethritis, skin and skin structure infections, prostatitis, and urinary tract infections.

c. Lomefloxacin, levofloxacin, and enoxacin are approved for the treatment of urinary tract infections. Lomefloxacin, moxifloxacin, and levofloxacin are also used in lower respiratory infections.

d. Moxifloxacin is approved for the treatment of complicated intra-abdominal infections but should not be used for urinary tract infections.

4. Precautions and monitoring effects

a. Occasional adverse effects include nausea, dyspepsia, headache, dizziness, insomnia, cardiac QT prolongation, arthropathy, tendonitis, CNS effects, photosensitivity, and hypoglycemia.

Table 44-3. **Quinolone Agents Classified by Generation**

	Agent	Spectrum of Coverage	Site of Infection
First-generation	Cinoxacin (Cinoxacin, Cinobac)	Gram negatives	Urinary tract
	Enoxacin (Penetrex)		
	Nalidixic acid (NegGram)		
	Norfloxacin (Noroxin)		
Second-generation	Lomefloxacin (Maxaquin)	Gram negatives	Urinary tract
	Ciprofloxacin (Cipro)		Systemic, urinary tract
	Ofloxacin (Floxin)		Systemic, urinary tract
Third-generation	Levofloxacin (Levaquin)	Gram negatives	Systemic, urinary tract
	Moxifloxacin (Avelox)	Atypicals	Systemic only

b. Infrequent adverse effects include rash, urticaria, leukopenia, and elevated liver enzymes. Crystalluria occurs with high doses at alkaline pH.

c. The FDA has added a black box warning about the increased risk of developing tendinitis and tendon rupture in patients taking this class of medications.

5. Significant interactions

a. Ciprofloxacin has been shown to increase theophylline levels. Variable effects on theophylline levels have been reported from other members of the group. In patients requiring fluoroquinolones, theophylline levels should be monitored.

b. Antacids and sucralfate and divalent or trivalent cations such as iron significantly decrease the absorption of fluoroquinolones.

c. Fluoroquinolones may increase prothrombin times in patients receiving warfarin.

d. Concurrent use with nonsteroidal anti-inflammatory drugs (NSAIDs) may increase the risk of CNS stimulation (seizures).

e. Fluoroquinolones may produce prolonged QT interval when administered with cisapride and antiarrhythmic agents. Some fluoroquinolones (i.e., gatifloxacin, moxifloxacin) should be avoided in patients with known prolongation of the QTC interval, with uncorrected hypocalcemia, or who are receiving class IA or class III antiarrhythmic drugs.

f. Some fluoroquinolones have been reported to enhance the effects of oral anticoagulants.

g. Hyperglycemia and hypoglycemia have been reported in patients receiving quinolones and an antidiabetic agent. Blood glucose monitoring is recommended in such patients.

h. Didanosine should be administered at least 4 hr after gatifloxacin.

J. Urinary tract antiseptics. Concentrating in the renal tubules and bladder, these agents exert local antibacterial effects; most do not achieve blood levels high enough to treat systemic infections. However, some new quinolone derivatives, such as ciprofloxacin and ofloxacin, are valuable in the treatment of certain infections outside the urinary tract (see II.H.3.b).

1. Mechanism of action

a. Methenamine is hydrolyzed to ammonia and formaldehyde in acidic urine; formaldehyde is antibacterial against gram-positive and gram-negative organisms. Mandelic and hippuric acids, with which methenamine is combined, provide supplementary antibacterial action.

b. Nitrofurantoin is bacteriostatic; in high concentrations, it may be bactericidal. Presumably, it disrupts bacterial enzyme systems.

c. Quinolones. Nalidixic acid and its analogs and derivatives—oxolinic acid, norfloxacin, cinoxacin, ciprofloxacin, and others—interfere with DNA gyrase and inhibit DNA synthesis during bacterial replication.

d. Fosfomycin tromethamine is bactericidal in the urine at therapeutic doses. The bactericidal action is because of its inactivation of the enzyme enolpyruvyl transferase, thereby blocking the condensation of uridine diphosphate-N-acetylglucosamine with p-enolpyruvate, one of the first steps in bacterial cell wall synthesis.

2. Spectrum of activity

a. Methenamine is active against both gram-positive and gram-negative organisms (e.g., Enterobacter, Klebsiella, Proteus, P. aeruginosa, S. aureus).

b. Nitrofurantoin is active against many gram-positive and gram-negative organisms, including some strains of E. coli, S. aureus, Proteus, Enterobacter, and Klebsiella.

c. Quinolones (see II.H)

(1) Nalidixic acid and oxolinic acid are active against most gram-negative organisms that cause urinary tract infections, including P. mirabilis, E. coli, Klebsiella, and Enterobacter organisms. These drugs are not effective against Pseudomonas organisms.

(2) Norfloxacin is active against E. coli, Enterobacter, Klebsiella, Proteus, P. aeruginosa, S. aureus, Citrobacter, and some Streptococcus organisms.

(3) Cinoxacin is active against E. coli, Klebsiella, P. mirabilis, Proteus vulgaris, Proteus morganii, Serratia, and Citrobacter organisms.

3. Therapeutic uses

a. Methenamine and nitrofurantoin are used to prevent and treat urinary tract infections.

b. Quinolones are administered to treat urinary tract infections; some also are used in such diseases as osteomyelitis and respiratory tract infections.

c. Fosfomycin is indicated for treatment of uncomplicated urinary tract infection (acute cystitis) in women caused by susceptible strains of E. coli or E. faecalis.

4. Precautions and monitoring effects

a. Methenamine may cause nausea, vomiting, and diarrhea; in high doses, it may lead to urinary tract irritation (e.g., dysuria, frequency, hematuria, albuminuria). Skin rash also may develop.

b. Nitrofurantoin may cause various adverse effects.

(1) GI distress (e.g., nausea, vomiting, diarrhea) is relatively common.

(2) Hypersensitivity reactions to nitrofurantoin may involve the skin, lungs, blood, or liver; manifestations include fever, chills, hepatitis, jaundice, leukopenia, hemolytic anemia, granulocytopenia, and pneumonitis.

(3) Adverse CNS effects include headache, vertigo, and dizziness. Polyneuropathy may develop with high doses or in patients with renal impairment.

c. Quinolones

(1) Nalidixic acid and oxolinic acid may cause nausea, vomiting, abdominal pain, urticaria, pruritus, skin rash, fever, eosinophilia, and CNS effects, such as headache, dizziness, confusion, vertigo, drowsiness, and weakness.

(2) Cinoxacin may induce nausea, vomiting, diarrhea, headache, insomnia, skin rash, pruritus, and urticaria.

5. Significant interactions

a. The effects of methenamine are inhibited by alkalinizing agents and are antagonized by acetazolamide.

b. Nitrofurantoin absorption is decreased by magnesium-containing antacids. Nitrofurantoin blood levels are increased and urine levels decreased by sulfinpyrazone and probenecid, leading to increased toxicity and reduced therapeutic effectiveness.

c. Quinolones

(1) Cinoxacin urine levels are decreased by probenecid, reducing therapeutic effectiveness.

(2) Norfloxacin is rendered less effective by antacids.

K. Miscellaneous antibacterial agents

1. Aztreonam (Azactam). This agent was the first commercially available monobactam (monocyclic β-lactam compound). It resembles the aminoglycosides in its efficacy against many gram-negative organisms but does not cause nephrotoxicity or ototoxicity. Other advantages of this drug include its ability to preserve the body's normal gram-positive and anaerobic flora, activity against many gentamicin-resistant organisms, and lack of cross-allergenicity with penicillin.

a. Mechanism of action. Aztreonam is bactericidal; it inhibits bacterial cell wall synthesis.

b. Spectrum of activity. This drug is active against many gram-negative organisms, including Enterobacter and P. aeruginosa.

c. Therapeutic uses. Aztreonam is therapeutic for urinary tract infections, septicemia, skin infections, lower respiratory tract infections, and intra-abdominal infections resulting from gram-negative organisms. Increased incidence of P. aeruginosa resistant to aztreonam have been reported.

d. Precautions and monitoring effects

(1) Aztreonam sometimes causes nausea, vomiting, and diarrhea.

(2) Liver enzymes may increase transiently during aztreonam therapy.

(3) This drug may induce skin rash.

2. Chloramphenicol. A nitrobenzene derivative, this drug has broad activity against rickettsia as well as many gram-positive and gram-negative organisms. It also is effective against many ampicillin-resistant strains of H. influenzae.

a. Mechanism of action. Chloramphenicol is primarily bacteriostatic, although it may be bactericidal against a few bacterial strains.

b. Spectrum of activity. This agent is active against rickettsia and a wide range of bacteria, including H. influenzae, Salmonella typhi, Neisseria meningitidis, Bordetella pertussis, Clostridium, B. fragilis, S. pyogenes, and S. pneumoniae.

c. Therapeutic uses. Because of its toxic side effects, chloramphenicol is used only to suppress infections that cannot be treated effectively with other antibiotics. Such infections typically include

(1) Typhoid fever

(2) Meningococcal infections in cephalosporin-allergic patients

(3) Serious H. influenzae infections, particularly in cephalosporin-allergic patients

(4) Anaerobic infections (e.g., those originating in the pelvis or intestines)

(5) Anaerobic or mixed infections of the CNS

(6) Rickettsial infections in pregnant patients, tetracycline-allergic patients, and renally impaired patients

d. Precautions and monitoring effects

(1) Chloramphenicol can cause bone marrow suppression (dose-related) with resulting pancytopenia; rarely, the drug leads to aplastic anemia (not related to dose).

(2) Hypersensitivity reactions may include skin rash and, in extremely rare cases, angioedema or anaphylaxis.

(3) Chloramphenicol therapy may lead to gray baby syndrome in neonates (especially premature infants). This dangerous reaction, which stems partly from inadequate liver detoxification of the drug, is manifested by vomiting, gray cyanosis, rapid and irregular respirations, vasomotor collapse, and in some cases death.

e. Significant interactions

(1) Chloramphenicol inhibits the metabolism of phenytoin, tolbutamide, chlorpropamide, and dicumarol, leading to prolonged action and intensified effect of these drugs.

(2) Phenobarbital shortens chloramphenicol's half-life, thereby reducing its therapeutic effectiveness.

(3) Penicillins can cause antibiotic antagonism.

(4) Acetaminophen elevates chloramphenicol levels and may cause toxicity.

3. Clindamycin (Cleocin). This agent has essentially replaced lincomycin, the drug from which it is derived. It is used to treat skin, respiratory tract, and soft-tissue infections caused by staphylococci, pneumococci, and streptococci.

a. Mechanism of action. Clindamycin is bacteriostatic; it binds to the 50S ribosomal subunit, thereby suppressing bacterial protein synthesis.

b. Spectrum of activity. This agent is active against most gram-positive and many anaerobic organisms, including B. fragilis.

c. Therapeutic uses. Because of its marked toxicity, clindamycin is used only against infections for which it has proven to be the most effective drug. Typically, such infections include abdominal and female genitourinary tract infections caused by B. fragilis.

d. Precautions and monitoring effects

(1) Clindamycin may cause rash, nausea, vomiting, diarrhea, and pseudomembranous colitis as evidenced by fever, abdominal pain, and bloody stools.
(2) Blood dyscrasias (e.g., eosinophilia, thrombocytopenia, leukopenia) may occur.
e. Significant interactions. Clindamycin may potentiate the effects of neuromuscular blocking agents.
4. Dapsone. A member of the sulfone class, this drug is the primary agent in the treatment of all forms of leprosy.
a. Mechanism of action. Dapsone is bacteriostatic for Mycobacterium leprae; its mechanism of action probably resembles that of the sulfonamides.
b. Spectrum of activity. This drug is active against M. leprae; however, drug resistance develops in up to 40% of patients. Dapsone also has some activity against P. carinii organisms and the malarial parasite Plasmodium.
c. Therapeutic uses
(1) Dapsone is the drug of choice for treating leprosy.
(2) This agent may be used to treat dermatitis herpetiformis, a skin disorder.
(3) Maloprim, a dapsone-pyrimethamine product, is valuable in the prophylaxis and treatment of malaria.
(4) Dapsone, with or without trimethoprim, is used for prophylaxis of P. carinii pneumonia in patients with AIDS.
d. Precautions and monitoring effects
(1) Hemolytic anemia can occur with daily doses > 200 mg. Other adverse hematological effects include methemoglobinemia and leukopenia.

(2) Nausea, vomiting, and anorexia may develop.
(3) Adverse CNS effects include headache, dizziness, nervousness, lethargy, paresthesias, and psychosis.
(4) Dapsone occasionally results in a potentially lethal mononucleosis-like syndrome.
(5) Paradoxically, this drug sometimes exacerbates leprosy.
(6) Other adverse effects include skin rash, peripheral neuropathy, blurred vision, tinnitus, hepatitis, and cholestatic jaundice.
e. Significant interactions. Probenecid elevates blood levels of dapsone, possibly resulting in toxicity.
5. Clofazimine is phenazine dye with antimycobacterial and anti-inflammatory activity.
a. Mechanism of action. Clofazimine appears to bind preferentially to mycobacterial DNA, inhibiting replication and growth. It is bactericidal against M. leprae, and it appears to be bacteriostatic against MAI.

b. Spectrum of activity. Clofazimine is active against various mycobacteria, including M. leprae, M. tuberculosis, and MAI.
c. Therapeutic uses. Clofazimine is used to treat leprosy and a variety of atypical Mycobacterium infections.
d. Precautions and monitoring effects
(1) Pigmentation (pink to brownish) occurs in 75%-100% of patients within a few weeks. This skin discoloration has led to severe depression (and suicide).
(2) Urine, sweat, and other body fluids may be discolored.
(3) Other effects include ichthyosis and dryness of skin (8%-28%), rash and pruritus (1%-5%), and GI intolerance (e.g., abdominal/epigastric pain, diarrhea, nausea, vomiting) in 40%-50% of patients. Clofazimine should be taken with food.
6. Daptomycin (Cubicin) is a unique lipopeptide antibiotic with clinical activity in the treatment of resistant gram-positive infections.
a. Mechanism of action. Daptomycin is bactericidal; unlike other antibiotics, it binds to the bacterial cell membrane, causing depolarization of the membrane potential leading to inhibition of RNA, DNA, and protein synthesis.
b. Spectrum of activity. This drug is active against vancomycin-susceptible E. faecium and S. aureus (including methicillin-resistant strains) as well as other aerobic gram-positive bacteria.
c. Therapeutic uses. Daptomycin is indicated for the treatment of complicated skin and skin structure infections and S. aureus bacteremia. It is not indicated for the treatment of pneumonia.
d. Precautions and monitoring effects
(1) Reported side effects are generally mild and self-limiting and include constipation, abnormal liver function tests, and renal failure.
(2) Cases of myalgia and/or muscle weakness, exacerbations of myasthenia gravis, and increases in creatine phosphokinase (CPK) have been reported.
7. Linezolid (Zyvox) is a synthetic oxazolidinone that has clinical use in the treatment of infections caused by aerobic gram-positive bacteria.
a. Mechanism of action. Linezolid is bacteriostatic against Enterococci and Staphylococci, and bactericidal against Streptococci. Linezolid binds to the 23S ribosomal RNA of the 50S subunit and thus inhibits protein synthesis.
b. Spectrum of activity. The drug is active against vancomycin-resistant Enterococcus faecium and S. aureus (methicillin-susceptible and -resistant strains) as well as other aerobic gram-positive bacteria.
c. Therapeutic uses. Linezolid is indicated for treatment of infections caused by vanco-mycin-resistant E. faecium, nosocomial pneumonia caused by methicillin-susceptible and -resistant strains of S. aureus, community-acquired pneumonia caused by penicillin-susceptible strains of S. pneumoniae, and skin and skin structure infections owing to these organisms.
d. Precautions and monitoring effects

(1) Safety data are limited. Adverse effects generally are minor (e.g., gastrointestinal complaints, headache, rash).
(2) Thrombocytopenia or a significant reduction in platelet count has been reported (2.4%) and is related to duration of therapy. Monitor platelets in patients with risk of bleeding, preexisting thrombocytopenia, platelet disorders (including those

caused by concurrent medications) and in patients receiving linezolid lasting longer than 2 weeks.
(3) Myelosuppression owing to direct bone marrow suppression has been reported rarely.
e. Significant interactions. Patients receiving concomitant therapy with adrenergic or serotonergic agents or consuming more than 100 mg of tyramine a day may experience an enhancement of the drug's effect or serotonin syndrome.
8. Quinupristin/dalfopristin (Synercid) is an intravenous streptogramin antibiotic composed of two chemically distinct compounds.
a. Mechanism of action. Quinupristin binds to the 50S subunit, and dalfopristin binds tightly to the 70S ribosomal particle.
b. Spectrum of activity. Synercid has activity against Staphylococci spp., including resistant strains. This combination has better activity against E. faecium than Enterococcus faecalis and is also active against some gram-negative organisms and anaerobes; activity has not been shown against Enterobacteriaceae.
c. Therapeutic uses. It is used for treatment of vancomycin-resistant E. faecium (VREF) bacteremia and skin and skin structure infections caused by S. aureus and S. pyogenes.
d. Precautions and monitoring effects
(1) Reported side effects are generally mild and infusion related: pain, erythema, or itching at the infusion site; increases in pulse and diastolic pressure; headache; nausea or vomiting; and diarrhea. It may increase liver function tests slightly.
(2) Drug interactions are a result of cytochrome P450 3A4 inhibition. Potential drug interactions include cyclosporin, nifedipine, and midazolam.
(3) Concomitant use of medications that may prolong QTc interval should be avoided.
(4) Mild to life-threatening pseudomembranous colitis has been reported.
9. Rifaximin. Is a semi-synthetic antibiotic that is structurally related to rifamycin.
a. Mechanism of action. It inhibits bacterial RNA synthesis by binding to the beta-subunit of bacterial DNA-dependent RNA polymerase.
b. Spectrum of activity. This non-systemically absorbed drug has activity against both enterotoxigenic and enteroaggregative strains of Escherichia coli.

c. Therapeutic uses. Rifaximin is used in the treatment of Traveler's diarrhea with noninvasive strains of E. coli. High resistance rates have been reported after 5 days of treatment.
d. Precautions and monitoring effects. Because of its limited systemic absorption, adverse effects are few but include constipation, vomiting, flatulence and headache.
10. Spectinomycin. An aminocyclitol agent related to the aminoglycosides, this antibiotic is useful against penicillin-resistant strains of gonorrhea.
a. Mechanism of action. Spectinomycin is bacteriostatic; it selectively inhibits protein synthesis by binding to the 30S ribosomal subunit.
b. Spectrum of activity. This agent is active against various gram-negative organisms.
c. Therapeutic uses. Spectinomycin is used only to treat gonococcal infections in patients with penicillin allergy or when such infection stems from penicillinase-producing gonococci (PPNG).
d. Precautions and monitoring effects. Because spectinomycin is given only as a single-dose IM injection, it causes few adverse effects. Nausea, vomiting, urticaria, chills, dizziness, and insomnia occur rarely.
11. Telithromycin (Ketek) is the first of a new class of antimicrobials called the ketolides. It is an oral semisynthetic derivative of erythromycin.
a. Mechanism of action. Telithromycin may be bactericidal or bacteriostatic; it inhibits bacterial protein synthesis.
b. Spectrum of activity. This drug is active against many aerobic and anaerobic gram-positive organisms, including multidrug- resistant S. pneumoniae, some gram-negative organisms as well as atypical pathogens.
c. Therapeutic uses. Telithromycin is indicated for the treatment of mild to moderate community-acquired pneumonia only. The FDA removed the previous 2 approved indications and added a black box warning.

d. Precautions and monitoring effects
(1) GI effects (including diarrhea, nausea, and vomiting) were the most common side effects followed by dizziness and visual disturbances (such as diplopia and blurred and abnormal vision); serious liver toxicity has been reported.
(2) Cross-sensitivity with the other macrolides occurs.
(3) Concomitant use of drugs or conditions that may prolong the QTc interval should be avoided.
(4) Contraindicated in patients with myasthenia gravis, hepatitis, or jaundice.
e. Significant interactions
(1) Co-administration of telithromycin with either cisapride or pimozide is contraindicated.

(2) Concomitant administration of drugs metabolized by cytochrome P450 3A4 in patients with telithromycin should be closely monitored.
(3) Patients on bepridil, mesoridazine, terfenadine, thioridazine, or ziprasidone should not be prescribed telithromycin owing to the high potential for toxicity.
(4) This agent has a high potential to interact with many drugs. Check product information for the most current interaction information.
12. Tigecycline (Tygacil). An intravenous glycylcycline antibiotic developed as a semisynthetic analogue of tetracycline with a broad spectrum of activity.
a. Mechanism of action. Tigecycline is bacteriostatic; it inhibits bacterial protein synthesis by reversibly binding to the 30S ribosome subunit.
b. Spectrum of activity. The drug is active against vancomycin-susceptible E. faecalis, methicillin-resistant S. epidermidis, and S. aureus (methicillin-susceptible and -resistant strains) as well as some gram-negative aerobes and anaerobes.
c. Therapeutic uses. Tigecycline is indicated for the treatment of complicated intra-abdominal infections caused by E. coli, vancomycin-susceptible E. faecalis, S. aureus (methicillin-susceptible strains only) and B. fragilis. Also indicated for the treatment of complicated skin and skin structure infections caused by E. faecalis (vancomycin-susceptible strains), S. pyogenes and S. aureus (methicillin-susceptible and -resistant strains).
d. Precautions and monitoring effects.
(1) Safety data are limited. Side effects are generally mild with GI disturbances—for example, nausea (22%-35%) and vomiting (13%-19%)—the most commonly reported. The mechanism of these reactions is uncertain.
(2) May cause permanent discoloration of the teeth similar to the tetracyclines.
(3) Caution in patients with a history of hypersensitivity reactions to tetracyclines.
(4) Phototoxic reactions, pancreatitis, and increases in BUN may occur.
e. Significant interactions. Closely monitor the prothrombin time or international sensitivity index (INR) in patients on warfarin during concomitant administration of tigecycline.
13. Trimethoprim. A substituted pyrimidine, trimethoprim is most commonly combined with sulfamethoxazole (a sulfonamide discussed in II.F) in a preparation called cotrimoxazole. However, it may be used alone for certain urinary tract infections.
a. Mechanism of action. Trimethoprim inhibits dihydrofolate reductase, thus blocking bacterial synthesis of folic acid.
b. Spectrum of activity
(1) Trimethoprim is active against most gram-negative and gram-positive organisms. However, drug resistance may develop when this drug is used alone.

(2) Trimethoprim-sulfamethoxazole is active against a variety of organisms, including S. pneumoniae, N. meningitidis, and Corynebacterium diphtheriae; some strains of S. aureus, Staphylococcus epidermidis, P. mirabilis, Enterobacter, Salmonella, Shigella, Serratia, and Klebsiella spp.; and E. coli.
(3) The trimethoprim-sulfamethoxazole combination is synergistic; many organisms resistant to one component are susceptible to the combination.
c. Therapeutic uses
(1) Trimethoprim may be used alone or in combination with sulfamethoxazole to treat uncomplicated urinary tract infections caused by E. coli, P. mirabilis, and Klebsiella and Enterobacter organisms.
(2) Trimethoprim-sulfamethoxazole is therapeutic for acute gonococcal urethritis, acute exacerbation of chronic bronchitis, shigellosis, and Salmonella infections.

(3) Trimethoprim-sulfamethoxazole may be given as prophylactic or suppressive therapy in P. carinii pneumonia. It is the drug of choice for the treatment of Stenotrophomonas maltophilia infections.
d. Precautions and monitoring effects
(1) Most adverse effects involve the skin (possibly from sensitization). These include rash, pruritus, and exfoliative dermatitis.
(2) Rarely, trimethoprim-sulfamethoxazole causes blood dyscrasias (e.g., acute hemolytic anemia, leukopenia, thrombocytopenia, methemoglobinemia, agranulocytosis, aplastic anemia).
(3) Adverse GI effects including nausea, vomiting, and epigastric distress glossitis may occur.
(4) Neonates may develop kernicterus.
(5) Patients with AIDS sometimes suffer fever, rash, malaise, and pancytopenia during trimethoprim therapy.
14. Vancomycin. This glycopeptide destroys most gram-positive organisms.
a. Mechanism of action. Vancomycin is bactericidal; it inhibits bacterial cell wall synthesis.
b. Spectrum of activity. This drug is active against most gram-positive organisms, including methicillin-resistant strains of S. aureus and Enterococci.
c. Therapeutic uses. Vancomycin usually is reserved for serious infections, especially those caused by methicillin-resistant staphylococci. It is particularly useful in patients who are allergic to penicillin or cephalosporins. Typical uses include endocarditis, osteomyelitis, and staphylococcal pneumonia.
(1) Oral vancomycin is valuable in the treatment of antibiotic-induced pseudomembranous colitis caused by C. difficile or S. aureus enterocolitis. Because vancomycin is not absorbed after oral administration, it is not

useful for systemic infections. Because of resistance, the Centers for Disease Control and Prevention (CDC) recommend vancomycin as the second choice to metronidazole for C. difficile infections.
(2) Because 1 g provides adequate blood levels for 7-10 days, IV vancomycin is particularly useful in the treatment of anephric patients with gram-positive bacterial infections.
d. Precautions and monitoring effects
(1) Ototoxicity may arise; nephrotoxicity is rare but can occur with high doses.
(2) Vancomycin may cause hypersensitivity reactions, manifested by such symptoms as anaphylaxis and skin rash.
(3) Therapeutic levels peak at 20-40 μg/mL. The trough is < 15 μg/mL.
(4) Red man's syndrome may occur. This is facial flushing and hypotension owing to too rapid infusion of the drug. Infusion should be over a minimum of 60 min for a 1-g dose.
(5) IV solutions are very irritating to the vein.
e. Vancomycin-resistant enterococci. A few strains of vancomycin-resistant enterococci are susceptible to teicoplanin (investigational by Hoechst Marion Roussel), linezolid (Zyvox), or quinupristin/dalfopristin (Synercid). These agents may be useful for multiple-drug-resistant E. faecium.

III. Systemic Antifungal Agents

A. Definition. These agents treat systemic and local fungal (mycotic) infections—diseases that resist treatment with antibacterial drugs.
B. Amphotericin B (Fungizone). This polyene antifungal antibiotic is therapeutic for various fungal infections that frequently proved fatal before the drug became available. It is used increasingly in the empiric treatment of severely immunocompromised patients in certain clinical situations.
1. Mechanism of action. Amphotericin B is both fungistatic in clinically obtained concentrations and may be fungicidal in the presence of susceptible organisms. It binds to sterols in the fungal cell membrane, thereby increasing membrane permeability and permitting leakage of intracellular contents. Other mechanisms may be involved as well.

2. Spectrum of activity. Amphotericin B is a broad-spectrum antifungal agent with activity against Aspergillus, Blastomyces, Candida spp. (albicans, krusei tropicalis, and glabrata), Cryptococcus, Coccidioides, Histoplasma, Paracoccidioides, Phycomycetes (mucor), and Sporothrix. It is also useful against some protozoa such as Leishmania, Naegleria, and Acanthamoeba.
3. Therapeutic uses. Amphotericin B is the most effective antifungal agent in the treatment of systemic fungal infections, especially in immunocompromised patients.

a. It is the treatment of choice for pulmonary Aspergillus infections; Blastomyces infections, which are life-threatening with AIDS or CNS involvement; deep-organ infections with Candida; Coccidioides infections with severe pulmonary involvement or with disseminated nonmeningeal immunocompetent or immunocompromised patients; all Cryptococcus infections; disseminated Histoplasma infections involving CNS or immunosuppressed patients; Malassezia furfur fungemia; pulmonary and extrapulmonary Phycomycetes (mucormycosis); Penicillium marneffei; and extracutaneous Sporothrix.
b. This agent may be used to treat coccidioidal arthritis.
c. Topical preparations are given to eradicate cutaneous and mucocutaneous candidiasis.
d. It may be used as empiric therapy in febrile, neutropenic patients.
e. It is used as secondary prophylaxis of fungal infections in HIV-positive patients, guarding against recurrence of infection.
f. It may be used prophylactically in neutropenic cancer patients and bone marrow transplant or solid-organ transplant patients to reduce the incidence of Aspergillus and Candida infections.
4. Precautions and monitoring effects. Because amphotericin B can cause many serious adverse effects, it should be administered in a hospital setting—at least during the initial therapeutic stage. The adverse effects are divided into infusion reactions and others.
a. Infusion reactions occur while the drug is being administered and include fever, shaking chills, hypotension, anorexia, nausea, vomiting, headache, dyspnea, and tachypnea. Premedication with acetaminophen and diphenhydramine has been helpful in prophylaxing against infusion reactions. In addition, hydrocortisone 10-50 mg may be added to the infusion as prophylaxis against infusion-related reactions. Meperidine 25-50 mg IV is effective treatment of active shaking chills/rigors. Meperidine is also effective in prophylaxis of rigors.
b. Nephrotoxicity frequently occurs. Dosage adjustment or drug discontinuation or changing to a liposomal amphotericin B product may be necessary as renal impairment progresses.
c. Electrolyte abnormalities, including hypokalemia, hypomagnesemia, and hypocalcemia, are common. Monitor and replace electrolytes as needed.
d. Normocytic, normochromic anemia will develop over long-term use (10 weeks). Monitor hematocrit periodically.
e. Bronchospasm, wheezing, and anaphylaxis or anaphylactoid reactions have occurred. A test dose of 1 mg of amphotericin B is often administered before infusion of large quantities of the drug.
f. Phlebitis or thrombophlebitis is reported with conventional amphotericin B. Heparin (500-1000 U) can be added to the infusion to aid in prevention.
g. CNS effects include headache, peripheral neuropathy, malaise, depression, seizure, myasthenia, and hallucinations.

h. Elevated liver transaminases, aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, bilirubin, γ-glutamyltransferase (GGT), and lactate dehydrogenase (LDH) may occur.
i. Amphotericin B parenteral use should be mixed only in dextrose 5% in water (D5W) and should be protected from light.
5. Significant interactions. Other nephrotoxic drugs (aminoglycosides, capreomycin, colistin, cisplatin, cyclosporine, methoxyflurane, pentamidine, polymyxin B, and vancomycin) may cause additive nephrotoxicity.
6. Amphotericin B lipid complex (Abelcet), amphotericin B cholesterol sulfate complex (Amphotec), and liposomal amphotericin B (AmBisome) offer alternative formulations of amphotericin B for the treatment of severe fungal infections in patients who are intolerant of or whose disease is refractory to conventional treatment.

C. Echinocandins. Three echinocandins are approved in the US: capsofungin (Cancidas), micafungin (Mycamine) and anidulafungin (Eraxis). These agents have a broad spectrum of activity against Candida species with micafungin and anidulafungin having similar MICs that are generally lower than the MIC of capsofungin.
1. Mechanism of action. Caspofungin works by causing fungal cell wall lysis. By being a noncompetitive inhibitor of β (1,3) synthase, which is an essential component of fungal cell wall synthesis, it causes osmotic instability within the fungus and fungal cell wall lysis.
2. Spectrum of activity. Echinocandins have fungicidal activity against Candida species and fungistatic activity against Aspergillus species. All three agents in this class appear to have good activity in vitro for most isolates of Candida species, including those that are either Amphotericin-B or fluconazole and itraconazole-resistant, such as C. glabrata.
3. Therapeutic uses. All three agents are indicated for the treatment of esophageal candidiasis
a. Caspofunfin and anidulafungin are also indicated for the treatment of candidemia and other infections caused by Candida species, including intrabdominal abscesses and peritonitis.
b. Caspofungin may also be used for the treatment of candidal pleural space infections, empiric treatment of presumed fungal infections in neutropenic patients, and treatment of invasive aspergillosis in patients refractory to or intolerant of other antifungals (i.e., amphotericin B, itraconazole).
c. Micafungin is indicated for the prophylaxis of candidal infections in patients indergoing hematopoietic stem cell transplantation (HSCT).
4. Precautions and monitoring effects. Although this class has adverse events associated with its use, the overall toxicity profile is significantly better than that of amphotericin B.

a. Infusion vein complications (not defined by manufacturer) and thrombophlebitis have been seen on infusion of caspofungin.
b. Hematological decreases in hemoglobin and hematocrit may occur; however, the incidence does not differ from that of having a fungal disease.
c. Headache may occur.
d. Slight decreases in serum potassium may occur, but nowhere near the magnitude of that caused by amphotericin B.
e. Anorexia, nausea, vomiting, and diarrhea have occurred.
f. Rare increases in serum creatinine; however, there have been no reported cases of nephrotoxicity.
g. Possible slight increases in serum aminotransferases
h. Allergic reactions occur in < 5% of patients and anaphylaxis in < 2% of patients.
i. Pregnancy category C embryotoxic reactions have occurred in animals.
5. Significant interactions
a. When cyclosporine is combined with caspofungin, clinically significant rises in ALT were observed. Serum transaminases should be monitored, and this combination should be avoided in patients with preexisting liver disease.
b. When used in combination, carbamazepine, nelfinavir, nevirapine, phenytoin, and rifampin increases the clearance of caspofungin. Higher doses of caspofungin (70 mg every day) should be considered when this combination is administered.
c. Tacrolimus clearance will be increased when the combination is used; monitor tacrolimus serum levels closely.
D. Flucytosine (Ancobon). This fluorinated pyrimidine usually is given in combination with amphotericin B.
1. Mechanism of action. Flucytosine penetrates fungal cells and is converted to fluorouracil, a metabolic antagonist. Incorporated into the RNA of the fungal cell, flucytosine causes defective protein synthesis. It is either fungistatic or fungicidal, depending on the concentration of the drug.
2. Spectrum of activity. This drug is primarily active against Cryptococcus and Candida. It is most commonly used in conjunction with amphotericin B. Fungal resistance against flucytosine alone has been well documented. Flucytosine may also possess some activity against chromomycosis and some strains of Aspergillus (in vitro testing only).

3. Therapeutic uses. Flucytosine is adjunctively used with amphotericin B for severe systemic infections (e.g., septicemia, endocarditis, pulmonary and urinary tract infections, meningitis). Use of flucytosine alone is not recommended.
4. Precautions and monitoring effects

a. Frequent adverse effects include GI intolerance with nausea, vomiting, and diarrhea.
b. Occasional adverse reactions are more severe and include marrow suppression with leukopenia or thrombocytopenia (dose related, especially with renal failure or concurrent amphotericin B use). Confusion, rash, hepatitis, enterocolitis, headache, and photosensitivity reactions can also occur.
c. Rare reactions include hallucinations, blood dyscrasias with agranulocytosis and pancytopenia, fatal hepatitis, anaphylaxis, and anemia.
d. Flucytosine may cause a markedly false elevation of serum creatinine if an Ektachem analyzer is used.
5. Significant interactions. Beneficial drug interactions occur with flucytosine. Flucytosine has demonstrated synergy with amphotericin B and fluconazole against Cryptococcus and Candida spp.
E. Griseofulvin (Fulvicin). Produced from Penicillium griseofulvin Dierckx, this drug is deposited in the skin, bound to keratin.
1. Mechanism of action. This agent is fungistatic; it inhibits fungal cell activity by interfering with mitotic spindle structure. Its mechanism of action is similar to colchicine.
2. Spectrum of activity. Griseofulvin is active against various strains of Microsporum, Epidermophyton, and Trichophyton.
3. Therapeutic uses. Griseofulvin is effective in tinea infections of the skin, hair, and nails (including athlete's foot, jock itch, and ringworm) caused by Microsporum, Epidermophyton, and Trichophyton.
a. Generally, this agent is given only for infections that do not respond to topical antifungal agents.
b. Griseofulvin is available only in oral form.
c. It possesses vasodilatory activity and may be used in Raynaud disease.
d. It may be used to treat gout.
4. Precautions and monitoring effects
a. Griseofulvin rarely results in serious adverse effects. However, the following problems have been reported.
(1) Common: headache, fatigue, confusion, impaired performance, syncope, and lethargy, which generally resolve with continued use
(2) Occasional: leukopenia, neutropenia, and granulocytopenia
(3) Rare: serum sickness, angioedema, urticaria, erythema, and hepatotoxicity
b. The dosage depends on the particle size of the product: 250 mg of ultramicrosize (Fulvicin P/G) is equivalent in therapeutic effects to 500 mg of microsize (Fulvicin U/F).
5. Significant interactions
a. Griseofulvin may increase the metabolism of warfarin, leading to decreased prothrombin time.
b. Barbiturates may reduce griseofulvin absorption.
c. Alcohol consumption may cause tachycardia and flushing.

d. Oral contraceptives may cause amenorrhea or increased breakthrough bleeding.

F. Imidazoles. The substituted imidazole derivatives ketoconazole (Nizoral), miconazole (Monistat), fluconazole (Diflucan), itraconazole (Sporanox), voriconazole (Vfend) and posaconazole (Noxafil) are valuable in the treatment of a wide range of systemic fungal infections.

1. Mechanism of action. Imidazoles inhibit sterol synthesis in fungal cell membranes and increase cell wall permeability; this, in turn, makes the cell more vulnerable to osmotic pressure. These agents are fungistatic.

2. Spectrum of activity. These agents are active against many fungi, including yeasts, dermatophytes, actinomycetes, and some Phycomycetes.

3. Therapeutic uses

a. Ketoconazole, an oral agent, successfully treats many fungal infections that previously yielded only to parenteral agents.

(1) It is therapeutic for systemic and vaginal candidiasis, mucocandidiasis, candiduria, oral thrush, histoplasmosis, coccidioidomycosis, chromomycosis, dermatophytosis (tinea), and paracoccidioidomycosis.

(2) Because ketoconazole is slow acting and requires a long duration of therapy (up to 6 months for some chronic infections), it is less effective than other antifungal agents for the treatment of severe and acute systemic infections.

b. Miconazole, primarily administered as a topical agent, The parenteral form has been discontinued in the United States. It was a relatively toxic formulation which has been replaced by other members of this class (e.g., fluconazole).

(1) Topical miconazole is highly effective in vulvovaginal candidiasis, ringworm, and other skin infections.

c. Fluconazole. Available in oral and parenteral forms, fluconazole can be used against systemic and CNS infections involving Cryptococcus and Candida. Candida oropharyngeal infection and esophagitis may also be treated with fluconazole. Aspergillus, Coccidioides, and Histoplasma have demonstrated in vitro sensitivity.

d. Itraconazole is available as an oral agent with activity against systemic and invasive pulmonary aspergillosis without the hematological toxicity of amphotericin B. Other deep mycotic infections susceptible to itraconazole include blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis.

e. Voriconazole. Voriconazole is available as both an intravenous and an oral agent for the treatment of fungal infections involving invasive aspergillosis, Scedosporium apiospermum, and Fusarium spp., including those species that are refractory to other therapy.

f. Posaconazole. Available as an oral suspension indicated for the prevention of invasive infections caused by Aspergillus and Candida species in patients receiving HSCT or with neutropenis. Posaconazole may also be used to treat invasive fungal infections in patients who have previously failed or are intolerant to other antifungals.

4. Precautions and monitoring effects

a. Ketoconazole may cause nausea, vomiting, diarrhea, abdominal pain, and constipation. Rarely, it leads to headache, dizziness, gynecomastia, and fatal hepatotoxicity.

b. Fluconazole commonly causes GI disturbances (e.g., nausea, vomiting, epigastric pain, diarrhea). Reversible elevations in serum aminotransferase, exfoliative skin reactions, and headaches have been reported.

c. Itraconazole may cause nausea, vomiting, hypertriglyceridemia, hypokalemia, rash, and elevations in liver enzymes.

d. Voriconazole. Visual disturbances, fever, rash, vomiting, nausea, diarrhea, headache, sepsis, peripheral edema, abdominal pain, and respiratory disorders rarely occurred. Liver function test abnormalities have occurred.

e. Posaconazole. Most common adverse events have been nausea and headache. Rash, dry skin, taste disturbances, abdominal pain, dizziness, hypokalemia, thrombocytopenia, and flushing can occur. Posaconazole can cause abnormalities in liver function and has been associated with prolongation of the QT interval.

5. Significant interactions

a. Both ketoconazole and miconazole may enhance the anticoagulant effect of warfarin.

b. Ketoconazole may antagonize the antibiotic effects of amphotericin B.

c. Fluconazole has been shown to elevate serum levels of phenytoin, cyclosporine, warfarin, and sulfonylureas. Concurrent hepatic enzyme inducers, such as rifampin, have resulted in increased elimination of both fluconazole and itraconazole.

d. Coadministration of itraconazole or ketoconazole with astemizole or terfenadine may result in increased astemizole or terfenadine levels, possibly leading to life-threatening dysrhythmias and death.

e. Both ketoconazole and itraconazole need the presence of stomach acid for adequate absorption. Use with antacids, H_2-blockers, or proton pump inhibitors is contraindicated.

f. Concomitant use of imidazole antifungal agents with cisapride may result in increased concentrations of cisapride, which has been associated with adverse cardiac events such as torsades de pointes leading to sudden death.

g. Voriconazole. Cytochrome P450 2C19 is the major enzyme involved in metabolism. Voriconazole inhibits cytochrome P450 2C19, 2C9, and 3A4. Any medication that is metabolized via these routes may be affected, and monitoring of blood levels (if appropriate) or clinical signs and symptoms is necessary when taking concomitant medications.

h. Posaconazole serum levels are reduced by concurrent administration with cimetidine, phenytoin or rifbutin; avoid concommitant use if possible. Posaconazole may increase concentrations of cyclosporine, tacrolimus, rifabutin, midazolam, and phenytoin; dosage adjustments may be required. (1) Food increases the oral bioavailability; take posaconazole with a full meal or liquid nutritional supplement

G. Nystatin (Mycostatin). A polyene antibiotic, nystatin has a chemical structure similar to that of amphotericin B.

1. Mechanism of action. Nystatin is fungicidal and fungistatic; binding to sterols in the fungal cell membrane, it increases membrane permeability and permits leakage of intracellular contents.

2. Spectrum of activity. Nystatin is active primarily against Candida spp.

3. Therapeutic uses

a. This drug is used primarily as a topical agent in vaginal and oral Candida infections.

b. Oral nystatin is therapeutic for Candida infections of the GI tract, especially oral and esophageal infections; because the drug is not readily absorbed, it maintains good local activity.

4. Precautions and monitoring effects. Oral nystatin occasionally causes GI distress (e.g., nausea, vomiting, diarrhea). Rarely, hypersensitivity reactions occur.

H. Terbinafine (Lamisil) is a synthetic allylamine with structure and activity related to naftifine.

1. Mechanism of action. Terbinafine inhibits squalene monooxygenase, leading to an interruption of fungal sterol biosynthesis. Terbinafine may be fungicidal or fungistatic, depending on drug concentration and species.

2. Spectrum of activity. Terbinafine has activity against dermatophytic fungi (Trichophyton, Microsporum, and Epidermophyton), filamentous fungi (Aspergillus), and dimorphic fungi (Blastomyces). It may also possess some activity against yeasts.

3. Therapeutic uses

a. Oral terbinafine is useful against infections of the toenail and fingernail (onychomycosis, tinea unguium). Time to cure is reduced over imidazole antifungals for these indications. It is useful in patients who may not tolerate the adverse effect profile of imidazole antifungals.

b. It is also used in tinea capitis and tinea corporis infections.

4. Precautions and monitoring effects. Adverse effects include taste or ocular disturbances, symptomatic hepatobiliary dysfunction, decrease in lymphocyte count and neutropenia, and serious skin reactions.

IV. Topical Antifungal Agents

A. Definition. These agents are for topical use for fungal infections.

B. Amphotericin B (Fungizone) is available as a 3% cream or lotion or an oral suspension that is not absorbed through the GI tract.

1. Mechanism of action. See III.B.1.

2. Spectrum of activity. See III.B.2.

3. Therapeutic uses. Amphotericin B is used for oropharyngeal candidiasis, cutaneous and mucocutaneous candidal infections, or as a local irrigant for the bladder and intrapleural or intraperitoneal areas.

4. Precautions and monitoring effects. Compared with systemic administration, the topical formulations have relatively low toxicity.

a. Dry skin and local irritation with erythema, pruritus, or burning, along with mild skin discoloration, has occurred with the lotion and cream.

b. Rash and GI effects (e.g., nausea, vomiting, steatorrhea, diarrhea) tend to occur with the suspension. In addition, there have been case reports of urticaria, angioedema, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

C. Butenafine (Mentax) is a synthetic benzylamine related to the allylamine antifungal agents (naftifine, terbinafine).

1. Mechanism of action. Butenafine alters fungal membrane permeability and growth inhibition, interferes with sterol biosynthesis by allowing squalene to accumulate within the cell, and may be fungicidal in certain concentrations against susceptible organisms such as the dermatophytes.

2. Spectrum of activity. Butenafine is active against Trichophyton rubrum, Trichophyton mentagrophytes, Microsporum canis, Sporothrix schenckii, and yeasts including Candida parapsilosis and C. albicans.

3. Therapeutic uses. The 1% cream is used in dermatophytoses, including tinea corporis, tinea cruris, and tinea pedis.

4. Precautions and monitoring effects. If clinical improvement of fungal infection does not improve after the treatment period, the diagnosis should be reevaluated.

D. Butoconazole (Mycelex) is an azole antifungal cream available for vaginal use.

1. Mechanism of action. Butoconazole has fungistatic activity against susceptible organisms. The drug interferes with membrane permeability, secondary metabolic effects, and growth inhibition. Butoconazole contains antibacterial effects against some gram-positive organisms.

2. Spectrum of activity. Butoconazole is active against dermatophytes (Trichophyton concentricum, T. mentagrophytes, T. rubrum, Trichophyton tonsurans, Epidermophyton floccosum, M. canis, Microsporum gypseum),

yeasts (C. albicans, C. glabrata), and some gram-positive organisms (S. aureus, E. faecalis, and S. pyogenes).
3. Therapeutic uses. A 2% cream is used for vulvovaginal candidiasis and complicated, recurrent vulvovaginal candidiasis.
4. Precautions and monitoring effects
a. Vulvovaginal burning and itching are the most common; however, their incidence is low. Headache; itching of fingers; urinary frequency and burning; and vulvovaginal discharge, irritation, soreness, stinging, odor, and swelling rarely occur.
b. Butoconazole may damage birth-control devices such as condoms and diaphragms, leading to inadequate protection. Consider alternative methods of birth control.
c. Tampon use should be avoided with the use of butoconazole.
E. Ciclopirox (Loprox) is a synthetic antifungal agent that is chemically unrelated to any other antifungal agent. The ethanolamine contained in ciclopirox appears to enhance epidermal penetration.
1. Mechanism of action. Ciclopirox causes intracellular depletion of amino acids and ions necessary for normal cellular function.
2. Spectrum of activity. Ciclopirox is active against dermatophytes, yeasts, some gram-positive and gram-negative bacteria, Mycoplasma, and Trichomonas vaginalis. Specifically, ciclopirox has activity against T. mentagrophytes, T. rubrum, E. floccosum, M. canis, M. furfur, and C. albicans.
3. Therapeutic uses. Ciclopirox is used topically for the treatment of tinea pedis, tinea cruris, tinea corporis, tinea versicolor (from Malassezia), and cutaneous candidiasis (moniliasis) from C. albicans.

4. Precautions and monitoring effects. Local irritation manifested by erythema, pruritus, burning, blistering, swelling, and oozing has occurred. If this occurs, ciclopirox should be discontinued.
F. Clioquinol (formerly iodochlorhydroxyquin) is a topical antifungal in a 3% ointment that can be used alone or in combination with hydrocortisone.
1. Mechanism of action. Unknown
2. Spectrum of activity. It is active against dermatophytic fungi.
3. Therapeutic uses. It is used topically against the following:
a. Tinea pedis and tinea cruris (ringworm infections)
b. Previously used to treat diaper rash; however, it is no longer recommended, and use in children < 2 years of age is contraindicated
4. Precautions and monitoring effects
a. Local irritation, rash, and sensitivity reactions are common.
b. Systemic absorption after topical application may occur.

c. High doses of clioquinol over long periods of time have been associated with oculotoxic/neurotoxic effects, including optic neuritis, optic atrophy, and subacute myelooptic neuropathy.

G. Clotrimazole (Lotrimin) is an azole antifungal agent that is an imidazole derivative. It is related to other azole antifungal agents such as butoconazole, econazole, ketoconazole, miconazole, oxiconazole, sulconazole, and tioconazole.

1. Mechanism of action. Clotrimazole alters fungal cell membrane permeability by binding with phospholipids in the membrane.

2. Spectrum of activity. It is active against yeasts, dermatophytes (T. rubrum, T. mentagrophytes, E. floccosum, M. canis), and some gram-positive bacteria. At higher concentrations, clotrimazole inhibits M. furfur, Aspergillus fumigatus, C. albicans, and some strains of S. aureus, S. pyogenes, Proteus vulgaris, and Salmonella. At very high concentrations, clotrimazole has an effect on Sporothrix, Cryptococcus, Cephalosporium, Fusarium, and T. vaginalis.

3. Therapeutic uses

a. The lozenges, which are administered 5 times per day, are useful in treating oropharyngeal candidiasis. Lozenges are also used for primary prophylaxis of mucocutaneous candidiasis in HIV-infected infants or children with severe immunosuppression.

b. The cream, lotion, or solution is used to treat dermatophytoses, superficial mycoses, and cutaneous candidiasis.

c. Intravaginal dosage forms are useful in treating vulvovaginal candidiasis.

4. Precautions and monitoring effects

a. Cutaneous reactions with topical administration may include blistering, erythema, edema, pruritus, burning, stinging, peeling, skin fissures, and general irritation.

b. The vaginal tablets are associated with mild burning, skin rash, itching, vulval irritation, lower abdominal cramps, bloating, slight cramping, vaginal soreness during intercourse, and an increase in urinary frequency.

c. Cross-sensitization occurs with imidazole; however, it is unpredictable.

d. Abnormal liver function tests (elevated AST) have occurred in patients taking the lozenges.

H. Econazole (Spectazole) is an azole antifungal agent that is an imidazole derivative.

1. Mechanism of action. Econazole alters cell membranes and increases permeability (like many other azole agents).

2. Spectrum of activity. Econazole is active against dermatophytes, yeasts, some gram-positive bacteria, and T. vaginalis.

3. Therapeutic uses

a. The 1% topical cream, lotion, or solution is useful in treating dermatophytoses and cutaneous candidiasis (tinea corporis and tinea cruris).

b. Econazole is also used to treat pityriasis (tinea) versicolor (M. furfur).

4. Precautions and monitoring effects. In general, there is a low incidence of toxicity. Topically, a patient may experience burning, stinging sensations, pruritus, and erythema (after 2-4 days).

I. Gentian violet is a dye that possesses the ability to kill fungi, yeasts, and some gram-positive bacteria.

1. Mechanism of action. None known

2. Spectrum of activity. Gentian violet is active against Candida, Epidermophyton, Cryptococcus, Trichophyton, and some Staphylococcus spp.

3. Therapeutic uses. It is used to treat cutaneous C. albicans infections (monilia or thrush).

4. Precautions and monitoring effects

a. Gentian violet may cause irritation or sensitivity reactions or possibly ulceration of the mucous membranes. If the solution is swallowed, esophagitis, laryngitis, or tracheitis may occur.

b. Skin tattooing may occur if gentian violet is applied to granulation tissue.

c. Gentian violet should not be used in areas of extensive ulceration.

d. This drug is a dye and will stain clothing.

J. Ketoconazole (Nizoral) is an imidazole-derived antifungal drug that is available topically as a cream and a shampoo.

1. Mechanism of action. See III.E.1.

2. Spectrum of activity. See III.E.2.

3. Therapeutic uses

a. The 2% topical cream is used in treating tinea corporis, tinea cruris, and tinea pedis caused by the dermatophytes (E. floccosum, T. mentagrophytes, and T. rubrum).

b. It is used for cutaneous candidiasis.

c. The 2% topical cream or 2% shampoo may be used in treating tinea versicolor (M. furfur). Selenium-based shampoos may also be useful in this area.

d. The 2% topical cream is useful against seborrheic dermatitis. The 2% shampoo is useful in reducing scaling caused by dandruff.

e. When combined with a steroid, ketoconazole is useful in treating the following: atopic dermatitis, diaper rash, eczema, folliculitis, impetigo, intertrigo, lichenoid dermatitis, and psoriasis.

f. An ophthalmic suspension can be extemporaneously prepared to treat fungal keratitis.

4. Precautions and monitoring effects

a. Reactions from the 2% topical cream include local irritation, pruritus, and stinging. Contact dermatitis is possible and occurs with other imidazole derivatives.

b. The 2% shampoo may lead to increased hair loss, irritation, abnormal hair texture, scalp pustules, dry skin, pruritus, and oiliness or dryness of hair and scalp. It may in addition straighten otherwise curly hair.

K. Miconazole (Monistat) is an imidazole-derived antifungal drug that is available topically as a 2% aerosol, 2% aerosol powder, 2% cream, a kit, 2% powder and 2% tincture, 2% vaginal cream, and 100 mg and 200 mg vaginal suppositories.

1. Mechanism of action. See III.E.1.

2. Spectrum of activity. See III.E.2.

3. Therapeutic uses. Miconazole is advantageous over other agents such as nystatin and tolnaftate in that its activity covers dermatophytes as well as Candida.

a. Topical use is effective against tinea pedis, tinea cruris, and tinea corporis caused by dermatophytes (T. mentagrophytes, T. rubrum, and E. floccosum).

b. It is also effective against tinea versicolor from M. furfur.

c. Like other imidazole derivatives, it is useful in treating cutaneous fungal infections.

d. The vaginal cream and vaginal suppositories are effective in treating vulvovaginal candidiasis.

4. Precautions and monitoring parameters

a. Topical creams have caused local irritation and burning.

b. Vaginal preparations have led to vulvovaginal burning, itching, irritation, pelvic cramps, vaginal burning, headache, hives, and skin rash.

c. If vulvovaginal candidiasis persists for longer than 3 days, seek further medical attention.

d. Tampons should be avoided in patients using vaginal suppositories or cream; sanitary pads should be substituted.

e. Vaginal suppositories are manufactured from a vegetable oil base that may interact with latex products. Avoid using diaphragms or condoms concurrently with suppositories. Seek an alternative form of birth control.

L. Naftifine (Naftin) is a synthetic allylamine similar to terbinafine. It is available as a 1% topical cream and a 1% topical gel.

1. Mechanism of action. Naftifine is fungistatic and interferes with sterol biosynthesis by accumulating squalene in the fungal cell. Naftifine also possesses some local anti-inflammatory activity.

2. Spectrum of activity

a. Naftifine is active against T. mentagrophytes, T. rubrum, T. tonsurans, Trichophyton verrucosum, Trichophyton violaceum, E. floccosum, Microsporum audouinii, M. canis, and M. gypseum.

b. C. albicans, Candida krusei, Candida parapsilosis, and Candida tropicalis are affected by naftifine; however, the concentrations of naftifine vary for Candida killing, depending on the species.
c. In vitro activity has been demonstrated against Aspergillus flavus and Aspergillus fumigatus. Others include Sporothrix schenckii, Cryptococcus neoformans, Petriellidium boydii, Blastomyces dermatitidis, and Histoplasma capsulatum.
3. Therapeutic uses. Naftifine is active against dermatophytoses and cutaneous candidiasis.
a. It is also used to treat tinea cruris, tinea pedis, tinea corporis, and tinea manus (T. mentagrophytes, T. rubrum, T. verrucosum, T. violaceum, E. floccosum, or M. canis).
b. It is also useful in treating tinea unguium (onychomycosis).
4. Precautions and monitoring effects. Transient burning and stinging
M. Nystatin (Mycostatin). A polyene antibiotic, nystatin has a chemical structure similar to that of amphotericin B. It is available as an oral suspension, tablet, lozenge, topical cream, ointment, topical powder, and vaginal tablet.
1. Mechanism of action. Nystatin is fungicidal and fungistatic; binding to sterols in the fungal cell membrane, it increases membrane permeability and permits leakage of intracellular contents.
2. Spectrum of activity. Nystatin is active primarily against Candida spp.
3. Therapeutic uses. This drug is used primarily as a topical agent in vaginal and oral Candida infections.
4. Precautions and monitoring effects. Irritation has occurred in extremely rare instances.
N. Oxiconazole (Oxistat) is an imidazole-derived antifungal drug that is available as a 1% topical cream or 1% topical lotion.
1. Mechanism of action. See III.E.1.
2. Spectrum of activity. See III.E.2.
3. Therapeutic uses
a. The 1% cream or lotion is useful in treating tinea cruris, tinea corporis, tinea manus, and tinea pedis from dermatophytes.
b. Oxiconazole is also effective against tinea versicolor caused by M. furfur.
4. Precautions and monitoring effects. Adverse effects are rare and are confined to local irritation.

O. Sulconazole (Exelderm) is an imidazole-derived antifungal drug that is available as a 1% topical cream and a 1% topical solution.
1. Mechanism of action (see III.E.1). The antibacterial effects exerted by sulconazole are thought to be the result of a direct physicochemical effect

on the destruction of unsaturated fatty acids present in bacterial cell membranes.

2. Spectrum of activity

a. Sulconazole has activity against dermatophytes, including E. floccosum, M. audouinii, M. canis, M. gypseum, T. mentagrophytes, T. rubrum, T. tonsurans, and T. violaceum. It also has activity against M. furfur.

b. Sulconazole also has activity against selected gram-positive aerobes (S. aureus, S. epidermidis, Staphylococcus saprophyticus, E. faecalis, Micrococcus luteus, and Bacillus subtilis) and anaerobes (Clostridium and Propionibacterium acnes, Clostridium perfringens, Clostridium tetani, and Clostridium botulinum).

3. Therapeutic uses

a. The 1% topical cream or 1% topical solution is useful in treating tinea corporis and tinea cruris.

b. The 1% topical cream has been studied for use against tinea pedis; the solution has not been evaluated for this indication.

c. The 1% cream is useful against tinea versicolor (M. furfur).

d. There is not an approved indication for cutaneous candidiasis; however, sulconazole 1% is as effective as miconazole 2% or clotrimazole 1% in treating cutaneous candidiasis.

e. Sulconazole is useful in treating infections caused by bacteria such as impetigo (S. pyogenes) and ecthyma (S. aureus).

4. Precautions and monitoring effects. Adverse reactions include local effects such as burning and irritation, skin edema, dryness, scaling, fissuring, cracking, generalized red papules, and severe eczema.

P. Terbinafine (Lamisil AT) is a synthetic allylamine available as a 1% cream with structure and activity related to naftifine.

1. Mechanism of action. Terbinafine inhibits squalene monooxygenase, leading to an interruption of fungal sterol biosynthesis. Terbinafine may be fungicidal or fungistatic, depending on drug concentration and species.

2. Spectrum of activity. Terbinafine has activity against dermatophytic fungi (Trichophyton, Microsporum, and Epidermophyton), filamentous fungi (Aspergillus), and dimorphic fungi (Blastomyces). It may also possess some activity against yeasts.

3. Therapeutic uses. It is useful for tinea pedis, tinea corporis, and tinea cruris.

4. Precautions and monitoring effects. It can cause local irritation.

Q. Terconazole (Terazol-7) is an imidazole-derived antifungal drug that is available as a 0.4% and 0.8% vaginal cream and an 80-mg vaginal suppository.

1. Mechanism of action. It is fungicidal against C. albicans. Like other imidazole agents, terconazole alters cellular membranes, resulting in increased membrane permeability.

2. Spectrum of activity. It is active against dermatophytes; yeasts; and, at high concentrations, gram-positive and gram-negative bacteria.

3. Therapeutic uses are for complicated and uncomplicated vulvovaginal candidiasis.
4. Precautions and monitoring effects. Adverse reactions include burning, pruritus, irritation, headache, body pain, and pain of female genitalia.
R. Tioconazole (Vagistat-1) is an imidazole-derived antifungal drug that is available as a 6.5% vaginal ointment.
1. Mechanism of action. Tioconazole is fungicidal against C. albicans. Like other imidazole agents, tioconazole alters cellular membranes, resulting in increased membrane permeability.

2. Spectrum of activity
a. Activity against fungi includes most strains of Candida and the dermatophytes. There is also activity against Aspergillus and C. neoformans.
b. Tioconazole is active against the following aerobic gram-positive bacteria: Gardnerella vaginalis, Corynebacterium minutissimum, E. faecalis, S. aureus, S. epidermidis, and some Streptococci spp. Gram-negative bacteria: it is active against H. pylori, Haemophilus ducreyi, Moraxella catarrhalis, Neisseria gonorrhoeae, and N. meningitidis.
c. Other organisms that tioconazole has activity against are T. vaginalis, Lymphogranuloma venereum, and Chlamydia trachomatis.
3. Therapeutic uses. Tioconazole is used for simple and complicated vulvovaginal candidiasis. Other uses have been explored; however, topical creams for use in those scenarios are not available in the United States.
4. Precautions and monitoring effects. Local irritation has been manifested as vulvovaginal burning, vaginitis, and pruritus.
S. Tolnaftate (Tinactin) is available topically as a 1% aerosol, 1% powder, 1% cream, and 1% solution.
1. Mechanism of action. It may distort hyphae and stunt mycelial growth in susceptible fungi.
2. Spectrum of activity. Tolnaftate may be either fungistatic or fungicidal to the following organisms: M. gypseum, M. canis, M. audouinii, Microsporum japonicum, T. rubrum, T. mentagrophytes, Trichophyton schoenleinii, T. tonsurans, E. floccosum, Aspergillus niger, C. albicans, C. neoformans, and A. fumigatus.
3. Therapeutic uses. Tolnaftate is used for dermatophytoses and tinea versicolor.
4. Precautions and monitoring effects. There may be slight local irritation.

V. Antiprotozoal Agents

A. Classification. These drugs fall into two main categories: antimalarial agents, used to treat malaria infection, and amebicides and trichomonacides, used to treat amebic and trichomonal infections.

B. Antimalarial agents. Still a leading cause of illness and death in tropical and subtropical countries, malaria results from infection by any of four species of the protozoal genus Plasmodium. Antimalarial agents are selectively active during different phases of the protozoan life cycle. Major antimalarial drugs include chloroquine (Aralen), halofantrine (Halfan), hydroxychloroquine (Plaquenil), primaquine, pyrimethamine (Daraprim), quinine, and mefloquine (Lariam). In addition, two combination brands are available: sulfadoxine plus pyrimethamine (Fansidar) and atovaquone plus proguanil (Malarone).

1. Mechanism of action

a. Chloroquine and hydroxychloroquine bind to and alter the properties of microbial and mammalian DNA.

b. The mechanism of action of primaquine, quinine, Fansidar, and mefloquine is unknown.

c. Pyrimethamine impedes folic acid reduction by inhibiting the enzyme dihydrofolate reductase.

2. Spectrum of activity

a. Chloroquine and hydroxychloroquine are suppressive blood schizonticidal agents and are active against the asexual erythrocyte forms of Plasmodium vivax and Plasmodium falciparum and gametocytes of P. vivax, Plasmodium malariae, and Plasmodium ovale.

b. Primaquine, a curative agent, is active against liver forms of P. vivax and P. ovale and the primary exoerythrocyte forms of P. falciparum.

c. Pyrimethamine is active against chloroquine-resistant strains of P. falciparum and some strains of P. vivax.

d. Quinine, a generalized protoplasmic poison, is toxic to a wide range of organisms. In malaria, this drug has both suppressive and curative action against chloroquine-resistant strains.

e. Fansidar (sulfadoxine plus pyrimethamine) is a blood schizonticidal agent that is active against the erythrocytic forms of susceptible plasmodia. It is also activeagainst T. gondii.

f. Malarone (atovaquone plus proguanil) is active against the erythrocytic and exoerythrocytic forms of Plasmodium spp.

g. Mefloquine is a blood schizonticidal agent that is active against P. falciparum (both chloroquine-susceptible and -resistant strains) and P. vivax.

h. Halofantrine is a blood schizonticidal agent active against P. falciparum and P. vivax.

3. Therapeutic uses

a. Chloroquine is the preferred agent used to suppress malaria symptoms and to terminate acute malaria attacks resulting from P. falciparum and P. malariae infections.

(1) It is more potent and less toxic than quinine.
(2) Except where drug-resistant P. falciparum strains are prevalent, chloroquine is the most useful antimalarial agent.
b. Hydroxychloroquine is used as an alternative to chloroquine in patients who cannot tolerate chloroquine or when chloroquine is unavailable.
c. Primaquine is used to cure relapses of P. vivax and P. ovale malaria and to prevent malaria in exposed persons returning from regions where malaria is endemic.
d. Pyrimethamine is effective in the prevention and treatment of chloroquine-resistant strains of P. falciparum. It is now used almost exclusively in combination with a sulfonamide or sulfone.
e. Quinine
(1) Quinine sulfate, an oral form, is therapeutic for acute malaria caused by chloroquine-resistant strains.
(2) Quinine dihydrochloride, a parenteral form, is used in severe cases of chloroquine-resistant malaria. (It is available only from the CDC.)
(3) Quinine is almost always given in combination with another antimalarial agent.
f. Fansidar
(1) Fansidar is used for the suppression or prophylaxis of chloroquine-resistant P. falciparum malaria.
(2) It has been used for the prophylaxis of P. carinii infections in AIDS patients unable to tolerate cotrimoxazole (trimethoprim-sulfamethoxazole).
g. Mefloquine is indicated for the treatment of acute malaria and the prevention of P. falciparum and P. vivax infections.
h. Halofantrine is indicated for treatment of malaria in adults who can tolerate oral medication and who have mild to moderate malaria (≥ 100,000 parasites/mm^3) caused by P. falciparum or P. vivax.
i. Malarone
(1) Prophylaxis of P. falciparum malaria, including areas where chloroquine resistance has been reported.
(2) Treatment of acute, uncomplicated P. falciparum malaria. This combination has been shown to be effective in regions where the drugs chloroquine, halofantrine, mefloquine, and amodiaquine may have unacceptable failure rates, presumably because of drug resistance.
4. Precautions and monitoring effects
a. Chloroquine and hydroxychloroquine
(1) Because these drugs concentrate in the liver, they should be used cautiously in patients with hepatic disease.
(2) Chloroquine must be administered with extreme caution in patients with neurological, hematological, or severe GI disorders.
(3) Visual disturbances, headache, skin rash, and GI distress have been reported.
b. Primaquine

(1) This agent is contraindicated in patients with rheumatoid arthritis and lupus erythematosus and in those receiving other potentially hemolytic drugs or bone marrow suppressants.
(2) Primaquine may cause agranulocytosis, granulocytopenia, and mild anemia. In patients with G6PD deficiency, it may cause hemolytic anemia.
(3) Abdominal cramps, nausea, vomiting, and epigastric distress sometimes occur.
c. Pyrimethamine
(1) In high doses, this drug may cause agranulocytosis, megaloblastic anemia, aplastic anemia, and thrombocytopenia.

(2) Erythema multiforme (Stevens-Johnson syndrome), nausea, vomiting, and anorexia may develop during pyrimethamine therapy.
d. Quinine
(1) Quinine is contraindicated in patients with G6PD deficiency, tinnitus, and optic neuritis.
(2) Quinine overdose or hypersensitivity reactions may be fatal. Manifestations of quinine poisoning include visual and hearing disturbances; GI symptoms (e.g., nausea, vomiting); hot, flushed skin; headache; fever; syncope; confusion; shallow, then depressed, respirations; and cardiovascular collapse.
(3) Quinine must be used cautiously in patients with atrial fibrillation.
(4) Renal damage and anuria have been reported.
e. Fansidar
(1) Severe, sometimes fatal, hypersensitivity reactions have occurred. In most cases, death resulted from severe cutaneous reactions, including erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis.
(2) Adverse hematological and hepatic effects as seen with sulfonamides have been reported.
f. Mefloquine
(1) Concomitant use of mefloquine with quinine, quinidine, or β-adrenergic blockade may produce electrocardiographic abnormalities or cardiac arrest.
(2) Concomitant use of mefloquine and quinine or chloroquine may increase the risk of convulsions.
g. Halofantrine
(1) Do not administer with drugs known to prolong the QTc interval; interaction with mefloquine further prolongs the QTc interval.
(2) A sevenfold increase in peak plasma level and threefold increase in the area under the curve (AUC) occurred when given with high-fat food. Similar increases occur when doses are administered 2 hr after a meal. Administer halofantrine on an empty stomach.
h. Malarone

(1) Concomitant administration with tetracycline has been associated with 40% reduction in plasma concentrations of atovaquone. Similarly, concurrent rifampin is known to reduce atovaquone levels by 50%.
(2) Take malarone with food or milk.
C. Amebicides and trichomonacides. These agents are crucial in the treatment of amebiasis, giardiasis, and trichomoniases—the most common protozoal infections in the United States. The major amebicides include diloxanide, iodoquinol (Yodoxin), metronidazole (Flagyl), nitazoxanide (Alinia), paromomycin (Humatin), quinacrine, and tinidazole (Tindamax).
1. Mechanism of action
a. Diloxanide, a dichloroacetamide derivative, is amebicidal; its mechanism of action is unknown. (Not available commercially but can be compounded by Panorama Compounding Pharmacy, Van Nuys, CA—per Medical Letter 8/04.)
b. Metronidazole is a synthetic compound with direct amebicidal and trichomonacidal action; it works at both intestinal and extraintestinal sites. Its mechanism of action involves disruption of the helical structure of DNA.
c. Nitazoxanide is designated by the U.S. Food and Drug Administration (FDA) as an orphan drug. Its antiprotozoal activity is believed to be the result of interference with the pyruvate: ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reaction essential for energy metabolism.
d. Quinacrine is an acridine derivative that inhibits DNA metabolism.
e. Iodoquinol is a luminal or contact amebicide that is effective against the trophozoites of Entamoeba histolytica located in the lumen of the large intestine.
f. Paromomycin is a poorly absorbed amebicidal aminoglycoside whose mechanism of action parallels other aminoglycosides (i.e., protein synthesis inhibitor). It is also effective against enteric bacteria Salmonella and Shigella.
g. Tinidazole precise mechanism of action is unknown.
2. Spectrum of activity and therapeutic uses
a. Diloxanide

(1) This drug is used to treat asymptomatic carriers of amebic and Giardia cysts.
(2) Diloxanide is therapeutic for invasive and extraintestinal amebiasis (given in combination with a systemic or mixed amebicide).
(3) Diloxanide is not effective as single-agent therapy for extraintestinal amebiasis.
b. Metronidazole
(1) This agent is the preferred drug in amebic dysentery, giardiasis, and trichomoniasis.

(2) Metronidazole also is active against all anaerobic cocci and gram-negative anaerobic bacilli.
(3) This agent is the treatment of choice by the CDC for the treatment of C. difficile colitis infections owing to the emerging use of broad-spectrum antibiotics. This therapy is cost-effective.
c. Quinacrine is useful in the treatment of giardiasis and tapeworms (see VIII.H.2).
d. Iodoquinol is indicated for treatment of intestinal amebiasis. It is active against the protozoa E. histolytica.
e. Nitazoxanide is indicated for treatment of diarrhea caused by Cryptosporidium parvum and Giardia lamblia in children.
f. Paromomycin is indicated for acute and chronic intestinal amebiasis; it is not useful for extraintestinal amebiasis because it is not absorbed. Paromomycin has been used for Dientamoeba fragilis, Taenia saginata, Dipylidium caninum, and Hymenolepis nana.
g. Tinidazole is a second-generation synthetic nitroimidazole active against trichomoniasis, Giardia duodenalis/G. lamblia, and E. histolytica.
3. Precautions and monitoring effects
a. Diloxanide rarely causes serious adverse effects. Vomiting, flatulence, and pruritus have been reported.
b. Metronidazole
(1) The most common adverse effects of this drug are nausea, epigastric distress, and diarrhea.
(2) Metronidazole is carcinogenic in mice and should not be used unnecessarily.
(3) Headache, vomiting, metallic taste, and stomatitis have been reported.
(4) Occasionally, neurological reactions (e.g., ataxia, peripheral neuropathy, seizures) develop.
(5) A disulfiram-type reaction may occur with concurrent ethanol use.
c. Quinacrine. See VIII.H.4.
(1) This drug frequently causes dizziness, headache, nausea, and vomiting. Nervousness and seizures also have been reported.
(2) Quinacrine should not be taken in combination with primaquine because this may increase primaquine toxicity.
(3) Quinacrine should be administered with extreme caution in patients with psoriasis because it may cause marked exacerbation of this disease.
d. Iodoquinol may produce optic neuritis or atrophy or peripheral neuropathy with high-dose, long-term use. Protein-bound iodine levels may be increased during treatment and may interfere with the results of thyroid tests for 6 months after treatment. Iodoquinol should not be used in patients who are hypersensitive to 8-hydroxy-quinolone (e.g., iodoquinol, iodochlorhydroxyquin) or iodine-containing agents or in patients with hepatic disorders.

e. Paromomycin may cause nausea, cramping, and diarrhea at high doses (> 3 g/day). Inadvertent absorption through ulcerative bowel lesions may result in ototoxicity or renal damage.
f. Nitazoxanide may cause abdominal pain, diarrhea, vomiting, headache, flatulence, fever, eye discoloration, rhinitis, and discolored urine.
g. Tinidazole may produce metallic taste, nausea, anorexia, dyspepsia, vomiting, weakness, dizziness, and headache.
D. Pentamidine isethionate (Pentam 300) is an aromatic diamide antiprotozoal agent. It can be administered intramuscularly, intravenously, or by inhalation.
1. Mechanism of action is not fully understood, but in vitro studies indicate interference with nuclear metabolism and inhibition of DNA, RNA, phospholipid, and protein synthesis.
2. Therapeutic uses
a. Pentamidine is indicated for the prevention and treatment of infections caused by P. carinii.

b. Unlabeled uses include treatment of trypanosomiasis, visceral leishmaniasis, and babesiosis.
3. Precautions and monitoring effects
a. Nephrotoxicity, bronchospasm, and cough are the most common effects produced by intravenous or inhaled pentamidine.
b. Severe hypotension may occur after a parenteral dose of pentamidine. Cardiorespiratory arrest can occur after a single rapid infusion of the drug.
c. Pain, erythema, and tenderness may occur after an IM administration of the drug. This can be minimized by using the Z-track technique of drug administration. Phlebitis may occur following IV administration.
d. Hypoglycemia may occur with initial administration of drug via the IV, IM, or inhalational route. After the patient has been on the drug for a period of time, hyperglycemia will result. The effect of the drug may actually induce a reversible insulin-dependent diabetes mellitus.
e. Leukopenia and thrombocytopenia, which can be severe, occur occasionally.
f. Pentamidine may result in elevated liver function tests, AST, and ALT.
g. GI effects can also occur, including nausea, vomiting, abdominal discomfort, pain, diarrhea, and dysgeusia.
h. Neurological effects can occur with parenteral administration and may include dizziness, tremors, confusion, anxiety, insomnia, and seizures.
i. Hypocalcemia and fever have also been reported and may be severe at times.
E. Atovaquone (Mepron) is a hydroxynaphthoquinone initially synthesized as an antimalarial drug.

1. Mechanism of action. Atovaquone blocks mitochondrial electron transport at complex III of the respiratory chain of protozoa, resulting in inhibition of pyrimidine synthesis.
2. Spectrum of activity. It is active against P. carinii, T. gondii, C. parvum, P. falciparum, Isosporidia, and Microsporidia.
3. Therapeutic uses. Atovaquone is used for second-line treatment of mild to moderate P. carinii pneumonia in patients intolerant of cotrimoxazole or other sulfonamides or who are nonresponsive to cotrimoxazole.
4. Precautions and monitoring effects
a. Oral absorption significantly increases when administered with food (especially a high-fat meal).
b. Rash, nausea, diarrhea, headache, fever, abdominal pain, dizziness, and elevated liver function tests commonly are reported.
5. Significant interactions. Atovaquone is highly bound to plasma protein. It should be used with caution when administered with other highly protein-bound drugs with a narrow therapeutic range.
F. Eflornithine HCl (Ornidyl). This is an IV antiprotozoal agent. Its activity has been attributed to the inhibition of the enzyme ornithine decarboxylase.
1. Mechanism of action. This is a specific, enzyme-activated, irreversible inhibitor of ornithine decarboxylase.
2. Spectrum of activity and therapeutic uses. Eflornithine is active in the treatment of the meningoencephalitic stage of Trypanosoma brucei gambiense (sleeping sickness).
3. Precautions and monitoring effects
a. Myelosuppression is the most frequent serious side effect.
b. Seizures occur in about 8% of treated patients.
c. Cases of hearing impairment have been reported.

VI. Antitubercular Agents

A. Definition and classification. Drugs used to treat tuberculosis suppress or kill the slow-growing mycobacteria that cause this disease. Antitubercular agents fall into two main categories: first-line

and second-line drugs. Because the causative organisms tend to develop resistance to any single drug, combination drug therapy has become standard in the treatment of tuberculosis.
1. The incidence of tuberculosis in the United States is increasing owing to shifts in populations considered to be endemic for tuberculosis, the rise in HIV-positive patients, and drug resistance.
2. Agents chosen for therapy must eradicate mycobacterium. First-line agents available include isoniazid, ethambutol, pyrazinamide, rifampin, rifabutin, and rifapentine. Combination chemotherapy is essential. Agents showing the lowest incidence of resistance (isoniazid, rifampin) are usually used in combination with pyrazinamide or ethambutol.

3. Choice of therapy depends on many patient and disease factors (e.g., duration of therapy needed, likelihood of drug resistance, and HIV status).
4. Treatment choices based on CDC recommendations (Table 44-4).
B. First-line. These drugs, isoniazid, ethambutol, rifampin, rifabutin, rifapentine, and pyrazinamide usually offer the greatest effectiveness with the least toxicity; they are successful in most tuberculosis patients. At least three to four drug combinations are recommended. The CDC recommends daily treatment with isoniazid, rifampin, pyrazinamide, and ethambutol for the initial phase of 2 months, followed by a continuation phase of isoniazid and rifampin for 4-5 months (Table 44-4).
1. Ethambutol (Myambutol) is a synthetic water-based compound.
a. Mechanism of action. This drug is bacteriostatic. Its precise mechanism of action is unknown; however, it has demonstrated activity only against susceptible bacteria actively undergoing cell division.
b. Spectrum of activity and therapeutic uses. Ethambutol is active against many M. tuberculosis strains as well as many other mycobacterial species. However, drug resistance develops fairly rapidly when it is used alone. In most cases, ethambutol is given adjunctively in combination with isoniazid or rifampin for tuberculosis. It is also useful in combination with other agents such as clarithromycin or azithromycin and rifabutin in treating MAC.

Table 44-4. **Treatment for Active Tuberculosis**

		Initial Phase	Continuation Phase	
Rank	**Agent**	**Dosage**	**Agent**	**Dosage**
1	INH	7 days a week × 8 weeks	INH/RIF	7 days a week × 18 weeks
	RIF	*or*		*or*
	PZA	5 days a week × 8 weeks		5 days a week × 18 weeks
	EMB			
2	INH RIF	7 days a week × 2 weeks, *then* 2 times a week × 6 weeks	INH/RIF	2 times a week × 18 weeks
	PZA	*or*		

	EMP	5 days a week × 2 weeks, *then* 2 times a week × 6 weeks		
3	INH	3 times a week × 8 weeks	INH/RIF	3 times a week × 19 weeks
	RIF			
	PZA			
	EMB			
4	INH	7 days a week × 8 weeks	INH/RIF	7 days a week × 31 weeks
	RIF	*or*		*or*
	EMP	5 days a week × 8 weeks		5 days a week × 31 weeks
				or
				2 times a week × 31 weeks

EMB, ethambutol; *INH,* isoniazid; *PZA,* pyrazinamide; *RIF,* rifampin.

Adapted with permission from CDC guidelines for treatment of tuberculosis 2003. MMWR 2003; 52 (RR11); 1-77.

c. Precautions and monitoring effects. Rarely, ethambutol causes such adverse effects as reversible dose-related (= 15 mg/kg/day) optic neuritis, drug fever, abdominal pain, headache, dizziness, and confusion. Liver

function tests should be periodically monitored. Visual testing and renal function (reduce dose with impairment) should also be monitored.

2. Isoniazid (Nydrazid) is a hydrazide of isonicotinic acid. The mainstay of antitubercular therapy, this drug should be included (if tolerated) in all therapeutic regimens.

a. Mechanism of action. Isoniazid is bacteriostatic for resting bacilli and bactericidal for rapidly dividing organisms. Its mechanism of action is not fully known; the drug probably disrupts bacterial cell wall synthesis by inhibiting mycolic acid synthesis.

b. Spectrum of activity. Isoniazid has activity only against organisms in the genus Mycobacterium. More specifically, it has demonstrated activity against M. tuberculosis, Mycobacterium bovis, and select strains of Mycobacterium kansasii.

c. Therapeutic uses

(1) The most widely used antitubercular agent, isoniazid should be given in combination with other antitubercular drugs (such as rifampin, ethambutol, and pyrazinamide) to prevent drug resistance in tuberculosis.

(2) Treatment of latent infection (previously referred to as preventive therapy of chemoprophylaxis). Isoniazid may be administered alone for up to 1 year in adults or children who have a positive tuberculin test result but lack active lesions.

d. Precautions and monitoring effects

(1) The most common adverse effects of isoniazid are skin rash, fever, jaundice, and peripheral neuritis.

(2) Hepatitis, an occasional reaction, can be severe and, in some cases, fatal. The risk of hepatitis increases with the patient's age and rises with alcohol abuse. Monitor liver function tests.

(3) Blood dyscrasias (e.g., agranulocytosis, aplastic or hemolytic anemia, thrombocytopenia) may occur. Monitor complete blood count (CBC) routinely.

(4) Adverse GI effects include nausea, vomiting, and epigastric distress.

(5) CNS toxicity may result from pyridoxine deficiency. Signs and symptoms include insomnia, restlessness, hyperreflexia, and convulsions. Pyridoxine 15-50 mg/day should be administered to patients taking isoniazid to minimize the peripheral neuropathy associated with its use (especially in patients with diabetes, HIV, uremia, alcoholism, malnutrition, pregnancy, or seizure disorder).

e. Significant interactions

(1) With concurrent phenytoin therapy, blood levels of both phenytoin and isoniazid may increase, possibly causing toxicity.

(2) Aluminum-containing antacids may reduce isoniazid absorption.

(3) Concurrent carbamazepine therapy may increase the risk of hepatitis.

(4) Use of isoniazid with other antitubercular agents, such as cycloserine or ethionamide, may cause additive nervous system effects.

(5) There is the potential for the serotonin syndrome to exist when isoniazid is used in combination with selective serotonin reuptake inhibitors or in patients taking meperidine. Isoniazid has been shown to have some monoamine oxidase (MAO) inhibiting activity.

3. Rifampin (Rimactane) is a complex macrocyclic agent.

a. Mechanism of action. This drug is bactericidal; it impairs bacterial RNA synthesis by binding to DNA-dependent RNA polymerase.

b. Spectrum of activity. Rifampin has activity against most mycobacterial strains. In addition, rifampin has activity against many other organisms, including N. meningitidis, S. aureus, H. influenzae, Legionella pneumophila, and C. trachomatis.

c. Therapeutic uses

(1) In recommended combinations for treatment of active tuberculosis

(2) Prophylactic rifampin is effective when administered to carriers of N. meningitidis disease and chemoprophylaxis of patients with H. influenzae type b organisms.

(3) Rifampin may be used in combination with dapsone for the treatment of leprosy.

d. Precautions and monitoring effects

(1) Serious hepatotoxicity may result from rifampin therapy. Liver function tests should be routinely conducted.

(2) In rare cases, this drug induces an influenza-like syndrome.

(3) Other adverse effects include skin rash, drowsiness, headache, fatigue, confusion, nausea, vomiting, and abdominal pain.

(4) Rifampin colors urine, sweat, tears, saliva, and feces orange red.

e. Significant interactions

(1) Rifampin induces hepatic microsomal cytochrome P450 isoenzymes and thus may decrease the therapeutic effectiveness of corticosteroids, warfarin, oral contraceptives, quinidine, digitoxin, protease inhibitors (PIs), nonnucleoside reverse transcriptase inhibitors, ketoconazole, verapamil, methadone, oral antidiabetic agents, cyclosporine, dapsone, chloramphenicol, and barbiturates.

(2) Probenecid may increase blood levels of rifampin.

(3) Aminosalicylic acid may impair absorption of rifampin secondary to bentonite, an excipient used in preparation of aminosalicylic granules.

f. The newer rifamycins, rifabutin (Mycobutin) and rifapentine (Priftin) may be substituted for rifampin in special situations, e.g., intolerance or serious drug interactions.

4. Rifabutin (Mycobutin) is an antimycobacterial agent that is similar to rifampin, with activity against both tubercular and nontubercular mycobacterial, and offers no clear advantage over rifampin.

a. Mechanism of action. In addition to its antimycobacterial activity against tubercular and nontubercular mycobacterial, rifabutin has been reported to inhibit reverse transcriptase and block the in vitro infectivity and replication of HIV.

b. Therapeutic uses. Rifabutin is indicated for the prevention of disseminated MAI complex disease in patients with advanced HIV infections.

c. Precautions and monitoring effects. The use of rifabutin has resulted in mild elevation of liver enzymes and thrombocytopenia.

d. Significant interactions

(1) Rifabutin antagonizes and potentially negates the immune response mediated by the bacillus Calmette-Guérin (BCG) vaccine.

(2) Rifabutin may increase the clearance of drugs by inducing hepatic microsomal enzymes, but does so to a lesser extent than rifampin. The concentrations of the following drugs may be reduced while taking rifabutin: cyclosporine, zidovudine, prednisone, digitoxin, quinidine, ketoconazole, protease inhibitors, propranolol, phenytoin, sulfonylureas, and warfarin. Serum cyclosporine levels should be monitored in patients receiving both agents.

5. Rifapentine (Priftin) is a long-acting rifamycin-derivative and has a similar profile of microbiological activity to rifampin. It is usually administered once or twice weekly.

a. Mechanism of action. Rifapentine is bactericidal against intracellular and extracellular M. tuberculosis at therapeutic levels.

b. Spectrum of activity and therapeutic uses. Indicated for treatment of primary tuberculosis. Rifapentine should always be used in conjunction with ≥ 1 other antituberculosis drug to which the isolate is susceptible.

c. Precautions and monitoring effects. Rifapentine induces cytochrome P450 isoenzymes 3A4 and 2C8/9 responsible for inactivation of certain calcium channel blocking agents (verapamil, diltiazem, nifedipine), antifungals (ketoconazole, fluconazole, itraconazole), sulfonylurea antidiabetic agents, methadone, corticosteroids, cardiac glycosides, certain antiarrhythmic agents (disopyramide, mexiletine, quinidine, tocainide), quinine, dapsone, chloramphenicol, clarithromycin, doxycycline, fluoroquinolones, transcriptase inhibitor cyclosporin, tacrolimus, and warfarin. Concomitant use of rifapentine with these drugs may decrease plasma concentrations and dosage adjustments may be required.

6. Pyrazinamide is a pyrazine analog of nicotinamide.

a. Mechanism of action. This drug is bactericidal and/or bacteriostatic, depending on the cell concentration achieved.

b. Spectrum of activity and therapeutic uses. Pyrazinamide is a highly specific agent and has activity only against M. tuberculosis. Pyrazinamide is used as a primary agent with isoniazid and rifampin for at least 2 months, followed by isoniazid and rifampin.

c. Precautions and monitoring effects. This agent may result in hepatotoxicity and, rarely, hepatic necrosis resulting in death. Anorexia, nausea, vomiting, malaise, and fever have

been reported. Hyperuricemia may result in gouty exacerbations. Both liver function tests and uric acid levels should routinely be monitored.

C. Second-line agents. These agents include aminosalicylic acid (Paser), capreomycin (Capastat), cycloserine (Seromycin), ethionamide (Trecator-SC), quinolones (ciprofloxacin, ofloxacin, levofloxacin, sparfloxacin), streptomycin and kanamycin. Second-line drugs are mainly substituted or added to preferred therapy owing to intolerance or drug resistance. These agents are less effective, more toxic, and are used in combination with primary agents.

1. Mechanism of action

a. Aminosalicylic acid is bacteriostatic; it probably inhibits the enzymes responsible for folic acid synthesis.

b. Cycloserine can be bacteriostatic or bactericidal, depending on its concentration at the infection site; it impairs amino acid use, thereby inhibiting bacterial cell wall synthesis.

c. The mechanism of action of capreomycin (bacteriostatic), ethionamide (bactericidal), and pyrazinamide (bactericidal) is unknown.

2. Spectrum of activity and therapeutic uses. Second-line antitubercular agents are active against various microorganisms, including M. tuberculosis. These agents generally are reserved for patients with extensive extrapulmonary or drug-resistant disease or for patients who need retreatment. These drugs are almost always administered in combination.

3. Precautions and monitoring effects

a. Adverse effects of aminosalicylic acid include leukopenia, agranulocytopenia, thrombocytopenia, hemolytic anemia, mononucleosis-like syndrome, malaise, joint pain, fever, and skin rash.

b. Capreomycin and streptomycin are ototoxic and nephrotoxic; they should not be administered together.

c. Cycloserine may cause adverse CNS effects, including headache, suicidal and psychotic tendencies, hyperirritability, confusion, paranoia, and nervousness.

d. Ethionamide may induce nausea, vomiting, orthostatic hypotension, metallic taste, epigastric distress, and peripheral neuropathy.

e. Streptomycin. See II.B.3.

D. Alternative agents

1. Rifater. A combination of rifampin 120 mg, isoniazid 50 mg, and pyrazinamide 300 mg in one tablet is used in patients expected to have low compliance with tuberculosis drug therapy. One disadvantage is that many

patients are required to take as many as 5-6 tablets daily, which may reduce compliance.

2. Quinolones. Ciprofloxacin and levofloxacin are used in tuberculosis therapy. Levofloxacin is preferred owing to increased serum concentrations. Levofloxacin is usually used in combination with other tuberculosis agents for active treatment. For prophylaxis, levofloxacin is combined with pyrazinamide.

3. Macrolides. Clarithromycin and azithromycin have shown limited activity against M. tuberculosis.

VII. Antiviral Agents

A. Definition. These drugs treat viral infections by affecting viral replication. Because viruses lack independent metabolic activity and can replicate only within living host cells, antiviral agents tend to injure host as well as viral cells. Although most antiviral drugs are active against either DNA or RNA viruses, some (e.g., adefovir, ribavirin) are active against both.

B. DNA viruses. Currently approved antiviral therapies against the Herpesviridae family of DNA viruses—herpes simplex virus 1 and 2 (HSV-1, HSV-2), varicella-zoster virus (VZV), cytomegalovirus (CMV)—are virustatic and arrest DNA synthesis by inhibiting viral DNA polymerase. Many of these agents are prodrugs and require viral and host cellular enzymes (e.g., thymidine, deoxyguanosine kinase) to phosphorylate them into the active triphosphate form before exerting their antiviral activity. Hence, a common mechanism of resistance is a deficiency or

structural alteration in viral thymidine kinase (Table 44-5). Some of these agents also demonstrate activity against RNA viruses, including hepatitis C and HIV.

Table 44-5. **Activity of Various Anti-DNA Viral Agents**

Agent	HSV-1	HSV-2	VZV	CMV	Influenza A	Influenza B
Acyclovir[a]	+	+	+	—	—	—
Amantadine	—	—	—	—	+	—
Cidofovir	—	—	—	+	—	—
Famciclovir	+	+	+	—	—	—

Foscarnet	+	+	+	+	—	—
Ganciclovir[a]	—	—	—	+	—	—
Oseltamivir	—	—	—	—	+	+
Rimantadine	—	—	—	—	+	—
Valacyclovir[a]	+	+	+	—	—	—
Valganciclovir[a]	—	—	—	+	—	—
Zanamivir	—	—	—	—	+	+

HSV, herpes simplex virus, *VZV,* varicella-zoster virus; *CMV,* cytomegalovirus.

[a] Requires activation into triphosphate form.

1. Acyclovir (Zovirax) is a synthetic acyclic analog of guanosine with activity against various herpes viruses.

a. Mechanism of action. Acyclovir monophosphate is phosphorylated to the triphosphate, where it becomes incorporated into viral DNA and inhibits viral replication.

b. Spectrum of activity. This agent is active against herpes viruses, particularly HSV-1, HSV-2, VZV, and chickenpox (varicella).

c. Therapeutic uses

(1) Acyclovir is used to treat initial and recurrent HSV-1 and HSV-2 infections and for acute treatment of herpes zoster (shingles) and chickenpox. It is also used orally for long-term suppression of genital HSV infections.

(2) This agent is available in topical, oral, and IV forms. Topical acyclovir is applied directly on herpes lesions in recurrent herpes labialis (cold sores). It is not recommended for use on genital herpes lesions due to poor efficacy.

(3) Acyclovir may be administered intravenously in the treatment of initial and recurrent mucocutaneous HSV infection and VZV infection in

immunocompromised patients, as well as in the treatment of HSV infections that are disseminated or affect the central nervous system.

d. Precautions and monitoring effects

(1) Oral acyclovir may induce nausea, vomiting, diarrhea, and headache.

(2) IV administration may cause dose-dependent renal impairment, crystalline nephropathy, neurological effects (e.g., lethargy, confusion, tremors, agitation, seizures, coma, obtundation), hypotension, rash, itching, and phlebitis at the injection site.

(3) Local discomfort and pruritus may result from topical administration.

(4) Acyclovir is removed by hemodialysis. Doses should be adjusted in renal impairment and hemodialysis.

e. Significant interactions. Probenecid reduces the renal clearance of acyclovir, resulting in increases in acyclovir half-life and serum concentration.

2. Adefovir dipivoxil (Hepsera) is a phosphonate nucleotide analog with activity against various DNA and RNA viruses.

a. Mechanism of action. Adefovir is phosphorylated to the active diphosphate form by cellular kinases. It is then incorporated into viral DNA, resulting in termination of replication.

b. Spectrum of activity and therapeutic uses

(1) Adefovir is active against hepatitis B virus (including lamivudine-resistant strains), herpes viruses, and HIV.

(2) However, adefovir is approved for use only for treatment of chronic hepatitis B infection in adults with evidence of active viral replication with persistently elevated liver function tests or histologically active disease.

c. Precautions and monitoring effects

(1) Severe acute hepatitis exacerbations have occurred in patients who discontinue therapy (black box warning). If therapy is discontinued, liver function tests must be monitored closely.

(2) Nephrotoxicity has been reported with adefovir, especially in patients with underlying renal dysfunction or those taking concomitant nephrotoxins (black box warning).

(3) Other adverse effects include rash, GI disturbances, headache, and weakness.

(4) Dose adjustment is required for renal insufficiency.

3. Amantadine (Symmetrel) is a synthetic tricyclic amine with a unique chemical structure similar to rimantadine. It is effective against influenza A viral infection.

a. Mechanism of action. Amantadine inhibits replication of the influenza A virus by interfering with viral attachment and uncoating.

b. Spectrum of activity and therapeutic uses

(1) Due to increasing rates of resistance, amantadine is no longer recommended for prophylaxis or treatment of influenza A virus.
(2) This drug may also be used to treat parkinsonism as well as drug-induced extrapyramidal symptoms.
c. Precautions and monitoring effects
(1) The most pronounced adverse effects of amantadine are ataxia, nightmares, and insomnia. Other CNS effects include depression, confusion, dizziness, fatigue, anxiety, and headache. Elderly patients may be at increased risk of CNS adverse reactions. Patients with a history of seizures or psychiatric disorders should be monitored closely during therapy.
(2) Anticholinergic reactions (e.g., dry mouth, blurred vision) have been reported.
(3) Dosage adjustment is needed for patients with impaired renal function.
4. Cidofovir (Vistide) is a synthetic acyclic purine nucleoside phosphonate derivative.
a. Mechanism of action. Cidofovir diphosphate suppresses CMV replication by selective inhibition of viral DNA synthesis.
b. Spectrum of activity. In vitro activity has been demonstrated against CMV, VZV, Epstein-Barr virus (EBV), and HSV-1 and HSV-2. Controlled clinical studies are limited to patients with AIDS and CMV retinitis.
c. Therapeutic use includes the treatment, but not the cure of, CMV retinitis in patients with AIDS.
d. Precautions and monitoring effects
(1) Avoid using this drug in patients with serum creatinine > 1.5 mg/dL or creatinine clearance (CrCl) ≤ 55 mL/min or in patients who are receiving (or have received in the past 7 days) nephrotoxic agents.
(2) Cidofovir is contraindicated in patients with a history of severe hypersensitivity to probenecid or sulfa-containing medications.
(3) The dose-limiting toxicity of cidofovir is nephrotoxicity; neutropenia, peripheral neuropathy, and diarrhea are common adverse effects.
(4) Probenecid must be administered before and after each cidofovir dose. The patient must be hydrated with 1 L of normal saline before infusing. Cidofovir is available only in IV form.
5. Entecavir (Baraclude) is a carbocyclic analog of guanosine used for treatment of chronic hepatitis B infection.
a. Mechanism of action. Once phosphorylated to the active triphosphate form, entecavir inhibits hepatitis B viral polymerase and ultimately halts hepatitis B DNA synthesis.
b. Spectrum of activity. Entecavir exhibits activity against hepatitis B virus, including lamivudine-resistant strains. Development of HIV resistance to nucleoside reverse transcriptase inhibitors is possible if entecavir is used without antiretroviral treatment in HIV and hepatitis B virus co-infection.
c. Therapeutic uses

(1) Entecavir is approved for treatment of chronic hepatitis B infection in adults with evidence of active viral replication and persistent elevations in liver function tests or histologically active disease.
(2) It is effective for patients who have failed treatment with lamivudine owing to resistance development.

(3) Entecavir is not recommended for use in patients with hepatitis B virus infection who are co-infected with HIV and are not receiving antiretroviral therapy.
d. Precautions and monitoring effects
(1) Severe acute exacerbations of hepatitis B have been observed in patients who discontinue therapy, necessitating close monitoring (black box warning).
(2) Common adverse effects include dizziness, fatigue, headache, and nausea.
(3) Dose adjustment is required for renal insufficiency.
(4) Counsel patients to take entecavir on an empty stomach.
6. Famciclovir (Famvir) is a prodrug of the antiviral agent penciclovir.
a. Mechanism of action. Famciclovir is rapidly phosphorylated in virus-infected cells by viral thymidine kinase to penciclovir monophosphate. Penciclovir is a competitive inhibitor of viral DNA polymerase and prevents viral replication by inhibition of herpes virus DNA synthesis.
b. Spectrum of activity and therapeutic uses
(1) Famciclovir has activity against HSV-1, HSV-2, and VZV. The drug is indicated for management of acute herpes zoster (shingles) and oral and genital herpes.
(2) Therapy must be promptly initiated as soon as herpes zoster is diagnosed (within 48-72 hr), at a dose of 500 mg every 8 hr for 7 days.
c. Precautions and monitoring effects
(1) Common adverse events include fatigue, GI complaints (nausea, diarrhea, vomiting, constipation), and anorexia. Headache is also commonly reported.
(2) Dose adjustment is necessary in patients with renal dysfunction. Famciclovir is removed by hemodialysis.
7. Foscarnet (Foscavir) is a synthetic pyrophosphate analog that directly inhibits enzymes involved in viral DNA synthesis without incorporation into viral DNA. It is a broad-spectrum antiviral agent and is an option in cases of acyclovir or ganciclovir resistance.
a. Mechanism of action
(1) Viral DNA replication requires the addition of deoxynucleoside triphosphates at the end of the DNA strand by DNA polymerase and the subsequent cleavage of pyrophosphate from the newly attached nucleotide. Foscarnet binds noncompetitively to DNA polymerase to form an inactive

complex and prevents pyrophosphate cleavage. Viral DNA chain elongation is thus terminated.
(2) Foscarnet is also active against HIV. It is a noncompetitive, reversible inhibitor of HIV reverse transcriptase, the enzyme responsible for converting viral RNA to viral DNA.
b. Spectrum of activity and therapeutic uses. Foscarnet has in vitro activity against HSV-1 and HSV-2, CMV, VZV, EBV DNA polymerases, influenza polymerase, and HIV reverse transcriptase. Therapeutically, the drug is used to treat CMV disease as well as acyclovir-resistant HSV and VZV infections.
(1) Foscarnet is an alternative to ganciclovir and valganciclovir for treatment of CMV infection in immunocompromised patients. Foscarnet causes less hematologic toxicity than ganciclovir in patients who have received allogeneic stem cell transplants. An initial induction therapy lasts 2-3 weeks. Maintenance therapy is needed to prevent relapse.
(2) Foscarnet is indicated for the treatment of acyclovir-resistant mucocutaneous HSV in immunocompromised patients. It is not, however, a cure for HSV infections.
(3) Foscarnet is able to cross the blood-brain barrier.
c. Precautions and monitoring effects
(1) IV foscarnet is highly nephrotoxic, causing acute tubular necrosis. The incidence of acute renal failure can be markedly reduced if adequate hydration and daily monitoring of serum creatinine and BUN are maintained throughout therapy.
(2) Other common adverse effects include electrolyte abnormalities (e.g., hypocalcemia, hypomagnesemia, hypophosphatemia and hyperphosphatemia, hypokalemia), anemia, fever, headache, and seizures.
(3) Dose adjustment for renal dysfunction is required. Foscarnet is removed by hemodialysis.
(4) Foscarnet must be administered using an infusion pump over at least 1.5-2 hr. Do not administer the drug as an IV bolus.

d. Significant interactions
(1) Concomitant nephrotoxins (aminoglycosides, amphotericin B, etc.) increase the risk of renal toxicity.
(2) Foscarnet is exclusively eliminated by glomerular filtration; concurrent nephrotoxic agents should be avoided whenever possible.
8. Ganciclovir (Cytovene) is a synthetic purine nucleoside analog that is approved for the treatment and prophylaxis of CMV infections in immunocompromised patients (e.g., HIV-positive patients, transplant recipients).

a. Mechanism of action. After conversion to ganciclovir triphosphate, ganciclovir is incorporated into viral DNA, which inhibits viral DNA polymerase, thereby terminating viral replication.
b. Spectrum of activity. Ganciclovir has in vitro activity against HSV-1 and HSV-2, VZV, EBV, and CMV (owing to its enhanced ability to penetrate host cells).
c. Therapeutic uses. It is indicated for treatment of CMV retinitis in patients with HIV/AIDS. It is also used for prophylaxis of CMV infection in HIV-positive patients (secondary prophylaxis) and transplant recipients at risk for CMV disease.
(1) Conversion into the triphosphate form is greater in infected host cells, even though drug penetration occurs in both uninfected and infected cells.
(2) Inhibitory concentrations for the viral DNA polymerase are lower than those for the host cellular polymerase.
(3) It is available in oral and IV formulations as well as an intraocular implant. Although the oral formulation is approved for prevention and maintenance treatment of CMV, its poor bioavailability has limited its use. Valganciclovir has become the drug of choice for these indications, owing to its markedly improved bioavailability.
d. Precautions and monitoring effects
(1) Ganciclovir has a black box warning concerning increased potential for neutropenia, anemia, and thrombocytopenia. It is also teratogenic, carcinogenic, and mutagenic.
(2) Adverse effects commonly include fever, rash, and GI disturbances. Phlebitis and pain may occur at the site of infusion.
(3) Because ganciclovir is cleared by glomerular filtration and tubular secretion, renal function and adequate hydration should be monitored. Doses should be adjusted in cases of renal impairment and hemodialysis.
(4) Solutions of ganciclovir are extremely alkaline. Avoid direct contact with skin.
e. Significant interactions
(1) Probenecid may increase ganciclovir concentrations and possibly toxicity.
(2) Use of zidovudine, azathioprine, or mycophenolate mofetil in combination with ganciclovir may result in neutropenia; careful monitoring of neutrophil count is required when these are taken concurrently with ganciclovir.
(3) Imipenem-cilastatin in combination with ganciclovir may increase the potential for seizures.
9. Oseltamivir (Tamiflu) is pharmacologically similar to zanamivir but structurally different. Both of these agents are in a class known as the neuraminidase inhibitors and have a unique mechanism of action.
a. Mechanism of action. Oseltamivir is a prodrug that must be hydrolyzed to oseltamivir carboxylate in vivo to exert its antiviral activity. It is a potent

selective inhibitor of the influenza virus enzyme, neuraminidase. Inhibition of this enzyme prevents viral replication and spread to other host cells.
b. Spectrum of activity. This agent is active against both influenza A and B viruses.
c. Therapeutic uses
(1) It is approved for the symptomatic treatment of influenza A and B infections in patients 1 year of age and older who present with symptoms within 48 hr.
(2) Oseltamivir has been shown to decrease the duration of symptoms by 1-2 days if taken within 48 hr of onset of viral symptoms.
(3) It is also approved for the prophylaxis of influenza infections in patients 1 year of age and older. Note: The influenza virus vaccine is still the gold standard for prophylaxis.
(4) Oseltamivir demonstrates some activity against strains of avian influenza, making it a possible option for treatment and prophylaxis.

d. Precautions and monitoring effects
(1) The most common adverse effects are nausea and vomiting. There have been post marketing reports of self-injury and delirium (mostly in Japan) among pediatric patients. Close monitoring for abnormal behavior is recommended.
(2) Dosage adjustments are required for patients with impaired renal function.
(3) Cross-resistance between oseltamivir and zanamivir has been reported.
10. Ribavirin (Rebetol, Copegus) is a synthetic nucleoside analog.
a. Mechanism of action. Ribavirin may inhibit RNA and DNA synthesis by depleting intracellular nucleotide reserves.
b. Spectrum of activity. This agent is active in vitro against a broad spectrum of DNA and RNA viruses, including influenza A and B, RSV, herpes simplex, and hepatitis C virus.
c. Therapeutic uses. The aerosolized form of ribavirin is no longer recommended for treatment of RSV in infants and children, owing to inconsistent clinical benefits observed in clinical trials. Combination therapy with oral ribavirin and subcutaneous interferon-α is effective in treatment of chronic hepatitis C.
d. Precautions and monitoring effects
(1) Common adverse effects of oral ribavirin include hemolytic anemia and GI disturbances. Hemoglobin and hematocrit should be monitored carefully, especially during the first 4 weeks of treatment.
(2) Ribavirin is teratogenic; its use is contraindicated in pregnancy.
(3) Ribavirin should be avoided in patients with a CrCl < 50 mL/min.
(4) Ribavirin should never be used as monotherapy in treatment of chronic hepatitis C.

11. Rimantadine (Flumadine) is a synthetic antiviral agent and an α-methyl derivative of amantadine that blocks the early step in the replication of the influenza A virus.

a. Mechanism of action. Rimantadine inhibits the early viral replication cycle, possibly inhibiting the uncoating of the virus. It has the same mechanism of action and spectrum of activity as amantadine.

b. Spectrum of activity and therapeutic uses

(1) Due to increasing rates of resistance, rimantadine is no longer recommended for prophylaxis or treatment of influenza A virus.

(2) Influenza vaccination is the method of choice for prevention of influenza infection.

c. Precautions and monitoring effects

(1) Rimantadine may increase the incidence of seizure in patients with seizure disorder.

(2) The most frequent adverse reactions include GI disturbance (e.g., nausea, vomiting, anorexia) and CNS toxicity (e.g., insomnia, dizziness, headache), which are less than those observed with amantadine.

(3) Dose reductions are recommended in patients with hepatic or renal dysfunction.

12. Telbivudine (Tyzeka) is a synthetic thymidine nucleoside analog used for treatment of chronic hepatitis B infection.

a. Mechanism of action. Telbivudine is phosphorylated into the active triphosphate form that inhibits hepatitis B viral DNA polymerase, with ultimate termination of the DNA chain and inhibition of viral replication.

b. Spectrum of activity.

(1) Telbivudine exhibits activity against hepatitis B virus but not HIV.

(2) There is a high incidence of cross-resistance between lamivudine-resistant hepatitis B virus and telbivudine.

c. Therapeutic uses.

(1) Telbivudine is indicated for treatment of chronic hepatitis B infection in adults with active viral replication and persistent elevations in liver function tests or histologically active disease.

(2) When compared with lamivudine, telbivudine produced a greater virologic response in controlled clinical trials.

d. Precautions and monitoring effects.

(1) There is a black box warning regarding severe exacerbations of hepatitis B in patients discontinuing therapy, requiring close monitoring.

(2) Common adverse effects include elevations in creatine phosphokinase, headache, fatigue, nausea, and vomiting.

(3) Dosage adjustment is required in patients with renal insufficiency.

(4) May be taken without regard to meals.

13. Valacyclovir (Valtrex) is the L-valyl ester prodrug of the antiviral agent acyclovir.

a. Mechanism of action. Valacyclovir is rapidly converted to acyclovir. Acyclovir is selective for the thymidine kinase enzyme, beginning the conversion of acyclovir to acyclovir triphosphate, stopping the replication of herpes viral DNA.

b. Spectrum of activity and therapeutic uses

(1) Valacyclovir is active against HSV-1, HSV-2, and VZV.

(2) This agent is used for the acute treatment of herpes zoster (shingles), herpes labialis (cold sores), and genital herpes in immunocompetent adults. It is also effective for suppression of recurrent episodes of genital herpes in immunocompetent and HIV-infected people as well as reduction of transmission of genital herpes.

(3) Advantages over acyclovir include oral dosing of only once to three times daily and attainment of higher plasma concentrations than oral acyclovir. A disadvantage is that there is no IV form available.

c. Precautions and monitoring effects

(1) Valacyclovir has caused thrombotic thrombocytopenic purpura/hemolytic uremic syndrome in immunocompromised individuals, including those with advanced HIV and transplant recipients.

(2) Begin therapy within 72 hr of herpes zoster rash onset.

(3) Most commonly reported adverse reactions are mild and include nausea, headache, and vomiting. Dosage adjustment is needed in patients with renal dysfunction.

14. Valganciclovir (Valcyte) is the L-valyl ester prodrug of the antiviral agent ganciclovir.

a. Mechanism of action. Valganciclovir is converted in vivo to ganciclovir. After conversion to the active form, ganciclovir triphosphate, ganciclovir is incorporated into viral DNA, which inhibits viral DNA polymerase, thereby terminating viral replication.

b. Spectrum of activity and therapeutic uses

(1) For in vitro activity, see VII.B.8.b.

(2) Valganciclovir is indicated for the treatment of CMV retinitis in patients with AIDS and for prevention of CMV after transplantation of kidney, heart, and kidneypancreas. It is not indicated for liver transplant recipients, due to an increased risk of tissue-invasive CMV as compared with ganciclovir.

(3) The markedly improved bioavailability of valganciclovir over oral ganciclovir has resulted in the widespread use of valganciclovir for treatment and prevention of CMV disease.

c. Precautions and monitoring effects

(1) Same black box warnings as for ganciclovir.

(2) Doses should be adjusted in cases of renal impairment. Do not use in hemodialysis patients; ganciclovir must be used.

(3) Only available orally. Do not substitute doses of oral valganciclovir 1:1 for oral ganciclovir; they are not equivalent.

(4) A potential carcinogen and teratogen; common adverse effects are the same as for ganciclovir.
(5) If the tablet is broken, avoid contact with skin owing to teratogenic and carcinogenic potential.
(6) Be aware of the potential for errors as a result of the look-alike and sound-alike names of valganciclovir and valacyclovir.
d. Significant interactions. Same as for ganciclovir; see VII.B.8.e.
15. Zanamivir (Relenza) is the first of a class of antiviral agents called neuraminidase inhibitors approved by the FDA for the treatment of influenza A and B infections in adults and children at least 7 years of age. It is also indicated for prevention of influenza in adults and children at least 5 years of age.
a. Mechanism of action. Zanamivir inhibits replication of the influenza A and B viruses by selective inhibition of the influenza virus neuraminidase enzyme.
b. Spectrum of activity. This agent is active against both the influenza A and B viruses. It demonstrates activity against avian influenza in animal studies.

c. Therapeutic uses
(1) It is approved for the treatment of uncomplicated influenza A and B infection for patients who have been symptomatic for < 48 hr. It is also indicated for influenza prophylaxis.
(2) Zanamivir is approved for oral inhalation use only, using the Diskhaler device provided by the manufacturer.
(3) Zanamivir may be considered for prevention or treatment of avian influenza.
(4) Shown to decrease duration of symptoms by approximately 1.5 days if taken within 48 hr of onset of viral symptoms.
d. Precautions and monitoring effects
(1) The use of zanamivir is generally not recommended in patients with a history of asthma or chronic obstructive pulmonary disease, owing to the risk of bronchospasm and acute decline in lung function.
(2) The most common adverse effects were mild and included diarrhea, nausea, and vomiting. The incidence of these was no different than placebo.
(3) Do not puncture the Rotadisk blister until immediately before administering the dose to ensure full dosage. Manual dexterity required for this device.
C. RNA viruses (HIV)
1. Currently, six classes of antiretroviral agents are approved. These drugs are active against HIV and include the nucleoside reverse transcriptase inhibitors (NRTIs) abacavir, didanosine, emtricitabine, lamivudine,

stavudine, zalcitabine, and zidovudine; the nucleotide reverse transcriptase inhibitor (NtRTI) tenofovir disoproxil fumarate; the nonnucleoside reverse transcriptase inhibitors (NNRTIs) delavirdine, efavirenz, nevirapine and etravirine; and the protease inhibitors (PIs) amprenavir, atazanavir, darunavir, fosamprenavir, indinavir, lopinavir/ritonavir, nelfinavir, ritonavir, saquinavir, and tipranavir; the fusion inhibitor enfuvirtide; the entry inhibitor maraviroc; and the integrase inhibitor raltegravir.

2. These agents are virustatic and require lifelong therapy. They are currently approved for use in various combinations known as potent combination antiretroviral therapy.

a. Appropriate combinations include those that have demonstrated efficacy and safety in controlled clinical trials (Table 44-6).

b. Monotherapy with any single antiretroviral agent is unacceptable in the treatment of HIV infection owing to rapid development of viral resistance.

c. Before designing a treatment plan, a minimum of two $CD4^+$ cell counts and one HIV RNA level (viral load) should be obtained to confirm the initial measurements and determine if treatment should be initiated. After starting therapy, repeat these measurements in 2-8 weeks, followed by every 3-4 months thereafter.

d. A minimum of 1.0-$\log_{10}$ copies/mL decline in HIV RNA levels should be seen after the first 2-8 weeks of therapy for clinical response; a subsequent decrease to undetectable levels should be achieved by 16-24 weeks.

3. Reverse transcriptase inhibitors are classified as either nucleosides or nucleotides. These agents are competitive inhibitors of reverse transcriptase, which leads to chain termination when incorporated into the viral DNA chain. They are inactive until phosphorylated by human cellular kinases into the active triphosphate metabolite. Each agent has a corresponding three-letter acronym as well as a brand name. With the exception of abacavir, each agent in this class of antiretrovirals requires dosage adjustment in patients with renal dysfunction. All agents in this class have a black box warning concerning the potential for development of lactic acidosis and severe hepatomegaly with steatosis.

a. Abacavir (ABC; Ziagen) is a synthetic carbocyclic nucleoside analog indicated for the treatment of both adult and pediatric patients with HIV.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Abacavir is approved for use in adults and children ≥ 3 months of age only in combination with other antiretroviral agents.

(a) Abacavir is available alone or co-formulated as a combination tablet with lamivudine and zidovudine (Trizivir) which is dosed twice daily.

(b) Abacavir is also available in a combination tablet with lamivudine (Epzicom) which is dosed once daily.

(3) Precautions and monitoring effects. Abacavir has a black box warning for a life-threatening hypersensitivity reaction that can lead to death. It occurs in approximately 5% of patients taking this drug, typically within the

first 6 weeks of therapy. This reaction involves respiratory symptoms, fever, rash, and GI complaints. Reexposure following these symptoms can mimic anaphylaxis and may result in death. Therefore, rechallenge is contraindicated. A Medication Guide describing this reaction should be dispensed with each new prescription and refill of abacavir-containing products. The HLA-B*5701 screening test should be used prior to initiating therapy to reduce the risk of this reaction.

Table 44-6. **Department of Health and Human Services Guidelines for the Use of Antiviral Agents in HIV-1-Infected Adults and Adolescents**

When to begin treatment					
Treat any patient with history of AIDS defining illness					
Treat any patients with $CD4^+$ cell count < 200/mm^3 or between 200-350/mm^3					
Treat patients who are pregnant, have HIV-associated nephropathy or those co-infected with hepatitis B virus (when treatment for hepatitis B is indicated).					
Note: The optimal time to start treatment in patients with $CD4^+$ cell count > 350/mm^3 is not well defined.					
Regimen selection					
Selection of a treatment regimen should be individualized for each patient based on adverse effect profiles, drug interactions, comorbidities, pill burden, etc. Preferred and alternative treatment regimens in previously untreated patients are as follows:					
To select an antiretroviral regimen, select one component from Column A and one from Column B:					
Column A (NNRTI or PI Options)				**Column B (Dual NRTI Options)**	
Preferr	NNRT	o	PI	Preferr	Tenofovir/em

ed Components	I Efavirenz[a]	r	Atazanavir or ritonavir Fosamprenavir + ritonavir (b.i.d.) Lopinavir/ritonavir (b.i.d.)	ed Components	tricitabine or abacavir/lamivudine
Alternative to Preferred Components	NNRTI Nevirapine[b]	or	PI Atazanavir Fosamprenavir Fosamprenavir/ritonavir (once daily) Lopinavir/ritonavir (once daily) Saquinavir + ritonavir	Alternative to Preferred Components	Zidovudine/lamivudine or didanosine + (emtricitabine or lamivudine)
Agents or combinations that should not be offered at any time					
All monotherapies					
2-NRTI regimens					
Abacavir + tenofovir + lamivudine as a triple NRTI regimen					
Tenofovir + didanosine + lamivudine as a triple NRTI regimen					
Saquinavir as the sole PI in a PI-based regimen					
Zidovudine + stavudine					
Didanosine + stavudine					
Lamivudine + emtricitabine					

Atazanavir + indinavir
2-NNRTI combination
Monitoring
Before initiating drug therapy, must obtain $CD4^+$ cell count and plasma HIV RNA levels plus complete blood count, chemistry, lipid profile, liver enzymes, and genotypic resistance testing
If HIV RNA does not reach undetectable levels (< 50 copies/mL) by 16-24 weeks, perform resistance testing, compliance assessment, and consider a regimen change
NNRTI, nonnucleoside reverse transcriptase inhibitor; *NRTI,* nucleoside reverse transcriptase inhibitor; *PI,* protease inhibitor.
[a] Cannot be used in the first trimester of pregnancy or in women who wish to conceive or are not using effective contraception. [b] Should not be initiated in women with pre-nevirapine $CD4^+$ cell counts > $250/mm^3$ or men with pre-nevirapine $CD4^+$ cell counts > $400/mm^3$ owing to high incidence of hepatic adverse effects.

(4) Significant interactions. Alcohol increases abacavir's AUC by 41%.

b. Didanosine (ddI; Videx), a synthetic purine analog, inhibits HIV replication and has a longer intracellular half-life (> 20 hr) than zidovudine (7 hr).

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Didanosine is approved for the treatment of adults and children only in combination with other antiretroviral agents.

(3) Precautions and monitoring effects

(a) Didanosine can cause reversible peripheral neuropathy and acute, potentially lethal pancreatitis (black box warning). Serum triglycerides should be monitored, and didanosine should be withheld when initiating potential pancreatitis-inducing agents (e.g., IV pentamidine, sulfonamides). Transiently elevated serum amylase may not reflect pancreatitis.

(b) Other adverse effects include headaches, diarrhea, nausea, and hyperuricemia (because didanosine is catalyzed to uric acid).
(c) Didanosine is available in an enteric coated capsule or buffered oral tablet formulation to prevent degradation at acidic pH. It must be taken on an empty stomach.
(d) Do not use in combination with stavudine or zalcitabine because of additive potential for toxicity.
(e) Do not use the combination regimen of didanosine and tenofovir in treatmentnaïve patients, owing to high rates of early virologic failure.
(4) Significant interactions. Pancreatitis-inducing drugs, alcohol, and those known to cause peripheral neuropathy should not be used with didanosine. Ribavirin should not be co-administered with didanosine.
c. Emtricitabine (FTC; Emtriva) is a synthetic nucleoside analog structurally related to lamivudine with activity against HIV infection.
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses. Emtricitabine is indicated for use in HIV-infected adults and children in combination with other antiretroviral agents. It is available by itself or as a combination tablet with tenofovir (Truvada) and as a combination tablet with tenofovir and efavirenz (Atripla). Although it demonstrates activity against hepatitis B virus, it is not approved for use in treatment of this infection.
(3) Precautions and monitoring effects
(a) Adverse effects most commonly observed in clinical trials were mild-moderate and include headache, rash, diarrhea, and nausea. Hyperpigmentation of the palms or soles may occur.
(b) Serious acute exacerbations of hepatitis B have been documented in HIV/hepatitis B co-infected patients who discontinued therapy with emtricitabine (black box warning); therefore, liver function tests should be monitored for several months after discontinuation.
(4) Significant interactions. None have been identified.
d. Lamivudine (3TC; Epivir) is a synthetic nucleoside analog with activity against HIV and hepatitis B virus.
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses. Lamivudine is indicated for use in HIV-positive adults and children > 3 months of age in combination with other antiretroviral agents. It is also used in a lower dosage for the treatment of chronic hepatitis B in patients with active liver inflammation and evidence of hepatitis B viral replication.
(a) Lamivudine is available alone or within a twice daily combination tablet containing lamivudine, zidovudine and abacavir (Trizivir).
(b) Lamivudine is also available as a combination tablet with abacavir (Epzicom) and zidovudine (Combivir).

(3) Precautions and monitoring effects
(a) Reported adverse reactions are minor and include headache, fatigue, and GI reactions such as nausea, vomiting, and diarrhea. CNS toxicity includes neuropathy, dizziness, and insomnia. Lab test abnormalities such as neutropenia and elevations in liver enzymes have also been reported.
(b) Do not use in combination with zalcitabine owing to antagonism of effects.
(c) Lamivudine has the same black box warning regarding acute exacerbations of hepatitis B as emtricitabine (see VII.C.3.c).
(4) Significant interactions. Co-administration with cotrimoxazole results in increased lamivudine levels. No dose adjustment is required.
e. Stavudine (d4T; Zerit) is a synthetic thymidine nucleoside analog that is active against HIV.
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses. Stavudine is indicated for use in combination with other antiretroviral agents in adults and children of all ages.
(3) Precautions and monitoring effects
(a) The major toxicity with stavudine is a dose related but reversible peripheral neuropathy occurring in up to 21% of patients.
(b) Other adverse effects include headache, rash, diarrhea, nausea, and vomiting.
(c) Fatal episodes of pancreatitis have been reported.
(4) Significant interactions. Do not use in combination with zidovudine or zalcitabine.
f. Tenofovir disoproxil fumarate (TDF; Viread) is an acyclic nucleoside phosphonate diester analog (nucleotide) with antiviral activity against HIV and hepatitis B virus.
(1) Mechanism of action. Tenofovir (a prodrug) is rapidly hydrolyzed by plasma esterases to tenofovir, with subsequent conversion to the active tenofovir diphosphate. Note: NtRTIs are active as the diphosphate, unlike the NRTIs, which require conversion to the triphosphate.
(2) Spectrum of activity and therapeutic uses. Tenofovir is approved for use in combination with other antiretroviral agents for the treatment of HIV in adults. It is also available as a once daily combination tablet containing tenofovir and emtricitabine (Truvada) and tenofovir, emtricitabine, and efavirenz (Atripla).
(3) Precautions and monitoring effects
(a) Minor adverse effects have been reported in clinical trials. These include complaints of diarrhea, vomiting, and nausea.
(b) Additional adverse effects observed during postmarketing surveillance include acute renal failure and decreases in bone mineral density.
(c) Tenofovir has the same black box warning that emtricitabine has for patients with concomitant hepatitis B (see VII.C.3.c).
(d) Dose adjustment is required for renal insufficiency.

(4) Significant interactions
(a) Tenofovir increases didanosine serum concentrations, necessitating a dose reduction of didanosine.
(b) Tenofovir decreases serum concentrations of atazanavir. When these 2 agents are used together, ritonavir must be added to the regimen.
g. Zalcitabine (ddC; Hivid) is a synthetic pyrimidine nucleoside analogue that is active against HIV.
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses. Zalcitabine is no longer recommended as a component of initial combination therapy of HIV owing to its severe adverse effect profile. The manufacturer discontinued its production in 2006.
(3) Precautions and monitoring effects
(a) The major clinical toxicity of zalcitabine is peripheral neuropathy, which occurs in up to 35% of patients and may be potentially disabling.
(b) Other adverse effects include pancreatitis, stomatitis, cardiomyopathy, and hypersensitivity reactions.
(c) Do not use in combination with lamivudine, stavudine, or zidovudine.
(4) Significant interactions
(a) Drugs that have the potential to cause peripheral neuropathy should be avoided. These include chloramphenicol, cisplatin, dapsone, didanosine, disulfiram, hydralazine, isoniazid, metronidazole, nitrofurantoin, phenytoin, ribavirin, and vincristine.

(b) Zalcitabine treatment should be interrupted when a drug with the potential to cause pancreatitis is initiated (i.e., pentamidine).
(c) Do not take with magnesium-, calcium-, or aluminum-containing antacids.
(d) Cimetidine and probenecid may increase zalcitabine levels, causing increased zalcitabine toxicity.
h. Zidovudine (AZT; Retrovir) is a synthetic thymidine analog. This agent was the first available drug for the treatment of HIV infection.
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses
(a) Zidovudine is indicated in the treatment of adults and children > 6 weeks of age for the treatment of HIV.
(b) It is indicated for the prevention of maternal-fetal HIV transmission.
(c) Zidovudine is available as oral capsules, tablets, and solution as well as an IV solution.
(d) Oral zidovudine is also available as a co-formulation with lamivudine (Combivir) and with lamivudine and abacavir (Trizivir).
(3) Precautions and monitoring effects

(a) Zidovudine can cause severe bone marrow suppression, including macrocytic anemia and neutropenia after the first few weeks to months of therapy. The risk is increased in patients with preexisting bone marrow suppression or who are taking concomitant medications that cause bone marrow suppression.
(b) Erythropoietin can be considered as an adjunctive therapy in patients with zidovudine-induced anemia, in cases for which it cannot be discontinued.
(c) Other adverse effects include headache, malaise, seizures, anxiety, fever, and rash.
(d) Prolonged use may lead to symptomatic myopathy.
(4) Significant interactions
(a) Cotrimoxazole, atovaquone, valproic acid, methadone, and probenecid may increase zidovudine concentrations, causing increased risk of zidovudine toxicity.
(b) Other cytotoxic drugs, such as ganciclovir, dapsone, and interferon-α, can cause additive bone marrow suppression.
(c) Ribavirin, rifabutin, and rifampin may decrease levels of zidovudine.
4. Nonnucleoside reverse transcriptase inhibitors. The NNRTI class binds directly to and produces a noncompetitive inhibition of the HIV reverse transcriptase, leading to chain termination. These agents are indicated for use in adults and pediatric patients in combination with either NRTIs or possibly PIs. Efavirenz is considered a preferred NNRTI, whereas the others are currently recommended as alternatives. NNRTI-based regimens provide potent antiviral activity with less pill burden than many PI-based regimens. All NNRTIs may cause rash and hepatotoxicity; patients should be monitored closely for these adverse effects.
a. Delavirdine (Rescriptor)
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses. Delavirdine is approved for use in adults in the treatment of HIV in combination with other antiretroviral agents. Its use has fallen out of favor owing to its three times daily dosing schedule.
(3) Precautions and monitoring effects
(a) In clinical trials, 4.3% of patients discontinued delavirdine because of rash. Cases of Stevens-Johnson syndrome have been reported.
(b) Other adverse effects include headache and nausea.
(4) Significant interactions
(a) The concentrations of the following medications are greatly increased by delavirdine and must be avoided: alprazolam, midazolam, triazolam, simvastatin, lovastatin, rifabutin, and cisapride.
(b) Decreased delavirdine concentrations result when it is administered with St. John's wort, carbamazepine, phenobarbital, phenytoin, or rifampin. Concomitant use should be avoided.

(c) Because delavirdine requires an acidic GI tract for optimal absorption, its use is contraindicated with proton pump inhibitors and H_2-receptor antagonists.

b. Efavirenz (Sustiva)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Efavirenz is approved for use in combination with other antiretroviral agents for the treatment of HIV infection in adults and pediatric patients (≥ 3 years of age). Its advantage over other NNRTIs is once-daily dosing. It is available alone or as a combination tablet with tenofovir and emtricitabine (Atripla).

(3) Precautions and monitoring effects

(a) Most common adverse effects are CNS-related (52%), including insomnia, dizziness, drowsiness, nightmares, and hallucinations, necessitating bedtime dosing to minimize these effects. These effects typically subside after 2-4 weeks of treatment.

(b) Owing to its teratogenic effects, efavirenz should be avoided in the first trimester of pregnancy and in women of childbearing potential who wish to conceive.

(c) Other adverse effects include rash, increased transaminases, and GI disturbances.

(4) Significant interactions

(a) Efavirenz induces and inhibits the cytochrome P450 3A4 isoenzyme system. It should not be used concomitantly with cisapride, midazolam, triazolam, or ergot derivatives.

(b) St. John's wort decreases efavirenz concentrations and should be avoided.

(c) Efavirenz decreases methadone concentrations by 60%; patients should be monitored for opiate withdrawal and have their doses titrated accordingly.

c. Etravirine (Intelence)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Etravirine is indicated for use in combination with at least two additional antiretroviral agents in treatment-experienced adults who demonstrate viral replication and documented resistance to other NNRTIs. It is not for use in treatment-naïve patients.

(3) Precautions and monitoring effects.

(a) Adverse effects include nausea and rash.

(b) Since food increases the absorption of etravirine by 50%, it should be taken following a meal.

(4) Significant interactions.

(a) Etravirine induces and inhibits a variety of cytochrome P450 isoenzymes. It should not be used concomitantly with carbamazepine, phenobarbital, phenytoin, unboosted PIs, atazanavir/ritonavir, fosamprenavir/ritonavir, tipranavir/ritonavir, or other NNRTIs.
(b) St. John's wort and rifampin decrease etravirine concentrations and should be avoided.
(c) Etravirine may decrease serum concentrations of methadone; patients should be monitored closely.
d. Nevirapine (Viramune) was the first NNRTI approved for use by the FDA for the treatment of HIV infection.
(1) Mechanism of action. See VII.C.3.
(2) Spectrum of activity and therapeutic uses. Nevirapine is indicated in combination with other antiretrovirals in adult and pediatric (≥ 2 months old) HIV patients.
(3) Precautions and monitoring effects
(a) Nevirapine has the highest incidence of Stevens-Johnson syndrome of all NNRTIs.
(b) Symptomatic hepatitis, including fatal hepatic necrosis, has been observed with nevirapine (black box warning). The frequency of this adverse effect is increased in women with pre-nevirapine $CD4^+$ counts > 250 cells/mm^3 and men with $CD4^+$ counts > 400 cells/mm^3. Nevirapine should not be initiated in these patients.
(c) Other adverse effects include fever, nausea, and headache.
(d) To decrease the frequency of adverse effects, a 2-week dose escalation is required.
(4) Significant interactions
(a) Nevirapine induces cytochrome P450 3A4, resulting in decreased concentrations of caspofungin, ketoconazole, itraconazole, oral contraceptives, and protease inhibitors.

(b) Use of rifampin and St. John's wort should be avoided, as they decrease the serum concentrations of nevirapine.
(c) Methadone concentrations decrease significantly with nevirapine, often necessitating a dose increase.
5. Protease inhibitors. The PIs competitively inhibit the viral protease enzyme, preventing the enzyme from cleaving the gag and gag-pol polyproteins necessary for virion production. PIs are used in combination with other antiretroviral agents, including other PIs, to suppress HIV replication. All of the PIs are cytochrome P450 inhibitors; ritonavir is the most potent inhibitor. All PIs are contraindicated with numerous drugs, including simvastatin, lovastatin, rifampin, cisapride, pimozide, midazolam, triazolam, ergots, and St. John's wort. Concomitant therapy with antiepileptic drugs, erectile dysfunction drugs, and azole antifungals must

be undertaken with caution. Owing to the wide array of drug interactions with PIs, always assess medication profiles carefully for drug interactions before initiation.

a. Amprenavir (Agenerase)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Amprenavir is no longer recommended for use in treatment regimens for HIV due to its discontinuation in late 2007.

(3) Precautions and monitoring effects.

(a) Use of the oral solution in pregnant women, children < 4 years old, and patients with hepatic or renal insufficiency is contraindicated owing to the propylene glycol vehicle (black box warning).

(b) Because amprenavir is a sulfonamide, the potential for cross-sensitivity to other sulfonamides exists.

(c) Adverse effects include hyperlipidemia, hyperglycemia, fat maldistribution, rash, and GI disturbances.

(d) Dosage adjustment is required for hepatic insufficiency.

(4) Significant interactions (see VII.C.5). Amprenavir decreases methadone concentrations, possibly requiring a methadone dose increase to prevent withdrawal.

b. Atazanavir (Reyataz)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Atazanavir is a component of preferred and alternative PI-based regimens for HIV. It is dosed once daily.

(3) Precautions and monitoring effects.

(a) Atazanavir may prolong the PR interval and possibly cause first-degree AV block. Electrocardiogram (ECG) should be monitored.

(b) Other adverse effects include fat maldistribution, hyperglycemia, and indirect hyperbilirubinemia. In contrast to the other PIs, atazanavir appears to be devoid of effects on lipids.

(c) Dose adjustment is required for hepatic insufficiency.

(4) Significant interactions (see VII.C.5). Atazanavir is the most problematic of all PIs in terms of drug interactions.

(a) If used in combination with efavirenz or tenofovir, low-dose ritonavir must be administered concomitantly.

(b) Because atazanavir requires an acidic GI tract for optimal absorption, concomitant use of proton pump inhibitors is contraindicated. If other acid suppressants are used with atazanavir, the doses must be separated by as much time as possible (up to 12 hr apart).

c. Darunavir (Prezista)

(1) Mechanism of action. See VII.C.5

(2) Spectrum of activity and therapeutic uses. Darunavir is the newest PI to receive FDA approval for the treatment of HIV. Its use is limited to highly treatment-experienced patients or patients with HIV resistance mutations.

(3) Precautions and monitoring effects

(a) Darunavir must be co-administered with ritonavir
(b) Because darunavir contains a sulfonamide moiety, cross-reactivity may occur in sulfa-allergic patients.
(c) Adverse effects include nausea, increased amylase, hepatotoxicity, hyperlipidemia, hyperglycemia, and rash.
(4) Significant interactions. See VII.C.5.
d. Fosamprenavir (Lexiva)
(1) Mechanism of action. See VII.C.5. Fosamprenavir is the prodrug of amprenavir.

(2) Spectrum of activity and therapeutic uses. Fosamprenavir has largely replaced amprenavir because of its improved dosing convenience. It is recommended as one of the preferred components in PI-based regimens for initial treatment of HIV.
(3) Precautions and monitoring effects
(a) Fosamprenavir may be dosed once daily in treatment naïve patients. PI-experienced patients require twice daily dosing. In most cases, fosamprenavir is administered with low dose ritonavir.
(b) Adverse effects are the same as those with amprenavir (see VII.C.5.a.(3). b, c and d).
(4) Significant interactions (see VII.C.3). If used in combination with efavirenz, fosamprenavir must be administered with a booster dose of ritonavir.
e. Indinavir (Crixivan)
(1) Mechanism of action. See VII.C.5.
(2) Spectrum of activity and therapeutic uses. Indinavir, in combination with ritonavir, is no longer recommended as part of regimen for patients receiving initial treatment for HIV due to a high incidence of nephrolithiasis.
(3) Precautions and monitoring effects
(a) Because indinavir may cause nephrolithiasis (kidney stones), patients should be instructed to drink at least 1.5 L of water daily to prevent this adverse effect.
(b) Indinavir can cause indirect hyperbilirubinemia. Combination therapy with atazanavir is not recommended owing to the potential for additive effects.
(c) Other adverse effects include hyperglycemia, hyperlipidemia, fat maldistribution, headache, and GI intolerance.
(d) Dose adjustment is required for hepatic insufficiency.
(4) Significant interactions (see VII.C.5). Vitamin C in doses > 1 g daily decreases indinavir concentrations. Caution patients not to exceed the recommended daily allowance for vitamin C.
f. Lopinavir/ritonavir (Kaletra)
(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. This product is available as a co-formulation of lopinavir with a “booster” dose of ritonavir, which inhibits lopinavir metabolism and results in higher serum concentrations. Lopinavir/ritonavir is a preferred PI used in initial PI-based regimens owing to its potency and convenient dosing.
(3) Precautions and monitoring effects
(a) Lopinavir/ritonavir was recently reformulated as a film-coated tablet that does not require refrigeration. It is also available as an oral solution containing 42% alcohol.
(b) Adverse effects include GI intolerance, hyperlipidemia, hyperglycemia, fat maldistribution, and pancreatitis.
(4) Significant interactions. See VII.C.5.
(a) Lopinavir/ritonavir decreases methadone concentrations, possibly necessitating a methadone dose increase to prevent opiate withdrawal.
(b) Concomitant administration with voriconazole is contraindicated because of the risk of decreased voriconazole efficacy.
(c) Dosing varies due to drug interactions with concomitant use of efavirenz, nevirapine, fosamprenavir, or nelfinavir. Be sure to check appropriate references for proper dosing.
g. Nelfinavir (Viracept)
(1) Mechanism of action. See VII.C.5.
(2) Spectrum of activity and therapeutic uses. Nelfinavir is a possible component of an alternative PI-based regimen for initial treatment of adults with HIV infection. Unlike the other PIs, it is never used in combination with ritonavir. It is not generally recommended due to inferior virologic efficacy.
(3) Precautions and monitoring effects
(a) Diarrhea is commonly reported with nelfinavir. This can often be managed with antidiarrheals.
(b) Other adverse effects are similar to those with lopinavir/ritonavir.
(c) Use caution with look-alike, sound-alike names (nelfinavir and nevirapine).
(4) Significant interactions (see VII.C.5.) Nelfinavir decreases methadone concentrations, necessitating increased monitoring and dose adjustment if indicated.
h. Ritonavir (Norvir)
(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Ritonavir is rarely used as the sole PI in a PI-based regimen owing to its poor tolerability and high pill burden when administered in full doses. Alternatively, it is used in low doses as a pharmacokinetic boosting agent with other PIs. Because it is such a potent cytochrome 450 enzyme inhibitor, ritonavir markedly

increases the serum concentrations of other PIs, resulting in higher concentrations with improved viral suppression.
(3) Precautions and monitoring effects
(a) Capsules should be refrigerated before dispensing. Capsules then may be stored at room temperature for up to 30 days.
(b) Oral solution should not be refrigerated.
(c) Adverse effects include GI intolerance, circumoral paresthesias, hyperlipidemia, hyperglycemia, fat maldistribution, increased liver function tests, and taste perversion.
(4) Significant interactions (see VII.C.5). Many drug interactions occur with ritonavir because it is such a potent inhibitor of so many cytochrome P450 isoenzymes. Always refer to proper resources to assess for drug interactions.
i. Saquinavir (Invirase)
(1) Mechanism of action. See VII.C.5.
(2) Spectrum of activity and therapeutic uses. Use of saquinavir without booster doses of ritonavir is not recommended because of the poor bioavailability of saquinavir.
(3) Precautions and monitoring effects
(a) Saquinavir is available as a hard gel capsule and tablet (Invirase) and was previously available as a soft gel capsule (Fortovase). The various dosage forms are not bioequivalent and cannot be used interchangeably.
(b) The soft gel capsule formulation is no longer manufactured (effective February 2006).
(c) Adverse effects are similar to lopinavir/ritonavir.
(4) Significant interactions. See VII.C.5.
j. Tipranavir (Aptivus)
(1) Mechanism of action. See VII.C.5.
(2) Spectrum of activity and therapeutic uses. The use of tipranavir is limited to highly treatment-experienced patients with HIV who are resistant to other PIs as well as to other classes of antiretrovirals.
(3) Precautions and monitoring effects.
(a) Owing to the poor bioavailability of tipranavir, it must be co-administered with ritonavir.
(b) Capsules must be refrigerated. Once dispensed, they are stable at room temperature for up to 60 days.
(c) Tipranavir has been associated with clinical hepatitis and fatal hepatic decompensation (black box warning). Liver function tests should be monitored closely, especially in patients with underlying liver disease.
(d) Rarely, there have been reports of fatal and nonfatal intracranial hemorrhage with tipranavir (black box warning).
(e) Because the structure of tipranavir contains a sulfonamide moiety, cross-reactivity may occur in sulfa-allergic patients.
(f) Other adverse effects include rash, hyperlipidemia, hyperglycemia, and fat maldistribution.

(4) Significant interactions (see VII.C.5). Loperamide may decrease tipranavir concentrations.

6. Fusion inhibitors. Enfuvirtide (T-20; Fuzeon) is the first and only member of this class of antiretrovirals.

a. Mechanism of action. Enfuvirtide inhibits the entry of HIV into $CD4^+$ cells by interfering with the fusion of viral and cellular membranes.

b. Spectrum of activity and therapeutic uses. Enfuvirtide is primarily used in highly treatment-experienced patients with extensive viral resistance. It is not recommended for use as initial therapy in treatment-naive patients, as it has not been studied in this population.

c. Precautions and monitoring effects

(1) Enfuvirtide is injected subcutaneously twice daily. Local injection site reactions occur in almost all patients, including pain, redness, pruritus, and nodules.

(2) Other adverse effects include hypersensitivity reactions and increased rate of bacterial pneumonia.

(3) No dose adjustment is necessary for renal impairment.

d. Significant interactions. There are no significant drug interactions with enfuvirtide.

7. Entry inhibitor. Maraviroc (Selzentry) is the first and only member of this class of antiretroviral therapy.

a. Mechanism of action. Maraviroc is a chemokine receptor 5 (CCR5) coreceptor antagonist. It binds to the CCR5 receptor on the CD4 cell membrane, preventing entry of the virus into the cell.

b. Spectrum of activity and therapeutic uses. Maraviroc is used along with other antiretrovirals only in highly treatment-experienced adult patients who are infected with HIV that binds to the CCR5 receptor.

c. Precautions and monitoring effects.

(1) Hepatotoxicity was observed during clinical trials with maraviroc (black box warning). This may be preceded by a systemic allergic reaction. Patients should be evaluated immediately if either occurs.

(2) Use caution in patients with liver disease or cardiovascular risk factors.

(3) Adverse effects include cough, rash, fever, musculoskeletal symptoms, dizziness, and abdominal pain.

(4) Not recommended for use in patients with renal insufficiency unless no alternative option is available.

d. Significant interactions.

(1) Dosing for maraviroc varies depending upon concomitant medications that interact:

(a) When used with cytochrome P450 inhibitors, such as PIs (except tipranavir/ritonavir), delavirdine, ketoconazole, itraconazole, and clarithromycin, administer maraviroc 150 mg twice daily.

(b) When used with cytochrome P450 inducers (such as carbamazepine, phenobarbital, phenytoin, efavirenz, and rifampin) without a strong cytochrome P450 inhibitor, administer maraviroc 600 mg twice daily.
(c) When used with other medications, including tipranavir/ritonavir, nevirapine, NRTIs, and enfuvirtide, administer maraviroc 300 mg twice daily.
(2) Concomitant administration with St. John's wort is not recommended due to reduction in maraviroc serum concentrations.
8. Integrase inhibitor. Raltegravir (Isentress) is the first and only member of this class of antiretroviral therapy.
a. Mechanism of action. Raltegravir inhibits the viral enzyme integrase, thereby preventing the insertion of HIV genetic material into the CD4 cell genome and halting the viral replication process.
b. Spectrum of activity and therapeutic uses. Raltegravir is used along with other antiretrovirals only in treatment-experienced adult patients who demonstrate resistant strains of HIV.
c. Precautions and monitoring effects.
(1) Since elevations in creatine kinase, along with myopathy and rhabdomyolysis, may occur with raltegravir, use with caution in patients who are receiving concomitant medications that may cause these adverse effects.
(2) The most common adverse effects include nausea, diarrhea, headache, and fever.
d. Significant interactions. Rifampin decreases the serum concentration of raltegravir and should be used with caution.

VIII. Anthelmintics

A. Definition. These drugs are used to rid the body of worms (helminths). These agents may act locally to rid the GI tract of worms or work systemically to eradicate worms that are invading organs or tissues.
B. Mebendazole (Vermox) is a synthetic benzimidazole-derivative anthelmintic.
1. Mechanism of action. Mebendazole interferes with reproduction and survival of helminths by inhibiting the formation of microtubules and irreversibly blocking glucose uptake, thereby depleting glycogen stores in the helminth.
2. Spectrum of activity. Mebendazole is active against various nematodes that are pathogenic to humans, including Ancylostoma duodenale (common hookworm), Ascaris lumbricoides

(roundworm), Capillaria philippinensis (Philippine threadworm), Enterobius vermicularis (pinworm), Necator americanus (American hookworm), and Trichuris trichiura (whipworm).

3. Therapeutic uses. Mebendazole is used for the treatment of single or mixed infections with the helminths listed in VIII.B.2. Immobilization and subsequent death of helminths are slow, with complete GI clearance up to 3 days after therapy.

4. Precautions and monitoring effects

a. In cases of massive infection, abdominal pain, nausea, and diarrhea associated with expulsion of organisms may result.

b. Myelosuppression (neutropenia and thrombocytopenia) can occur with high doses (40-50 mg/kg/day).

c. If the patient is not cured in 3 weeks, retreatment is necessary.

5. Significant interactions. Agents that may reduce the serum concentrations and subsequent efficacy of mebendazole include carbamazepine and phenytoin.

C. Albendazole (Albenza) is a synthetic benzimidazole-derivative anthelmintic.

1. Mechanism of action. See VIII.B.1.

2. Spectrum of activity. Albendazole is active against Taenia solium (pork tapeworm) and Echinococcus granulosus (dog tapeworm).

3. Therapeutic uses. Albendazole is used to treat parenchymal neurocysticercosis in combination with corticosteroids as well as cystic hydatid disease (before and after surgical removal of the disease).

4. Precautions and monitoring effects

a. The drug should be administered with a fatty meal to achieve optimal absorption.

b. Hepatotoxicity occurs in 16% of patients; liver function tests every 2 weeks are recommended while taking albendazole.

c. Rarely, leukopenia, thrombocytopenia, granulocytopenia, pancytopenia, and agranulocytosis occur. A CBC should be checked every 2 weeks while taking albendazole.

D. Diethylcarbamazine citrate (Hetrazan)

1. Mechanism of action. Diethylcarbamazine citrate is a synthetic organic compound highly specific for several common parasites.

2. Spectrum of activity. This agent is active against Wuchereria bancrofti, Onchocerca volvulus, Brugia malayi, Mansonella perstans, Mansonella ozzardi, Ascaris lumbricoides, and Loa loa.

3. Therapeutic uses. Diethylcarbamazine citrate is used for the treatment of Bancroft's filariasis, onchocerciasis, ascariasis, and loiasis. It is available directly from the manufacturer for compassionate use only.

4. Precautions and monitoring effects

a. Patients treated for W. bancrofti infection often present with headache and general malaise. Severe allergic phenomena in conjunction with a skin rash have been reported.

b. Patients treated for onchocerciasis present with pruritus, facial edema, and systemic symptoms secondary to the inflammatory response caused by pathogen death (known as a Mazzotti reaction). Severe reactions may be

noted after a single dose. For this reason, ivermectin is used to treat onchocerciasis.
c. Children who are undernourished or are suffering from debilitating ascariasis infection may experience giddiness, malaise, nausea, and vomiting after treatment. Other drugs are available to treat Ascaris (mebendazole and albendazole).
E. Pyrantel (Pin-Rid) is a pyrimidine-derivative anthelmintic.
1. Mechanism of action. Pyrantel is a depolarizing neuromuscular blocking agent that causes a spastic paralysis of the helminth.
2. Spectrum of activity. Pyrantel is active against A. lumbricoides (roundworm), E. vermicularis (pinworm), A. duodenale (hookworm), N. americanus (hookworm), and Trichostrongylus orientalis (hairworm).
3. Therapeutic uses. Pyrantel is used for the treatment of roundworm, pinworm, and hookworm infections.

4. Precautions and monitoring effects
a. Most commonly reported reactions include anorexia, nausea, vomiting, diarrhea, headache, and rash.
b. A single dose may be mixed with food, milk, juice, or taken on an empty stomach.
F. Thiabendazole (Mintezol), a pyrazinoisoquinoline derivative, is a synthetic heterocyclic anthelmintic.
1. Mechanism of action is not known precisely. Thiabendazole is shown to inhibit the helminth-specific enzyme, fumarate reductase. Thiabendazole also demonstrates anti-inflammatory, antipyretic, and analgesic effects.
2. Spectrum of activity. It is active against most intestinal nematodes, including Ancylostoma braziliense (dog and cat hookworm), A. duodenale (hookworm), A. lumbricoides (roundworm), E. vermicularis (pinworm), N. americanus (hookworm), Strongyloides stercoralis (threadworm), T. trichiura (whipworm), T. spiralis, and Toxocara canis and Toxocara cati (dog and cat roundworms).
3. Therapeutic uses. Thiabendazole is used for the treatment of strongyloidiasis (threadworm infection), cutaneous larva migrans (creeping eruption), and visceral larva migrans. It is used for the treatment of uncinariasis (hookworm), N. americanus, A. duodenale, trichuriasis (whipworm), and ascariasis (large roundworm) when more specific therapy is unavailable or further treatment is required with a second agent.
4. Precautions and monitoring effects
a. Adverse effects of thiabendazole are usually mild and transient, occurring 3-4 hr after the drug has been administered and lasting for 2-8 hr.
b. Most common reactions include anorexia, nausea, vomiting, and dizziness.

c. Giddiness, seizures, vertigo, paresthesias, and psychic disturbances may also occur, but less frequently.
d. If hypersensitivity develops, the drug should be discontinued. Erythema multiforme (including Stevens-Johnson syndrome) has been reported.
5. Significant interactions. Serum xanthine levels (theophylline and caffeine) may increase.
G. Ivermectin (Stromectol)
1. Mechanism of action. Ivermectin potentiates the inhibitory effects of γ-aminobutyric acid (GABA) in various nematodes and arthropods, resulting in paralysis and death of the organisms.
2. Spectrum of activity. This agent is active against S. stercoralis (intestinal forms only) and O. volvulus (immature forms only). It is also useful for treatment of infections with A. lumbricoides, E. vermicularis, M. ozzardi, T. trichiura, and W. bancrofti.
3. Therapeutic uses
a. Ivermectin is useful for treatment of infections with the parasites listed in VIII.G.2.
b. Two studies demonstrated that ivermectin was more effective than albendazole for treatment of strongyloidiasis.
c. Ivermectin is often favored over diethylcarbamazine citrate owing to its less severe adverse effect profile.
4. Precautions and monitoring effects,
a. May cause a Mazzotti reaction (see VIII.D.4.b) that is less severe than with diethylcarbamazine citrate.
b. Reports of serious and possibly fatal encephalopathy have occurred in patients with concomitant L. loa infection
c. Other adverse effects include edema, dizziness, headache, rash, and GI disturbances.
d. Counsel patients to take ivermectin with water.
H. Praziquantel (Biltricide)
1. Mechanism of action. Praziquantel increases cell membrane permeability in susceptible helminths, with loss of intracellular calcium and paralysis of their musculature. Vacuolization and disintegration of the schistosome tegument result, followed by attachment of phagocytes to the parasite and death.

2. Spectrum of activity. Praziquantel is active against trematodes (flukes), including all Schistosoma spp. and Clonorchis sinensis, Opisthorchis viverrini, Fasciola hepatica (liver flukes), Paragonimus uterobilateralis, Paragonimus westermani (lung flukes), Metagonimus yokogawai, Fasciolopsis buski, and Heterophyes heterophyes (intestinal flukes).
3. Therapeutic uses. Praziquantel is active in treating all types of schistosomiasis that are pathogenic to humans; clonorchiasis and

opisthorchiasis (Chinese and southeast Asian liver flukes); many other types of infections involving intestinal, liver, and lung flukes; and cestodiasis (tapeworm) infections.

4. Precautions and monitoring effects

a. Treatment of ocular cysticercosis is contraindicated because parasite destruction within the eyes may cause irreparable lesions.

b. In general, adverse effects are generally mild and well tolerated. It is difficult to differentiate between effects caused by the praziquantel versus effects demonstrated by dying parasites.

c. The most common side effects are transient and may include malaise, headache, dizziness, and abdominal discomfort.

d. Praziquantel may impair activities that require mental alertness.

STUDY QUESTIONS

Directions for questions 1-12: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

1. Isoniazid is a primary antitubercular agent that

(A) requires pyridoxine supplementation.

(B) may discolor the tears, saliva, urine, or feces orange red.

(C) causes ocular complications that are reversible if the drug is discontinued.

(D) may be ototoxic and nephrotoxic.

(E) should never be used because of hepatotoxic potential.

View Answer*1. The answer is A***[see V.B.2.d.(5)].2. All of the following factors may increase the risk of nephrotoxicity from gentamicin therapy except which one?**

(A) age > 70 years

(B) prolonged courses of gentamicin therapy

(C) concurrent amphotericin B therapy

(D) trough gentamicin levels < 2 mg/mL

(E) concurrent cisplatin therapy

View Answer*2. The answer is D***[see**II.B.4.b**].**mgmL**3. In which of the following groups do all four drugs warrant careful monitoring for drug-related seizures in high-risk patients?**

(A) penicillin G, imipenem, amphotericin B, metronidazole

(B) penicillin G, chloramphenicol, tetracycline, vancomycin

(C) imipenem, tetracycline, vancomycin, sulfadiazine

(D) cycloserine, metronidazole, vancomycin, sulfadiazine

(E) metronidazole, imipenem, doxycycline, erythromycin

View Answer*3. The answer is A***[see II.E.1.e.(2); II.J.5.d.(2);**III.B.4.b**].4. AC is a 34-year-old male admitted with a diagnosis of peritonitis. Cultures are positive for Bacteroides fragilis, Enterococcus faecalis, and Staphylococcus aureus. Which of the following would be the best initial therapy to recommend?**

(A) telithromycin

(B) quinupristin/dalfopristin

(C) tigecycline

(D) trimethoprim/sulfamethoxazole

(E) kanamycin

View Answer*4. The answer is C***[see**II.K.13**].5. TJ is a 45-year-old female presenting with an Enterobacter aerogenes bacteremia with a low-grade fever (101.6°F). The most appropriate management of her fever would be to**

(A) give acetaminophen 1000 mg orally every 6 hr.

(B) give aspirin 650 mg orally every 4 hr.

(C) give alternating doses of aspirin and acetaminophen every 4 hr.

(D) withhold antipyretics and use the fever curve to monitor her response to antibiotic therapy.

(E) use tepid water baths to reduce the fever.

View Answer*5. The answer is D***[see**I.H. 1**].6. BC has an upper respiratory infection. Two years ago, she experienced an episode of bronchospasm after penicillin therapy. Current cultures are positive for a strain of Streptococcus pneumoniae that is sensitive to all of the following drugs. Which of these drugs would be the best choice for this patient?**

(A) amoxicillin/clavulanate

(B) telithromycin

(C) ampicillin

(D) cefaclor

(E) loracarbef

View Answer*6. The answer is B***[see II.K. 12].7. All of the following drugs are appropriate therapies for a lower urinary tract infection owing to Pseudomonas aeruginosa except**

(A) norfloxacin.

(B) trimethoprim-sulfamethoxazole.

(C) ciprofloxacin.

(D) tobramycin.

(E) methenamine mandelate.

(A) dicloxacillin 125 mg every 6 hr

(B) vancomycin 250 mg every 6 hr

(C) methicillin 500 mg every 6 hr

(D) cefazolin 1 g every 8 hr

(E) penicillin V 500 mg every 6 hr

View Answer*8. The answer is A***[see**II.C**].**P.980

9. RC is a 33-year-old male with a history of HIV for 10 years who now presents with Mycobacterium avium-intracellulare (MAI). Which of the following drugs has demonstrated in vitro activity against MAI?

(A) daptomycin

(B) clarithromycin

(C) erythromycin base

(D) cloxacillin

(E) minocycline

View Answer*9. The answer is B***[see II.D.6.a-b].Toxoplasma gondiiCryptosporidium10. All of the following statements regarding pentamidine isethionate are true except which one?**

(A) It is indicated for treatment or prophylaxis of infection owing to Pneumocystis carinii.

(B) It may be administered intramuscularly, intravenously, or by inhalation.

(C) It has no clinically significant effect on serum glucose.

(D) It is effective in the treatment of leishmaniasis.

View Answer*10. The answer is C***[see**IV.D**].P. carinii.11. RE is a 23-year-old male with a history of influenza A infections. An outbreak of influenza A has just been reported in his community, and he is exhibiting initial symptoms of the infection. Which agent would be the most useful to treat RE?**

(A) cidofovir

(B) famciclovir

(C) oseltamivir

(D) foscarnet

(E) ribavirin

View Answer*11. The answer is C***[see**VII.B.9**].12. Dr. Jones requests your help in prescribing a protease inhibitor for his patient. He has heard that not all agents are the same and asks for your recommendation as to which agent would be least likely to cause the patient's cholesterol to increase. Which agent would you recommend?**

(A) saquinavir

(B) ritonavir

(C) indinavir

(D) nelfinavir

(E) atazanavir

View Answer*12. The answer is E***[see**VII.C.5.b.(3).(b)**].**Directions for questions 13-14: The questions and incomplete statements in this section can be correctly answered or completed by one or more of the suggested answers. Choose the answer, A-E.

13. Drugs usually active against penicillinase-producing Staphylococcus aureus include which of the following?

(I) piperacillin-tazobactam

(II) amoxicillin-clavulanate

(III) nafcillin

A if I only is correct

B if III only is correct

C if I and II are correct

D if II and III are correct

E if I, II, and III are correct

View Answer*13. The answer is E***(I, II, III) [see**II.E.23**and**4**].S. aureus14. Antiviral agents that are active against cytomegalovirus (CMV) include which of the following?**

(I) ganciclovir

(II) foscarnet

(III) acyclovir

A if I only is correct

B if III only is correct

C if I and II are correct

D if II and III are correct

E if I, II, and III are correct

A clofazimine

B itraconazole

C lomefloxacin

D neomycin

View Answer*17. The answer is B***[see**III.E.5.d**].**P.981

ANSWERS AND EXPLANATIONS

1. The answer is A [see V.B.2.d.(5)].
Isoniazid increases the excretion of pyridoxine, which can lead to peripheral neuritis, particularly in poorly nourished patients. Pyridoxine (a form of vitamin B_6) deficiency may cause convulsions as well as the neuritis, involving synovial tenderness and swelling. Treatment with the vitamin can reverse the neuritis and prevent or cure the seizures.
2. The answer is D [see II.B.4.b].
Trough serum levels < 2 mg/mL are considered appropriate for gentamicin and are recommended to minimize the risk of toxicity from this aminoglycoside. Because aminoglycosides accumulate in the proximal tubule of the kidney, nephrotoxicity can occur.
3. The answer is A [see II.E.1.e.(2); II.J.5.d.(2); III.B.4.b; IV.C.3.c].
Seizures have been attributed to the use of penicillin G, imipenem, amphotericin B, and metronidazole. Seizures are especially likely with high doses in patients with a history of seizures and in patients with impaired drug elimination.
4. The answer is C [see II.K.13].
Although active against various gram-positive and negative organisms, tigecycline is only agent approved for the treatment of intra-abdominal infections caused by these organisms.
5. The answer is D [see I.H. 1].
The fever curve is useful for monitoring a patient's response to antimicrobial therapy. Antipyretics can be used to reduce high fever in patients at risk for complications (e.g., seizures) or, in some cases, to make the patient more comfortable.
6. The answer is B [see II.K. 12].
Amoxicillin and ampicillin are all penicillins and should be avoided in patients with histories of hypersensitivity to other penicillin compounds. Although the risk of cross-reactivity with cephalosporins (e.g., cefaclor, loracarbef) is now considered low, most clinicians avoid the use of these agents in patients with histories of type I hypersensitivity reactions (e.g., anaphylaxis, bronchospasm, giant hives).
7. The answer is B [see II.E.4; II.H.3.a and b; II.I.2.a; II.I.3.a; II.J.7].

Norfloxacin, ciprofloxacin, tobramycin, and methenamine mandelate achieve urine concentrations high enough to treat urinary tract infections caused by P. aeruginosa. Trimethoprim-sulfamethoxazole is not useful for treating infection caused by this organism, although the combination is useful for treating certain other urinary tract infections.

8. The answer is A [see II.C; II.E. 1.c.(3); II.E.2.b; II.J.8].

Although vancomycin, methicillin, and cefazolin have excellent activity against staphylococci, they are not effective orally for systemic infections. Vancomycin is prescribed orally for infections limited to the gastrointestinal tract, but because it is poorly absorbed orally, it is not effective for systemic infections. Most hospital- and community-acquired staphylococci are currently resistant to penicillin. Thus of the drugs listed, the most appropriate drug for oral therapy of staphylococcal cellulitis is dicloxacillin.

9. The answer is B [see II.D.6.a-b].

Clarithromycin, an alternative to erythromycin, has demonstrated in vitro activity against MAI. Clarithromycin is also used against Toxoplasma gondii and Cryptosporidium spp., and it is more active than erythromycin against staphylococci and streptococci. Vancomycin and cloxacillin are used to treat staphylococci and streptococci, but has no demonstrated activity versus MAI.

10. The answer is C [see IV.D].

Pentamidine isethionate is indicated for both treatment and prophylaxis of infection from P. carinii. It can be administered intramuscularly, intravenously, or by inhalation. Inhalation may produce bronchospasm. Blood glucose should be carefully monitored because pentamidine may produce either hyperglycemia or hypoglycemia.

11. The answer is C [see VII.B.9].

Cidofovir, famciclovir, and foscarnet have little or no in vivo activity against influenza A. Ribavirin has some activity but is a second-line agent for influenza A and is mainly indicated for treatment of hepatitis C in combination with interferon. Oseltamivir is an agent that demonstrates activity against influenza A and B. It is indicated for the prophylaxis and treatment of influenza infections.

12. The answer is E [see VII.C.5.b.(3).(b)].

The majority of protease inhibitors cause hyperlipidemia. Atazanavir does not cause this adverse effect and may be preferred in certain clinical situations.

13. The answer is E (I, II, III) [see II.E.2, 3 and 4].

Piperacillin and amoxicillin each include a β-lactamase inhibitor. These combinations offer activity against S. aureus similar to that of the penicillinase-resistant penicillins, such as nafcillin.

14. The answer is C (I and II) [see VII.B. 1; VII.B.7 and 8].

Only ganciclovir and foscarnet are active against CMV infections. These agents are virustatic and arrest DNA synthesis by inhibiting viral DNA polymerase. Foscarnet is a broad-spectrum antiviral agent and is used in patients with ganciclovir resistance. Acyclovir is not clinically useful for the treatment of CMV infections because CMV is relatively resistant to acyclovir in vitro.

15. The answer is C [see II.H.3.c].

Lomefloxacin may be administered daily for treating urinary tract infections. Enoxacin is another fluoroquinolone used to treat urinary tract infections. Compared to other fluoroquinolones, neither lomefloxacin nor enoxacin improves the spectrum of activity.

16. The answer is A [see II.J. 9].

Because clofazimine contains phenazine dye, it can cause pink to brown skin pigmentation. This change in pigmentation occurs in 75%-100% of patients taking clofazimine, and it occurs within a few weeks of the initiation of therapy. The discoloration of skin has reportedly led to severe depression and even suicide in some patients. Clofazimine is used in the treatment of leprosy and several atypical Mycobacterium infections.

17. The answer is B [see III.E.5.d].

Administration of itraconazole or ketoconazole with astemizole or terfenadine may increase the level of astemizole or terfenadine, which can lead to life-threatening dysrhythmias and death. Itraconazole, which is an imidazole, is a fungistatic agent. Specifically, itraconazole can be taken orally to treat aspergillosis infections and other deep fungal infections, such as blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis.

Thyroid Disease

John E. Janosik

I. PHYSIOLOGY

A. Thyroid hormone regulation

1. The thyroid gland synthesizes, stores, and secretes hormones that are important to growth, development, and the metabolic rate. These hormones are **thyroxine (T_4)** and **triiodothyronine (T_3).**

2. The thyroid gland also secretes **calcitonin,** which reduces blood calcium ion concentration.

3. Thyroid hormone secretion and transport are controlled by **thyroid-stimulating hormone (thyrotropin; TSH).** TSH is released by the anterior pituitary gland, which is triggered by **thyrotropin-releasing hormone (TRH),** secreted from the hypothalamus.

a. The process produces increased levels of thyroid hormone (circulating free T_4 and free T_3), which, in turn, signals the pituitary to stop releasing TSH (**negative feedback**).

b. Conversely, low blood levels of free hormone trigger pituitary release of TSH, which stimulates the thyroid gland to secrete T_4 and T_3 until free hormone levels return to normal. At this point, the pituitary gland ceases to release TSH, which completes the feedback loop (Figure 55-1).

c. This homeostatic mechanism attempts to maintain the level of circulating thyroid hormone within a narrow range.

B. Biosynthesis (Figure 55-2)

1. Essential to synthesis of thyroid hormones is dietary iodine, reduced to **inorganic iodide,** which the thyroid actively extracts from the plasma through iodide trapping (**iodide pump**). Some of this iodide is stored within the colloid; some diffuses into the lumen of thyroid follicles.

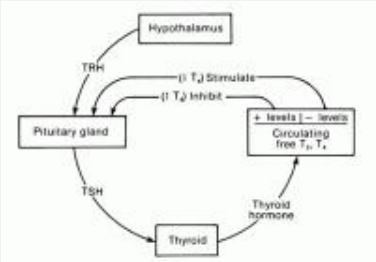

Figure 55-1. Thyroid hormone regulation loop. This carefully balanced hormone regulation system uses both positive (stimulating) and negative (inhibiting) feedback to maintain homeostasis. Disruption of any of these elements can produce serious consequences, such as myxedema crisis (under availability of thyroid hormone) or thyroid storm (overabundance of thyroid hormone). *T_3*, triiodothyronine; *T_4*, thyroxine; *TRH,* thyroid-releasing hormone; *TSH,* thyroid-stimulating hormone.

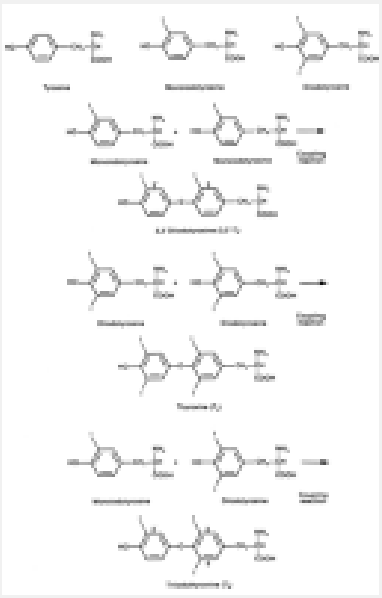

Figure 55-2. Biosynthesis of thyroid hormones. The major products are thyroxine (T_4) and triiodothyronine (T_3). These are formed in the follicle cells of the thyroid gland by iodination of tyrosine residues. Monoiodotyrosine and diiodotyrosine residues are formed first. These then react to form T_3 and T_4.

P.1200

2. Iodide is oxidized by peroxidase and bound to tyrosyl residues within the thyroglobulin molecule in a process called **organification.**

a. The synthesis begins with iodide binding to tyrosine, forming **monoiodotyrosine (MIT).**

b. MIT then binds another iodide to form **diiodotyrosine (DIT).**

c. Then, slowly, a coupling reaction binds MIT and DIT, producing T_3 and T_4.

C. Hormone transport

1. After TSH stimulation of the thyroid gland, T_3 and T_4 are cleaved from thyroglobulin and released into the circulation.

2. When in the circulation, thyroid hormone is transported bound to several plasma proteins, a process that

a. Helps protect the hormone from premature metabolism and excretion

b. Prolongs its half-life in the circulation

c. Allows the thyroid hormone to reach its site of action

3. Most thyroid hormone is transported by **thyroxine-binding globulin (TBG).** **Prealbumin** and **albumin** also serve as carriers.

D. Hormone metabolism

1. Peripheral conversion of T_4 to T_3 occurs in the pituitary gland, liver, and kidneys and accounts for about 80% of T_3 generation.

2. Deiodination accounts for most hormone degradation. The major steps in this process are shown in Figure 55-3.

3. Deiodinated hormones are excreted in feces and urine.

4. Minor nondeiodination pathways of metabolism include conjugation with sulfate and glucuronide, deamination, and decarboxylation.

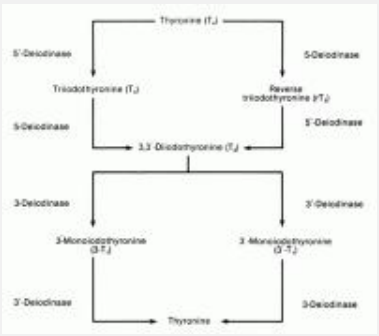

Figure 55-3. Thyroxine metabolism—major steps in the primary and alternative deiodination pathways.

E. Hormone function. Although the effects of thyroid hormones are known, the basic mechanisms producing these effects elude precise definition; however, they seem to activate the messenger RNA (mRNA) transcription process and can promote protein synthesis or (in excessive amounts) protein catabolism. **Thyroid hormones** affect the following:

1. Growth and development

2. Calorigenics by increasing the rate of basal metabolism

3. Cardiovascular system by increasing the metabolic rate, which increases blood flow, cardiac output, and heart rate (may be related in part to an increased tissue sensitivity to catecholamines)

4. The central nervous system (CNS) by increasing or diminishing cerebration

5. Musculature by causing a fine tremor

6. Sleep by inducing fatigued wakefulness with hyperthyroidism or somnolence with hypothyroidism

7. Lipid metabolism by stimulating lipid mobilization and degradation

F. Thyroid function studies (Table 55-1)

1. Serum total thyroxine (TT_4)

a. This test provides the most direct reflection of thyroid function by indicating hormone availability to tissues. Total (free and bound) T_4 is determined by radioimmunoassay, which is sensitive and rapid.

b. Changes in thyroid globulin concentration, particularly TBG, which increases during pregnancy, alter the total concentration of T_4 and may produce a misleading high or low test result.

c. However, these changes in TBG do not affect the concentration of free T_4. Therefore, to clarify thyroid function, either protein-binding (T_3 uptake test) or free T_4 must be measured.

d. An elevated TT_4 level indicates hyperthyroidism; a decreased TT_4 level, hypothyroidism. However, the TT_4 level in a euthyroid patient can be altered by other factors, such as pregnancy or febrile illnesses (which elevate the TT_4), nephrotic syndrome or cirrhosis (which lower it), and various drugs (Table 55-2).

2. Serum total triiodothyronine (TT_3)

a. This sensitive and highly specific test measures total (free and bound) T_3.

b. Serum T_3 and T_4 usually rise and fall together; however, hyperthyroidism commonly causes a disproportionate rise in T_3, and the TT_3 can rise before the TT_4 level. Therefore, TT_3 is useful for early detection or to rule out hyperthyroidism. Many of the symptoms associated with hyperthyroidism are the result of the elevated TT_3.

c. This test may not be diagnostically significant for hypothyroidism, in which TT_3 levels may fall but stay within the normal range. The TT_3 may be low in only 50% of patients with hypothyroidism.

Table 55-1. Test Results in Thyroid Disorders

Thyroid Function Test	Hypothyroidism	Hyperthyroidism
Serum resin triiodothyronine uptake (RT_3U)	↓ (< 35%)	↑ (> 45%)
Serum total thyroxine (TT_4)	↓ (< 5 µg/dL)	↑ (> 12 µg/dLl)
Serum total triiodothyronine (TT_3)	↓ (< 80 ng/dL)	↑ (> 180 ng/dLl)
Free thyroxine index (FTI)	↓ (< 5.5)	↑ (< 10.5)
Serum thyrotropin (TSH) assay[a]	↑ (> 4.5 µU/mL)	↓ (< 0.4 µU/mL)[b]

↑, increased levels;

↓, decreased levels.

[a] In clinical practice the third-generation test is commonly used with sensitivity to detect 0.01-0.02 mIU/L.

[b] Fourth-generation assays detect 0.001-0.002 mIU/L.

Table 55-2. Effects of Drugs on Thyroid Function Tests

Drug	Serum T_4	Resin T_3 Uptake	Free Thyroxine Index	Serum T_3	Serum TSH	Comment
p-Aminosalicylic acid	↓	n/d	↓	n/d	↑[a]	Antithyroid effect, rarely, with long-term use
Aminoglutethimide *(Cytadren)*	↑	n/d	n/d	n/d	↑	
Amiodarone[b]	↑	n/d	n/d	↓	↑[q]	Inhibits peripheral conversion of T_4 to T_3
Anabolic steroids and androgens	↓	↑	0	↓[a]	n/d	Decreased serum TBG
Antithyroid drugs (propylthiouracil or methimazole)	↓	↓	↓	↓	0 or ↑	TSH may increase if patient becomes hypothyroid
Asparaginase (Elspar)	↑	↑	n/d	↓[a]	↑[a]	Decreased serum TBG
Barbiturates	↓[c]	n/d	↓	n/d	n/d	Stimulates T_4 metabolism
Calcium carbonate[d]	↓	n/d	n/d	0	↑	Subclinical signs of hypothyroidis

						m; separate time of ingestion of calcium and levothyroxine
Ciprofloxacin[e]	↓	n/d	n/d	↓	↑	Clinical signs of hypothyroidism; separate administration by 6 hr.
Contraceptives, oral	↑	↓	0	↑	0	TBG usually increased
Corticosteroids	0 or ↓	0 or ↑	0 or ↓	↓	↓	Usual doses decrease TBG; high doses may increase TBG
Danazol (Danocrine)	↓	↑	0[p]	↓	0 or ↓	Decreased serum TBG
Estrogens and SERMs[g]	↑	↓	0	↑	0	Increased serum TBG
Ethionamide (Trecator-SC)	↓	n/d	↓[a]	n/d	↑[a]	Antithyroid effect
Fluorouracil (Adrucil)	↑	↓	n/d	↑	0	Patients clinically euthyroid; TBG increased
Heparin, IV	↑[h]	0 or	↑[a]	0	n/d	FTI is increased

		↑				with some measures
Hypoglycemics (sulfonylureas)	0[i]	0[i]	0[i]	n/d	n/d	
Iodides, inorganic	0	0	0	n/d	n/d	
Iodides, organic	0	0	0	n/d	n/d	
Levodopa and levodopacarbidopa (Sinemet, Parcopa)	0	0	0	0	↓[j]	
Levothyroxine (Levothroid, Levoxyl, Synthroid, Unithroid)	↑s[k,l]	↑ or 0 or ↓[k,l]	0 or ↑[k,l]	↑ or 0[k,l]	↑ or 0[k]	
Liothyronine (Cytomel)	↓[k]	0 or ↓[k]	↓[k]	↑ or ↓[k,l]	0[k]	
Liotrix (Thyrolar)	0[k] or ↓s	0[k]	0[k]	0[k,l]	0[k]	
Lithium carbonate (Eskalith, Lithobid)	0 or ↓	0 or ↓	0 or ↓	0 or ↓	0 or ↑	
Methadone (Dolophine)	↑s	↓	0	↑	0	Increased serum TBG

Mitotane (Lysodren)	↓	0	0[a]	n/d	n/d	
Nitroprusside (Nitropress)	↓	n/d	n/d	n/d	n/d	Clinical hypothyroidism
Oxyphenbutazone and phenylbutazone (Butazolidin)	0 or ↓	↑	↓	n/d	↑[a]	May compete with T_4 for TBG binding, rarely, overt hypothyroidism and goiter may occur
Perphenazine (Trilafon)	↑	↓	↓	↑	0[a]	
Phenytoin (Dilantin)	↓	0 or ↑s	0 or ↓s	↓	0	Stimulates T_4 metabolism and may compete with T_4 for TBG binding
Propranolol (Inderal)	0 or ↑[m]	0[n]	n/d	↓[o]	0	
Raloxifene[g] (Evista)	↑	↓	0	↑	0	Increased serum TBG
Resorcinol (excessive topical use)	↓	↓	↓	↓	↑	
Salicylates (large doses)	↓	↑S	↓[a]	↓	0[a]	Compete with T_4 for TBG binding

Tamoxifen[g]	↑	↓	0	↑	0	Increased serum TBG

[a] Effect deduced, not based on reported clinical evidence.

[b] Data from Rae P, Farrar J, Beckett G, Toft A. Assessment of thyroid status in elderly people. Br Med J 1993;307:177-180.

[c] Patients requiring thyroid-replacement therapy have decreased serum thyroxine when barbiturates are given.

[d] Data from Singh N, Singh P, Hershman JM. Effect of calcium carbonate on the adsorption of levothyroxine. JAMA 2000;283:2822-2825.

[e] Data from Cooper JG, HarboeK, Frost SK, Skadberg O. Ciprofloxacin interacts with thyroid replacement therapy. Br Med J 2005;330:1002.

[f] May increase slightly but usually remains in the normal range.

[g] Data from Siraj ES, Gupta MK, Reddy SK. Raloxifene causing malabsorption of levothyroxine. Arch Intern Med 2003;163:1367-1370.

[h] T_4 assay by competitive protein binding is spuriously increased, but T_4 radioimmunoassay is probably not affected. Free thyroxine measured by dialysis may be increased.

[i] May occasionally decrease serum T_4 and increase resin T_3 uptake.

[j] Slight decrease in euthyroid patients; but in long-standing hypothyroid patients, levodopa considerably decreases the elevated TSH.

[k] In a patient on adequate doses for thyroid replacement.

[l] Increased T_4, FTI, and T_3 tend to return to normal after several months of therapy with levothyroxine. After liothyronine, T_3 may be elevated 2 hr after a dose and depressed 24 hr after a dose.

[m] Increased T_4 levels are reported in one study, but not in others.

[n] With short-term propranolol in hyperthyroid patients.

[o] In euthyroid patients, the decreased serum T_3 returns to normal with continued propranolol therapy.

[p] Free thyroxine index may increase slightly but usually remains in the normal range.

[q] Data from Batcher EL, Tang XT, Singh BN, et al. Thyroid Function Abnormalities during Amiodarone Therapy for Persistent Atrial Fibrillation. Am J Med 2007;120:880-885. *FTI,* free thyroxine index; *IV,* intravenous; *n/d,* no data; *s,* slight effect; *SC,* subcutaneous; *SERMs,* selective estrogen receptor modulators; *T_3,* triiodothyronine; *T_4,* thyroxine; *TBG,* thyroxine-binding globulin; *TSH,* thyroid-stimulating hormone; *0,* no effect; ↑, increased; ↓, decreased.

d. If there is an abnormality in binding proteins, this test can yield the same misleading results as the TT_4 readings. Other factors affecting test results include pregnancy (which increases TT_3 levels), malnutrition or hepatic or renal disease (which lower TT_3 levels), or various drugs (Table 55-2).

3. Resin triiodothyronine uptake (RT_3U)

a. This test clarifies whether abnormal T_4 levels are the result of a thyroid disorder or to abnormalities in the binding proteins because it evaluates the binding capacity of TBG.

b. If an abnormal amount (high or low) of thyroid hormone is present in the blood, the RT_3U results **change in the same direction** as the altered level—elevated in hyperthyroidism, decreased in hypothyroidism.

c. However, if abnormalities in binding proteins underlie the abnormal levels of TT_4, TT_3, or both, the RT_3U results **change in the opposite direction**—decreasing as TBG increases, increasing as TBG decreases.

d. Several drugs can cause spurious changes in the RT_3U (Table 55-2).

4. Serum thyrotropin (TSH) assays

a. This test is the **most sensitive** test for detecting the hypothyroid state because the hypothalamic-pituitary axis compensates very quickly for even slight decreases in circulating free hormone by releasing more TSH. The TSH levels may be elevated even before low circulating levels of TT_4 are detectable by diagnostic testing.

b. The early TSH assay used radioimmunoassay (RIA) methodology. The sensitivity of the assay has improved since, moving to the use of monoclonal antibodies in the late 1980s. Nomenclature established by the American Thyroid Association (ATA) has classified the improvement in sensitivity based on the lower limit of detection. The new classification follows a generational format, as shown in Table 55-3.

c. The current (third-generation) serum TSH assay (level of detection 0.01-0.02 mIU/L) uses monoclonal antibodies referred to as immunoradiometric or immunometric (IMA) methodology (instead of the older radioimmunoassay

techniques) and demonstrates greater sensitivity in the detection of thyroid disease than older tests.

d. This assay is usually used to diagnose thyroid disease and monitor patients receiving replacement therapy to control overtreatment. (Overtreatment—TSH < 0.4 mIU/L—may contribute to excessive bone demineralization (reduced bone density), electrocardiogram [ECG] changes, atrial fibrillation, or elevation of liver function tests.)

e. The IMA technique is very sensitive. The fourth-generation IMA can detect TSH levels in the range of 0.001-0.002 mIU/L.

f. The third-generation IMA assays may also detect subclinical thyroid disease (TSH = 0.1-0.45 mIU/L). Treatment of subclinical hypothyroidism is controversial because there is insufficient evidence to indicate a benefit.

g. TSH levels may also be influenced by psychiatric illness. Some studies of hospitalized patients have reported abnormally high or low TSH levels in otherwise euthyroid patients. Current findings in HIV-positive patients are uncertain; however, autoimmune thyroid disease appears to be more prevalent in these patients.

h. Effects of drugs on the serum TSH are shown in Tables 55-2 and 55-4.

5. Free thyroxine index (FTI)

a. This is not a separate test but rather an estimation of the free T_4 level through a mathematical interpretation of the relationship between RT_3U and serum T_4 levels.

$$FTI = \frac{TT_4 \times RT_3U}{\text{mean serum } RT_3U}$$

Table 55-3. Serum Thyroid-Stimulating Hormone Assay Nomenclature

Generation	Lower Level of Detection
First (RIA method)	1-2 mIU/L
Second	0.1-0.2 mIU/L
Third	0.01-0.02 mIU/L
Fourth	0.001-0.002 mIU/L

Table 55-4. Medications Influencing Thyroid-Stimulating Hormone (TSH) Levels

Agent	Mechanisms	Potential Clinical Thyroid Effect(s)	Effect on TSH	Effect on Other Thyroid Function Tests	Comments
Amiodarone	Iodine effects (see Iodine below)	Clinical or subclinical hypothyroidism; subclinical hyperthyroidism infrequently	Hypothyroidism is usually detected during the first 3 months after starting therapy; continue to detect patients at 6 months. Overt hypothyroidism (TSH >10 μU/mL) has been observed at 6 months. Mild elevations (TSH 4.5-10μU/mL) have been observed at 12 months.	Increased total T_4 levels	The large iodine load with the administration of amiodarone is the primary contributor to the drug interaction. Regions where patients have adequate intake of iodine in their diet have been associated with higher rates of hypothyroidism. Biochemical changes in thyroid

			Subclinical hyperthyroidism (TSH <0.35µU/mL) has been observed occasionally		function noted in a majority of patients on therapy, requiring frequent monitoring
	Direct inhibition of T_4 to T_3 conversion			Increased free T_4 levels	
	Direct toxic effects on thyroid			Increased reverse T_3 levels	
	Induction of thyroid autoimmunity	Hyperthyroidism		Decreased total and free T_3	
Calcium carbonate	Adsorption of levothyroxine to calcium in acid environment	Subclinical hypothyroidism	Elevation	Decrease free T_4 and total T_4	

Ciprofloxacin	Decreases absorption of levothyroxine	Hypothyroidism	Elevation	Decreased thyroid hormone levels	Clinical hypothyroidism detected
Corticosteroids	Central suppression of TSH release	Minimal or none	Suppression	Usually within normal range, although total T_4, free T_4, T_3 reduced, and reverse T_3 increased from baseline	Compensatory mechanisms lead to normalization of TSH levels with chronic exposure
	Reduction of thyroid iodine uptake				
	Inhibition of T_4 to T_3 conversion				

	Reduction of thyroidbinding globulin levels				
Dopamine and dopamine agonists	Central suppression of TSH release	Minimal or none	Suppression	Normal or decreased hormone levels	Prolonged use of dopamine in high doses may potentiate the low thyroxine state of critical illness
Dopamine antagonists	Release of central TSH inhibition	Minimal or none	Elevation	Usually normal	Effects not well characterized
Iodine	Inhibition of iodine uptake and organification	Clinical or subclinical hypothyroidism	Elevation	Decreased thyroid hormone levels	Clinical hypothyroidism most common in those with underlying organification defects, such as autoimmune thyroiditis or previous

					radioiodine therapy; iodine-induced hyperthyroidism is generally confined to those with iodine deficiency or autoimmune thyroid disease
	Impairment of thyroid hormone				
	Inhibition of T_4 to T_3 conversion	Hyperthyroidism	Suppression	Elevated thyroid hormone levels	
	Induction of thyroid autoimmunity				
Interferon	Unclear; likely owing to	Hypothyroidism (silent	Elevation	Decreased thyro	No apparent direct

	immunomodulating properties and stimulation of autoimmunity	thyroiditis, Graves disease)		id hormone levels	influence on TSH secretion: pretreatment detectable antimicrosomal antibodies may represent a risk factor for interferon-induced thyroid disease
		Hyperthyroidism (with or without autoantibodies)	Suppression	Increased thyroid hormone levels	
Lithium salts	Inhibition of iodothyronine biosynthesis	Clinical or subclinical hypothyroidism	Elevation	Normal or decreased thyroid hormone levels	Some sources recommend thyroid function testing at 6-month intervals while on therapy

	Reduction of thyroid iodine concentration				
	Suppression of thyroid hormone release				
	Induction of thyroid autoimmunity				
Radiographic contrast media	Iodine effects (See Iodine above)	Minimal or none	Elevation	Normal or decreased thyroid hormone levels	Alterations are maximal 3-4 days after administration and may persist for up to 2 weeks
	Direct inhibition of T_4 to T_3 conversion			Elevation of reverse T_3 levels	
Raloxifene	Malabsorption; mechanism unknown	Hypothyroidism	Elevation	Decreased thyroid hormone	Clinical hypothyroidism detected

				level s	
Somato statin and analogs	Central suppressio n of TSH release	Minimal or none	Suppress ion	Usua lly norm al	Effects not well characte rized

T_3, triiodothyronine; T_4, thyroxine.

P.1208

b. FTI values are elevated in hyperthyroidism, when TBG is low, and decreased in hypothyroidism, when TBG is elevated.

c. Effects of drugs on FTI are shown in Table 55-2.

G. Strategies and cost considerations for testing

1. The **most frequently** used and **least expensive** tests for screening are the TT_4 and the RT_3U, which are used to calculate the FTI. A serum TSH assay may also be used, but at an additional cost (Figure 55-4).

2. Thyroid disease screening for the otherwise generally healthy population has been shown to **not be cost-effective** based on the rate of detection and cost associated with massive screening. However, with increased use and improvements in technology, costs have been falling (Figure 55-5).

3. The most appropriate **target population** for screening includes elderly patients hospitalized for exacerbations of chronic diseases or who are coincidentally diagnosed with a chronic

P.1209

disease—for example, congestive heart failure (CHF), rheumatoid arthritis—mental status changes, or psychosocial problems.

Figure 55-4. Algorithm for using a sensitive thyroid-stimulating hormone (TSH) assay as a single test of thyroid function. The algorithm assumes a clinically intact hypothalamic-pituitary axis, absence of medications known to influence TSH or other thyroid indices, and generally good physical and psychiatric health. The TSH assay should meet the American Thyroid Association criteria for a sensitive assay and/or have a known functional sensitivity limit at the second-generation (0.1 mIU/L) level or greater. *Close follow-up*, clinical observation for signs and symptoms of hyperthyroidism or hypothyroidism and repeated TSH determinations at intervals of 6 to 12 months. T_3, trirodothyronine; T_4, thyroxine.

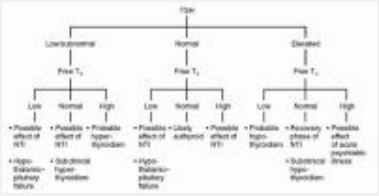

Figure 55-5. Algorithm for the use of sensitive thyroid-stimulating hormone (TSH) testing in patients with nonthyroidal illness (NTI). The TSH assay should meet the American Thyroid Association criteria for a sensitive assay and/or have a known functional sensitivity limit at the second-generation (0.1 mIU/L) level or greater. Medications known to alter TSH levels (i.e., corticosteroids, dopamine) must be considered when interpreting results.

4. The ATA recommends a free thyroxine (FT_4) and a sensitive TSH assay as the primary laboratory tests for diagnosing thyroid disease. The sensitive TSH assay is useful in detecting patients at risk of receiving an excess amount of thyroxine as replacement therapy.

II. HYPOTHYROIDISM.

The inability of the thyroid gland to supply sufficient thyroid hormone results in varying degrees of hypothyroidism from mild, clinically insignificant forms to the life-threatening extreme, myxedema coma.

A. Classification

1. Primary hypothyroidism is the result of

a. Gland destruction or dysfunction caused by disease or medical therapies (e.g., radiation, surgical procedures)

b. Failure of the gland to develop or congenital incompetence (i.e., **cretinism**)

2. Secondary hypothyroidism is the result of a pituitary disorder that inhibits TSH secretion. The thyroid gland is normal but lacks appropriate stimulation by TSH.

3. Tertiary hypothyroidism refers to a condition in which the pituitary-thyroid axis is intact, but the hypothalamus lacks the ability to secrete TRH to stimulate the pituitary.

4. Subclinical hypothyroidism refers to patients without clinical symptoms, a normal FT_4, and elevated TSH levels. Currently there is insufficient evidence to support treatment because consequences of nontreatment are minimal.

B. Causes

1. Hashimoto thyroiditis, which is a chronic lymphocytic thyroiditis that is considered to be an autoimmune disorder

2. Treatment of hyperthyroidism, such as radioactive iodine therapy, subtotal thyroidectomy, or administration of antithyroid agents

3. Surgical excision

4. Goiter (enlargement of the thyroid gland)

a. Endemic goiter results from inadequate intake of dietary iodine. This is common in regions with iodine-depleted soil and in areas of endemic malnutrition.

b. Sporadic goiter can follow ingestion of certain drugs or foods containing **progoitrin** (L-5-vinyl-2-thiooxazolidone), which is inactive and converted by hydrolysis to goitrin.

(1) Goitrins inhibit oxidation of iodine to iodide and prevent iodide from binding to thyroglobulin, thereby decreasing thyroid hormone production.

(2) Progoitrin has been isolated in cabbage, kale, peanuts, brussels sprouts, mustard, rutabaga, kohlrabi, spinach, cauliflower, and horseradish.

(3) Goitrogenic drugs include propylthiouracil (PTU), iodides, phenylbutazone, cobalt, and lithium.

c. Less common causes include acute (usually traumatic) and subacute thyroiditis, nodules, nodular goiter, and thyroid cancer.

C. Signs and symptoms

1. Early clinical features tend to be somewhat vague: lethargy, fatigue, forgetfulness, sensitivity to cold, unexplained weight gain, and constipation.

2. Progressively, the characteristic features of myxedema emerge: dry, flaky, inelastic skin; coarse hair; slowed speech and thought; hoarseness; puffy face, hands, and feet; eyelid droop; hearing loss; menorrhagia; decreased libido; and slow return of deep tendon reflexes (especially in the Achilles tendon). If untreated, myxedema coma will develop.

D. Laboratory findings (Table 55-1)

E. Treatment goal is replacement therapy using oral agents (Table 55-5).

Table 55-5. Thyroid Replacement Preparations

Preparation (Trade Names)	Advantage	Disadvantage	Comments	Source
Desiccated thyroid (Thyroid USP, Thyroid Strong, Armour Thyroid, Thyrar, S-P-T)	Low cost	Some preparations have unpredictable results; inconsistent T_3:T_4 ratio T_3 increases adverse effects	Contains T_3; some brands are standardized by iodine content[a]	Porcine, bovine, or ovine thyroid glands
Liothyronine (Cytomel)	Predictable results; useful for myxedema crisis	Lacks T_4	Usually reserved for myxedema crisis	Synthetic
Liotrix (Thyrolar)	Standardized formulation	T_3 increases adverse effects; expensive	Fixed T_3:T_4 ratio of 1:4; metabolism of T_4 to T_3 renders T_3 component unnecessary	Synthetic
Levothyroxine[b] (Levothroid, Synthroid, Levoxyl, Unithroid)	Predictable results, intravenous preparation available	Expensive	Agent of choice; does not contain T_3; all preparations may be interchangeable	Synthetic

[a] Iodine content and T_3:T_4 ratio vary with species.

[b] Generic formulations manufactured by Pharmaceuticals Basics for Geneva Generics and Rugby have been shown to be bioequivalent to Synthroid and Levoxyl. (Dong BJ, Hauck WW, Gambertoglio JG, et al. Bioequivalence of generic and brand-name levothyroxine products in the treatment of hypothyroidism. JAMA 1997;277:1205-1213.) *T_3*, triiodothyronine; *T_4*, thyroxine.

F. Therapeutic agents

1. Desiccated thyroid preparations

a. At one time the agent of choice, desiccated thyroid (Armour Thyroid) has fallen out of favor since standardized synthetic levothyroxine preparations have become available.

b. Desiccated thyroid preparations are not considered bioequivalent; they have evidenced varying amounts of active substances. Although they met established *United States Pharmacopeia* (USP) criteria for iodine content, variation in activity was noted. The content assay, while specific for iodine, was unable to specify the ratio of T_3 to T_4, and this ratio varies with the animal source. Porcine gland preparations have a higher T_3 to T_4 ratio than those from ovine and bovine sources.

2. Fixed-ratio liotrix (Thyrolar) preparations. In an effort to standardize the T_3 to T_4 ratio, substances that mimic glandular content were developed. However, the T_3 component proved unnecessary (because T_4 is metabolized to T_3) and even disadvantageous because of T_3-induced **adverse effects** (e.g., tremor, headache, palpitations, diarrhea).

3. Levothyroxine

a. Predictable results and lack of T_3-induced side effects have made levothyroxine (Levothroid, Synthroid, Levoxyl) the agent of choice.

b. The **three major brands** of levothyroxine preparations (Levothroid, Synthroid, Levoxyl) have been compared for bioequivalence and were shown to be equivalent in patients with hypothyroidism.

c. Recent studies in patients with hypothyroidism have compared brand and generic formulations of levothyroxine, which include Synthroid, Levoxyl, and generic formulations manufactured by Pharmaceutical Basics and sold by Geneva Generic and Rugby. Bioequivalence has been demonstrated with these formulations. However, when switching formulations, it is recommended to monitor the patient

closely because there may be some individual patient variability among formulations (Figure 55-6).

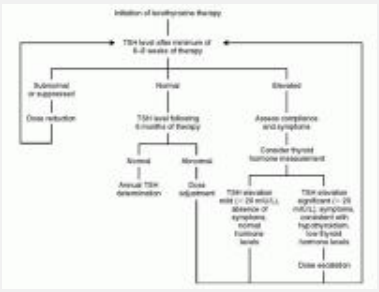

Figure 55-6. Algorithm for management of patients on levothyroxine therapy. *TSH*, tyroid-stimulating hormone.

P.1212

d. The **average adult maintenance** dose is 75-150 µg/day. The dose range has been shown to be 1.5-1.7 µg/kg/day or an average of 1.6 µg/kg/day for otherwise healthy adults.

e. Elderly or **chronically ill patients** require an average dose of 50-100 µg/day, which is 25-50 µg/day less than otherwise healthy adults of the same height and weight.

f. Thyroxine levels return to normal within a few weeks. Clinical improvement begins in 2 weeks with full resolution of signs and symptoms of hypothyroidism by 3-6 months of therapy.

g. TSH levels begin to decrease after starting thyroid replacement. TSH remains elevated for some time after T_4 levels return to normal. Generally, TSH levels return to normal after a minimum of 6-8 weeks, but may continue to fall over 6-12 months (Figure 55-6).

G. Precautions and monitoring effects

1. Adult patients with a history of cardiac disease and elderly patients should begin therapy with lower doses (e.g., 25 µg/day of levothyroxine). After 2-4 weeks, the dose should be increased gradually to an individually adjusted maintenance dose (usually < 100 µg daily).

2. Patients should be observed on initiation of therapy for possible **cardiac complications,** such as angina, palpitations, or arrhythmias.

3. Serum thyroid levels should be monitored, particularly T_4, sensitive TSH and RT_3U levels, and the FTI. Serum thyroxine tests remain elevated during the first few months of treatment even with the presence of clinical symptoms. Serum thyroxine tests do not predict the clinical state. Testing is unnecessary unless noncompliance is suspected.

4. It is recommended to monitor the sensitive TSH test 2-6 months after the last dose change. However, this test continues to change for up to 1 year. Testing early may result in overtreatment. Refer to Figure 55-6 for the management of patients on levothyroxine therapy.

5. Levothyroxine administration, particularly long-term therapy, can induce thyrotoxicosis; T_4 levels can rise even though the dosage remains unchanged. Monitor for clinical signs of thyroid disease.

6. Accelerated bone loss has been associated with overtreatment. Patients receiving replacement therapy with low TSH values may have lower bone mineral density because excess hormone accelerates the rate of remodeling (rate of reporption > rate of formation) and may contribute to an increased incidence of nontraumatic fracture.

7. Drug interactions

a. Cholestyramine (Questran) and colestipol (Colestid), bile acid sequestrants, can contribute to a decrease in **thyroxine** bioavailability when administered concomitantly. Bile acid sequestrants should be administered at least 6 hr after oral thyroxine to reduce the potential for this clinically significant drug interaction.

b. Calcium carbonate (Os-Cal, Tums) can reduce thyroxine bioavailability by adsorption in an acid environment. These should be administered separately to avoid interaction.

c. Estrogens (Estrace, Premarin) and selective estrogen receptor modulators (SERMs) tamoxifen (Nolvadex) or raloxifene (Evista) may contribute to lower levels of FT_4 and elevated TSH levels, requiring an increase in levothyroxine dose.

d. Raloxifene has been shown to cause malabsorption of levothyroxine when co-administered resulting in hypothyroidism. Absorption studies demonstrated that separating administration times by ~ 12 hr for the two medications prevents the interaction.

e. Ciprofloxacin (Cipro) has been reported to interact with levothyroxine when given together, resulting in elevated TSH and reduced FT_4 and FT_3 levels. Administration of the drugs separately, with a 6-hr interval, resulted in rapid normalization of the thyroid function tests.

H. Myxedema coma is a life-threatening complication with a high mortality rate.

1. It is **most common** in elderly patients with preexisting, although usually undiagnosed, hypothyroidism.

2. Precipitating factors include alcohol, sedative, or narcotic use; overuse of antithyroid agents; abrupt discontinuation of thyroid hormone therapy; infection; exposure to cold temperatures; and iatrogenic insult owing to radiation therapy or thyroid surgery.

3. The patient usually declines from profound lethargy to coma, hypothermia, and a significant decrease in respiratory rate, potentially leading to respiratory failure as the crisis progresses. Hypometabolism produces a fluid and electrolyte imbalance

that leads to fluid retention and hyponatremia. **Cardiac effects** include decreased heart rate and contractility, decreasing cardiac output.

4. Treatment consists of rapid restoration of T_3 and T_4 levels to normal.

a. A loading dose of levothyroxine 400-500 µg is given as an intravenous (IV) bolus. Liothyronine (Cytomel), 25 µg, is then given orally every 6 hr.

b. Treatment is continued until improvement is noted. Then liothyronine is discontinued, and levothyroxine is changed to the oral preparation. A maintenance dose is then determined (see II.F.3).

III. HYPERTHYROIDISM

is the overabundance of thyroid hormone. **Thyrotoxicosis** is the general term applied to overactivity of the thyroid gland.

A. Graves disease (diffuse toxic goiter)

1. The **most common form** of hyperthyroidism, Graves disease occurs primarily, but not exclusively, in **young women.**

2. The basis of this disease is an **autoimmune disorder** in which antibodies bind to and activate TSH receptors, resulting in the overproduction of thyroid hormone.

a. These antibodies are termed **long-acting thyroid stimulators (LATS)** because their duration of action extends beyond that of TSH. As TSH is only mimicked, not overabundant, neither testing for TSH nor attempts to influence it are productive.

b. Antibody titers often are elevated in patients with Graves disease.

3. Signs and symptoms characteristic of Graves disease include

a. Diffusely enlarged nontender goiter

b. Nervousness, irritability, anxiety, and insomnia

c. Heat intolerance and profuse sweating

d. Weight loss despite increased appetite

e. Tremor and muscle weakness

f. Palpitations and tachycardia

g. Exophthalmos, stare, and lid lag (slow upper lid closing)

h. Diarrhea

i. Thrill or bruit over the thyroid

j. Periorbital edema

B. Plummer disease (toxic nodular goiter)

1. This **form of thyrotoxicosis** is less common than Graves disease. Its underlying cause remains unknown, but its incidence is highest in patients > 50 years of age, and it arises usually from a long-standing nontoxic goiter.

2. The thyrotoxicosis is a result of one or more adenomatous nodules autonomously secreting excessive thyroid hormone, which suppresses the rest of the gland. Scanning confirms the diagnosis if it indicates that activity and iodine uptake are confined to the nodular mass, unless TSH is introduced.

3. Signs and symptoms are essentially the same as for Graves disease except that one or more nodular masses are found, rather than diffuse glandular enlargement, and ophthalmopathy is usually absent. **Cardiac abnormalities** (e.g., CHF, tachyarrhythmias) are commonly seen with Plummer disease.

C. Less common forms of hyperthyroidism

1. Jodbasedow phenomenon is an overproduction of thyroid hormone following a sudden, large increase in iodine ingestion—through either a sudden reversal of an iodine-deficient diet or the introduction of iodide or iodine in contrast agents or drugs (e.g., the antiarrhythmic agent amiodarone).
P.1214

2. Factitious hyperthyroidism occurs with abusive ingestion of thyroid-replacement agents, usually in a misguided effort to lose weight. Diagnosis is aided by the absence of glandular swelling and of exophthalmos and the lack of autoimmune activity found in Graves disease.
3. Subclinical hyperthyroidism refers to patients without clinical symptoms, a normal FT_4 and FT_3 and TSH levels below the lower limits of normal (<0.4 mIU/L). Currently there is insufficient evidence to support treatment because consequences of nontreatment are minimal.
D. Laboratory findings (Table 55-1)
E. Treatment goal. Symptomatic relief is provided until definitive treatment can be effected.
F. Therapeutic agents
1. β-Adrenergic blocking agents—propranolol
a. Propranolol (Inderal) reduces some of the peripheral manifestations (e.g., tachycardia, sweating, severe tremor, nervousness) of hyperthyroidism.
b. In addition to providing symptomatic relief, propranolol inhibits the peripheral conversion of T_4 to T_3.
2. Antithyroid agents—propylthiouracil (PTU) and methimazole (Tapazole)
a. Action. These agents may help attain remission through direct interference with thyroid hormone synthesis. Both agents inhibit iodide oxidation and iodothiouracil coupling. In addition, PTU (but not methimazole) diminishes peripheral deiodination of T_4 to T_3.
b. Therapeutic uses of these drugs include
(1) Definitive treatment in which remission is achieved
(2) Adjunctive therapy with radioactive iodine until the radiation takes effect
(3) Preoperative preparation to establish and maintain a euthyroid state until definitive surgery can be performed
c. Dosages
(1) Propylthiouracil
(a) For **adults,** the initial dose is 300-450 µg/day in three divided doses (i.e., 100-150 µg every 8 hr). Adult patients with severe disease may require as much as 600-1200 µg/day initially.
(b) The initial dose is continued for about 2 months; then a maintenance dose of 100-150 µg/day is given, as a single dose or divided into two doses.
(c) Maintenance therapy is continued for approximately 1 year, then gradually discontinued over 1-2 months while the patient is monitored for signs of recurrent hyperthyroidism. The patient may remain in remission for several years. A recurrent

episode of hyperthyroidism is most likely to occur within 3-6 months of drug discontinuation.

(d) If hyperthyroidism recurs after drug therapy is stopped, the agent should be restarted and alternative therapy should be considered (e.g., thyroid gland ablation or removal).

(2) Methimazole

(a) The initial dose range is 5-60 µg/day in three divided doses, depending on disease severity. After 2 months of therapy, a maintenance dose of 5-30 µg/day is initiated.

(b) Maintenance therapy is continued for approximately 1 year at which time the drug is gradually discontinued, usually over 1-2 months.

d. Precautions and monitoring effects

(1) Serum thyroid levels and the FTI should be monitored for a return to normal.

(2) Goiter size should decrease with reduced hormone output.

(3) The incidence of **adverse effects** is < 1% with PTU and < 3% with methimazole. The adverse effects are similar for the two agents.

(a) The most bothersome are **dermatologic reactions** (e.g., rash, urticaria, pruritus, hair loss, skin pigmentation). Others include headache, drowsiness, paresthesia, nausea, vomiting, vertigo, neuritis, loss of taste, arthralgia, and myalgia.

(b) Severe adverse effects—agranulocytosis, granulocytopenia, thrombocytopenia, drug fever, hepatitis, and hypoprothrombinemia—occur less frequently. Patients receiving methimazole who are > 40 years old and are receiving doses above 40 µg/day are at increased risk of developing agranulocytosis. Patients receiving

PTU who are > 40 years old are at increased risk of developing agranulocytosis, but no dose association has been established.

3. Radioactive iodine (RAI)

a. Action. The thyroid gland picks up the radioactive element iodine-131 (^{131}I) as it would regular iodine. The radioactivity subsequently destroys some of the cells that would otherwise concentrate iodine and produce T_4, thus decreasing thyroid hormone production.

b. Advantages

(1) High cure rate—almost 100% for patients with Graves disease and only slightly less for patients with Plummer disease

(2) Avoids surgical risks—such as adverse reaction to anesthetics, hypoparathyroidism, nerve palsy, bleeding, and hoarseness

(3) Less expensive—avoids cost of hospitalization

c. Disadvantages

(1) Risk of delayed hypothyroidism

(2) Slight, though undocumented, risk of genetic damage

(3) Multiple doses, which may be required, may delay therapeutic efficacy for a long period (many months or a year).

d. Dosage. A dose of 80-100 mCi of ^{131}I per estimated gram of thyroid gland is recommended. Some protocols use lower dosages, but these may be less effective, requiring retreatment. When the dose is higher, there is a potential risk that hypothyroidism will develop.

e. Precautions and monitoring effects

(1) Radioiodine therapy generally is reserved for patients past the childbearing years because effects on future offspring are not known.

(2) Response to ^{131}I is hard to gauge, and patients must be monitored early for recurrence of hyperthyroidism, and later for hypothyroidism, which may develop even 20 years or more after therapy.

4. Subtotal thyroidectomy. Partial removal of the thyroid gland may be indicated if drug therapy fails or radioactive iodine is undesirable. This is a difficult procedure, but the success rate is high and the cure rapid. Risks include those mentioned in III.F.3.b.(2), precipitating thyroid storm, and permanent postoperative hypothyroidism. The risk of inducing thyroid storm can be minimized by obtaining a euthyroid state through use of antithyroid agents (see III.F.2) or propranolol (see III.F.1).

G. Complications

1. Hypothyroidism may occur iatrogenically or, it has been proposed, as a natural sequel to Graves disease.

2. Thyroid storm (thyrotoxic crisis) is a sudden exacerbation of hyperthyroidism caused by rapid release (leakage) of thyroid hormone. It is invariably fatal if not treated rapidly. In this crisis, unchecked hypermetabolism leads ultimately to dehydration, shock, and death.

a. Precipitating factors include thyroid trauma or surgery, RAI therapy, infection, and sudden discontinuation of antithyroid therapy.

b. Characteristics. It is characterized by a TT_4 level of 25-30 µg/dl, rapidly rising fever, tachycardia disproportionate to the fever, and unexplained, pronounced restlessness and tremor.

c. Treatment

(1) PTU, in doses of 150-250 µg orally every 6 hr, is the preferred agent because PTU blocks peripheral deiodination of T_4 to T_3, whereas methimazole does not. However, if necessary, **methimazole,** 15 mg orally every 6 hr, can be used instead.

(2) Propranolol, in doses of 20-200 mg orally every 6 hr or 1-3 mg intravenously every 4-6 hr, should be administered unless contraindicated (e.g., if the patient has CHF).

(3) Potassium iodide, in doses of 50-100 mg every 12 hr, is given (after PTU) to minimize intrathyroidal iodine uptake.

(4) Other supportive therapy includes rehydration, cooling, antibiotics, rest, and sedation.

STUDY QUESTIONS

Directions for questions 1-16: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. What is the correct formula to use for calculating the free thyroxine index (FTI)?

(A) $T_4 \times RT_3U$/mean serum RT_3U

(B) $T_3 \times T_3$/mean serum RT_3U

(C) $T_3 \times RT_3U$/mean serum RT_3U

(D) $T_4 \times RT_3U \times$ mean serum RT_3U

(E) $T_3 \times RT_3U \times$ mean serum RT_3U

View Answer***1. The answer is A[see I.F.15].*****2. What is the necessary precursor besides dietary iodine required for thyroxine biosynthesis?**

(A) triiodothyronine (T_3)

(B) threonine

(C) tyrosine

(D) thyrotropin (thyroid-stimulating hormone)

(E) thyroxine-binding globulin (TBG)

View Answer***2. The answer is C[see].*****3. All of the following conditions are causes of hyperthyroidism *except***

(A) Graves disease.

(B) Hashimoto thyroiditis.

(C) toxic multinodular goiter.

(D) triiodothyronine toxicosis.

(E) Plummer disease.

View Answer***3. The answer is B[seeand*****4. Which of the following preparations is used to attain remission of thyrotoxicosis?**

(A) propranolol

(B) liotrix

(C) levothyroxine

(D) propylthiouracil

(E) desiccated thyroid

View Answer***4. The answer is D[seeand].*****5. The thyroid gland normally secretes which of the following substances into the serum?**

(A) thyrotropin-releasing hormone (TRH)

(B) thyrotropin (thyroid-stimulating hormone)

(C) diiodothyronine (DIT)

(D) thyroglobulin

(E) thyroxine (T_4)

View Answer***5. The answer is E[see].*****6. All of the following conditions are causes of hypothyroidism *except***

(A) endemic goiter.

(B) surgical excision.

(C) Hashimoto thyroiditis.

(D) goitrin-induced iodine deficiency.

(E) Graves disease.

View Answer***6. The answer is E[see].*****7. Common tests to monitor patients receiving replacement therapy for hypothyroidism include all of the following *except***

(A) thyrotropin (TSH) stimulation test.

(B) serum TSH assay.

(C) free thyroxine index (FTI).

(D) resin triiodothyronine uptake (RT_3U).

(E) total thyroxine (TT_4).

View Answer***7. The answer is A[see].*****8. Which of the following pairs of preparations has been studied for bioequivalence?**

(A) Levoxyl—Thyrolar

(B) thyroglobulin

(C) Levothroid—Synthroid

(D) Cytomel—Synthroid

(E) desiccated thyroid—Armour Thyroid

View Answer***8. The answer is C[seeand].*****9. The inhibition of pituitary thyrotropin secretion is controlled by which of the following?**

(A) free thyroxine (T_4)

(B) thyroid-releasing hormone (TRH)

(C) free thyroxine index (FTI)

(D) reverse triiodothyronine (rT_3)

(E) total thyroxine (TT_4)

View Answer***9. The answer is A[see].*****10. Which of the following agents has been shown to interact with oral thyroxine (T_4) replacement therapy?**

(A) propylthiouracil

(B) cholestyramine

(C) thyrotropin

(D) levothyroxine

(E) lovastatin

View Answer***10. The answer is B[see].***P.1217

11. What laboratory tests are currently recommended by the American Thyroid Association to diagnose thyroid disease?

(A) resin triiodothyronine uptake (RT_3U) and total thyroxine (TT_4)

(B) thyrotropin (TSH) and free thyroxine index (FTI)

(C) total thyroxine (TT_4) and sensitive TSH assay

(D) free T_4 and sensitive TSH assay

(E) free T_4 and RT_3U

View Answer***11. The answer is D[see].*****12. What patient population should be screened for thyroid disease?**

(A) hospitalized patients

(B) elderly patients with chronic disease

(C) elderly hospitalized patients

(D) college students

(E) women > 20 years old

View Answer***12. The answer is B[see].*****13. What is the average replacement dose of levothyroxine for an otherwise healthy adult?**

(A) 25-50 µg/day

(B) 50-100 µg/day

(C) 75-150 µg/day

(D) 100-200 µg/day

(E) 200-400 µg/day

View Answer***13. The answer is C[see].*****14. What factors affect the optimal replacement dose of levothyroxine?**

(A) age, height, and weight

(B) duration of hypothyroidism

(C) pretreatment thyroid-stimulating hormone (TSH) level

(D) presence of chronic illness

(E) All of the above

View Answer***14. The answer is E[see].*****15. Which of the values represents the lower level of detection for the fourth-generation sensitive TSH assay as established by the American Thyroid Association?**

(A) 0.5-5 mIU/L

(B) 1-2 mIU/L

(C) 0.01-0.02 mIU/L

(D) 0.001-0.002 mIU/L

(E) 0.0001-0.0002 mIU/L

View Answer***15. The answer is D[seeand].*****16. In which of the following clinical presentations should the TSH assay be used?**

(A) population screening for thyroid disease

(B) screening hospitalized patients

(C) patients receiving thyroid replacement after 6-8 weeks of therapy

(D) patients who are HIV positive

(E) screening patients with psychiatric illness

View Answer***16. The answer is C[see].*****Directions for question 17:** The question in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

17. A 62-year-old woman with a 5-year history of well managed hypothyroidism was recently started on raloxifene 60 mg daily in the morning for the prevention of postmenopausal osteoporosis. Her thyroid disease had been well controlled on 150 µg levothyroxine (Synthroid) daily in the morning. Her TSH has remained within the normal range while on treatment. Her most recent TSH of 2.5 mIU/L and normal FT_4 values where noted last year. She presents today with an elevated TSH 15.5 mIU/L after 4 months of raloxifene therapy and symptoms of hypothyroidism. What change in therapy would be best for this patient?

(I) repeat the TSH test and FT_4 Tests

(II) increase the dose of levothyroxine to 200 µg daily

(III) switch the dosing of the raloxifene to the evening

A if **I only** is correct
B if **III only** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

View Answer***17. The answer is B(III) [seeand].***P.1218

Directions for question 18: The question in this section can be correctly answered by **one** of the suggested answers. Choose the **best** answer.

18. A 69-year-old woman with hypertension and hypothyroidism is being treated for a wound infection. In the past, she was maintained on 125 µg **levothyroxine (Levoxyl) daily with a normal TSH of 2.0 mIU/L. After 6 weeks of treatment with oral ciprofloxacin (500 mg twice a day) she complains of fatigue and sensitivity to cold. Her serum TSH level was 14 mIU/L and FT_4 was below normal. What is the best management for this patient.**

(A) increase the dose of levothyroxine
(B) switch the patient from Levoxyl to Synthroid
(C) discontinue levothyroxine until the wound is healed
(D) continue therapy without any changes
(E) separate the administration of ciprofloxacin and levothyroxine by at least 6 hr

View Answer***18. The answer is E[seeand*****Directions for question 19:** The questions in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

19. Which of the following agents have been shown to interact with oral thyroxine (T_4) replacement therapy?

(I) atenolol
(II) calcium carbonate
(III) ciprofloxacin
(IV) levothyroxine
(V) raloxifene

A if **I only** is correct
B if **IV only** is correct
C if **I and IV** are correct
D if **I, II, III, and IV** are correct
E if **II, III, and V** are correct

View Answer***19. The answer is E(I, III, V) [seeand].*****20. What is the effect of amiodarone therapy on thyroid function?**

(A) Patients with underlying thyroid dysfunction are at an increase risk of developing hypothyroidism within 6 months of therapy
(B) Patients without underlying thyroid dysfunction routinely develop subclinical hyperthyroidism with amiodarone therapy
(C) Amiodarone interacts directly with circulating serum thyrotropin
(D) Amiodarone has no effect on thyroid function.
(E) None of the above

View Answer***20. The answer is A[and].***P.1219

ANSWERS AND EXPLANATIONS

1. The answer is A *[see I.F.15].*

The FTI is a mathematical interpretation of the relationship between the rRT_3U and T_4 levels, compared to the mean population value for RT_3U. The FTI is calculated using reported values for TT_4 and RT_3U. The normal FTI value in euthyroid patients is 5.5-12.

2. The answer is C *[see* I.B*].*

Biosynthesis of thyroid hormones begins with iodide binding to tyrosine, which forms MIT. MIT binds another iodide atom to form DIT. When MIT and DIT are formed, a coupling reaction occurs, which produces T_3, T_4, reverse triiodothyronine (rT_3), and other by-products.

3. The answer is B *[see* II.B.1; III.A *and* B]

Hashimoto thyroiditis (chronic lymphocytic thyroiditis) is a cause of hypothyroidism. The incidence of Hashimoto thyroiditis is 1%-2%, and it increases with age. It is more common in women than in men and more common in whites than in blacks. There may be a familial tendency. Patients with Hashimoto thyroiditis have elevated titers of antibodies to thyroglobulin: A titer < 1:32 is seen in > 85% of patients. Two variants of Hashimoto thyroiditis have been described: gland fibrosis and idiopathic thyroid atrophy, which is most likely an extension of Hashimoto thyroiditis.

4. The answer is D *[see* III.F.1 *and 2].*

In hyperthyroid patients, remission of thyrotoxicosis is achieved with PTU by two mechanisms: (1) interference of iodination of the tyrosyl residues, ultimately reducing production of T_4 and (2) inhibition of peripheral conversion of T_4 to T_3. Propranolol is commonly used as an adjunct to PTU for symptomatic management of hyperthyroidism.

5. The answer is E *[see* I.A.1*].*

The major compounds secreted by the thyroid gland, after its stimulation by thyrotropin, are T_3 and T_4. When released from the thyroid, T_3 and T_4 are transported by plasma proteins—namely TBG, thyroxine-binding prealbumin, and albumin.

6. The answer is E *[see* II.B; III.A.1*].*

Graves disease (diffuse toxic goiter) is the most common form of hyperthyroidism. It occurs most often in women in the 3rd and 4th decades of life. There is a genetic and familial predisposition. The cause is linked to an autoimmune reaction between immunoglobulin G (IgG) and the thyroid.

7. The answer is A *[see* II.G.3*].*

The TSH stimulation test measures thyroid tissue response to exogenous TSH. It is not commonly used to monitor thyroid-replacement therapy. It may be useful in the initial diagnosis of hypothyroidism.

8. The answer is C *[see* II.F.3.b *and* c*].*

Many brands of levothyroxine are currently available. Both generic and trade name preparations have been studied, with an emphasis on Levothroid and Synthroid. The importance of bioequivalence becomes apparent when patients have received different brands of levothyroxine and have exhibited changes in therapeutic response to equivalent replacement doses.

9. The answer is A *[see* I.A.3.a*].*

An increase in the blood level of thyroid hormone (see circulating free T_4 and free T_3) signals the pituitary to stop releasing TSH. The free fraction of T_4 is available to bind at the pituitary receptors.

10. The answer is B *[see* II.G.7*].*

Euthyroid patients receiving oral replacement therapy have become hypothyroid after concomitant administration of bile acid sequestrant therapy. It appears that bioavailability is reduced as a result of administering these agents at close dosing intervals. It is recommended that at least 6 hr pass before administration of a bile acid sequestrant. It would be preferable to select another nonbile acid sequestrant when clinically possible.

11. The answer is D *[see* I.G.4*].*

The free T_4 and the (third-generation) TSH assay should be used only for the diagnosis of patients most likely to have thyroid disease based on clinical presentation and relative risk (e.g., age, sex, family history), not for population screening. The third-generation TSH assay is also more commonly used to monitor replacement therapy and to minimize overtreatment and the corresponding risk of accelerated bone loss.

12. The answer is B *[see* I.G.3*].*

Cost versus benefit is critical to the decision of choosing to screen entire populations. Because the frequency of detection has been proven to be higher in elderly patients (2%-5%) with chronic disease, the relative minor costs associated to obtain RT_3U and TT_4 to calculate a FTI are worth the cost. A serum TSH assay can be reserved for patients with an abnormal FTI. Another consideration is to use the sensitive TSH assay for diagnosis in place of the serum TSH assay at a higher cost but without the necessity of retesting. If patients admitted to the hospital for an acute illness were screened and the results were misleading, they may be prescribed inappropriate therapy because acute illness may be associated with the temporary effects causing abnormal test results.

13. The answer is C *[see* II.F.3.d*].*

The average adult maintenance dose is 75-150 µg/day, which has been shown to be 1.5-1.7 µg/kg/day. The dose is usually adjusted in increments of 25-50 µg/day every 4 weeks. The total daily dose used to be 100-200 µg/day, which resulted in overtreatment after the introduction of the sensitive TSH assay. Elderly or chronically ill patients require an average dose of 50-100 µg/day, which is 25-50 µg/day less than otherwise healthy adults of the same height and weight.

14. The answer is E *[see* II.F.3.e*].*

Elderly or chronically ill patients require an average dose of 50-100 µg/day, which is 25-50 µg/day less than otherwise healthy adults of the same height and weight. Because the average dose for replacement therapy is between 1.5 and 1.7 µg/kg/day, weight affects the total daily dose.

15. The answer is D *[see* I.F.4.e *and* f*].*

The American Thyroid Association has established standard nomenclature that indicates each technological improvement and the ability to detect lower levels of TSH using monoclonal antibodies. As the sensitivity of the assay improves, the lower level of detection is reported as a range in milli-International Units per liter. The most sensitive test is currently the fourth-generation IMA, with a reported lower level of detection of 0.001-0.002 mIU/L. In usual clinical practice the third-generation IMA is most commonly used, with sensitivity in the range of 0.01-0.02 mIU/L.

16. The answer is C *[see* I.F.4.g; II.6; Figure 55-6*].*

The current third-generation TSH assay is not indicated for use in hospitalized patients who are not suspected to have thyroid disease. Studies have indicated that abnormally high or low TSH levels are detected in euthyroid hospitalized patients. Psychiatric illness may also influence TSH levels.

17. The answer is B *(III) [see* II.G.7; Tables 55-2 *and* 55-4*].*

The patient is most likely experiencing a drug interaction between raloxifene and levothyroxine. The best choice is to separate the medications by at least 12 hr. A repeat of the TSH assay will only confirm the results, which are significantly elevated. Increasing the dose of levothyroxine may result in overtreatment.

18. The answer is E *[see* II.G.7; Tables 55-2 *and* 55-4]

This patient is most likely experiencing a drug interaction between levothyroxine and ciprofloxacin when taken concomitantly. There is no benefit to switching to another brand of levothyroxine or increasing the dose. The best solution is to separate the doses of ciprofloxacin by 6 hr.

19. The answer is E *(I, III, V) [see* II.G.7; Tables 55-2 *and* 55-4*].*

Patients receiving oral replacement therapy who take calcium carbonate concomitantly have been shown to experience decreased free T_4 and total T_4 levels that resulted in an elevated TSH. The mechanism appears to be adsorption of levothyroxine to calcium carbonate at acid pH levels, which may reduce bioavailability. It is recommended to separate the time of ingestion of each product to reduce the chance of this interaction. Ciprofloxacin and Raloxifene have also been shown to interact with levothyroxine when administered together. Separate administration times by 6 hr for ciprofloxacin and by 12 hr for raloxifene.

20. The answer is A *[*Tables 55-2 *and* 55-4*].*

Patients receiving amiodarone therapy are at risk of developing hypothyroidism especially if there is underlying thyroid disease. Amiodarone delivers high levels of iodine to the system contributing to subclinical or clinical hypothyroidism more often. Subclinical hyperthyroidism has been observed rarely. Some patients without underlying thyroid disease may experience changes in thyroid function while patients with underlying disease are more likely to present with hypothyroidism.

Patients should be monitored closely for thyroid function when beginning amiodarone therapy.

56

Renal Failure

Andrew L. Wilson

I. ACUTE RENAL FAILURE

A. Definition. Acute renal failure (ARF) is the sudden, potentially reversible interruption of kidney function, resulting in retention of nitrogenous waste products in body fluids.

B. Classification and etiology. ARF is classified according to its cause.

1. Prerenal ARF stems from impaired renal perfusion, which may result from:

a. Reduced arterial blood volume [e.g., dehydration, hemorrhage, vomiting, diarrhea, other gastrointestinal (GI) fluid loss]

b. Urinary losses from excessive diuresis

c. Decreased cardiac output [e.g., from congestive heart failure (CHF) or pericardial tamponade]

d. Renal vascular obstruction (e.g., stenosis)

e. Severe hypotension

2. Intrarenal ARF (intrinsic or parenchymal ARF) reflects structural kidney damage resulting from any of the following conditions.

a. Acute tubular necrosis (ATN), the leading cause of ARF, may be associated with:

(1) Exposure to nephrotoxic aminoglycosides, anesthetics, pesticides, organic metals, and radiopaque contrast materials

(2) Ischemic injury (e.g., surgery, circulatory collapse, severe hypotension)

(3) Pigment (e.g., hemolysis, myoglobinuria)

b. Acute glomerulonephritis

c. Tubular obstruction, as from hemolytic reactions or uric acid crystals

d. Acute inflammation (e.g., acute tubulointerstitial nephritis, papillary necrosis)

e. Renal vasculitis

f. Malignant hypertension

g. Radiation nephritis

3. Postrenal ARF results from obstruction of urine flow anywhere along the urinary tract. Causes of postrenal ARF include:

a. Ureteral obstruction, as from calculi, uric acid crystals, or thrombi

b. Bladder obstruction, as from calculi, thrombi, tumors, or infection

c. Urethral obstruction, as from strictures, tumors, or prostatic hypertrophy

d. Extrinsic obstruction, as from hematoma, inflammatory bowel disease, or accidental surgical ligation

C. Pathophysiology. ARF progresses in three phases.

1. Initiating phase

a. The initiating phase is defined as the time between the renal insult and the point at which extrarenal factors no longer reverse the damage caused by the obstruction or other cause of ARF. This phase may not be well-defined clinically and may escape notice or diagnosis.

b. Urine output may drop markedly to 400 mL/day or less **(oliguria).** In some patients, urine output falls below 100 mL/day **(anuria).** Oliguria may last only hours or as long as 4-6 weeks. However, it has been shown that 40%-50% of ARF patients are not oliguric or anuric.

c. Nitrogenous waste products accumulate in the blood.

(1) Azotemia reflects urea accumulation due to impaired glomerular filtration and concentrating capacity.

(2) Serum creatinine concentration, sulfate, phosphate, and organic acid levels climb rapidly.

d. The **serum sodium concentration** falls below normal from intracellular fluid shifting and dilution.

e. Hyperkalemia occurs due to the accumulation of organic acids (metabolic acidosis). If potassium intake is not restricted or body potassium is not removed, hyperkalemia results. Without treatment, hyperkalemia may lead to neuromuscular depression and paralysis, impaired cardiac conduction, arrhythmias, respiratory muscle paralysis, cardiac arrest, and ultimately death.

2. Maintenance phase

a. This phase begins when urine output rises above 500 mL/day—typically after several days of oliguria. A rise in urine output or a “diuretic response” may not be seen in non-oliguric patients. Increased urinary output does not signal recovery of renal function.

b. Urine output rises in increments of several milliliters to 300-500 mL/day. Urine output may double from day to day in the initial recovery period.

c. Azotemia and associated laboratory findings may persist until urine output reaches 1000-2000 mL/day.

d. The maintenance phase carries a risk of fluid and electrolyte abnormalities, GI bleeding, infection, and respiratory failure.

3. Recovery phase. During the recovery phase, renal function gradually returns to normal. Most recovered renal function appears in the first 2 weeks; however, recovery of renal function may continue for a year. Residual impairment may persist indefinitely.

D. Clinical evaluation

1. Physical findings. Initially, ARF causes azotemia and, in 50%-60% of cases, oliguria. Later, electrolyte abnormalities and other severe systemic effects occur.

a. Urine output typically is **low,** from 20-500 mL/day. Complete anuria is rare.

b. Signs and **symptoms of hyperkalemia,** resulting from metabolic acidosis and reduced potassium excretion by impaired kidneys, include:

(1) Neuromuscular depression (e.g., paresthesias, muscle weakness, paralysis)

(2) Diarrhea and abdominal distention

(3) Slow or irregular pulse

(4) Electrocardiographic changes with potential cardiac arrest

c. Uremia, caused by excessive nitrogenous waste retention, leads to nausea, vomiting, diarrhea, edema, confusion, fatigue, neuromuscular irritability, and coma.
d. Metabolic acidosis, a common complication of ARF, is evidenced by:
(1) Deterioration of mental status, obtundation, coma, and lethargy
(2) Depressed cardiac contractility and decreased vascular resistance, leading to hypotension, pulmonary edema, and ventricular fibrillation
(3) Nausea and vomiting
(4) Respiratory abnormalities (e.g., hyperventilation, Kussmaul's respiration)
e. Hyperphosphatemia arises from decreased phosphate excretion. It is generally not seen in ARF.
(1) As serum phosphate rises, hypocalcemia results from the formation of insoluble calcium phosphate complexes.
(2) The signs and symptoms relate to resultant hypocalcemia and metastatic soft-tissue calcification.
(3) Manifestations of hypocalcemia include:
(a) Neuromuscular irritability, cramps, spasms, and tetany
(b) Hypotension
(c) Soft-tissue calcification
(d) Mental status changes (e.g., confusion, mood changes, loss of intellect and memory)
(e) Hyperactive deep-tendon reflexes and Trousseau's and Chvostek's signs
(f) Abdominal cramps
(g) Stridor and dyspnea
f. Hyponatremia results from dilution and intravascular fluid shifts during the diuretic phase of ARF. Physical findings include lethargy, weakness, seizures, cognitive impairment, and possible reduction in level of consciousness.
g. Intravascular volume depletion, suggesting **prerenal failure,** may cause:
(1) Flat jugular venous pulses when the patient lies supine
(2) Orthostatic changes in blood pressure and pulse
(3) Poor skin turgor and dry mucous membranes

h. Other findings suggesting **prerenal failure** include:
(1) An abdominal bruit, possibly indicating renal artery stenosis
(2) Increased paradoxus, suggesting pericardial tamponade
(3) Increased jugular venous pressure, pulmonary rales, and a third heart sound, signaling CHF
i. Postrenal failure caused by obstructed urinary flow may manifest itself in:
(1) A suprapubic or flank mass
(2) Bladder distention
(3) Costovertebral angle tenderness
(4) Prostate enlargement
2. Diagnostic test results

a. Urinalysis includes an examination of sediment; identification of proteins, glucose, ketones, blood, and nitrites; and measurement of urinary pH and urine-specific gravity (concentration) or osmolality (dilution). Prior administration of fluids, diuretics, and changes in urinary pH may confound accurate diagnosis, using urinalysis.

(1) Urinary sediment examination

(a) Few casts and formed elements are found in prerenal ARF.

(b) Pigmented cellular casts and renal tubular epithelial cells appear with ATN.

(c) Red blood cell and white blood cell casts generally reflect inflammatory disease.

(d) Large numbers of broad white cell casts suggest chronic renal failure.

(2) The presence of blood in the urine **(hematuria)** or proteins **(proteinuria)** indicates renal dysfunction.

(3) Urine-specific gravity ranges from 1.010-1.016 in ARF.

(4) Urine osmolality typically rises in prerenal ARF due to increased secretion of antidiuretic hormone.

b. Measurement of urine sodium and **creatinine levels** can help classify ARF.

(1) In **prerenal** ARF, the urine creatinine concentration **increases,** and urine sodium level **decreases.**

(2) In **intrarenal** ARF resulting from ATN, the urine creatinine concentration **decreases,** and the urine sodium level **increases.**

c. Creatinine clearance, an index of the **glomerular filtration rate (GFR),** allows estimation of the number of functioning nephrons; decreased creatinine clearance indicates renal dysfunction. A timed urine collection should be used to calculate GFR in acute renal failure.

d. Blood chemistry provides an index of renal excretory function and body chemistry status. Findings typical of ARF include:

(1) Increased blood urea nitrogen (BUN)

(2) Increased serum creatinine concentration

(3) Possible increase in hemoglobin and hematocrit values due to dehydration

(4) Abnormal serum electrolyte values

(a) Serum potassium level above 5 mEq/L

(b) Serum phosphate level above 2.6 mEq/L (4.8 mg/dl)

(c) Serum calcium level below 4 mEq/L (8.5 mg/dl), reflecting hypocalcemia. (The serum calcium level must be correlated with the serum albumin level. Each rise or fall of 1 g/dl of serum albumin beyond its normal range is responsible for a corresponding increase or decrease in serum calcium of approximately 0.8 mg/dl. A below-normal serum albumin level may result in a deceptively low serum calcium level.)

(d) Serum sodium level below 135 mEq/L, reflecting hyponatremia

(5) Abnormal arterial blood gas values [pH below 7.35, bicarbonate concentration (HCO^-3) below 22], reflecting metabolic acidosis

e. Renal failure index (RFI) is the ratio of urine sodium concentration to the urine-to-serum creatinine ratio. The RFI helps determine the etiology of ARF. Typically, the RFI is less than 1 in prerenal ARF or acute glomerulonephritis (a cause of

intrarenal ARF). The RFI is greater than 2 in postrenal ARF and in other intrarenal causes of ARF.

f. Electrocardiography (ECG) may show evidence of hyperkalemia—that is, tall, peaked T waves; widening QRS complexes; prolonged PR interval, progressing to decreased amplitude and disappearing P waves; and, ultimately, ventricular fibrillation and cardiac arrest.

g. Radiographic findings

(1) Ultrasound may detect upper urinary tract obstruction.

(2) Kidney, ureter, or **bladder radiography** may reveal:

(a) Urinary tract calculi

(b) Enlarged kidneys, suggesting ATN

(c) Asymmetrical kidneys, suggesting unilateral renal artery disease, ureteral obstruction, or chronic pyelonephritis

(3) Radionuclide scan may reveal:

(a) Bilateral differences in renal perfusion, suggesting serious renal disease

(b) Bilateral differences in dye excretion, suggesting parenchymal disease or obstruction as the cause of ARF

(c) Diffuse, slow, dense radionuclide uptake, suggesting ATN

(d) Patchy or absent radionuclide uptake, possibly indicating severe, acute glomerulonephritis

(4) Computed tomography (CT) scan may provide better visualization of an obstruction.

h. Renal biopsy may be performed in selected patients when other test results are inconclusive.

E. Treatment objectives

1. Correct reversible causes of ARF, preventing or minimizing further renal damage or complications.

a. Discontinue nephrotoxic drugs; remove other nephrotoxins through dialysis or gastric lavage for poisonings.

b. Treat underlying infection.

c. Remove any urinary tract obstructions.

2. Correct and maintain proper fluid and electrolyte balance. Match fluid, electrolyte, and nitrogen intakes to urine output.

3. Treat body chemistry alterations, especially hyperkalemia and metabolic acidosis, when present. Treatment may include renal dialysis.

4. Improve urine output.

5. Treat systemic manifestations of ARF.

F. Therapy

1. Conservative management alone may suffice in uncomplicated ARF.

a. Fluid management

(1) Fluid intake should match fluid losses. **Sensible losses** (i.e., urine, stool, tube drainage) and **insensible losses** (i.e., skin, respiratory tract) of 500-1000 mL/day should be included in fluid balance calculations.
(2) Volume overload should be avoided to minimize the risk of hypertension and CHF.
(3) The patient should be weighed daily to determine fluid volume status.
b. Dietary measures
(1) Because catabolism accompanies renal failure, the patient should receive a **high-calorie, low-protein diet.** Such a diet helps to:
(a) Reduce renal workload by decreasing production of end products of protein catabolism that the kidneys cannot excrete
(b) Prevent ketoacidosis
(c) Alleviate manifestations of uremia (e.g., nausea, vomiting, confusion, fatigue)
(2) If edema or hypertension is present, sodium intake should be restricted.
(3) Potassium intake must be limited in most patients. Fruits, vegetables, and salt substitutes containing potassium should be limited or avoided.
2. Management of body chemistry alterations
a. Treatment of hyperkalemia
(1) Dialysis may be used to treat acute, life-threatening hyperkalemia (see II.F.7).
(2) Calcium chloride or calcium gluconate
(a) Mechanism of action and therapeutic effects. Calcium chloride or calcium gluconate replaces and maintains body calcium, counteracting the cardiac effects of acute hyperkalemia.

(b) Administration and dosage. When used to reverse hyperkalemia-induced cardiotoxicity, calcium chloride is given intravenously, as 5-10 mL of a 10% solution (1.4 mEq Ca^{2+}/mL) administered over 2 minutes. Doses of up to 20 mL of a 10% solution are safe when given slowly. Another 10-20 mL of a 10% solution placed in a larger fluid volume and administered slowly may follow the initial dose. Calcium gluconate is administered as 10 mL of a 10% solution (1 g) over 2-5 minutes. This may be repeated a second time.
(c) Precautions and monitoring effects
(i) Intravenous (IV) calcium is contraindicated in patients with ventricular fibrillation or renal calculi.
(ii) The infusion rate should not exceed 0.5 mL/min. Patients should remain recumbent for about 15 minutes after infusion.
(iii) The ECG should be monitored during calcium gluconate therapy.
(iv) Calcium gluconate should not be mixed with solutions containing sodium bicarbonate because this can lead to precipitation.
(v) Adverse effects include hypotension, tingling sensations, and renal calculus formation.
(d) Significant interactions. Calcium may cause increased digitalis toxicity when administered concurrently with digitalis preparations.

(3) Sodium bicarbonate may be given as an emergency measure for severe hyperkalemia or metabolic acidosis.

(a) Mechanism of action and therapeutic effect. IV sodium bicarbonate restores bicarbonate that the renal tubules cannot reabsorb from the glomerular filtrate and increases arterial pH. This results in a shift of potassium into cells and reduces serum potassium concentration.

(b) Onset of action is 15-30 minutes.

(c) Administration and dosage

(i) Sodium bicarbonate is administered intravenously.

(ii) The dosage is calculated as follows:

[50% of body weight (kg)] × [desired arterial bicarbonate (HCO^-3) - actual HCO^-3]

One ampule (50 mEq) may be given intravenously over 5 minutes.

(d) Precautions and monitoring effects

(i) To avoid sodium and fluid overload, sodium bicarbonate must be given cautiously. Half of the patient's bicarbonate deficit is replaced over the first 12 hours of therapy.

(ii) Sodium bicarbonate may precipitate calcium salts in IV solutions and should not be mixed in the same infusion fluid.

(iii) Arterial blood gas values and serum electrolyte levels should be monitored closely during sodium bicarbonate therapy.

(4) Regular insulin with dextrose

(a) Mechanism of action and therapeutic effect. The insulin causes an intracellular shift of potassium. The combination of insulin with dextrose deposits potassium with glycogen in the liver, reducing the serum potassium.

(b) Onset of action is 15-30 minutes.

(c) Administration and dosage. Regular insulin (10 units in 500 mL of 10% dextrose) is administered intravenously over 60 minutes.

(d) Precautions and monitoring effects

(i) The serum glucose level should be monitored during therapy.

(ii) The patient should be assessed for signs and symptoms of fluid overload.

(5) Sodium polystyrene sulfonate (SPS)

(a) Mechanism of action. SPS is a potassium-removing resin that exchanges sodium ions for potassium ions in the intestine (1 g of SPS exchanges 0.5-1 mEq/L of potassium). The SPS is distributed throughout the intestines and excreted in the feces.

(b) Therapeutic effect. Administered as an adjunctive treatment for hyperkalemia, SPS reduces potassium levels in the serum and other body fluids.

(c) Onset of action of orally administered SPS is 2 hours; effects are seen in 1 hour when SPS is administered as a retention enema.

(d) Administration and dosage

(i) SPS is usually administered orally, although it may be given through a nasogastric tube. The oral dose is 15-30 g in a suspension of 70% sorbitol, administered every 4-6 hours until the desired therapeutic effect is achieved.
(ii) When oral or nasogastric administration is not possible due to nausea, vomiting, or paralytic ileus, SPS may be given by retention enema. The rectal dose is 30-50 g in 100 mL of sorbitol as a warm emulsion, administered deep into the sigmoid colon every 6 hours. Administration may be done with a rubber tube that is taped in place or via a Foley catheter with a balloon inflated distal to the anal sphincter.
(e) Precautions and monitoring effects
(i) The patient's serum electrolyte levels should be monitored closely during SPS therapy. Sodium, chloride, bicarbonate, and pH should be monitored in addition to potassium.
(ii) SPS therapy usually continues until the serum potassium level drops to between 4 and 5 mEq/L.
(iii) The patient should be assessed regularly for signs of potassium depletion, including irritability, confusion, cardiac arrhythmias, ECG changes, and muscle weakness.
(iv) SPS exchanges sodium for potassium, so sodium overload may occur during therapy. Patients with hypertension or CHF should be closely monitored.
(v) For oral administration, SPS should be mixed only with water or sorbitol. Orange juice, which has a high potassium content, should not be used because it decreases the effectiveness of the SPS. For rectal administration, SPS should be mixed only with water and sorbitol, never with mineral oil.
(vi) Adverse effects of SPS include constipation, fecal impaction with rectal administration, nausea, vomiting, and diarrhea.
(vii) SPS should not be used as the sole agent in the treatment of severe hyperkalemia; other agents or therapies should be used in conjunction with this agent.
(f) Significant interactions. Magnesium hydroxide and other nonabsorbable cationdonating laxatives and antacids may decrease the effectiveness of potassium exchange by SPS and may cause systemic alkalosis.
b. Treatment of metabolic acidosis. Sodium bicarbonate may be given if the arterial pH is below 7.35 [see I.F.2.a.(3)].
c. Treatment of hyperphosphatemia
(1) IV calcium is first-line therapy for severe life-threatening hyperphosphatemia. Calcium reduces the serum phosphorus concentration by chelation.
(2) Oral calcium salts bind dietary phosphorus in the GI tract.
(3) Sevelamer is a non-ionic polymer that binds dietary phosphorus in the GI tract.
(4) Dialysis may be used to treat acute, life-threatening hyperphosphatemia accompanied by acute hypocalcemia (see II.F.7). It is also performed when volume overload is present.
(5) Aluminum hydroxide (an aluminum-containing antacid)
(a) Mechanism of action and therapeutic effect. Aluminum binds excess phosphate in the intestine, thereby reducing phosphate concentration.
(b) Onset of action is 6-12 hours.

(c) Administration and dosage. Aluminum hydroxide is administered orally as a tablet or suspension. For the treatment of hyperphosphatemia, 0.5-2 or 15-30 mL of suspension is administered three or four times daily with meals.

(d) Precautions and monitoring effects

(i) Aluminum hydroxide may cause constipation and anorexia.

(ii) Serum phosphate levels should be monitored because aluminum hydroxide can cause phosphate depletion.

(iii) Aluminum hydroxide can cause calcium resorption and bone demineralization.

d. Treatment of hypocalcemia. Immediate treatment is necessary if the patient has severe hypocalcemia, as evidenced by tetany.

(1) Calcium gluconate [see I.F.2.a.(2)]

(a) Mechanism of action and therapeutic effect. This drug replaces and maintains body calcium, raising the serum calcium level immediately.

(b) Administration and dosage. When used to reverse hypocalcemia, calcium gluconate is administered intravenously in a dosage of 1-2 g over a period of 10 minutes, followed by a slow infusion (over 6-8 hours) of an additional 1 g.

(c) Precautions, monitoring effects, and significant interactions [see I.F.2.a.(2).(c), (d)]

(2) Oral calcium salts. Calcium carbonate, chloride, gluconate, or lactate may be given by mouth when oral intake is permitted or if the patient has relatively mild hypocalcemia. The usual adult dosage is 4-6 g/day given in three or four divided doses.

e. Treatment of hyponatremia

(1) Moderate or asymptomatic hyponatremia may require only **fluid restriction.**

(2) Sodium chloride may be given for severe symptomatic hyponatremia (i.e., a serum sodium level below 120 mEq/L).

(a) Mechanism of action and therapeutic effect. Sodium chloride replaces and maintains sodium and chloride concentration, thereby increasing extracellular tonicity.

(b) Administration and dosage

(i) A 3% or 5% sodium chloride solution may be administered by slow IV infusion. The amount of solution needed is calculated from the following equation:
(Normal serum sodium level - actual serum sodium level) × total body water

(ii) Typically, 400 mL or less is administered.

(c) Precautions and monitoring effects

(i) Hypertonic sodium chloride must be administered very slowly to avoid circulatory overload, pulmonary edema, or central pontine demyelination.

(ii) Serum electrolyte levels must be monitored frequently during therapy.

(iii) Excessive infusion may cause hypernatremia and other serious electrolyte abnormalities and may worsen existing acidosis. Infusion rates should not exceed 0.5 mEq/kg/hr.

3. Management of systemic manifestations

a. Treatment of fluid overload and edema. As water and sodium accumulate in extracellular fluid during ARF, fluid overload and edema may occur. **Diuretics** and dopamine may be given to reduce fluid volume excess and edema. Treatment should be initiated as soon as possible after oliguria begins. **Mannitol** or a **loop diuretic** may be used; thiazide diuretics are avoided in renal failure because they are ineffective when creatinine clearance is less than 25 mL/min, and they may worsen the patient's clinical status.

(1) Step 1. Loop (high-ceiling) diuretics. These agents include **furosemide, bumetanide, torsemide** and **ethacrynic acid.** Loop diuretics are more potent and faster-acting than thiazide diuretics.

(a) Mechanism of action and therapeutic effects. Loop diuretics inhibit sodium and chloride reabsorption at the loop of Henle, promoting water excretion.

(b) Onset of action for an oral dose is 1 hour; several minutes for an IV dose. Duration of action for an oral dose is 6-8 hours; 2-3 hours for an IV dose.

(c) Administration and dosage

(i) Furosemide, the **most commonly used** loop diuretic, usually is administered intravenously in patients with ARF to hasten the therapeutic effect. The dose is titrated to the patient's needs; the usual initial dose is 1-1.5 mg/kg. If the first dose does not produce a urine output of 10-15 mL within 20-30 minutes, a dose of 2-3 mg/kg is administered; if the desired response still does not occur, a dose of 3-6 mg/kg is administered 20-30 minutes after the second dose.

(ii) Bumetanide may be given to patients who are unresponsive or allergic to furosemide. The usual dosage, administered intravenously or intramuscularly in the treatment of ARF, is 0.5-1 mg/day; however, some patients may require up to 20 mg/day. A second or third dose may be given at intervals of 2-3 hours. When bumetanide is given orally, the dosage is 0.5-2 mg/day, repeated up to two times, if necessary, at intervals of 2-3 hours.

(iii) Ethacrynic acid is **less commonly used** to treat ARF because ototoxicity (sometimes irreversible) is associated with its use. It may be given intravenously (slowly over several minutes) in a dose of 50-100 mg. The usual oral dosage is 50-200 mg/day; some patients may require up to 200 mg twice daily. Ethacrynic acid can be safely given to patients who may have a sulfonamide

allergy, which would preclude them from therapy with furosemide or torsemide.

(iv) Torsemide may also be given to patients unresponsive to or allergic to furosemide. The usual dose is 20 mg, administered intravenously. Doses may be increased by doubling up to 200 mg; 10-20 mg of torsemide is equipotent to 40 mg of furosemide or 1 mg bumetanide. Torsemide offers better bioavailability compared to other loop diuretics; however, it is considerably more expensive.

(d) Precautions and monitoring effects

(i) Loop diuretics must be used cautiously because they may cause overdiuresis leading to orthostatic hypotension, fluid and electrolyte abnormalities, including volume depletion and dehydration, hypocalcemia, hypokalemia, hypochloremia,

hyponatremia, hypomagnesemia, and transient ototoxicity, especially with rapid IV injection.

(ii) Serum electrolyte levels should be monitored frequently and the patient assessed regularly for signs and symptoms of electrolyte abnormalities.

(iii) Blood pressure and pulse rate should be assessed during diuretic therapy.

(iv) GI reactions include abdominal pain and discomfort, diarrhea (with furosemide and ethacrynic acid), and nausea (with bumetanide).

(v) Blood glucose levels should be monitored in diabetic patients receiving loop diuretics because these agents may cause hyperglycemia and impaired glucose tolerance.

(vi) Patients who are allergic to sulfonamides may be hypersensitive to bumetanide and furosemide.

(vii) Furosemide and ethacrynic acid may cause agranulocytosis.

(e) Significant interactions

(i) Aminoglycoside antibiotics may potentiate ototoxicity when administered with any loop diuretic.

(ii) Nonsteroidal anti-inflammatory drugs (NSAIDs) may hamper the diuretic response to furosemide and bumetanide; **probenecid** may hamper the diuretic response to bumetanide.

(iii) Ethacrynic acid may potentiate the anticoagulant effects of **warfarin.**

(2) Step 2. Mannitol, an osmotic diuretic, is a non-reabsorbable polysaccharide.

(a) Mechanism of action and therapeutic effect. Mannitol increases the osmotic pressure of the glomerular filtrate; fluid from interstitial spaces is drawn into blood vessels, expanding plasma volume and maintaining or increasing the urine flow. This drug may be given to prevent ARF in high-risk patients, such as those undergoing surgery or suffering from severe trauma or hemolytic transfusion reactions.

(b) Onset of action is 15-30 minutes. Duration of action is 3-4 hours.

(c) Administration and dosage. Mannitol is available in solutions, ranging from 5%-25%. For the treatment of oliguric ARF or the prevention of ARF, the usual initial dose is 12.5-25 g, administered intravenously; the maximum daily dosage is 100 g, administered intravenously. The exact concentration of the solution is determined by the patient's fluid requirements.

(d) Precautions and monitoring effects

(i) Mannitol is contraindicated in patients with anuria, pulmonary edema or congestion, severe dehydration, and intracranial hemorrhage (except during craniotomy).

(ii) Mannitol may cause or worsen pulmonary edema and circulatory overload. If signs and symptoms of these problems develop, the infusion should be stopped.

(iii) Other adverse effects of mannitol include fluid and electrolyte abnormalities, water intoxication, headache, confusion, blurred vision, thirst, nausea, and vomiting.

(iv) Vital signs, urine output, daily weight, cardiopulmonary status, and serum and urine sodium and potassium levels should be monitored during mannitol therapy.

(v) Mannitol solutions with undissolved crystals should not be administered.

4. Dialysis. If the above strategies fail, hemodialysis or peritoneal dialysis may be necessary in ARF patients who develop anuria, acute fluid overload, severe hyperkalemia, metabolic acidosis, or a BUN level above 100 mg/dl. For a discussion of dialysis, see II.F.7.

II. CHRONIC KIDNEY DISEASE

A. Definition. Chronic kidney disease (CKD) is the progressive, irreversible deterioration of renal function. Usually resulting from long-standing disease, CKD sometimes derives from ARF that does not respond to treatment.

B. Classification and pathophysiology

1. CKD is defined as kidney damage or GFR <60 mL/min/1.73 m2 for ≥3 months. Kidney damage is defined as pathological abnormalities or markers of damage, including abnormalities in blood or urine tests or imaging studies. CKD has recently been reclassified as stages I-V to denote the severity of renal impairment. Generally, CKD, if left untreated, progresses at a predictable, steady rate from stage I through stage V.

a. Stage 1 is defined as kidney damage with a normal or increased GFR. The corresponding GFR in stage I CKD is usually >90 mL/min/1.73 m2.

b. Stage 2 is defined as kidney damage or a mildly decreased GFR (60-89 mL/min/1.73 m2).

c. Stage 3 signifies moderate reductions in GFR (30-59 mL/min/1.73 m2).

d. Stage 4 connotes a GFR of 15-29 mL/min/1.73 m2.

e. Stage 5 is kidney failure or a GFR of <15 mL/min/1.73 m2.

2. As CKD progresses, nephron destruction worsens, leading to deterioration in the kidneys' filtration, reabsorption, and endocrine functions.

3. Renal function typically does not diminish until about 75% of kidney tissue is damaged. Ultimately, the kidneys become shrunken, fibrotic masses.

C. Etiology. Causes of CKD in adults include:

1. Diabetic nephropathy

2. Hypertension

3. Glomerulonephritis

4. Polycystic kidney disease

5. Long-standing vascular disease (e.g., renal artery stenosis)

6. Long-standing obstructive uropathy (e.g., renal calculi)

7. Exposure to nephrotoxic agents

D. Clinical evaluation

1. Physical findings. Signs and symptoms, which vary widely, do not appear until renal insufficiency progresses to renal failure.

a. Metabolic abnormalities include loss of the ability to maintain sodium, potassium, and water homeostasis, leading to hyponatremia or hypernatremia, based on relative sodium or water intake. Hyperkalemia is uncommon until end-stage disease. Fluid overload, edema, and CHF may become a problem unless fluid

intake is closely managed. As renal failure progresses, the inability to excrete acid and maintain buffer capacity leads to metabolic acidosis (see I.D.1.b, d, g, h). Calcium and phosphate metabolism is altered due to hyperparathyroidism.

b. Neurological manifestations include short attention span, loss of memory, and listlessness. As CKD progresses, these advance to confusion, stupor, seizures, and coma. Neuromuscular findings include peripheral neuropathy; pain, itching, and a burning sensation, particularly in the feet and legs. Patients may appear intoxicated. If dialysis is not started after these abnormalities occur, motor involvement begins, including loss of deep-tendon reflexes, weakness, and finally, quadriplegia.

c. Cardiovascular problems include arterial hypertension, peripheral edema, CHF, and pulmonary edema. Uremic pericarditis is now increasingly infrequent as a result of early dialysis.

d. GI **manifestations** include hiccups, anorexia, nausea, vomiting, constipation, stomatitis, and an unpleasant taste in the mouth. CKD patients have an increased incidence of ulcers, pancreatitis, and diverticulosis.

e. Respiratory problems include dyspnea when CHF is present, pulmonary edema, pleuritic pain, and uremic pleuritis.

f. Integumentary findings typically include pale yellowish, dry, scaly skin; severe itching; uremic frost; ecchymoses; purpura; and brittle nails and hair.

g. Musculoskeletal changes range from muscle and bone pain to pathological fractures and calcifications in the brain, heart, eyes, joints, and vessels. Soft-tissue calcification and renal osteodystrophy may occur.

h. Hematological disturbances include anemia. The signs and symptoms of anemia arise from lack of epoetin alfa and reduced life span of red blood cells, including:

(1) Pallor of the skin, nail beds, palms, conjunctivae, and mucosa

(2) Abnormal bruising or ecchymoses, and uremic bleeding due to platelet inactivation

(3) Dyspnea and angina pectoris

(4) Extreme fatigue

2. Diagnostic test results

a. Creatinine clearance may range from 0-90 mL/min, reflecting renal impairment.

b. Blood tests typically show:

(1) Elevated BUN and serum creatinine concentration

(2) Reduced arterial pH and bicarbonate concentration

(3) Reduced serum calcium level

(4) Increased serum potassium and phosphate levels

(5) Possible reduction in the serum sodium level

(6) Normochromic, normocytic anemia (hematocrit 20%-30%)

c. Urinalysis may reveal glycosuria, proteinuria, erythrocytes, leukocytes, and casts. Specific gravity is fixed at 1.010.

d. Radiographic findings. Kidney, ureter, and bladder radiography, IV pyelography, renal scan, renal arteriography, and nephrotomography may be performed. Typically, these tests reveal small kidneys (less than 8 cm in length).

E. Treatment objectives

1. Improve patient comfort and prolong life.

2. Treat systemic manifestations of CKD.

3. Correct body chemistry abnormalities.

F. Therapy. Management of the CKD patient is generally conservative. Dietary measures and fluid restriction relieve some symptoms of CKD and may increase patient comfort and prolong life until dialysis or renal transplantation is required or available (see I.F.1.a, b).

1. Treatment of edema. Angiotensin-converting enzyme (ACE) inhibitors and **diuretics** may be given to manage edema and CHF and to increase urine output.

a. ACE inhibitors—captopril, enalapril, lisinopril, fosinopril—are widely used to delay progression of CKD because they help preserve renal function and typically cause fewer adverse effects than other antihypertensive agents (see Chapter 39). They also decrease proteinuria and nephrotic syndrome.

b. Diuretics. An osmotic diuretic, a loop diuretic, or a thiazide-like diuretic may be given.

(1) Osmotic and loop diuretics. See I.F.3.a.(1), (2) for information on the use of these drugs in renal failure.

(2) Thiazide-like diuretics. Metolazone is the most commonly used thiazide diuretic in CKD.

(a) Mechanism of action and therapeutic effect. Metolazone reduces the body's fluid and sodium volume by decreasing sodium reabsorption in the distal convoluted tubule, thereby increasing urinary excretion of fluid and sodium.

(b) Administration and dosage. Metolazone is given orally at 5-20 mg/day; the dose is titrated to the patient's needs. Due to its long half-life, metolazone may be given every other day. Furosemide and metolazone act synergistically. Combination use is common, and metolazone should be administered 30 minutes before furosemide to achieve the optimal diuretic effect.

(c) Precautions and monitoring effects

(i) Metolazone should not be given to patients with hypersensitivity to sulfonamide derivatives, including thiazides.

(ii) To avoid nocturia, the daily dose should be given in the morning.

(iii) Metolazone may cause hematological reactions, such as agranulocytosis, aplastic anemia, and thrombocytopenia.

(iv) Fluid volume depletion, hypokalemia, hyperuricemia, hyperglycemia, and impaired glucose tolerance may occur during metolazone therapy.

(v) Metolazone may cause hypersensitivity reactions, including vasculitis and pneumonitis.

(d) Significant interactions

(i) Diazoxide may potentiate the antihypertensive, hyperglycemic, and hyperuricemic effects of metolazone.

(ii) Colestipol and **cholestyramine** decrease the absorption of metolazone.

2. Treatment of hypertension. Antihypertensive agents may be needed if blood pressure becomes dangerously high as a result of edema and the high renin levels that occur in CKD. Antihypertensive therapy should be initiated in the lowest effective dose and titrated according to the patient's needs.

a. ACE inhibitors—captopril, enalapril, lisinopril, fosinopril—as above in II.F.1.a (see also Chapter 39).

b. Dihydropyridine calcium-channel blockers, including **amLodipine** and **felodipine,** have similar effects and may be used instead of ACE inhibitors.

c. β-Adrenergic blockers, including **propranolol** and **atenolol,** reduce blood pressure through various mechanisms (see Chapter 39).

d. Other antihypertensive agents are sometimes used in the treatment of CKD, including α-adrenergic drugs, **clonidine,** and vasodilators, such as **hydralazine** (see Chapter 39).

3. Treatment of hyperphosphatemia involves administration of a phosphate binder, such as aluminum hydroxide or calcium carbonate (see I.F.2.c).

4. Treatment of hypocalcemia

a. Oral calcium salts [see I.F.2.d.(2)]

b. Vitamin D

(1) Mechanism of action and therapeutic effect. Vitamin D promotes intestinal calcium and phosphate absorption and utilization and, thus, increases the serum calcium concentration.

(2) Choice of agent. For the treatment of hypocalcemia in CKD and other renal disorders, **calcitriol** (vitamin D3, the active form of vitamin D) is the preferred vitamin D supplement because of its greater efficacy and relatively short duration of action. Other single-entity preparations include dihydrotachysterol, ergocalciferol, and calcifediol. Newer vitamin D analogues include doxercalciferol and paricalcitol.

(3) Administration and dosage. Calcitriol is given orally or via IV; the dose is titrated to the patient's needs (0.5-1 mg/day may be effective).

(4) Precautions and monitoring effects

(a) Vitamin D administration may be dangerous in patients with renal failure and must be used with extreme caution.

(b) Vitamin D toxicity may cause a wide range of signs and symptoms, including headache, dizziness, ataxia, convulsions, psychosis, soft-tissue calcification, conjunctivitis, photophobia, tinnitus, nausea, diarrhea, pruritus, and muscle and bone pain.

(c) Vitamin D has a narrow therapeutic index, necessitating frequent measurement of BUN and serum urine calcium and potassium levels.

5. Treatment of other systemic manifestations of CKD

a. Treatment of anemia includes administration of iron (e.g., ferrous sulfate), folate supplements, and epoetin alfa.

(1) Severe anemia may warrant transfusion with packed red blood cells.

(2) Epoetin alfa stimulates the production of red cell progenitors and the production of hemoglobin. It also accelerates the release of reticulocytes from the bone marrow.

(a) An initial dose of epoetin alfa is 50-100 U/kg intravenously or subcutaneously three times a week. The dose may be adjusted upward to elicit the desired response.

(b) Epoetin alfa works best in patients with a hematocrit below 30%. During the initial treatment, the hematocrit increases 1%-3.5% in a 2-week period. The target

hematocrit is 33%-35%. Maintenance doses are titrated based on hematocrit after this level is reached.

(c) Epoetin alfa therapy should be temporarily stopped if hematocrit exceeds 36%. Additional side effects include hypertension in up to 25% of patients. Headache and malaise have been reported.

(d) The effects of epoetin alfa are dependent on a ready supply of iron for hemoglobin synthesis. Patients who do not respond should have iron stores checked. This includes serum iron, total iron-binding capacity, transferrin saturation, and serum ferritin. Iron supplementation should be increased as indicated.

(3) Darbepoeitin is a new epoetin alfa analogue. Its advantage is a prolonged plasma half-life, thus allowing it to be administered once weekly or biweekly.

(4) Intravenous iron products may be given to replete iron stores. This route is preferred to oral supplementation due to low oral bioavailability and GI intolerance. Iron dextran is commonly used; however, it is associated with hypotension and anaphylaxis. Newer iron products include sodium ferric gluconate and iron sucrose, which are better tolerated and can be infused more rapidly compared to iron dextran. Patients with severe iron deficiency may receive up to a total of 1 g of an iron preparation over several days. The rate of infusion depends on the preparation used.

b. Treatment of GI **disturbances**

(1) Antiemetics help control nausea and vomiting.

(2) Docusate sodium or methylcellulose may be used to prevent constipation.

(3) Enemas may be given to remove blood from the GI tract.

c. Treatment of skin problems. An antipruritic agent, such as diphenhydramine, may be used to alleviate itching.

6. Management of body chemistry abnormalities (see I.F.2)

7. Dialysis. When CKD progresses to end-stage renal disease and no longer responds to conservative measures, long-term dialysis or renal transplantation is necessary to prolong life.

a. Hemodialysis is the preferred dialysis method for patients with a reduced peritoneal membrane, hypercatabolism, or acute hyperkalemia.

(1) This technique involves shunting of the patient's blood through a dialysis membranecontaining unit for diffusion, osmosis, and ultrafiltration. The blood is then returned to the patient's circulation.

(2) Vascular access may be obtained via an arteriovenous fistula or an external shunt.
(3) The procedure takes only 3-8 hours; most patients need three treatments a week. With proper training, patients can perform hemodialysis at home.
(4) The patient receives heparin during hemodialysis to prevent clotting.
(5) Various complications may arise, including clotting of the hemofilter, hemorrhage, hepatitis, anemia, septicemia, cardiovascular problems, air embolism, rapid shifts in fluid and electrolyte balance, itching, nausea, vomiting, headache, seizures, and aluminum osteodystrophy.
b. Peritoneal dialysis is the preferred dialysis method for patients with bleeding disorders and cardiovascular disease.
(1) The peritoneum is used as a semipermeable membrane. A plastic catheter inserted into the peritoneum provides access for the dialysate, which draws fluids, wastes, and electrolytes across the peritoneal membrane by osmosis and diffusion.
(2) Peritoneal dialysis can be carried out in three different modes.
(a) Intermittent peritoneal dialysis is an automatic cycling mode lasting 8-10 hours, performed three times a week. This mode allows nighttime treatment and is appropriate for working patients.
(b) Continuous ambulatory peritoneal dialysis is performed daily for 24 hours with four exchanges daily. The patient can remain active during the treatment.
(c) Continuous cyclic peritoneal dialysis may be used if the other two modes fail to improve creatinine clearance. Dialysis takes place at night; the last exchange is retained in the peritoneal cavity during the day, then drained that evening.
(3) Advantages of peritoneal dialysis include a lack of serious complications, retention of normal fluid and electrolyte balance, simplicity, reduced cost, patient independence, and a reduced need (or no need) for heparin administration.
(4) Complications of peritoneal dialysis include hyperglycemia, constipation, and inflammation or infection at the catheter site. Also, this method carries a high risk of peritonitis.

8. Renal transplantation. This surgical procedure allows some patients with end-stage renal disease to live normal and, in many cases, longer lives.
a. Histocompatibility must be tested to minimize the risk of transplant rejection and failure. Human leukocyte antigen (HLA) type, mixed lymphocyte reactivity, and blood group types are determined to assess histocompatibility.
b. Renal transplant material may be obtained from a living donor or a cadaver.
c. Three types of graft rejection can occur.
(1) Hyperacute (immediate) rejection results in graft loss within minutes to hours after transplantation.
(a) Acute urine flow cessation and bluish or mottled kidney discoloration are intraoperative signs of hyperacute rejection.
(b) Postoperative manifestations include kidney enlargement, fever, anuria, local pain, sodium retention, and hypertension.

(c) Treatment for hyperacute rejection is immediate nephrectomy.
(2) Acute rejection may occur 4-60 days after transplantation.
(3) Chronic rejection occurs more than 60 days after transplantation.
(a) Signs and symptoms include low-grade fever, increased proteinuria, azotemia, hypertension, oliguria, weight gain, and edema.
(b) Treatment may include alkylating agents, cyclosporine, antilymphocyte globulin, and corticosteroids. In some cases, nephrectomy is necessary.
d. Complications include:
(1) Infection, diabetes, hepatitis, and leukopenia, resulting from immunosuppressive therapy
(2) Hypertension, resulting from various causes
(3) Cancer (e.g., lymphoma, cutaneous malignancies, head and neck cancer, leukemia, colon cancer)
(4) Pancreatitis and mental and emotional disorders (e.g., suicidal tendencies, severe depression, brought on by steroid therapy)

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.
Questions 1-5 A 48-year-old black man has a history of mild to severe hypertension. His hypertension has been poorly controlled with enalapril and hydrochlorothiazide. On prior visits, his blood pressure control has varied and seems to correspond with a lack of compliance with his treatment regimen. The patient states that he occasionally forgets his pills or does not take them when he is feeling “okay.” The patient's history does not include diabetes mellitus or heart disease. He completed a 14-day course of clarithromycin for an upper respiratory infection in the past month and has returned to the clinic for follow-up review of the infection and his hypertension therapy.
On this visit, the patient complains of dizziness, loss of energy, increased frequency of urination, and edema of the lower extremities. His physical examination reveals an overweight man with a standing blood pressure of 175/100 mm Hg, moderate edema of the ankles, and a slight third heart sound. Laboratory results include blood urea nitrogen (BUN) of 45 mg/dl, serum creatinine concentration of 3.7 mg/dl, serum calcium of 5.3 mg/mL, serum potassium of 6.3 mg/mL, and a hematocrit of 25. Serum iron, total iron-binding capacity, transferrin saturation, and serum ferritin are normal. Microscopic urine and chemical analyses reveal mild proteinuria and a specific gravity of 1.010.
1. The history, physical examination, laboratory values, and current signs and symptoms suggest that the patient has which of the following conditions?
(A) Acute renal failure brought on by a nephrotoxic drug (clarithromycin, enalapril)
(B) Acute renal failure resulting from renal obstruction by a kidney stone

(C) Acute renal failure precipitated by severe dehydration

(D) Chronic renal failure resulting from hypertension

View Answer***1. The answer is D[].*****2. Treatment of the patient's fluid retention and edema should begin with all of the following EXCEPT**

(A) restriction of fluid intake

(B) therapy with furosemide or metolazone

(C) treatment of hypertension using a β-blocker or angiotensin-converting enzyme inhibitor

(D) digitalis glycoside therapy if congestive heart failure is present

(E) hemodialysis

View Answer***2. The answer is E[].*****3. The most likely cause of the anemia seen in this patient is**

(A) urinary blood loss

(B) vitamin B_{12} deficiency

(C) iron deficiency

(D) decreased red cell life span and a deficiency of epoetin alfa

View Answer***3. The answer is D[].*****4. This patient's symptoms seemed to appear suddenly and may result from his history of uncontrolled hypertension. Which statement best describes hypertension?**

(A) A major cause of chronic renal failure

(B) A major cause of acute renal failure

(C) A major cause of both chronic and acute renal failure

(D) Only seen in patients whose renal failure has caused excessive fluid retention

View Answer***4. The answer is A[].*****5. When should peritoneal dialysis or hemodialysis be considered to treat this patient's renal failure?**

(A) As soon as possible to prevent further complications resulting from decreased renal function

(B) Only when renal function has decreased to a point where fluid and electrolyte status cannot be maintained using conservative measures

(C) On an intermittent basis as the situation demands

(D) Only if the patient is a kidney transplant candidate

View Answer***5. The answer is B[].*****6. Acute renal failure (ARF) may be caused by all of the following EXCEPT**

(A) acute tubular necrosis (ATN) due to drug therapy (e.g., aminoglycosides, contrast media)

(B) severe hypotension or circulatory collapse

(C) decreased cardiac output, as from congestive heart failure

(D) hemolysis and myoglobinuria

(E) hyperkalemia

View Answer***6. The answer is E[and].***P.1235

7. Life-threatening cardiac arrhythmias due to hyperkalemia should be treated with

(A) calcium chloride or calcium gluconate intravenously

(B) digoxin or other digitalis preparations
(C) loop diuretics to rapidly eliminate potassium
(D) sodium polystyrene sulfonate (SPS)

View Answer***7. The answer is A[].*****8. Aluminum hydroxide is used to treat hyperphosphatemia associated with renal failure. Chronic use of aluminum hydroxide may cause all of the following conditions EXCEPT**
(A) phosphate depletion
(B) calcium resorption and bone demineralization
(C) anorexia and constipation
(D) fluid retention

View Answer***8. The answer is D[and].*****9. The diuretic of choice for the initial treatment of a patient with either acute or chronic renal failure (ARF, CKD) whose creatinine clearance is below 25** mL**/min is**
(A) hydrochlorothiazide
(B) bumetanide
(C) furosemide
(D) ethacrynic acid

View Answer***9. The answer is C[].*****10. Epoetin alfa is used commonly to treat the anemia associated with chronic renal failure (CKD). Which of the following conditions limits the effectiveness of epoetin alfa?**
(A) A patient's allergy to epoetin alfa
(B) Depletion of iron stores, requiring oral or parenteral supplementation
(C) The ineffectiveness of epoetin alfa, as 30% of patients do not respond
(D) The anemia of chronic renal failure is not due to a lack of epoetin alfa, so epoetin alfa will not ameliorate.

View Answer***10. The answer is B[].***P.1236

ANSWERS AND EXPLANATIONS

1. The answer is D *[*II.D.1*].*
The fluid and electrolyte status of the patient described in the case, combined with the urine-specific gravity, lack of crystals or casts in the urine, and the complaint of fatigue, suggest chronic renal failure resulting from uncontrolled hypertension or an unknown cause. The antibiotic therapy (clarithromycin) and antihypertensive drug (enalapril) are not nephrotoxic, and the patient's blood pressure and fluid status do not indicate a prerenal cause.

2. The answer is E *[*II.F.1, 2*].*
All of these measures are indicated as initial therapy for the treatment of edema and fluid retention due to chronic renal failure except hemodialysis, which should be reserved until more conservative measures are tried.

3. The answer is D *[*II.D.1.h*].*
There is no evidence of frank blood loss. The decreased hematocrit and the clinical signs indicate the anemia of chronic renal failure due to the shortened red blood cell life span. Decreased epoetin alfa is the cause.

4. The answer is A *[*II.C.2*].*
Systemic long-standing high blood pressure is the second most common cause of chronic renal failure (CKD). Only malignant hypertension can cause acute renal failure (ARF), which is not common. High blood pressure is common after substantial renal damage has occurred in both CKD and ARF, but it does not occur as the first or only manifestation.
5. The answer is B *[*II.F.7*].*
Dialysis should be considered when the patient's renal function has decreased to a point where conservative measures are ineffective. Peritoneal dialysis and hemodialysis have associated complications and morbidity, so intermittent or early use of these therapies is not indicated. Patients can be maintained on dialysis for extended periods, so eligibility for transplant is not required.
6. The answer is E *[I.B.1-3].*
Hyperkalemia is a sign of acute and chronic renal failure, resulting from the decreased renal function and changes in acid-base balance.
7. The answer is A *[*I.F.2.a*].*
Intravenous calcium chloride or gluconate is used to treat potassium-induced arrhythmias. Digoxin is not indicated. Loop diuretics and sodium polystyrene sulfonate (SPS) do not have a significant enough effect on potassium in a short period to treat a life-threatening arrhythmia. SPS and loop diuretics, along with dialysis, may be considered to remove potassium in the short term, preventing the recurrence of arrhythmias.
8. The answer is D *[*I.F.2.c.(5).(d).(i), (ii) *and* (iii)*].*
Common effects of the sustained use of aluminum-containing antacids include phosphate depletion, calcium resorption, bone demineralization, anorexia, and constipation. Fluid retention does not result from the use of antacids containing aluminum hydroxide.
9. The answer is C *[*I.F.3.a.(1).(c)*].*
Furosemide is the diuretic of choice for the initial treatment of a patient with either acute or chronic renal failure (ARF, CKD) whose creatinine clearance is below 25 mL/min. A thiazide diuretic has little effect at a creatinine clearance below 25 mL/min. Bumetanide, torsemide, and ethacrynic acid are appropriate only if the patient is allergic to furosemide or if repeated doses of furosemide are ineffective.
10. The answer is B *[*II.F.5.a.(2).(d)*].*
Epoetin alfa is widely used and highly effective in treating the anemia associated with chronic renal failure (CKD). Few reports of patients refractory to epoetin alfa therapy have appeared in medical literature. However, the depletion of iron stores will not allow the formation of red blood cells, even in the presence of appropriate amounts of epoetin alfa. All CKD patients receiving epoetin alfa require some iron supplementation, and most patients require parenteral iron to achieve sufficient supplies to continue developing hemoglobin over the term of their illness.

I. PRINCIPLES OF ONCOLOGY.

The term *cancer* refers to a heterogeneous group of diseases caused by an impairment of the normal functioning of genes, which leads to genetic damage.

A. Characteristics of cancer cells. Cancer cells are also referred to as tumors, or neoplasms. Tumors arise from a single abnormal cell, which continues to divide indefinitely. Uncontrolled growth, ability to invade local tissues, and ability to spread, or **metastasize,** are characteristics of cancer cells.

1. Carcinogenesis. The mechanism of how cancers occur is thought to be a multistage, multifactorial process that involves both genetic and environmental factors.

a. Initiation. The first step involves the exposure of normal cells to a carcinogen, producing genetic damage to a cell.

b. Promotion. The environment becomes altered to allow preferential growth of mutated cells over normal cells. The mutated cells become cancerous.

c. Progression. Increased proliferation of cancer cells allows for invasion into local tissue and metastasis.

2. Types of cancer. Tumors can be benign or malignant. **Benign** tumors are generally slow growing, resemble normal cells, are localized, and are not harmful. **Malignant** tumors often proliferate more rapidly, have an atypical appearance, invade and destroy surrounding tissues, and are harmful if left untreated. Malignant cancers are further categorized by the location from where the tumor cells arise.

a. Solid tumors. Carcinomas are tumors of epithelial cells. These include specific tissue cancers (e.g., lung, colon, breast). **Sarcomas** include tumors of connective tissue such as bone (e.g., osteosarcoma) or muscle (e.g., leiomyosarcoma).

b. Hematological malignancies. Lymphomas are tumors of the lymphatic system and include Hodgkin and non-Hodgkin lymphomas. **Leukemias** are tumors of blood-forming elements and are classified as acute or chronic, myeloid or lymphoid.

B. Incidence. Cancer is the **second leading cause of death** in the United States. The lifetime probability of developing cancer is > 30%. The estimated incidences of new cancers and cancer-related deaths by site are given in Figure 57-1. The most common cancers are breast, prostate, lung, and colorectal. The leading cause of cancer death is lung cancer.

C. Cause. Many factors have been implicated in the origin of cancer. Some of these factors are as follows:

1. Viruses, including Epstein-Barr virus (EBV), hepatitis B virus (HBV), and human papillomavirus (HPV)

2. Environmental and occupational exposures, such as ionizing and ultraviolet radiation and exposure to chemicals, including vinyl chloride, benzene, and asbestos

3. Lifestyle factors, such as high-fat, low-fiber diets and tobacco and ethanol use

4. Medications, including alkylating agents and immunosuppressants

5. Genetic factors, including inherited mutations, cancer-causing genes (oncogenes), and defective tumor-suppressor genes

D. Detection and **diagnosis** are critical for the appropriate treatment of cancer. Earlier detection may improve response to treatment.

P.1238

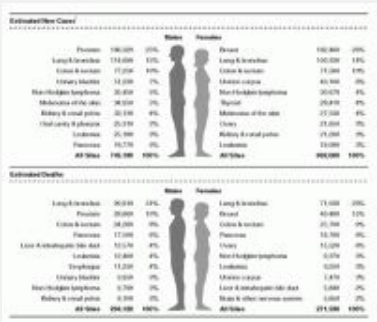

Figure 57-1. Cancer incidence and deaths. Leading cancer sites for estimated new cases and deaths by gender in the United States, 2007 estimates. [a]Excludes basal and squamous cell skin cancers and in situ carcinomas except urinary bladder. [Adapted with permission from Jemal A, Murray T, Ward E, et al. Cancer statistics, 2007. CA Cancer J Clin 2007;57:43-66.]

1. Warning signs of cancer have been outlined by the American Cancer Society.

a. Change in bowel or bladder habits

b. A sore that does not heal

c. Unusual bleeding or discharge

d. Thickening or lump in the breast or elsewhere

e. Indigestion or difficulty swallowing

f. Obvious change in a wart or mole

g. Nagging cough or hoarseness

2. Guidelines for screening asymptomatic people for the presence of cancer have been established by the American Cancer Society, the National Cancer Institute, and the U.S. Preventive Health Services Task Force. Because many cancers do not produce signs or symptoms until they have become large, the goal of screening is to detect cancers early, when the disease is curable, and to reduce mortality. The different sets of guidelines vary slightly in their recommendations for age and frequency of screening procedures. Table 57-1 provides the American Cancer Society's recommendations for screening.

3. Tumor markers are biochemical indicators of the presence of neoplastic proliferation detected in serum, plasma, or other body fluids. These tumor markers may be used initially as screening tests, to reveal further information after abnormal test results, or to monitor the efficacy of therapy. Elevated levels of these markers are not definitive for the presence of

P.1239

cancer because levels can be elevated in other benign and malignant conditions, and false-positive results do occur. Examples of some commonly used markers include

Table 57-1. American Cancer Society's Recommendations for the Early Detection of Cancer[a]

Cancer Site	Population	Starting Age	Tests or Procedures
Breast	Women	20+	Breast self-examination
		20+	Clinical breast examination
		40+	Mammography
Colorectal	Men and Women	50+	Fecal occult blood test or fecal immunochemical test
		50+	Flexible sigmoidoscopy
		50+	Colonoscopy
		50+	Double-contrast barium enema
Prostate	Men	50+	Digital rectal examination
		50+	Prostate-specific antigen
Cervix	Women	18+	Pap (Papanicolaou) test

[a]In average-risk, asymptomatic people.

Adapted with permission from Smith RA, Cokkinides V, Eyre HJ, et al. American Cancer Society guidelines for the early detection of cancer. CA Cancer J Clin 2005;55:31-44.

a. Carcinoembryonic antigen (CEA) for colorectal cancer

b. α-Fetoprotein (AFP) for hepatocellular carcinoma

c. Prostate-specific antigen (PSA) for prostate cancer

4. Tumor biopsy. The definitive test for the presence of cancerous cells is a biopsy and pathological examination of the biopsy specimen. Several types of procedures are used in the pathological analysis of tumors, including evaluating the morphological features (appearance) of the tissue and cells, looking for cell-surface markers, and cytogenetic evaluation for specific chromosomal abnormalities.

5. Imaging studies, such as x-rays, CT scans, MRI, and positron-emission tomography (PET), may be used to aid in the diagnosis or location of a tumor and to monitor response to treatment.

6. Other laboratory tests commonly used for cancer diagnosis include complete blood counts (CBCs) and blood chemistries. A CBC measures the levels of the three basic blood cells—white cells, red cells, and platelets.

a. The CBC will often include an ANC (absolute neutrophil count) which measures the absolute number of neutrophils in your white blood count. The ANC is calculated by multiplying the white blood count (WBC) × total neutrophils (segmented neutrophils% + segmented bands%) × 10 = ANC. Segmented neutrophils are often listed as “polys” and segmented bands are immature “polys.”

E. Staging is the categorizing of patients according to the extent of their disease. The stage of the disease is used to determine prognosis and treatment. Two different staging systems are widely employed for the staging of neoplasms.

1. TNM classification

a. *T* indicates tumor size and is classified from 0 to 4, with 0 indicating the absence of tumor.

b. *N* indicates the presence and extent of regional lymph node spread and is classified from 0 to 3, with 0 indicating no regional lymph node involvement and 3 indicating extensive involvement.

c. *M* indicates the presence of distant metastases and is be classified as 0 (for absence) or 1 (for presence of distant metastases).

d. For example, T2N1M0 indicates a moderate-size tumor with limited nodal disease and no distant metastases.

2. AJCC staging, developed by the American Joint Committee on Cancer, classifies cancers as stages 0-IV. An assigned TNM translates into a stage. A high number indicates larger tumors with extensive nodal involvement and/or metastasis. Generally, high numbers also indicate a worse prognosis. There are specific staging criteria for each tumor type.

F. Survival depends on the tumor type, the extent of disease, and the therapy received. Although some patients are free of all detectable disease, not all patients are cured. Oncologists prefer to use the term **complete response** or **remission** to indicate a patient with no evidence of disease after treatment. This is not a synonym for *cure.* For some slow-growing tumors, these disease-free periods may extend for 10-15 years after the initial remission. However, a number of patients who have achieved complete remission may relapse.

II. CELL LIFE CYCLE.

Knowledge of the cell life cycle and cell cycle kinetics is essential to the understanding of the activity of chemotherapy agents in the treatment of cancer (Figure 57-2).

A. Phases of the cell cycle

1. M **phase,** or **mitosis,** is the phase in which the cell divides into two daughter cells.

2. G_1 **phase,** or **postmitotic gap,** is when RNA and the proteins required for the specialized functions of the cell are synthesized in preparation for DNA synthesis.

3. S phase is the phase in which DNA synthesis and replication occurs.

4. G_2 **phase,** or the **premitotic** or **postsynthetic gap,** is the phase in which RNA and the enzymes topoisomerase I and II are produced to prepare for duplication of the cell.

5. G_0 **phase,** or **resting phase,** is the phase in which the cell is not committed to division. Cells in this phase are generally not sensitive to chemotherapy. Some of these cells may reenter the actively dividing cell cycle. In a process called **recruitment,** some chemotherapy regimens are designed to enhance this reentry by killing a large number of actively dividing cells.

B. Cell growth kinetics. Several terms describe cell growth kinetics.

1. Cell growth fraction is the proportion of cells in the tumor dividing or preparing to divide. As the tumor enlarges, the cell growth fraction decreases because a larger proportion of cells may not be able to obtain adequate nutrients and blood supply for replication.

2. Cell cycle time is the average time for a cell that has just completed mitosis to grow and again divide and again pass through mitosis. Cell cycle time is specific for each individual tumor.

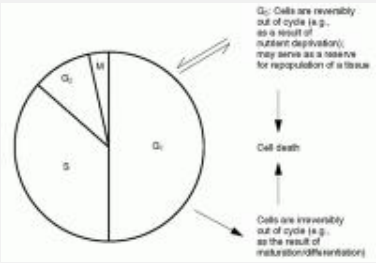

Figure 57-2. The cell cycle. The cell growth cycle, emphasizing the relationship between proliferating cell populations. [Reprinted with permission from Lenhard RE Jr., Osteen RT, Gansler T, et al., eds. The American Cancer Society's Clinical Oncology. Atlanta, American Cancer Society, 2001.]

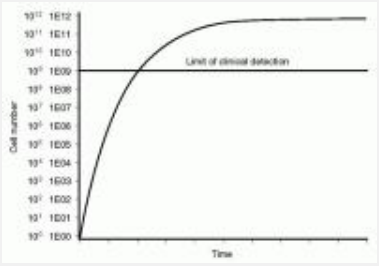

Figure 57-3. The gompertzian growth curve. During the early stages of its development, a tumor grows exponentially. But as a tumor enlarges, its growth slows. By the time a tumor becomes large enough to cause symptoms and be clinically detectable, the majority of its growth has already occurred and is no longer exponential. [Reprinted with permission from Lenhard MJ Jr., et al., eds. The American Cancer Society's Clinical Oncology. Atlanta, American Cancer Society, 2001.]

3. Tumor doubling time is the time for the tumor to double in size. As the tumor gets larger, its doubling time gets longer because it contains a smaller proportion of actively dividing cells owing to restrictions of space, nutrient availability, and blood supply.

4. The **gompertzian growth curve** illustrates these cell growth concepts (Figure 57-3).

C. Tumor cell burden is the number of tumor cells in the body.

1. Because of the large number of cells required to produce symptoms and be clinically detectable (approximately 10^9 cells), the tumor may be in the plateau phase of the growth curve by the time it is detected.

2. The **cell kill hypothesis** states that a certain percentage of tumor cells will be killed with each course of cancer chemotherapy.

a. As tumor cells are killed, cells in G_0 may be recruited into G_1, resulting in tumor regrowth.

b. Thus repeated cycles of chemotherapy are required to achieve a complete response or remission (Figure 57-4).

c. The percentage of cells killed depends on the chemotherapy dose.

3. In theory, the tumor burden would never reach absolute zero because only a percentage of cells are killed with each cycle. Less than 10^4 cells may depend on elimination by the host's immune system.

D. Chemotherapeutic agents may be classified according to their **reliance on cell cycle kinetics** for their cytotoxic effect. Combinations of chemotherapy agents that are active in different phases of the cell cycle may result in a greater cell kill. A cell cycle classification of some commonly used chemotherapeutic agents is given in II.D.1.a, b, c and d.

1. Phase-specific agents are most active against cells that are in a specific phase of the cell cycle. These agents are most effective against tumors with a high growth fraction. Theoretically, by administering these agents as continuous intravenous infusions or by multiple repeated doses, it may increase the likelihood of hitting the majority of cells in the specific phase at any one time. Therefore, these agents are also considered schedule-dependent agents. Examples are as follows:

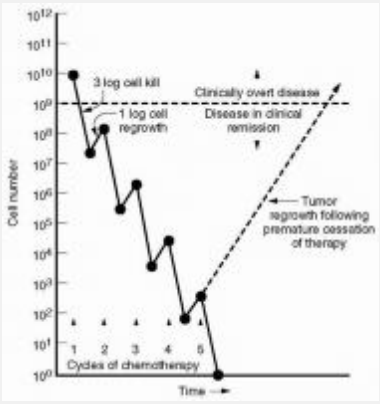

Figure 57-4. Chemotherapy and tumor cell survival. Relationship between tumor cell survival and chemotherapy administration. The exponential relationship between chemotherapy drug dose and tumor cell survival dictates that a constant proportion, not number, of tumor cells is killed with each cycle of treatment. In this example, each cycle of drug administration results in 99.9% (3 log) cell kill, and 1 log of cell regrowth occurs between cycles. The broken line indicates what would occur if the last cycle of therapy were omitted. Despite complete clinical remission of disease, the tumor would ultimately recur. [Reprinted with permission from Lenhard MJ Jr., et al., eds. The American Cancer Society's Clinical Oncology. Atlanta, American Cancer Society, 2001.]

a. M phase: mitotic inhibitors (e.g., vinca alkaloids, taxanes)

b. G_1 phase: asparaginase, prednisone

c. S phase: antimetabolites

d. G_2 phase: bleomycin, etoposide

2. Phase-nonspecific agents are effective while cells are in the active cycle but do not require that the cell be in a particular phase. These agents generally show more activity against slow-growing tumors. They may be administered as single bolus doses because their activity is independent of the cell cycle. These drugs are also considered dose-dependent agents. Examples are alkylating agents and antitumor antibiotics.

3. Cell cycle-nonspecific agents are effective in all phases, including G_0. Examples are carmustine, lomustine, and radiation.

III. CHEMOTHERAPY

A. Objectives of chemotherapy

1. A **cure** may be sought with aggressive therapy for a prolonged period of time to eradicate all disease. For leukemias, this curative approach may consist of remission induction, attempting the maximal cell kill, followed by consolidation therapy to eradicate all clinically undetectable disease and to lower the tumor cell burden below 10^3, at which level host immunological defenses may keep the cells in control.

2. If the goal is **palliation,** chemotherapy may be given to decrease tumor size, control growth, and reduce symptoms. Palliative therapy is usually given when complete eradication of the tumor is considered unlikely or the patient refuses aggressive therapy.

3. Adjuvant chemotherapy is given after more definitive therapy, such as surgery, to eliminate any remaining disease or undetected micrometastasis.
4. Neoadjuvant chemotherapy is given to decrease the tumor burden before definitive therapy, such as surgery or radiation.
5. Salvage chemotherapy is given as an attempt to get a patient into remission, after previous therapies have failed.
B. Chemotherapy dosing may be based on **body weight,** body surface area (BSA), or area under the concentration versus time curve (**AUC**). BSA is most frequently used because it provides an accurate comparison of activity and toxicity across species. In addition, BSA correlates with cardiac output, which determines renal and hepatic blood flow and thus affects drug elimination.
C. Dosing adjustments may be required for kidney or liver dysfunction to prevent toxicity.
D. Combination chemotherapy is usually more effective than single-agent therapy.
1. When combining chemotherapy agents, factors to consider include
a. Antitumor activity
b. Different mechanisms of action
c. Minimally overlapping toxicities
2. The reasons for administering combination chemotherapy include:
a. Overcoming or preventing resistance
b. Cytotoxicity to resting and dividing cells
c. Biochemical enhancement of effect
d. Rescue of normal cells
3. Dosing and **scheduling** of combination regimens are important because they are designed to allow recovery of normal cells. These regimens generally are given as short courses of therapy in cycles.
4. Acronyms often are used to designate chemotherapy regimens. For example, CMF refers to a combination of cyclophosphamide, methotrexate, and fluorouracil used in the treatment of breast cancer.
E. Administration
1. Routes of administration vary, although intravenous (IV) administration is employed most commonly.
2. Other administration techniques include oral, subcutaneous, intrathecal, intra-arterial, intraperitoneal, intravesical, continuous IV infusion, bolus IV infusion, and hepatic artery infusion.
3. Drugs that may be given **intrathecally** are methotrexate and cytarabine. Drugs should not be administered by the intrathecal route without specific information supporting intrathecal administration. Deaths have occurred when vincristine and other drugs have been administered by the intrathecal route. Caution should be used in the preparation and delivery of drugs to be used in this manner.

4. Products with different formulations, including liposomal or pegylated agents (e.g., liposomal doxorubicin, pegfilgrastim), are being used to decrease frequency of administration and/or reduce toxicities.

F. Response to chemotherapy is defined in a number of ways and does not always correlate with patient survival.

1. Complete response (CR) indicates disappearance of all clinical, gross, and microscopic disease.

2. Partial response (PR) indicates a > 50% reduction in tumor size, lasting a reasonable period of time. Some evidence of disease remains after therapy.

3. Response rate (RR) is defined as CR + PR.

4. Stable disease indicates tumor that neither grows nor shrinks significantly (< 25% change in size).

5. Progression or **no response** after therapy is defined by a > 25% increase in tumor size or the appearance of new lesions.

G. Factors affecting response to chemotherapy

1. Tumor cell heterogeneity. Large tumors have completed multiple cell divisions, resulting in several mutations and genetically diverse cells.

2. Drug resistance. The **Goldie-Coldman hypothesis** states that genetic changes are associated with drug resistance, and the probability of resistance increases as tumor size increases. The hypothesis assumes that at the time of diagnosis, most tumors possess resistant clones. The most well-studied mechanism of resistance involves the *mdr* (multidrug resistance) gene, which codes for membrane-bound P-glycoprotein. P-glycoprotein serves as a channel through which cellular toxins (i.e., chemotherapeutic agents) may be excreted from the cell.

3. Dose intensity is defined as a specific dose delivered over a specific period of time. Occasionally, the full dose cannot be given or a cycle is delayed owing to complications or toxicities. Suboptimal doses have resulted in reduced response rates and survival. **Dose density** involves shortening the usual interval between doses to maximize the drug effects on the tumor growth kinetics.

4. Patient-specific factors such as poor functional status, impaired organ function, or concomitant diseases may compromise how a chemotherapy regimen is given and affect how the patient responds to treatment.

IV. CLASSIFICATION OF CHEMOTHERAPEUTIC AGENTS

A. Alkylating agents were the first group of antineoplastic agents. The prototype of this class is mechlorethamine, or **nitrogen mustard,** which was researched as a chemical warfare agent. Alkylating agents cause cross-linking and abnormal base pairing of DNA strands, which inhibit replication of the DNA. This mechanism is known as **alkylation.** These are phase-nonspecific agents. Examples of alkylating agents and their toxicities are listed in Table 57-2.

B. Most of the **antitumor antibiotics** are obtained from organisms of the *Streptomyces* genus. These agents may act by either alkylation (mitomycin) or

intercalation. Intercalation is the process by which the drug slides between DNA base pairs and inhibits DNA synthesis. These are phase-nonspecific agents. Examples of antitumor antibiotics and their toxicities are listed in Table 57-2.

C. Antimetabolites are structural analogs of naturally occurring substrates for biochemical reactions. They inhibit DNA synthesis by acting as false substitutions in the production of nucleic acids. These are S phase-specific agents. Examples of antimetabolites and their toxicities are listed in Table 57-2.

D. Mitotic inhibitors. The vinca alkaloids arrest cell division by preventing microtubule formation. The taxanes promote microtubule assembly and stabilization, thus prohibiting cell division. These are M phase-specific agents. Examples of these agents and their toxicities are listed in Table 57-2.

E. Topoisomerase inhibitors inhibit the enzymes topoisomerase I or II. The topoisomerases are necessary for DNA replication and RNA transcription. These are G_2 phase-specific agents. Examples of these agents and their toxicities are listed in Table 57-2.

F. Enzymes. Asparaginase is an enzyme that causes the degradation of the essential amino acid asparagine to aspartic acid and ammonia (Table 57-2). Unlike normal cells, tumor cells lack the ability to synthesize asparagine. This is a G_1 phase-specific agent.

G. Protein tyrosine kinase inhibitors. Imatinib mesylate is a selective tyrosine kinase inhibitor that causes apoptosis or arrest of growth in cells expressing the Bcr-Abl oncoprotein (Table 57-2). Bcr-Abl is the product of a specific chromosomal abnormality (Philadelphia chromosome), which is present in virtually all patients with chronic myelogenous leukemia (CML). It is the first approved antineoplastic agent designed to have targeted enzyme activity. Erlotinib is a selective inhibitor of epidermal growth factor receptor (EGFR) tyrosine kinase. EGFR is a cell surface receptor that is overexpressed in certain solid tumors. The binding of the EGFR receptor to its ligand activates tyrosine kinase, which then stimulates cell proliferation and growth of the tumor. Erlotinib blocks the tyrosine kinase signaling cascade and inhibits cancer cell growth. These agents are also known as targeted agents because they affect specific receptors to induce cancer cell death.

Table 57-2. Cancer Chemotherapeutic Agents by Mechanism of Action and Toxicities

Drug	Toxicities
Alkylating agents	
Altretamine (hexamethylmelamine)	Nausea and vomiting, myelosuppression, paresthesias, CNS toxicity
Busulfan	Myelosuppression, pulmonary fibrosis, aplastic anemia, skin hyperpigmentation
Carmustine (BCNU)	Delayed myelosuppression, nausea and vomiting, hepatotoxicity
Chlorambucil	Myelosuppression, pulmonary fibrosis, hyperuricemia
Carboplatin	Myelosuppression, nausea and vomiting, peripheral neuropathy, ototoxicity
Cisplatin	Nephrotoxicity, nausea and vomiting, peripheral neuropathy, myelosuppression, ototoxicity
Cyclophosphamide	Myelosuppression, hemorrhagic cystitis, immunosuppression, alopecia, stomatitis, SIADH
Dacarbazine (DTIC)	Myelosuppression, nausea and vomiting, flulike syndrome, hepatotoxicity, alopecia, flushing
Estramustine	Myelosuppression, ischemic heart disease, thrombophlebitis, hepatotoxicity, nausea and vomiting
Ifosfamide	Myelosuppression, hemorrhagic cystitis, somnolence, confusion

Lomustine (CCNU)	Delayed myelosuppression, nausea and vomiting, hepatotoxicity, neurotoxicity
Mechlorethamine	Myelosuppression, nausea and vomiting, phlebitis, gonadal dysfunction
Melphalan	Myelosuppression, anorexia, nausea and vomiting, gonadal dysfunction
Oxaliplatin	Sensory peripheral neuropathy, nausea and vomiting, diarrhea, mucositis, transaminase elevations, alopecia
Procarbazine	Myelosuppression, nausea and vomiting, lethargy, depression, paresthesias, headache, flulike syndrome
Streptozocin	Renal toxicity, nausea and vomiting, diarrhea, altered glucose metabolism, liver dysfunction
Temozolomide	Myelosuppression, nausea and vomiting, fatigue, headache, peripheral edema
Thiotepa	Myelosuppression, nausea and vomiting, mucositis, skin rashes
Antitumor antibiotics	
Bleomycin	Pneumonitis, pulmonary fibrosis, fever, anaphylaxis, hyperpigmentation, alopecia
Dactinomycin	Stomatitis, myelosuppression, anorexia, nausea and vomiting, diarrhea, alopecia
Daunorubicin	Myelosuppression, cardiotoxicity, stomatitis, alopecia, nausea and vomiting

Doxorubicin	Myelosuppression, cardiotoxicity, stomatitis, alopecia, nausea and vomiting
Epirubicin	Myelosuppression, nausea and vomiting, cardiotoxicity, alopecia
Idarubicin	Myelosuppression, nausea and vomiting, stomatitis, alopecia, cardiotoxicity
Mitomycin C	Myelosuppression, nausea and vomiting, anorexia, alopecia, stomatitis
Mitoxantrone	Myelosuppression, cardiotoxicity, alopecia, stomatitis, nausea and vomiting
Valrubicin	Urinary frequency, dysuria, hematuria, bladder spasm, incontinence, cystitis (For intravesical bladder administration)
Antimetabolites	
Azacytidine	Myelosuppression, nausea and vomiting, diarrhea, constipation, injection site pain, muscle aches, fatigue, edema, dizziness
Capecitabine	Diarrhea, stomatitis, nausea and vomiting, hand-foot syndrome, myelosuppression
Cladribine (2Cda)	Myelosuppression, fever, rash
Cytarabine (Ara-C)	Myelosuppression, nausea and vomiting, diarrhea, stomatitis, hepatotoxicity, fever, conjunctivitis, CNS toxicity
Decitabine	Myelosuppression, petechiae, fatigue, diarrhea, constipation, hyperglycemia, myalgias/arthralgias, rash, edema

Fludarabine	Myelosuppression, nausea and vomiting, fever, malaise, pulmonary infiltrates
Floxuridine	Hepatotoxicity, gastritis, mucositis
5-Fluorouracil	Stomatitis, myelosuppression, diarrhea, nausea and vomiting, cerebellar ataxia
Gemcitabine	Myelosuppression, fever, flu-like syndrome, rash, mild nausea and vomiting
Hydroxyurea	Myelosuppression, mild nausea and vomiting, rash
6-Mercaptopurine	Myelosuppression, nausea and vomiting, anorexia, diarrhea, cholestasis
Methotrexate	Mucositis, myelosuppression, pulmonary fibrosis, hepatotoxicity, nephrotoxicity, diarrhea, skin erythema
Nelarabine	Neurologic toxicities disorders, somnolence, hypoesthesia, and seizures), thrombocytopenia, anemia, and neutropenia, fatigue, and nausea
Pemetrexed	Myelosuppression, edema, fatigue, nausea and vomiting, diarrhea, mucositis, skin rash
Pentostatin	Nephrotoxicity, CNS depression, myelosuppression, nausea and vomiting, conjunctivitis
6-Thioguanine	Myelosuppression, hepatotoxicity, stomatitis
Mitotic inhibitors	

Docetaxel	Myelosuppression, fluid retention, hypersensitivity, paresthesias, rash alopecia
Ixabepilone	Peripheral sensory neuropathy, neutropenia, fatigue, myalgia, arthralgia, stomatitis, hypersensitivity reactions, anorexia
Paclitaxel	Myelosuppression, peripheral neuropathy, alopecia, mucositis, anaphylaxis, dyspnea
Vinblastine	Myelosuppression, paralytic ileus, alopecia, nausea, stomatitis
Vincristine	Peripheral neuropathy, paralytic ileus, SIADH
Vinorelbine	Peripheral neuropathy, myelosuppression, nausea and vomiting, hepatic dysfunction
Topoisomerase inhibitors	
Etoposide	Myelosuppression, nausea and vomiting, diarrhea, fever, hypotension with infusion, alopecia
Irinotecan	Myelosuppression, diarrhea, nausea and vomiting, anorexia
Teniposide	Myelosuppression, nausea and vomiting, alopecia, hepatotoxicity, hypotension with infusion
Topotecan	Myelosuppression, fever, flulike syndrome, nausea and vomiting
Enzymes	

Asparaginase	Allergic reactions, nausea and vomiting, liver dysfunction, CNS depression, hyperglycemia
Pegasparaginase	Hypersensitivity reactions, hepatotoxicity, fever, nausea and vomiting
Protein tyrosine kinase inhibitors	
Dasatinib	Pleural and pericardial effusions, diarrhea, myelosuppresion, gastrointestinal hemorrhage, rash
Erlotinib (OSI-774)	Acneiform rash, diarrhea, nausea, pruritus, fatigue, eye irritation
Imatinib mesylate (STI-571)	Myelosuppression, hepatotoxicity, fluid retention, nausea, diarrhea
Lapatinib	Diarrhea, rash, nausea, fatigue, anemia, left ventricular and liver dysfunction
Nilotinib	Rash, headache, nausea, fatigue, thrombocytopenia, neutropenia
Sorafenib	Hand-and-foot syndrome, fatigue, hypertension, rash/desquamation, diarrhea
Sunitinib	Hand-and-foot syndrome, skin and hair discoloration, fatigue, diarrhea, hypothyroidism, hypertension, left ventricular dysfunction, mucositis/stomatitis, nausea
Temsirolimus	Hyperglycemia, hypophosphatemia, anemia, hypertriglyceridemia, rash, diarrhea, mucositis/stomatitis

Histone deacetylase inhibitors	
Vorinostat	Thrombocytopenia, anemia, diarrhea, nausea/vomiting, hyperglycemia
Miscellaneous	
Tretinoin (all-trans retinoic acid, ATRA)	Leukocytosis, arrhythmias, headache, nausea and vomiting, scaling of skin, ATRA syndrome (fever, dyspnea, weight gain, pulmonary infiltrates)
Arsenic trioxide	Arrhythmias, hyperleukocytosis, nausea and vomiting, diarrhea, abdominal pain, APL differentiation syndrome (fever, dyspnea, weight gain, pulmonary infiltrates)
Bexarotene (Targretin R)	Hyperlipidemia, pancreatitis, hypothyroidism, hypercalcemia, leukopenia, peripheral edema, rash
Bortezomib (Velcade R)	Fatigue, peripheral neuropathy, myelosuppression, hypotension, arthralgias, diarrhea, nausea and vomiting, headache, fever
Lenalidomide	Myelosuppression, thromboembolic events, bacterial infection, fatigue, diarrhea
Thalidomide	Fatigue; headache; numbness in hands, feet, arms, and legs; constipation; increased risk for thrombotic events
Hormonal agents	
Adrenocorticoids	Fluid retention, hyperglycemia, hypertension, infection

Dexamethasone	
Methylprednisolone	
Prednisone	
Estrogens	Fluid retention, feminization, uterine bleeding, nausea and vomiting, thrombophlebitis
Diethylstilbestrol	
Estradiol	
Progestins	Weight gain, fluid retention, feminization, cardiovascular effects
Medroxyprogesterone	
Megestrol acetate	
Antiestrogens	Hot flashes, nausea and vomiting, altered menses
Fulvestrant	
Tamoxifen	
Toremifene	
Estrogen agonist/antagonist	
Raloxifene	Hot flashes, arthralgias, flu-like syndrome
Aromatase Inhibitors	Rash, electrolytes disturbance, drowsiness,

	nausea, anorexia
Aminoglutethimide	
Anastrozole	
Exemestane	
Letrozole	
Androgens	Masculinization, amenorrhea, gynecomastia, nausea, water retention, changes in libido, skin hypersensitivity, hepatotoxicity
Testosterone	
Methyltestosterone	
Fluoxymesterone	
Antiandrogens	Hot flashes, decreased libido, impotence, diarrhea, nausea and vomiting, gynecomastia, hepatotoxicity
Bicalutamide	
Flutamide	
Nilutamide	
LHRH Analogs	Hot flashes, menstrual irregularity, sexual dysfunction, edema
Leuprolide	
Goserelin	
LHRH antagonist	Hypersensitivity reactions, hypotension,

	Abarelix	syncope, hot flashes, breast enlargement, prolongation of QT interval

APL, acute promyelocytic leukemia; *ATRA*, all-*trans*-retinoic acid; *CNS*, central nervous system; *LHRH*, luteinizing hormone-releasing hormone; *SIADH*, syndrome of inappropriate antidiuretic hormone.

H. Other **miscellaneous** agents are listed in Table 57-2.

1. Tretinoin (all-*trans* retinoic acid; ATRA) is a retinoid derived from vitamin A, used for a specific form of acute leukemia, known as acute promyelocytic leukemia (APL), to help cells differentiate into functionally mature cells.

2. Arsenic trioxide is an antineoplastic arsenic compound used for APL that may induce selective apoptosis of APL cells.

3. Bexarotene is a selective retinoid X receptor (RXR) ligand used for cutaneous T cell lymphoma. Activation of the retinoid receptors leads to regulation of gene expression and apoptosis.

4. Bortezomib is a proteosome inhibitor used in patients with multiple myeloma.

a. Proteosomes are enzyme complexes that are responsible for degrading proteins that control the cell cycle.

b. Bortezomib is specific in that it interferes with the degradation of nuclear factor κβ (NF-κβ). NF-κβ is released from its inhibitory partner protein and moves to the nucleus. When the inhibitory partner does not degrade because of the action of bortezomib, NF-κβ is prevented from transcribing the genes that promote cancer growth.

5. Thalidomide and Lenolidomide are immunomodulatory agents with a variety of mechanisms of action. They work as angiogenesis inhibitors by interfering with the growth of new blood vessels needed for tumor growth and survival. They inhibit the production of tumor necrosis factor α (TNF-α) production, causes oxidative damage to DNA, and help stimulate human T cells. They can be used as treatment for multiple myeloma in combination with dexamethasone.

I. Hormones are a class of heterogeneous compounds that have a variety of effects on cells. Table 57-2 lists some of the most commonly used hormonal agents in cancer therapy.

J. Biological response modifiers alter or enhance the patient's immune system to fight cancer or to lessen the side effects of the cancer treatment. Examples are given in Table 57-3.

P.1249

Table 57-3. Biological Agents Used in Oncology

Agent	Indications	Toxicity
Cytokine		
Interferon-α -2a, -2b (Roferon-AR, Intron A)	Malignant melanoma, chronic myelogenous leukemia, hairy-cell leukemia, Kaposi sarcoma, chronic hepatitis B and C, follicular lymphoma	Flulike syndrome, anorexia, depression, fatigue
Interleukin 2 (aldesleukin, Proleukin)	Renal cell carcinoma, malignant melanoma	Chills, fever, dyspnea, pulmonary congestion, edema, nephrotoxicity, hypotension, mental status changes, anemia, thrombocytopenia, diarrhea, nausea and vomiting
Interleukin 11 (oprelvekin, Neumega)	Thrombocytopenia	Fluid retention, peripheral edema, dyspnea, tachycardia, atrial arrhythmias, dizziness, blurred vision
Filgrastim (G-CSF, Neupogen)	Decrease incidence/duration of neutropenia, hematopoietic stem-cell mobilization	Bone pain, fever, malaise
Pegfilgrastim (Neulasta)	Decrease incidence/duration of neutropenia	Bone pain, fever, malaise

Sargramostim (GM-CSF, Leukine)	Acceleration of myeloid recovery, BMT failure or engraftment delay, induction for acute myelogenous leukemia, hematopoietic stem cell mobilization, myeloid reconstitution after BMT	Bone pain, arthralgia/myalgia, chills, fever, rash, first-dose reaction (hypotension, tachycardia, dyspnea)
Epoetin α (erythropoietin, Epogen, Procrit)	Anemia associated with chronic renal failure, cancer chemotherapy or HIV treatments, reduction of blood transfusions in surgery patients	Hypertension, headache, arthralgias
Darbepoetin α (Aranesp)	Anemia associated with chronic renal failure, chronic renal insufficiency, cancer- and chemotherapy-associated anemia	Hypertension, myalgia, headache, fever, tachycardia, nausea
Monoclonal antibody		
Alemtuzumab (Campath R)	B cell chronic lymphocytic leukemia	Infusion-related fevers, chills, rash, hypotension, shortness of breath, nausea and vomiting, opportunistic infections, neutropenia, thrombocytopenia
Bevacizumab (Avastin R)	Metastatic colorectal cancer, non-small cell lung cancer (nonsquamous)	Hypertension, proteinuria, GI perforation, thrombotic events, impaired wound healing
Cetuximab (Erbitux R)	Metastatic colorectal cancer	Acneiform rash, infusion related reactions, fatigue,

		nausea and vomiting, diarrhea
Gemtuzumab ozogamicin (Mylotarg R)	Acute myeloid leukemia	Infusion-related fever, chills, nausea and vomiting, headache, hypotension, myelosuppression, hepatotoxicity, hypersensitivity
Ibritumomab tiuxetan (Zevalin R)	Non-Hodgkin lymphoma	Infusion-related fevers, chills, rigors, hypersensitivity, hypotension, myelosuppression
Panitumumab	EGFR-expressing, metastatic colorectal carcinoma with disease progression on or following fluoropyrimidine-, oxaliplatin-, and irinotecan-containing chemotherapy regimens.	Transient acneiform skin rash, erythema, dry skin, skin fissures/exfoliation, diarrhea
Rituximab (Rituxan R)	Non-Hodgkin lymphoma	Hypersensitivity, infusion-related fevers, chills, rigors, hypotension
Tositumomab (Bexxar R)	Non-Hodgkin lymphoma	Hypersensitivity reactions, fever, chills, myelosuppression, especially thrombocytopenia, rash, nausea and vomiting, diarrhea
Trastuzumab (Herceptin R)	Breast cancer	Infusion-related fevers, chills, cardiac

		dysfunction including dyspnea, cough, peripheral edema, nausea and vomiting, hypersensitivity, hypotension, diarrhea
Immunotoxin		
Denileukin diftitox (Ontak R)	Cutaneous T cell lymphoma	Acute hypersensitivity, including hypotension, dyspnea, rash, chest pain, tachycardia, vascular leak syndrome, dizziness, nausea and vomiting, diarrhea

BMT, bone marrow transplant; *G-CSF,* granulocyte colony-stimulating factor; *GI,* gastrointestinal; *GM-CSF,* granulocyte-macrophage colony-stimulating factor.

1. Cytokines are soluble factors secreted or released by cells that affect the activity of other cells and/or the secreting cell itself. These agents generally act as regulatory or hematopoietic growth factors.

2. Monoclonal antibodies are recombinant antibodies designed to identify cancer-specific antigens, bind to the antigens on the patient's cancer cells, and allow the patient's immune system to eliminate those cells.

a. Some monoclonal antibodies are being conjugated to antitumor agents or radioisotopes (e.g., gemtuzumab ozogamicin, ibritumomab tiuxetan) to help target cytotoxic therapy to the tumor cells.

b. Another example of a monoclonal antibody is bevacizumab, which targets and inhibits vascular endothelial growth factor (VEGF). VEGF is an important regulator of the growth and survival of blood vessels known as angiogenesis. Bevacizumab works by inhibiting angiogenesis and, therefore, inhibiting the blood supply to the tumor.

c. Other monoclonal antibodies are listed in Table 57-3.

3. Immunotoxins. Denileukin diftitox is a fusion protein composed of diphtheria toxin and interleukin 2 (IL-2). It is designed to direct the cytocidal action of diphtheria toxin to cells with the IL-2 receptor on their surface. This form of therapy

is able to bypass the need for a functioning immune system, which may be defective in many cancer patients.

V. TOXICITIES OF CHEMOTHERAPY AGENTS.

Chemotherapeutic agents are most toxic to rapidly proliferating cells. The tissues most commonly affected are those of the mucous membranes,

skin, hair, gastrointestinal (GI) tract, and bone marrow. Of these, bone marrow toxicity can be the most life-threatening.

A. Bone marrow suppression is the **most common** dose-limiting **side effect** of cancer therapy.

1. Complications

a. Infections. White blood cells are most affected owing to their short life span (6-12 hr).

(1) A significant decrease in the white blood cell count, particularly a neutrophil count < 500/mm^3 (**neutropenia**), predisposes the patient to development of serious infections.

(2) The usual signs and symptoms of infection may be absent, and fever may be the only indicator (**febrile neutropenia**).

(3) Colony-stimulating factors—for example, **granulocyte colony-stimulating factor (G-CSF) and granulocyte-macrophage colony-stimulating factor (GM-CSF)**—may be used to stimulate neutrophil production and lessen the degree and duration of neutropenia.

b. Bleeding. Platelets have an intermediate life span of 5-10 days. Decreased platelets (**thrombocytopenia**) can also occur from chemotherapy, which can lead to bleeding and may require platelet transfusions.

c. Anemia and **fatigue** secondary to cancer chemotherapy may also occur. It generally does not occur as quickly as other bone marrow toxicities because of the long life span of red blood cells (about 120 days). **Human recombinant erythropoietin** (e.g., epoetin α, darbepoetin α) may be used to increase hemoglobin, decrease transfusion requirements, and decrease fatigue.

2. The **time course** of myelosuppression varies with the chemotherapy regimen. In general, the onset of myelosuppression is 7-10 days after the chemotherapy has been administered. The lowest point of the counts, called the **nadir,** is usually reached in 10-14 days. Recovery of counts usually occurs in 2-3 weeks.

3. A patient's counts must be sufficiently **recovered** before receiving subsequent chemotherapy cycles. Generally, the neutrophil count must be > 1,500/mm^3 and the platelet count > 100,000/mm^3 before the patient receives additional chemotherapy.

4. The extent of myelosuppression is related to the **chemotherapy agents** used and **doses** given. Drugs that can cause severe myelosuppression include carmustine, cytarabine, daunorubicin, doxorubicin, and paclitaxel.

5. Some chemotherapy agents cause little or no myelosuppression. These include asparaginase, bleomycin, and vincristine.

B. Dermatological toxicity

1. Alopecia is the loss of hair associated with chemotherapy. Not all agents cause alopecia, and hair loss may be partial or complete. Chemotherapy agents that commonly cause alopecia include cyclophosphamide, doxorubicin, mechlorethamine, and paclitaxel.

2. Drugs associated with necrosis of tissue are called **vesicants. Local necrosis** may result from **extravasation** of vesicant chemotherapy drugs outside the vein during their administration. Vesicant agents include dactinomycin, daunorubicin, doxorubicin, idarubicin, mechlorethamine, mitomycin, vinblastine, vincristine, and vinorelbine.

a. Most vesicant extravasations produce **immediate pain** or **burning.** However, a delayed reaction may occur hours or weeks later. Significant tissue injury, including ulceration or necrosis, may require plastic surgery intervention.

b. The **treatment** of extravasations varies, depending on the vesicant. Heat or cold packs and chemicals such as hyaluronidase or dimethyl sulfoxide (DMSO) may be used.

3. Cancer chemotherapy can also cause **skin changes** such as dryness and sensitivity to sunlight. Examples are fluorouracil and methotrexate.

C. GI **toxicities** are frequently experienced by patients receiving chemotherapy.

1. Nausea and **vomiting** are often the most distressing toxicities from the patient's perspective. However, this side effect can generally be prevented, or better controlled, with the use of currently available antiemetics.

a. Severe vomiting can result in dehydration, electrolyte imbalances, and esophageal tears and may cause the patient to discontinue therapy.

b. Nausea and vomiting may be **acute, delayed,** or **anticipatory** in nature. Antiemetics should be used prophylactically to prevent the occurrence of nausea and vomiting, particularly with chemotherapeutic agents that have a high emetogenic risk.

c. Table 57-4 lists **commonly used chemotherapeutic agents** and their emetogenic potential on a scale of 1-5.

(1) The emetogenic potential of combinations of chemotherapy agents can be estimated by identifying the most emetogenic agent in the combination.

(2) The contribution of the other agents can then be evaluated by using the following guidelines:

(a) Level 1 agents do not contribute to the emetogenicity of the regimen.

(b) Adding one or more level 2 agents increases the emetogenicity to one level higher than the most emetogenic agent in the combination.

(b) Adding level 3 or 4 agents increases the level of emetogenicity by one level per agent.

d. The occurrence of nausea and vomiting is influenced by the emetogenicity of the chemotherapeutic agent or combination of agents, the chemotherapeutic dose, the method of administration, and individual patient characteristics.

2. Stomatitis is a generalized inflammation of the oral mucosa or other areas of the GI tract. Because of the rapid turnover of epithelial cells in the GI tract, this is a common site of toxicity.

a. Signs and **symptoms** include erythema, pain, dryness of the mouth, burning or tingling of the lips, ulcerations, and bleeding.

b. Chemotherapy agents associated with stomatitis include capecitabine, fluorouracil, and methotrexate.

c. Time course. Stomatitis usually appears within a week after the offending agent is administered, and resolves in 10-14 days.

d. Consequences of stomatitis include infection of the ulcerated areas, inability to eat, pain requiring opioid analgesics, and subsequent decreases in chemotherapy doses.

Table 57-4. Emetogenic Potential of Cancer Chemotherapeutic Agents

Level 5: Very Highly Emetogenic	Level 4: Highly Emetogenic	Level 3: Moderately Emetogenic	Level 2: Low Emetic Risk	Level 1: Very Low Emetic Risk
Carmustine > 250 mg/m^2 Cisplatin ≥ 50 mg/m^2 Cyclophosphamide ≥ 1500 mg/m^2 Dacarbazine Mechlorethamine Streptozocin	Carmustine ≤ 250 mg/m^2 Cisplatin < 50 mg/m^2 Cyclophosphamide 750-1500 mg/m^2 Cytarabine > 1000 mg/m^2 Dactinomycin Doxorubicin > 60 mg/m^2 Lomustine Melphalan (intravenous > 50 mg/m^2) Methotrexate > 1000 mg/m^2 Procarbazine Temozolomide Thiotepa ≥ 15 mg/m^2	Carboplatin Cyclophosphamide ≤ 750 mg/m^2 Cytarabine < 1000 mg/m^2 Daunorubicin Doxorubicin ≤ 60 mg/m^2 Idarubicin Ifosfamide Methotrexate 250-1000 mg/m^2 Mitoxantrone Temozolamide Melphalan > 50 mg/m^2	Docetaxel Etoposide Fluorouracil Gemcitabine Irinotecan Methotrexate 50-250 mg/m^2 Mitomycin Paclitaxel Thiotepa < 15 mg/m^2 Topotecan Pemetrexed	Asparaginase Bleomycin Capecitabine Chlorambucil Dasatinib Decitabine Erlotinib Gemtuzumab Hydroxyurea Lenalidomide Methotrexate ≤50mg/m^2 Melphalan (oral) Nelarabine Rituximab

				Sorafenib Sunitinib Thalidomide Thioguanine Trastuzumab Vinblastine Vincristine Vinorelbine

e. Topical and local analgesics in the form of mouthrinses are commonly used and can help with mouth and throat pain.

3. Other GI toxicities include **diarrhea** (e.g., irinotecan, fluorouracil), **constipation** (e.g., vincristine), **anorexia,** and **taste changes.**

D. Tumor lysis syndrome (TLS) may occur in hematological malignancies such as leukemia and lymphoma, in which there is a high tumor cell burden or rapidly growing tumors. Owing to the spontaneous lysis of cells from treatment with chemotherapy, cell lysis causes release of intracellular products, including uric acid, potassium, and phosphate, which can lead to renal failure and cardiac arrhythmias. This may be prevented by giving intravenous hydration, by alkalinizing the urine, and by giving agents such as **allopurinol** or **rasburicase** (Elitek) to decrease uric acid.

E. Hypercalcemia may occur in patients with solid or hematologic malignancies and can often be the presenting sign of malignancy. The major cause of hypercalcemia is increased osteoclastic bone resorption, which is generally caused by the release of parathyroid hormone-related protein (PTHrP) by the tumor cells. Common presenting symptoms include mental status changes, fatigue and muscle weakness, polyuria, polydipsia, nausea and vomiting. Treatment includes aggressive hydration with normal saline, calciuric therapy which consists of calcitonin, and bisphosphonates such as pamidronate (Aredia) or zoledronic acid (Zometa).

F. Chills and **fever** may occur after the administration of some chemotherapy and biological agents. This fever generally can be differentiated from fever owing to infection because of its temporal relationship to chemotherapy administration. This reaction is commonly associated with bleomycin, cytarabine monoclonal antibodies, and IL-2.

G. Pulmonary toxicity is generally irreversible and may be fatal.

1. Signs and **symptoms** are shortness of breath, nonproductive cough, and low-grade fever. In some cases, the risk of pulmonary toxicity increases as the cumulative dose of the drug increases (e.g., bleomycin).

2. Chemotherapeutic agents associated with pulmonary toxicity include bleomycin, busulfan, carmustine, and mitomycin.

H. Cardiac toxicity may manifest as an acute or chronic problem.

1. Acute changes are generally transient electrocardiograph abnormalities that may not be clinically significant.

2. Chronic cardiac toxicity is irreversible congestive heart failure. **Risk factors** include chest irradiation and high cumulative doses of cardiotoxic chemotherapy.

3. Chemotherapy agents that are associated with chronic cardiotoxicity include daunorubicin, doxorubicin, epirubicin, idarubicin, and mitoxantrone. **Dexrazoxane** is a cardioprotective agent that may be used with doxorubicin to help prevent or lessen its toxic effects to the heart.

I. Hypersensitivity reactions may occur with any chemotherapy agent. Life-threatening reactions, including anaphylaxis, appear to be more common with asparaginase, carboplatin, cisplatin, etoposide, paclitaxel, and teniposide.

J. Neurotoxicity may occur with systemic or intrathecal chemotherapy.

1. Vincristine is associated with **autonomic** and **peripheral** neuropathies. Patients may experience gait disturbances, numbness and tingling of hands and feet, and loss of deep-tendon reflexes. Intrathecal administration of vincristine results in fatal neurotoxicity.

2. Peripheral neuropathy and **ototoxicity** are common dose-limiting toxicities of cisplatin. **Sensory** neuropathies, causing tingling or numbing of the hands and feet, may be associated with capecitabine, oxaliplatin, and paclitaxel.

3. High doses of cytarabine may produce **cerebellar toxicity** that manifests initially as loss of eye-hand coordination and may progress to coma.

4. Arachnoiditis has been associated with intrathecal administration of cytarabine and methotrexate.

K. Hemorrhagic cystitis is a bladder toxicity that is seen most commonly after administration of cyclophosphamide and ifosfamide. **Acrolein,** a metabolite of these agents, is thought to cause a chemical irritation of the bladder mucosa, resulting in bleeding. Preventive measures include aggressive hydration with subsequent frequent urination, and the administration of the uroprotectant mesna. **Mesna** acts by binding to acrolein and preventing it from contacting the bladder mucosa.

L. Renal toxicity may manifest by elevations in serum creatinine and blood urea nitrogen (BUN) as well as electrolyte abnormalities. Nephrotoxicity is associated with cisplatin, ifosfamide, methotrexate, and streptozocin. Intravenous hydration is used to protect the kidneys from the nephrotoxic effects of cisplatin. Osmotic diuresis with mannitol may also help reduce the incidence of cisplatin nephrotoxicity.

M. Hepatotoxicity may manifest as elevated liver function tests, jaundice, or hepatitis. Asparaginase, cytarabine, mercaptopurine, and methotrexate are known to cause hepatic toxicity.

N. Secondary malignancies, such as solid tumors, lymphomas, and leukemias, may occur many years after chemotherapy or radiation. Antineoplastic agents known to possess a high carcinogenic risk include cyclophosphamide, etoposide, melphalan, and mechlorethamine.

O. Chemotherapy may cause **infertility,** which may be temporary or permanent. Cyclophosphamide, chlorambucil, mechlorethamine, melphalan, and procarbazine are associated with a significant incidence of infertility in males and females.

VI. OTHER THERAPEUTIC MODALITIES

A. Surgery may be diagnostic (biopsy, exploratory laparotomy, second-look) or therapeutic (tumor debulking or removal). Surgery is often combined with chemotherapy and/or radiation.

B. Radiation therapy involves high doses of ionizing radiation directed at the cancerous tissue. Radiation may be combined with surgery and/or chemotherapy. Depending on the area of the body being irradiated, **adverse reactions** may include stomatitis, nausea and vomiting, diarrhea, and myelosuppression.

C. Hematopoietic stem-cell transplantation involves intravenous infusion of stem cells from a compatible donor to a recipient following high-dose chemotherapy. It is used for treatment of diseases involving the bone marrow or immune system and to allow for administration of high-dose chemotherapy or radiation for tumors resistant to standard doses. Stem cells can be obtained from bone marrow or peripheral blood.

1. In **autologous** transplants, stem cells are obtained from the patient, preserved, and later reinfused into the same patient. **Allogeneic** transplants involve two separate individuals. Cells are obtained from a matched donor and then infused into a separate patient.

2. Transplant-related complications include hepatic venoocclusive disease (VOD), acute and chronic graft versus host disease (GVHD), infection, and pulmonary complications.

STUDY QUESTIONS

Directions for questions 1-14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The top four most commonly diagnosed cancers include all of the following *except*

(A) lung.

(B) prostate.

(C) colon and rectum.

(D) thyroid.

(E) breast.

View Answer***1. The answer is D[see].*****2. Which statement regarding phase-specific chemotherapeutic agents is correct? They**

(A) are most effective in one phase of the cell cycle.

(B) are effective in all phases of the cell cycle.

(C) are only effective in G_0 phase.

(D) include the alkylating agents.

(E) include the antitumor antibiotics.

View Answer***2. The answer is A[seeand].*****3. Body surface area (**BSA**) is used in calculating chemotherapy doses because**

(A) BSA is an indicator of tumor cell mass.

(B) BSA correlates with cardiac output.

(C) BSA correlates with gastrointestinal transit time.

(D) the National Cancer Institute requires that BSA be used.

(E) the U.S. Food and Drug Administration (FDA) requires that BSA be used.

View Answer***3. The answer is B[see].*****4. The rationale for combination chemotherapy includes all of the following *except***

(A) biochemical enhancement of effect.

(B) rescue of normal cells.

(C) overcoming or preventing resistance.

(D) biochemical nullification of effect.

(E) cytotoxic to both resting and dividing cells.

View Answer***4. The answer is D[see].*****5. All of the following chemotherapy agents can be administered intrathecally *except***

(A) methotrexate.

(B) cytarabine.

(C) hydrocortisone.

(D) thiotepa.

(E) vincristine.

View Answer***5. The answer is E[see].*****6. Which of the following chemotherapeutic agents is classified as an alkylating agent?**

(A) cyclophosphamide

(B) etoposide

(C) mechlorethamine

(D) paclitaxel

(E) cyclophosphamide and mechlorethamine

View Answer***6. The answer is E[see IV.A. 1].*****7. Which of the following chemotherapy agents acts by intercalation?**

(A) vincristine

(B) paclitaxel

(C) doxorubicin

(D) vincristine and paclitaxel

(E) topotecan

View Answer***7. The answer is C[see IV.B.1].*****8. How do antimetabolites exert their cytotoxic effect?**

(A) inhibiting DNA synthesis by sliding between DNA base pairs
(B) inhibiting RNA synthesis by sliding between RNA base pairs
(C) acting as false metabolites in the microtubules
(D) acting as false substitutions in the production of nucleic acids
(E) promoting microtubule assembly and stabilization

View Answer***8. The answer is D[see].*****9. All of the following chemotherapy agents work through affecting microtubule function *except***

(A) docetaxel.
(B) vinblastine.
(C) mitoxantrone.
(D) vincristine.
(E) vinorelbine.

View Answer***9. The answer is C[see].*****10. Hormonal agents that are useful in the treatment of cancer include**

(A) tamoxifen.
(B) prednisone.
(C) flutamide.
(D) tamoxifen and flutamide.
(E) tamoxifen, prednisone, and flutamide.

View Answer***10. The answer is E[see].***P.1256

11. When does the neutrophil nadir associated with chemotherapy agents generally occur?

(A) during administration of the chemotherapy
(B) 1-2 days after therapy
(C) 10-14 days after therapy
(D) 1 month after therapy
(E) when the platelet count begins to rise

View Answer***11. The answer is C[see].*****12. Stomatitis is characterized by all of the following signs and symptoms *except***

(A) headache.
(B) erythema.
(C) bleeding.
(D) ulcerations.
(E) dryness of mouth.

View Answer***12. The answer is A[see].*****13. Which of the following statements describes hemorrhagic cystitis? It**

(A) is caused by excretion of tumor cell breakdown products.
(B) is associated with ifosfamide or cyclophosphamide administration.
(C) is caused by the administration of mesna.
(D) can be prevented or treated with acrolein.
(E) can be treated with granulocyte colony-stimulating factor (G-CSF).

View Answer***13. The answer is B[see V.J].*****14. All of the following chemotherapy agents are vesicants *except***

(A) doxorubicin.
(B) mechlorethamine.
(C) vincristine.
(D) methotrexate.
(E) idarubicin.

View Answer***14. The answer is D[see].*****Directions for questions 15-19:** Each agent in this section is most closely associated with **one** of the following adverse effects. Each effect is used only **once.** Choose the **best** answer, **A-E.**

15. Vincristine

A cardiotoxicity
B hypersensitivity
C diarrhea
D gastrointestinal hemorrhage
E constipation

View Answer***15. The answer is E[see].*****16. Irinotecan**

A cardiotoxicity
B hypersensitivity
C diarrhea
D gastrointestinal hemorrhage
E constipation

View Answer***16. The answer is C[see].*****17. Doxorubicin**

A cardiotoxicity
B hypersensitivity
C diarrhea
D gastrointestinal hemorrhage
E constipation

View Answer***17. The answer is A[see].*****18. Paclitaxel**

A cardiotoxicity
B hypersensitivity
C diarrhea
D gastrointestinal hemorrhage
E constipation

View Answer***18. The answer is B[see].*****19. Bleomycin**

A cardiotoxicity
B hypersensitivity
C diarrhea
D gastrointestinal hemorrhage
E constipation

View Answer***19. The answer is D[see].*****Directions for questions 20-24:** Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

For questions 20-22: P.A. is a 60-year-old man who has recently been diagnosed with stage IIB lung cancer. After his case was evaluated, it was decided that he

would undergo surgical resection of the primary tumor and then receive chemotherapy with carboplatin and docetaxel.

20. What type of chemotherapy is P.A. receiving?

(A) adjuvant

(B) salvage

(C) neoadjuvant

View Answer***20. The answer is A[see].*****21. What side effects would you counsel P.A. about?**

(A) nausea and vomiting

(B) peripheral neuropathy

(C) hemorrhagic cystitis

(D) A and B

(E) B and C

View Answer***21. The answer is D[see].*****22. P.A. received carboplatin and docetaxel and has an appointment in clinic 1 week after completing chemotherapy to check his CBC and electrolytes. His WBC = 2.7, Polys = 12%, and Bands = 2%. What is P.A.'s ANC?**

(A) 324

(B) 54

(C) 378

(D) 2700

View Answer***22. The answer is C[see I.C.6].***P.1257

23. If P.A. has recurrence of his lung cancer after therapy with carboplatin and docetaxel, which targeted agent may be considered for second-line therapy?

(A) doxorubicin

(B) busulfan

(C) cyclophosphamide

(D) erlotinib

(E) bleomycin

View Answer***23. The answer is D[see].*****24. What side effects are associated with erlotinib use?**

(A) Acneiform rash

(B) Diarrhea

(C) Peripheral neuropathy

(D) A and B

(E) Hypertension

View Answer***24. The answer is D[see].***P.1258

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* I.B*].*

Prostate cancer is the most common cancer in men, breast cancer is the most common cancer in women, followed by lung, then colon and rectum for both men and women.

2. The answer is A *[see* II.D.1, 2 *and* 3*].*

Phase-specific agents are most active in one specific phase of the cell cycle. These agents have no activity against cells in G_0, the resting phase. Examples of phase-specific agents include the mitotic inhibitors, asparaginase, the antimetabolites, and etoposide.

3. The answer is B *[see* III.B*].*

BSA correlates with cardiac output, which determines renal and hepatic blood flow and thus affects drug elimination.

4. The answer is D *[see* III.D.2*].*

Combination chemotherapy has been developed to have maximal cytotoxicity to tumor cells and minimal toxicity to normal cells. The drugs are dosed and scheduled such that maximal cell kill occurs, while sparing normal cells as much as possible. Combination regimens often contain agents with different spectrums of toxicity.

5. The answer is E *[see* III.E.3*].*

Intrathecally administered vincristine is fatal. All syringes of vincristine must be labeled “Fatal if given intrathecally. For intravenous use only.”

6. The answer is E *[see IV.A. 1].*

Cyclophosphamide and mechlorethamine are nitrogen mustards, a subgroup of the alkylating agents. Etoposide is a topoisomerase II inhibitor, and paclitaxel is a mitotic inhibitor.

7. The answer is C *[see IV.B.1].*

Doxorubicin is an antitumor antibiotic that inhibits DNA synthesis by intercalation. Vincristine and paclitaxel are mitotic inhibitors that act on microtubule assembly. Topotecan inhibits topoisomerase I.

8. The answer is D *[see* IV.C*].*

Antimetabolites are structural analogs of naturally occurring substrates for biochemical reactions. They inhibit DNA synthesis by acting as false substitutions in the production of DNA.

9. The answer is C *[see* IV.D*].*

Docetaxel is a taxane, which works by promoting microtubule assembly and stabilization, resulting in inhibition of cell division. Vincristine, vinblastine, and vinorelbine are vinca alkaloids, which work by preventing microtubule formation. Mitoxantrone is an antitumor antibiotic, which works by DNA intercalation.

10. The answer is E *[see* VI; Table 57-2*].*

Tamoxifen is an antiestrogen used in the treatment of breast cancer. Prednisone is used for its antilymphocytic properties in the treatment of non-Hodgkin lymphoma. Flutamide is an antiandrogen used in the treatment of prostate cancer.

11. The answer is C *[see* V.A.2*].*

Bone marrow suppression, particularly of the neutrophils, usually is the most profound 10-14 days after chemotherapy.

12. The answer is A *[see* V.C.2*].*

Stomatitis, or mucositis, is an inflammation of the mucous membranes, particularly the oral mucosa. Although the symptoms generally are limited to the mouth and throat, stomatitis may affect any part of the gastrointestinal tract, potentially causing diarrhea and anal fissures.

13. The answer is B *[see V.J].*
Hemorrhagic cystitis results from irritation of the lining of the bladder by acrolein, a metabolite of ifosfamide and cyclophosphamide. Mesna may be used to inactivate the acrolein, thus preventing hemorrhagic cystitis.
14. The answer is D *[see* V.B.2*].*
Vesicant chemotherapy agents may cause local necrosis if extravasated outside the vein. Doxorubicin, idarubicin, mechlorethamine, and vincristine are all classified as vesicants.
15. The answer is E *[see* V.C.3; V.E-G*].*
16. The answer is C *[see* V.C.3; V.E-G*].*
17. The answer is A *[see* V.C.3; V.E-G*].*
18. The answer is B *[see* V.C.3; V.E-G*].*
19. The answer is D *[see* V.C.3; V.E-G*].*
Cardiotoxicity is associated with cumulative doses of doxorubicin and other antitumor antibiotics. Hypersensitivity from paclitaxel may be the result of its Cremophor diluent. Severe diarrhea, requiring treatment with atropine, is associated with irinotecan. Pulmonary toxicity is associated with cumulative doses of bleomycin. Severe constipation and paralytic ileus is associated with the use of vincristine.
20. The answer is A *[see* III.A.3*].*
Receiving chemotherapy after potentially curative surgery is known as adjuvant chemotherapy.
21. The answer is D *[see* Table 57-2*].*
Nausea and vomiting are common side effects of carboplatin and docetaxel. Premedications with anti-nausea medications are given before these chemotherapy agents are given. Peripheral neuropathy can commonly be seen with docetaxel. Patients need to be counseled about this and followed up on this adverse event on routine clinic visits. If left untreated severe, disabling neuropathy can result. Hemorrhagic cystitis is an adverse event of some of the alkylating agents including ifosfamide and cyclophosphamide, but not carboplatin.
22. The answer is C *[see I.C.6].*
The ANC is calculated by multiplying the WBC × the total neutrophils (segmented neutrophil% + segmented band %) × 10. 2.7 × (12% + 2%) × 10 = 378.
23. The answer is D *[see* IV.G*].*
Erlotinib is an agent targeted for the epidermal growth factor receptor tyrosine kinase. Busulfan and cyclophosphamide are alkylating agents that are non cell cycle specific. Bleomycin and doxorubicin are antitumor antibiotics that intercalate with DNA and are phase non-specific agents.

24. The answer is D *[see* Table 57-2*].*

Erlotinib can cause acnieform rash, diarrhea, nausea, pruritis, fatigue, and eye irritation.

58

Pain Management

Alan F. Kaul

I. INTRODUCTION

A. Definitions

1. Pain is an unpleasant sensory and emotional experience that is associated with actual or potential tissue damage or described in terms of such damage. It is a subjective, individual experience that has physical, psychological, and social determinants. There is no objective measurement of pain. In the United States alone, recurrent or persistent pain is experienced by more than 75 million individuals.

2. Acute pain lasts > 30 days and occurs after muscle strains and tissue injury, such as trauma or surgery. The pain is usually self-limiting, decreasing with time as the injury heals. It is described as a linear process, with a beginning and an end. Increased autonomic nervous system activity often accompanies acute pain, causing tachycardia, tachypnea, hypertension, diaphoresis, and mydriasis. Increased anxiety also may occur.

3. Chronic pain is persistent or episodic pain of a duration or intensity that adversely affects the function or well-being of the patient and can persist after the resolution of an injury. Some define it as lasting more than 6 months.

a. Chronic nonmalignant pain may be a complication of acute injury in which the healing process does not occur as expected or may be caused by a disease such as a rheumatological disorder (e.g., osteoarthritis, rheumatoid arthritis, fibromyalgia).

b. The elderly are more likely to experience chronic pain because of the increased prevalence of degenerative disorders in this age group.

c. The pain is constant, does not improve with time, and is described as a cyclic process (vicious circle).

d. Compared to acute pain, there is no longer autonomic nervous system stimulation so the patient may not appear to be in pain. Instead, the patient may be depressed; suffer insomnia, weight loss, and sexual dysfunction; and may not be able to cope with the normal activities of daily living, including family and job-related activities.

4. Chronic cancer pain occurs in 60%-90% of patients with cancer. Its characteristics are similar to those of chronic nonmalignant pain. In addition to depression, prominent characteristics are fear, anger, and agony. The cause of chronic cancer pain can be related to the tumor or cancer therapy or can be idiosyncratic. Tumor causes of pain include bone metastasis, compression of nerve structures, occlusion of blood vessels, obstruction of bowel, or infiltration of soft tissue.

5. Breakthrough pain is the intermittent, transitory increase in pain that occurs at a greater intensity over baseline chronic pain. It may have temporal characteristics, precipitating factors, and predictability.

6. Neuropathic pain is a result of an injury or malfunction of the nervous system. Excluding patients with a progressive peripheral neuropathy or neuropathic pain associated with a cancer lesion, tissue damage is not ongoing. Neuropathic pain is

described as aching, throbbing, burning, shooting, stinging and tenderness or sensitivity of the skin.

B. Principles of management

1. Comprehensive pain assessment should determine the characteristics of the patient's pain complaint, clinical status, and pain management history.

a. Assessment of the pain complaint should include chronology and symptomatology of the presenting complaint such as information about onset, location, intensity, duration, quality, distribution, provocative factors, temporal qualities, severity, and pain history.

b. Assessment of clinical status should include the extent of underlying trauma or disease. Also, the patient's physical, psychological, and social conditions should be determined.

c. Assessment of pain management history includes drug allergies, analgesic response, onset, duration, and side effects.

2. Appropriate pain management targets should be established.

a. The primary pain management goal is to improve patient comfort.

b. For acute pain management, improved comfort can aid the healing and rehabilitation process.

c. For chronic pain, the specific objectives are to break the pain cycle (i.e., erase pain memory) and minimize breakthrough pain.

d. Other targets for chronic pain management include improvement of general well-being, sleep, outlook, self-esteem, activities of daily living, support, and mobility.

3. Individualized pain management regimens should be determined and initiated promptly.

a. The optimal analgesic regimen, including dose, dosing interval, and mode of administration, should be selected.

b. Additional pharmacological adjuncts and nonpharmacological therapies should be added if needed.

c. The most common regimens for acute pain include intermittent (as needed) dosing, patient-controlled analgesia (PCA), or epidural infusions with narcotic or nonnarcotic agents.

d. Although the practice is controversial and often not in the best interests of patients, narcotic use is often minimized or avoided for chronic nonmalignant pain. Pain management specialists are changing this suboptimal practice. Nonnarcotic analgesics and nonpharmacological management usually are maximized.

e. For chronic cancer pain, an individualized around-the-clock analgesic regimen is established, using a long-acting analgesic. An intermittent, as-needed regimen for breakthrough pain, using a short-acting analgesic, is also determined.

4. Monitoring the pain management regimen and **reassessment** of the patient's pain should occur on a continuous, timely basis. Any changes in analgesic, dose, dosing interval, or method of administration should be noted in the patient's medical record and carried out in a timely fashion.

II. ANALGESICS

A. Nonnarcotic analgesics include aspirin; other salicylates; acetaminophen; nonsteroidal anti-inflammatory drugs (NSAIDs); selective, cyclooxygenase 2 (COX-2) inhibitors; disease-modifying antirheumatic drugs (DMARDs); and tumor-necrosis factor α (TNF-α) inhibitors (Table 58-1). Aspirin products, acetaminophen, and some low-dose NSAIDs such as ibuprofen, ketoprofen, and naproxen sodium are available as over-the-counter (OTC) products.

1. Mechanism of action. Salicylates and NSAIDs are prostaglandin inhibitors and prevent peripheral nociception by vasoactive substances such as prostaglandins and bradykinins. Most NSAIDs inhibit both COX-1, which produces prostaglandins that are believed to be cytoprotective of the stomach lining, and COX-2, which produces prostaglandins responsible for pain and inflammation. Selective COX-2 inhibitors like celecoxib do not inhibit COX-1. Adalimumab, etanercept, and infliximab act by binding or capturing excess TNF-α, one of the dominant cytokines, or proteins, that play an important role in the inflammatory response. The exact mechanism of action of leflunomide, a novel drug used to treat rheumatoid arthritis, is not completely known but it is thought to inhibit pyrimidine synthesis.

2. Therapeutic effects

a. The peripherally acting, nonnarcotic analgesics have several effects in common. These effects distinguish these agents from narcotic analgesics.

(1) They are antipyretic.

(2) They are anti-inflammatory (except acetaminophen).

(3) There is a ceiling effect to the analgesia.

(4) They do not cause tolerance.

(5) They do not cause physical or psychological dependence.

b. The efficacy of nonnarcotics is compared to aspirin. Most drugs are comparable to aspirin; however, several NSAIDs have shown a superior effect to 650 mg of aspirin.

Table 58-1. Nonnarcotic Oral Analgesics and Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

Drug	Adult Dose Range (mg)	Dosing Interval (hr)	Maximum Dose/Day (mg)
Para-aminophenol derivatives			
Acetaminophen (Tylenol)	325-1000	4-6	4000
Salicylates			
Aspirin	325-1000	4-6	4000
Choline magnesium trisalicylate (Trilisate)	1000-1500	12	3000
Diflunisal (Dolobid)	250-1000	8-12	1500
Salsalate (Disalcid)	500-1000	8	3000
Arylpropionic acid derivatives			
Fenoprofen (Nalfon)	200	4-6	3200
Flurbiprofen (Ansaid)	50-100	6-12	300
Ibuprofen (Motrin)	300-800	6-8	3200
Ketoprofen (Orudis)	12.5-75	6-8	300
Naproxen (Naprosyn)	200-500	12	1250
Naproxen sodium (Anaprox)	275-550	12	1375
Oxaprozin (Daypro)	600-1200	12	1200
Heteroaryl acetic acid derivatives			

Diclofenac (Voltaren)	25-75	6-12	200
Ketorolac (intramuscular) (Toradol)	15-60	6	120
Ketorolac (oral)	10	4-6	40
Tolmetin (Tolectin)	200-600	6-8	1800
Indole and indene acetic acid derivatives			
Etodolac (Lodine)	200-400	6-12	1200
Indomethacin (Indocin)	25-50	8-12	200
Sulindac (Clinoril)	150-200	12	400
Anthranilic acid derivatives (fenamates)			
Meclofenamate	50-100	4-6	400
Mefenamic acid (Ponstel)	250	6	1000
Alkanone derivatives			
Nabumetone (Relafen)	1000	12-24	2000
Enolic acid derivatives (oxicams)			
Piroxicam (Feldene)	20	24	20
Cyclooxygenase 2 (COX-2) selective inhibitors			

Celecoxib (Celebrex)	100-200	12-24	400
Disease-modifying antirheumatic drugs (DMARDs)			
Leflunomide (Arava)	20	24	20[a]
Biological response modifiers (tumor necrosis factor α inhibitors)			
Adalimumab (Humira)	40 SC injection	Every other week	TBD
Etanercept (Enbrel)	25 SC injection	Once weekly	50 SC injection
Infliximab (Remicade)	3/kg IV. infusion	Every 4-6 weeks	10/kg

[a] Excludes loading dose of 100 mg/day for 3 days.

IV, intravenous; *SC,* subcutaneous; *TBD,* to be determined.

(1) Diflunisal (500 mg)
(2) Ibuprofen (200-400 mg)
(3) Naproxen sodium (550 mg)
(4) Ketoprofen (25-50 mg)

c. The newer classes of drugs, in general, have not been compared to aspirin.

P.1263

3. Clinical use

a. Generally, the nonnarcotic analgesics are used orally to manage mild to moderate pain.

(1) They are particularly suited for acute pain of skeletal muscle (orthopedic) or oral (dental) origin.

(2) They are used to treat pain and inflammation associated with osteoarthritis and rheumatoid arthritis.

(3) They are used in chronic pain and can have an additive effect with narcotic analgesics.

(4) They also may be effective in managing pain owing to bone metastases.

b. The NSAID ketorolac is administered intramuscularly and is useful in moderate to severe pain, particularly in cases in which narcotics are undesirable (e.g., with drug addicts, excessive narcotic sedation, respiratory depression).

c. The NSAID diclofenal epolamine is available as a topical patch (Flector Patch®) for treatment of strains, sprains, and contusions. One patch is applied to the most painful area twice a day (should not be applied to damaged or non-intact skin).

d. Patients may vary in their response and tolerance to nonnarcotic analgesics. If a patient does not respond to the maximum therapeutic dose, then an alternate NSAID should be tried. Likewise, if a patient experiences side effects with one drug, then another agent should be tried.

e. Several drugs (e.g., diflunisal, choline magnesium trisalicylate, naproxen, celecoxib, leflunomide, etanercept, infliximab, and adalimumab) have long half-lives and, therefore, may be administered less frequently.

f. The cost of nonnarcotic analgesics is highly variable and should be considered when an agent is selected. Pharmacotherapy with the COX-2 inhibitor celecoxib, the newer DMARDs like leflunomide or TNF-α inhibitors is significantly more expensive than older agents.

4. Adverse effects

a. Gastrointestinal (GI) effects. Most nonnarcotic analgesics cause GI symptoms secondary to prostaglandin inhibition. At normal doses, acetaminophen and choline magnesium trisalicylate produce minimal GI upset. Because of their mechanism of action, the COX-2 inhibitors have a GI toxicity similar to placebo. Adalimumab, etanercept, infliximab, and leflunomide have been associated with GI side effects including nausea, abdominal pain, dyspepsia, constipation, vomiting, hematochezia, intestinal obduction, intestinal perforation, pancreatitis, peritonitis, peptic ulcer, and diarrhea.

(1) The most common GI symptom is dyspepsia, but ulceration, bleeding, or perforation can occur.

(2) Patients most predisposed to severe GI effects include the elderly, patients with a history of ulcers or chronic disease, and those who smoke or use alcohol.

(3) To minimize GI effects, the lowest possible analgesic dose should be used. Aspirin, available as enteric-coated products, may minimize GI upset. Combination therapy with a GI "protectant" (e.g., antacid, H_2-antagonist, sucralfate, misoprostol) may be needed.

b. Hematological effects. Most nonnarcotic analgesics inhibit platelet aggregation. The effect is produced by reversible inhibition of prostaglandin synthetase. Aspirin is an irreversible inhibitor. Acetaminophen and choline magnesium trisalicylate lack antiplatelet effects. TNF-α inhibitors have been associated with anemia, aplastic anemia, leukopenia, neutropenia, pancytopenia, and thrombocytopenia. Leflunomide has been associated with anemia and ecchymosis.

(1) The effect of the NSAIDs correlates to the presence of an effective serum concentration.

(2) Use of anticoagulants (e.g., heparin, warfarin [Coumadin] is relatively contraindicated in combination with aspirin or NSAIDs.

c. Renal effects. NSAIDs can produce renal dysfunction. Etanercept has not been shown to affect renal function.

(1) The mechanism of NSAID-induced renal dysfunction includes prostaglandin inhibition, interstitial nephritis, impaired renin secretion, and enhanced tubular water/sodium reabsorption.

(2) Many risk factors have been implicated, including congestive heart failure (CHF), chronic renal failure (CRF), cirrhosis, dehydration, diuretic use, and atherosclerotic disease in elderly patients.

(3) Renal dysfunction is commonly manifested as abrupt onset oliguria with sodium/water retention. The effect reverses after discontinuation of the NSAID.

d. Malignancies and lymphoproliferative disorders

Agents that block TNF may affect host defenses against malignancies because TNF mediates inflammation and modulates cellular immune response. Lymphomas have occurred more frequently in patients receiving TNF-blocking agents than in controls.

e. Infections. Opportunistic and serious infections leading to sepsis and death have been associated with leflunomide and the TNF-blocking agents.

f. Miscellaneous effects

(1) Even in normal doses, acetaminophen can cause hepatotoxicity in patients with liver disease or chronic alcoholism. Hepatotoxicity has also been reported with the use of all NSAIDs including the COX-2 selective inhibitors. Leflunomide and infliximab have also been shown to cause transient elevations in liver function tests such as aspartate aminotransferase (AST)—serum glutamic-oxaloacetic transaminase (SGOT)—and alanine aminotransferase (ALT)—serum glutamic-pyruvic transaminase (SGPT)

(2) Some patients exhibit acute hypersensitivity reactions to aspirin. Manifestations include either a rhinitis or asthma presentation or a true allergic reaction (e.g., urticaria, wheals, hypotension, shock, syncope). A cross-sensitivity to other NSAIDs may develop.

(3) Some NSAIDs produce central nervous system (CNS) effects, including impaired mentation, headaches, and attention deficit disorder.

(4) Leflunomide has received a **black box warning** because of its Category X pregnancy warning. It has also been associated with weight loss, alopecia, rash, and anemia.

(5) TNF-blocking agents have been associated with reactions at the injection site and autoantibody production.

(6) As of April 2005, the U.S. Food and Drug Administration (FDA) issued a **black box warning** for celecoxib, a selective COX-2 inhibitor, because if its link to an increased risk for cardiovascular events (heart attack and stroke) This increased risk has been demonstrated to be a drug class effect for all NSAIDs, excluding aspirin. Celecoxib is also contraindicated in patients with sulfonamide allergy.

5. Drug interactions. Salicylates have two clinically significant drug interactions.

a. Oral anticoagulants. Aspirin should be carefully monitored, if used, in anticoagulated patients because it inhibits platelet function and can cause gastric mucosal damage. This can significantly increase the risk of bleeding in anticoagulated patients. Also, doses of > 3 g/day of aspirin produces hypoprothrombinemia. Choline magnesium trisalicylate or acetaminophen can be used if a nonnarcotic is needed in an anticoagulated patient.

b. Methotrexate. Salicylates may enhance the toxicity of methotrexate. The primary mechanism is blockage of methotrexate renal tubular secretion by salicylates. The resultant methotrexate toxicity has been reported as pancytopenia or hepatotoxicity. Salicylates should be avoided in patients receiving methotrexate.

c. TNF-blocking agents. Anakinra (Kineret), a recombinant interleukin 1 (IL-1) receptor antagonist, has been observed to cause an increased risk of serious infections as neutropenia when used concomitantly with etanercept in patients with rheumatoid arthritis. Consequently, its use is not recommended concomitantly with any TNF-blocking agent.

B. Narcotic analgesics include the opioid drugs (Table 58-2). Because of their abuse potential, opioids are classified as controlled drugs. Special regulations control their prescribing.

1. Mechanism of action

a. Endogenous opiates afford the body self-pain-relieving mechanisms. These endogenous peptides include the endorphins, enkephalins, and dynorphins.

b. Exogenous opiates are classified as agonists (stimulate opiate receptors), antagonists (displace agonists from opiate receptors), and mixed opiates (agonist-antagonist or partial agonist actions).

c. Opiate receptors are located in the brain and spinal cord. Several types of opiate receptors have been identified, including μ, κ, δ, σ, and ε.

d. Stimulation of μ receptors produces the characteristic narcotic (morphine-like) effects.

(1) Analgesia

(2) Miosis

(3) Euphoria

(4) Respiratory depression

(5) Sedation

Table 58-2. Some Commonly Used Opioid Analgesics

Drug	Parenteral Dose (mg)[a]	Oral Dose (mg)[a]	Duration (hr)
Morphine	10	60	4-7
Morphine (CR) (MS Contin)	n/a	n/a	12-24
Hydromorphone (Dilaudid)	1.3	7.5	4-6
Oxymorphone (Numorphan)	1	—	4-6
Levorphanol (Levo-Dromoran)	2	4	4-7
Methadone (Dolophine)	10	20	4-6
Meperidine (Demerol)	75	300	3-6
Fentanyl (Sublimaze)	0.1	—	1-2
Fentanyl transdermal (Duragesic)	n/a	n/a	48-72
Codeine	130	200	4-6
Hydrocodone[b]	—	5-10	4-5
Dihydrocodeine[b]	—	32	4-5
Oxycodone[b]	—	5-10	4-5
Oxycodone (CR) (OxyContin)		n/a	12-24
Propoxyphene (Darvon)	—	65-100	4-6

Nalbuphine (Nubain)	10	—	4-6
Butorphanol (Stadol)	2	—	4-6
Dezocine (Dalgan)	10	—	4-7

[a] Doses equivalent to 10 mg intramuscular or subcutaneous morphine

[b] Doses for moderate pain not necessarily equivalent to 10 mg morphine.

CR, controlled release; *n/a*, not applicable.

(6) Physical dependence

(7) Bradycardia

e. The specific mechanism (central and spinal) of opiate agonist is alteration of the effects of nociceptive neurotransmitters, possibly norepinephrine or serotonin.

2. Clinical use

a. Opioid analgesics are used for the management of moderate to severe pain (acute or chronic pain) of somatic or visceral origin.

b. The use of narcotics should be individualized for each patient. The optimal analgesic dose varies from patient to patient. Each analgesic regimen should be titrated by increasing the dose up to the appearance of limiting adverse effects. Changing to another analgesic should occur only after an adequate therapeutic trial.

c. The appropriate route of administration should be selected for each patient.

(1) Oral administration is the preferred route, particularly for patients with chronic, stable pain. Controlled-release morphine and oxycodone tablets are available for convenience in controlling continuous pain, particularly in those patients with cancer.

(2) Intramuscular and subcutaneous administration are very commonly used in the postoperative period. Fluctuations in absorption may occur, particularly in elderly or cachectic patients.

(3) Intravenous (IV) bolus administration has the most rapid, predictable onset of effect.

(4) IV infusion is used to titrate pain relief rapidly, particularly in patients with unstable chronic pain. Morphine is most commonly used, often with supplemental IV bolus doses for breakthrough pain. A mechanical infusion device is necessary.

(5) IV PCA is most often used for acute postoperative pain. It produces prompt analgesia with minimal side effects because small doses (e.g., 1-2 mg morphine) are delivered at frequent intervals (e.g., every 10 min). It allows patient control of pain management. Morphine and meperidine are the most commonly used agents. A mechanical infusion device and properly trained patient and staff are necessary.

(6) Epidural and **intrathecal administration** are used for acute postoperative pain and early management of chronic cancer pain. All drugs used epidurally or intrathecally must be preservative free because of the neurotoxicity of parabens and benzyl alcohol when administered via these routes. Intrathecal doses are generally 1/10 of the corresponding drug's epidural dose.

Table 58-3. Epidurally Administered Preservative-Free Opioids: Intermittent Dosing

Drug	Dose (mg)	Onset of Action (min)	Time to Peak Effect (min)	Duration of Action (hr)
Morphine	5-10	25	60	12-24
Fentanyl	0.1	5-10	20	6
Meperidine	50-100	5-10	15-30	7
Hydromorphone	1	10-15	20	12
Buprenorphine (Subutex)	0.3	30	40-60	8-9

(a) Low opiate doses stimulate spinal opiate receptors and reduce the amount of narcotic reaching the brain. This results in delayed or minimal effects such as sedation, nausea, and respiratory depression. The opiate distribution that causes such effects depends on the site of spinal injection, water solubility of the opiate, and volume infused. For example, after lumbar administration of a more water-soluble opiate (morphine), severe respiratory depression can be observed 12-24 hr after initial dosing.

(b) Local side effects of intrathecal opiate administration are itching and urinary retention. Depending on the opiate used and the type of pain being treated, intermittent doses or continuous infusions (via a mechanical infusion device) can be used (Tables 58-3 and 58-4).

(7) Rectal administration is an alternative for patients unable to take oral narcotics. Generally, poor absorption results in an unreliable analgesic response. It is an unacceptable route of administration for many patients.

(8) Transdermal administration is an alternative for patients with chronic pain who are unable to take oral narcotics. A controlled-release patch is available for fentanyl. Slow onset requires additional analgesia when starting treatment. The duration of analgesia is 48-72 hr per patch. A slow reduction of effect follows removal of the patch and requires 24-36 hr of monitoring.

d. Patients who have chronic pain or acute pain that is constant throughout the day should receive regularly scheduled (around-the-clock) doses of narcotics.

(1) Long-acting opiates (e.g., controlled-release morphine and oxycodone) are preferable.

(2) A supplement given as needed may be necessary to manage breakthrough pain, for which short-acting opiates (e.g., immediate-release morphine, hydromorphone) are preferable. If frequent supplements are required, then the around-the-clock regimen should be adjusted based on morphine equivalents (Table 58-2).

e. Although the analgesia and side effects of opiates are qualitatively similar, individual patients may respond differently. Analgesic selection is based on:

(1) Patient's past analgesia experience

(2) Need for a rapid onset of effect

(3) Preference for a long (or short) duration of action

(4) Preference for a particular mode of delivery

(5) Preference for a particular dosage form

(a) Controlled-release morphine or oxycodone for a long duration of action (8-12 hr) may be preferable to opiates with long half-lives (e.g., methadone, levorphanol), which can accumulate and cause overdose symptoms (e.g., respiratory depression).

Table 58-4. Epidurally Administered Preservative-Free Opioids: Continuous Infusion

Drug	Initial Bolus Dose (mg)	Infusion Concentration (mg/mL)	Rate (mg/hr)
Morphine	2	0.05-0.25	0.2-1.5
Fentanyl	0.05-0.1	0.005-0.025	0.02-0.15
Meperidine	50-100	10-20	5-20
Hydromorphone	0.5-1	0.02-0.05	0.15-0.3

(b) Transdermal fentanyl can be used for patients who are unable to swallow.

(c) Rectal suppositories can be used for patients who are unable to swallow. They are available for morphine, hydromorphone, and oxymorphone.
(d) Concentrated hydromorphone injection (10 mg/mL) can be used for cachectic patients who require subcutaneous injections and in patients whose injection volumes must be minimized.
(6) Individual sensitivity to side effects, which includes nausea, euphoria, sedation, and respiratory depression
(a) Partial agonists or mixed agonist-antagonists may be preferable for acute pain management in patients at risk for respiratory depression secondary to opiate agonists. These agents should not be used in patients who have received chronic doses of opiates because withdrawal symptoms will occur.
(b) Epidural administration may be preferable for critically ill patients at risk for respiratory depression secondary to systemic narcotic administration.
3. Adverse effects. All narcotics can produce a variety of side effects that range from bothersome to life-threatening.
a. Constipation occurs as a result of decreased intestinal tone and peristalsis. There is a patient variability, but generally most patients experience constipation after several days of therapy. Constipation may be more bothersome with certain types of opiates (e.g., codeine). It may occur sooner and be more problematic in hospitalized or bedridden patients or in patients who have received anesthesia or drugs with anticholinergic effects. Prophylaxis with a laxative/stool softener combination (e.g., bisacodyl/docusate (Gentlax-S) and dietary counseling are warranted for patients who need chronic opiate therapy.
b. Nausea and **vomiting** occur owing to central stimulation of the chemoreceptor trigger zone. It is more problematic with one-time or intermittent parenteral dosing for acute pain. Occasionally, patients require concomitant therapy with an antiemetic (e.g., hydroxyzine, prochlorperazine); however, these agents may add to the sedative effects of opiates.
c. Sedation is a dose-related effect but sometimes is enhanced by concomitant use of other drugs with sedating effects (e.g., benzodiazepines, antiemetics). Most chronic pain patients become tolerant to this effect, but occasionally the addition of a CNS stimulant, such as dextroamphetamine or methylphenidate, is needed.
(1) Patients starting therapy with narcotics should be warned about driving or operating machinery.
(2) Sedation may be a sign of excessive dosing or accumulation. However, sedation should not be confused with physiological sleep in patients who have pain-control difficulties. Patients in pain often develop insomnia. When pain is brought under control by appropriate narcotic titration, the patient initially may sleep for several hours.
d. Respiratory depression is the most serious adverse effect accompanying narcotic overdose. Respiratory depression may be a sign of an excessive dose, accumulation of long half-lived opiates (e.g., methadone, levorphanol), or accumulation of active morphine metabolites in renal failure patients.

(1) Respiratory rate should be carefully monitored in patients receiving IV or epidural opiates, in neonates, in elderly patients, and in patients receiving other drugs that cause respiratory depression.
(2) The opiate antagonists, naloxone and nalmefene, are administered intravenously to reverse life-threatening respiratory depression. Use of naloxone or nalmefene (Revex) in an opiate-dependent patient (e.g., a chronic cancer pain patient) can precipitate opiate withdrawal.
e. Anticholinergic effects, such as dry mouth and urinary retention, can be bothersome for some patients.
f. Hypersensitivity reactions, such as itching owing to histamine release, can occur secondary to opiate use, particularly with epidural or intrathecal administration. Wheals sometimes occur at the site of morphine injection. These reactions do not represent true allergy.
g. CNS excitation, such as myoclonus and other seizure-like activity, can be produced with the use of meperidine in renal failure. These symptoms have also been observed in patients with normal renal functions who receive high doses of meperidine (e.g., < 800 mg/day of intramuscular meperidine). The accumulation of the metabolite normeperidine is the cause.
P.1268

4. Drug interactions
a. Narcotics have additive CNS depressant effects when used in combination with other drugs that also are CNS depressants (e.g., alcohol, anesthetics, antidepressants, antihistamines, barbiturates, benzodiazepines, phenothiazines).
b. Narcotics, particularly meperidine, can cause severe reactions such as excitation, sweating, rigidity, and hypertension in patients receiving monoamine oxidase (MAO) inhibitors. Meperidine should be avoided and other narcotics started at lower doses in patients being treated with MAO inhibitors.
5. Tolerance means that increasing doses of opiate are needed to maintain analgesia. Tolerance usually develops to the analgesic, sedative, and euphoric effects of opioids, but not to the pupillary-constricting and constipating effects. This is usually observed as a decreasing duration of analgesia in chronic pain patients. The addition of an NSAID may help delay or provide adequate analgesia in tolerant patients.
6. Dependence. The use of opiates for chronic pain may result in physical dependence, such that the abrupt discontinuation of the opiate results in the development of withdrawal symptoms.
a. Withdrawal symptoms include anxiety, irritability, insomnia, chills, salivation, rhinorrhea, diaphoresis, nausea, vomiting, GI cramping and diarrhea, and piloerection.
(1) The appearance and intensity of withdrawal symptoms vary according to the half-life of the opiate. For example, the withdrawal symptoms after discontinuation of chronic methadone may take several days to develop and may be less intense than those of withdrawal from morphine owing to its shorter half-life.

(2) The development of tolerance may be associated with withdrawal symptoms.
(3) The use of naloxone or a partial agonist-antagonist such as pentazocine in a patient receiving chronic opiate therapy produces acute withdrawal.
b. The development of physical dependence seen in chronic pain patients is not the same as psychological dependence or addiction. Also, the drug-seeking behavior observed in many acute pain patients (i.e., from postoperative pain) is not a sign of addiction, but rather a need for adequate pain relief. Studies suggest that the addictive rates for long-term treatment of noncancer pain are low in patients without a prior history of addiction. The analgesic needs of this type of patient should be reassessed and usually necessitates increasing the dose of opiate, changing to a longer duration drug, changing to a PCA, or adding an analgesic adjunct.
C. Tramadol (Ultram) is an oral, centrally acting analgesic with weak opiate activity. It has not been placed in a controlled drug schedule.
1. Mechanism of action
a. Tramadol is a synthetic aminocyclohexanol that binds to opiate receptors, inhibiting norepinephrine and serotonin.
b. The analgesic effects are partially antagonized by naloxone.
2. Clinical use
a. Tramadol is used for moderate to moderately severe pain.
b. The recommended dosage is 50-100 mg every 4-6 hr, up to a maximum of 400 mg/day.
c. At maximum dosage, tramadol appears no more effective than acetaminophen-codeine combinations.
3. Adverse effects
a. GI **effects** include nausea, constipation, and dry mouth.
b. CNS effects include dizziness, headache, sedation, and seizures (overdose).
c. Diaphoresis
4. Drug interactions
a. Tramadol can increase the sedative effect of alcohol and hypnotics.
b. Tramadol inhibits monoamine uptake and should not be used with MAO inhibitors.
c. Tramadol used with selective serotonin reuptake inhibitors (SSRIs) and other agents that increase serotonergic activity can cause “serotonin syndrome,” which is characterized by irritability, anxiety, CNS excitation, and myoclonus.
D. Adjuvant analgesics
Adjuvant analgesics are drugs whose initial FDA approved indication was for a condition other than pain. Other classes of drugs affect nonopiate pain pathways and may be useful in certain types of pain (e.g., neuropathic pain). These drugs often are used with other analgesics and some may help manage narcotic side effects (Table 58-5).

Table 58-5. Analgesic Adjuncts

Class	Drugs	Indications
Tricyclic antidepressants	Amitriptyline (Elavil), desipramine (Norpramin), doxepin (Sinequan), imipramine (Tofranil)	Neurogenic pain; chronic pain complicated by depression or insomnia
Anticonvulsants	Gabapentin (Neurontin), pregabalin (Lyrica), carbamazepine (Tegretol), clonazepam (Klonopin), phenytoin (Dilantin), valproate (Depakote),	Lancinating neurogenic pain (e.g., trigeminal neuralgia, phantom limb pain, post-trauma neurogenic pain)
Neuroleptics	Fluphenazine (Prolixin), haloperidol (Haldol), prochlorperazine (Compazine)	Refractory neurogenic pain; pain complicated by delirium or nausea (prochlorperazine)
Corticosteroid	Dexamethasone (Decadron)	Pain from neural infiltration; pain associated with bony metastases
Antihistamine	Hydroxyzine (Atarax, Vistaril)	Pain complicated by anxiety or nausea
Benzodiazepines	Alprazolam (Xanax), lorazepam (Ativan)	Pain complicated by anxiety or muscle spasm
Amphetamines	Dextroamphetamine (Dexedrine), methylphenidate (Ritalin)	For excessive opiate-induced sedation in chronic pain patients

1. Neuropathic pain agents include anticonvulsants (e.g., gabapentin, pregabalin, lamotrigine, carbamazepine), systemic local anesthetic agents—for example, 5% lidocaine (Lidoderm) patch—and tricyclic antidepressants—such as, amitriptyline, nortriptyline, and desipramine. Gabapentin and systemic local anesthetic agents are considered first-line therapy in treating polyneuropathies.

a. Mechanism of action.

(1) Gabapentin and pregabalin may relieve neuropathic pain by the presynaptic binding of the α-2-δ subunit of voltage-sensitive calcium channels.

(2) Pregabalin may also modulate the release of the sensory neuropeptide substance P.
(3) Lamotrigine and carbamazepine are believed to block sodium channels at the site of ectopic discharge of damaged nerves.
(4) The use of local anesthetics allows for local pain relief without systemic toxicity, specifically by binding to the sodium channels in the damaged nerves.
(1) It is hypothesized that TCAs obtain their analgesic effects as a result of sodium channel blockade at the site of ectopic discharge in the peripheral nerves.
(6) All of these agents are recommended to aid in the reduction of neuronal hyperexcitability, whether it is peripherally or centrally.

b. Clinical use

(1) Data are available to give guidance on which agents to use to treat neuropathic pain, but they do not predict which agent will provide relief for each individual patient's pain.
(2) Typically, a **treatment algorithm** may recommend:

(a) First line

(i) Gabapentin
(ii) Pregabalin
(iii) 5% lidocaine patches
(iv) TCAs

(b) Second line

(i) Other anticonvulsants (lamotrigine or carbamazepine)
(ii) Other antidepressants (bupropion, citalopram, paroxetine, venlafaxine, imipramine)

(c) Other

(i) Capsaicin, clonidine

c. Adverse effects. the most common adverse events associated with anticonvulsants are dizziness, headaches, and drowsiness. Lamotrigine has been associated with the development of Stevens-Johnson syndrome (SJS). It is recommended that lamotrigine be titrated up every 2 weeks to minimize the occurrence of SJS.

E. Miscellaneous agents

1. Capsaicin, a component of red peppers, causes the release of substance P from sensory nerve fibers, resulting in prolonged cutaneous pain transmission, histamine release, and erythema because of reflex vasodilation. Repeated local application depletes the peripheral sensory C-nerve fiber of substance P, resulting in pain inhibition. Topical capsaicin cream 0.025% or 0.075% has been shown to be useful in treating joint pain and tenderness in patients with arthritis. Other uses may include treating diabetic neuralgia, reflex sympathetic dystrophy, trigeminal neuralgia, notalgia paresthetica, psoriasis and psoralen (P), and long-wave ultraviolet radiation (UVA) induced skin pain, and postherpetic neuralgia. Local

toxicity may include burning, stinging, erythema, pruritus, and superficial skin ulcers.

2. Glucosamine sulfate and chondroitin sulfate have been used with increasing frequency in the treatment of degenerative joint disease. Glucosamine sulfate appears to act as a substrate for and stimulant to the biosynthesis of glucosaminoglycans and hyaluronic acid for forming proteoglycans found in the structural matrix of joints. Chondroitin sulfate provides additional substrates for the formation of healthy joint matrix. Short-term side effects associated with glucosamine include GI problems, drowsiness, skin reactions, and headache. Further research is needed to validate their roles.

F. Nonpharmacological pain management. Other therapeutic modalities for pain management include cognitive behavioral interventions and physical methods. These modalities are appropriate for interested patients, patients experiencing anxiety with their pain, patients who have incomplete relief from analgesic therapy, and patients who need to avoid or reduce analgesic use (e.g., those with chronic nonmalignant pain).

1. Cognitive behavioral interventions include education and instruction, simple relaxation, biofeedback, and hypnosis.

2. Physical methods include acupuncture, physical therapy, compression gloves, orthotic devices, heat and cold applications, massage, exercise, rest, immobilization, and transcutaneous electrical nerve stimulation (TENS).

STUDY QUESTIONS

Directions for questions 1-7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. An emaciated 69-year-old man with advanced inoperable throat cancer is hospitalized for pain management. He is receiving a morphine solution (40 mg orally) every 3 hr for pain. He complains of dysphagia and the frequency with which he must take morphine. An appropriate analgesic alternative for this patient would be

(A) changing to a controlled-release oral morphine.

(B) increasing the dose of the oral morphine solution.

(C) changing to intramuscular methadone.

(D) changing to transdermal fentanyl.

(E) decreasing the frequency of oral morphine administration.

View Answer***1. The answer is D[see].*****For questions 2-3:** A 52-year-old woman with a diagnosis of ovarian cancer presents with complaints of pain. Her pain was reasonably well controlled with two capsules of oxycodone every 4 hr until 2 weeks ago, at which point she was hospitalized for pain control. She was placed on meperidine (75 mg) every 3 hr but still complained about pain. Her meperidine dosage was increased to 100 mg every 2 hr.

2. At this dosage of meperidine, the patient is likely to experience

(A) excellent pain relief.

(B) respiratory depression.

(C) worsening renal function.

(D) myoclonic seizures.

(E) excessive sedation.

View Answer***2. The answer is D[see].*****3. An appropriate next step in this patient's therapy would be to**

(A) add a nonsteroidal anti-inflammatory drug (NSAID).

(B) discontinue the meperidine and convert her to a controlled-release oral morphine or oxycodone.

(C) continue the present meperidine dosage because she will eventually get relief.

(D) decrease the meperidine dose to avoid side effects.

(E) consider hypnosis or relaxation techniques.

View Answer***3. The answer is B[see].*****4. A 20-year-old victim of a motor vehicle accident is 3 days postsurgery for orthopedic and internal injuries. He has been in severe pain and was placed on a regimen of intramuscular morphine (5-10 mg) every 4 hr as needed for pain. A pain consultant starts the patient with a 20-mg intravenous morphine loading dose and then begins a continuous intravenous morphine infusion with as-needed morphine boosters. About 2 hr after this regimen is started, the patient is asleep. The nurse is concerned and calls the physician. The physician should**

(A) call for a psychiatric consult.

(B) administer naloxone.

(C) examine the patient and reconfirm the dosage and monitoring parameters.

(D) add an injectable nonsteroidal anti-inflammatory drug (NSAID).

(E) add an amphetamine.

View Answer***4. The answer is C[see].***P.1272

5. Potential adverse effects associated with aspirin include all of the following *except*

(A) gastrointestinal ulceration.

(B) renal dysfunction.

(C) enhanced methotrexate toxicity.

(D) cardiac arrhythmias.

(E) hypersensitivity asthma.

View Answer***5. The answer is D[see].*****6. All of the following facts are true about nonsteroidal anti-inflammatory drugs (NSAIDs) *except* which one?**

(A) They are antipyretic.

(B) There is a ceiling effect to their analgesia.

(C) They can cause tolerance.

(D) They do not cause dependence.

(E) They are anti-inflammatory.

View Answer***6. The answer is C[see].*****7. Which of the following narcotics has the longest duration of effect?**

(A) methadone

(B) controlled-release morphine

(C) levorphanol

(D) transdermal fentanyl

(E) dihydromorphone

View Answer***7. The answer is D[see].*****Directions for questions 8-10:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

8. Agents that are safe to use in a patient with bleeding problems include

(I) choline magnesium trisalicylate

(II) acetaminophen

(III) ketorolac

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***8. The answer is C(I, II) [see].*****9. Which of the following drugs bind or capture excess TNF-α?**

(I) adalimumab

(II) etanercept

(III) leflunomide

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***9. The answer is C(I, II) [see].*****10. Leflunomide has been associated with**

(I) diarrhea.

(II) alopecia.

(III) anemia.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***10. The answer is E(I, II, III) [see].***P.1273

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* II.B.2.c.(8)*].*

Patients with throat cancer often cannot take oral analgesics. The patient described in the question is also having pain difficulties with an every 3-hr regimen. Transdermal fentanyl is a good alternative because, after titration, excellent analgesia can be produced without using oral or parenteral agents. Also, the frequency of analgesic use may be decreased when titration has occurred.

2. The answer is D *[see* II.B.3.g*].*

3. The answer is B *[see* II.B.2.c.(1); II.B.2.d.(1)*].*

Myoclonic seizures can occur after frequent, high-dose meperidine owing to the accumulation of the metabolite, normeperidine. Both oxycodone and meperidine have short durations of effect. In the chronic pain patient, an around-the-clock regimen, using a controlled-released oral morphine, would be an appropriate alternative. With titration, the patient should have good pain relief with an every 8- to 12-hr regimen.

4. The answer is C *[see* II.B.3.c*].*

A patient suffering from pain cannot sleep properly. When the pain is adequately controlled, the patient may sleep initially for many hours. This usually is not oversedation owing to the narcotic. These patients should be monitored closely (e.g., respiratory rate), and other sedating drugs should be eliminated. Usually, no other intervention is needed.

5. The answer is D *[see* II.A.4*].*

Aspirin has several adverse effects and drug interactions. However, cardiac arrhythmias are not induced by aspirin.

6. The answer is C *[see* II.A.2*].*

Unlike the opiates, NSAID use is not associated with the development of tolerance.

7. The answer is D *[see* Table 58-2*].*

Transdermal fentanyl is a controlled-release dosage form that is effective for up to a 72-hr period. All of the other drugs listed in the question are effective for periods of 1-8 hr.

8. The answer is C *(I, II) [see* II.A.4.b*].*

Unlike aspirin and NSAIDs, acetaminophen and choline magnesium trisalicylate lack antiplatelet effects. Therefore, they are safe to use for patients with bleeding problems.

9. The answer is C *(I, II) [see* II.A.1*].*

Adalimumab, etanercept, and infliximab act by binding or capturing excess TNF-α, one of the dominant cytokines or proteins that play an important role in the inflammatory response. The exact mechanism of action of leflunomide, a novel drug used to treat rheumatoid arthritis, is not completely known but it is thought to inhibit pyrimidine synthesis.

10. The answer is E *(I, II, III) [see* II.A.4.a; II.A.4.d.(4)*].*

Leflunomide has been associated with weight loss, diarrhea, nausea, alopecia, rash, anemia, and transient elevations in liver function tests.

59

Nutrition and the Hospitalized Patient

Robert A. Quercia

Kevin P. Keating

I. NUTRITIONAL PROBLEMS IN HOSPITALIZED PATIENTS

A. Incidence. It has been estimated that 30%-50% of patients admitted to hospitals have some degree of malnutrition. As many as 75% of patients undergo a deterioration of nutritional status while hospitalized.

B. Definitions

1. Malnutrition is a pathological state, resulting from a relative or absolute deficiency or excess of one or more essential nutrients.

2. Marasmus is a chronic disease that develops over months or years as a result of a deficiency in total caloric intake. Depletion of fat stores and skeletal protein occurs to meet metabolic needs. Marasmic patients are generally not hypermetabolic and are able to preserve their visceral protein compartment as determined by measurements of serum albumin, prealbumin, and transferrin.

a. Marasmus is a well-adapted form of malnutrition, and despite a cachectic appearance, immunocompetence, wound healing, and the ability to handle short-term stress are generally well preserved.

b. Nutritional support in these patients should be initiated cautiously because aggressive repletion can result in severe metabolic disturbances, such as hypokalemia and hypophosphatemia.

3. Kwashiorkor is an acute process that can develop within weeks and is associated with visceral protein depletion and impaired immune function. It is the result of poor protein intake with adequate to slightly inadequate caloric intake; thus patients usually appear well nourished. A hypermetabolic state (e.g., trauma, infection) combined with protein deprivation can rapidly develop into a severe kwashiorkor malnutrition characterized by hypoalbuminemia, edema, and impaired cellular immune function.

a. In hospitalized patients, the development of kwashiorkor has been implicated in poor wound healing, gastrointestinal (GI) bleeding, and sepsis.

b. Aggressive nutritional support to replete protein stores and decrease morbidity and mortality is indicated when the diagnosis of kwashiorkor is made.

4. Mixed marasmic kwashiorkor is a severe form of protein-calorie malnutrition that usually develops when a marasmic patient is subjected to an acute hypermetabolic stress, such as trauma, surgery, or infection.

a. This condition results in depletion of fat stores, skeletal muscle protein, and visceral protein.

b. Because of the marked immune dysfunction that develops in this state, vigorous nutritional support is indicated.

II. NUTRITIONAL ASSESSMENT AND METABOLIC REQUIREMENTS

A. Nutritional assessment. The most commonly used tools for nutritional assessment are as follows:

1. Subjective global assessment (SGA) relies heavily on the patient's history.

a. SGA takes into account:

(1) Recent weight change

(2) Diet history

(3) Type and length of symptoms affecting nutritional status (e.g., nausea, vomiting, diarrhea)

(4) Functional status

(5) Metabolic demands of the current disease process

(6) Gross physical signs

(a) Status of subcutaneous fat

(b) Evidence of muscle wasting

(c) Presence or absence of edema and ascites

b. Patients are then classified as being well nourished or moderately or severely malnourished.

2. Mini Nutritional Assessment (MNA) similar to the SGA, validated in elderly patients

a. MNA takes into account:

(1) Loss of appetite

(2) Weight loss

(3) Mobility

(4) Psychological/physical stress

(5) Neuro-psychological problems

(6) BMI

b. Patient is then assessed as being at no or increased nutritional risk. If at increased risk a full nutritional assessment is undertaken

3. Visceral Protein Markers (VPM) can be indicators of protein depletion if results are subnormal.

a. Most commonly used VPM are:

(1) Albumin

(2) Prealbumin (transthyretin)

(3) Transferrin

(4) Retinol-binding protein

4. Total lymphocyte count—an indicator of immune competence—subnormal levels can be an indicator of malnutrition.

5. Anthropomorphics—skin-fold measurements

a. Values <5th percentile can be indicators of fat and protein depletion

b. Most commonly used:

(1) Triceps

(2) Biceps

(3) Subscapular

(4) Suprailiac

6. Multifactorial Prognostic Indicators

a. Prognostic Nutritional Index (PNI) is derived from a formula that attempts to quantify a patient's risk of developing operative complications based on a variety of markers of nutritional status including:

(1) Visceral protein markers

(2) Anthropomorphics

(3) Immune competence

b. Prognostic Inflammatory Nutritional Index (PINI) is similar to the PNI but adds the inflammatory markers alpha 1 acid glycoprotein and c-reactive protein.

7. Body composition analysis assesses nutritional status by measuring and comparing the ratios of various body compartments.

a. Bioelectrical impedance. The resistance to an electrical current is used to calculate lean body mass. The equipment is relatively inexpensive and easy to use. The results are inaccurate in critically ill patients and patients with fluid and electrolyte abnormalities.

b. Dual-energy x-ray absorptiometry (DEXA). The differential attenuation of x-rays is used to measure fat and lean body mass. The equipment is expensive, and results are affected by hydration status.

c. Total body potassium estimates lean body mass by using a whole body counter to measure a potassium isotope concentrated in lean tissue. This method of body composition analysis is impractical and available at only a few centers.

d. Total body water estimates lean body mass from deuterium total body water measurements. This technique is clinically impractical.

e. In vivo neutron activation analysis. Unlike other techniques, this analysis divides the body into several compartments. This technique requires a significant dose of radiation and is available at only a few research centers.

8. Tests of physiological function attempt to quantitate malnutrition based on the decrease in muscle strength caused by amino acid mobilization.

a. Maximum voluntary grip strength is measured with isokinetic dynamometry. The results correlate well to total body protein. This test requires patient cooperation.

b. Electrical stimulation of the ulnar nerve measures contractile function of the adductor pollicis muscle. This technique does not require voluntary patient effort and is inexpensive and easy to do. Its prognostic reliability is still under evaluation.

B. Metabolic requirements

1. Energy requirements are determined as **nonprotein calories (NPCs).** It is important to avoid excess calories to minimize complications of nutrient delivery and to optimize nutrient metabolism. Energy requirements can be determined by the following three methods.

a. Indirect calorimetry or measured energy expenditure (MEE) is the most accurate method of determining caloric requirements.

(1) Oxygen (O_2) consumption and carbon dioxide (CO_2) production are measured directly.
(2) Energy expenditure is related directly to oxygen consumption and is calculated from these measurements.
(3) A respiratory quotient (RQ) can also be obtained from an MEE and is defined as the ratio of the amount of CO_2 produced to that of O_2 consumed during the course of oxidation of body fuels. The oxidation of carbohydrate results in an RQ of 1.0—that is, as much CO_2 is produced as O_2 is consumed. The oxidation of fat produces significantly less CO_2 and results in an RQ of 0.7. Normal mixed substrate oxidation results in an RQ of 0.8-0.9.
(4) The provision of excess carbohydrate calories causes their conversion to fat (lipogenesis). Lipogenesis produces significantly more carbon dioxide than oxidation does. This can result in an RQ > 1.0, which is consistent with overfeeding. The determination of RQ can, therefore, indicate patterns of substrate use.
b. Estimated energy expenditure (EEE) first requires the calculation of the **basal energy expenditure (BEE)** from the **Harris-Benedict equation;** the BEE is then multiplied by appropriate stress and activity factors.
(1) Men: BEE = 66.5 + [13.8 × weight (kg)] + [5 × height (cm)] - [6.8 × age (years)]
(2) Women: BEE = 655 + [9.6 × weight (kg)] + [1.8 × height (cm)] - [4.7 × age (years)]
(3) Stress factors: uncomplicated surgery 1.00-1.05, peritonitis 1.05-1.25, and sepsis or multiple trauma 1.25-1.5
(4) Activity factors: bedrest 0.95-1.10 and ambulation 1.10-1.30
c. Simple nomogram. The least accurate method of estimating caloric requirements, this technique is based on the patient's weight in kilograms. It is useful when the other methods cannot be used. Patients with mild to moderate degrees of stress require approximately 25-30 kcal/kg/day, whereas the severely stressed patient (e.g., a patient with major burns) may require 35 kcal/kg/day or more.
2. Protein (nitrogen) requirements can be determined by a number of techniques, but nitrogen balance determinations and nomograms appear to be the most practical.
a. Nitrogen balance techniques. The practitioner determines the patient's nitrogen output and develops a nutritional support program in which the protein administered results in a nitrogen input that exceeds losses.
(1) Nitrogen balance = 24-hr nitrogen intake - 24-hr nitrogen output.
(2) A 24-hr nitrogen intake = 24-hr total protein intake ÷ 6.25 (approximately 16% of protein is composed of nitrogen).
(3) A 24-hr nitrogen output = [24-hr urine urea nitrogen (UUN) × 1.25 + 2, where 1.25 accounts for non-UUN losses (e.g., ammonia, creatinine) and 2 accounts for non-urine nitrogen losses (e.g., skin, feces). Total urinary nitrogen (TUN) determinations

are currently available in some centers. Because TUN is a more accurate method of

assessing urinary nitrogen losses, it should be used when available in place of a 24-hr UUN × 1.25 when calculating a nitrogen balance.

(4) A positive nitrogen balance of 3-6 g is the goal.

(5) This method cannot be used in renally impaired patients.

b. Nomogram method. This method estimates protein needs based on lean body weight. Protein requirements are 1.5-2.0 g protein/kg/day for hospitalized patients.

c. Nonprotein calorie to nitrogen (NPC:N) ratio. An NPC:N ratio of 125-150:1 generally has been recommended for the mildly to moderately stressed patient to achieve optimal nitrogen retention and protein synthesis. In the severely stressed patient, some studies indicate that ratios as low as 85:1 may be effective.

3. Essential fatty acids (EFAs) are those polyunsaturated fatty acids that cannot be synthesized by humans. EFAs affect immune responses by influencing energy production, eicosanoid synthesis, and cell membrane fluidity. They also affect levels of arachidonic acid in lymphocytes—especially monocytes, macrophages, and polymorphonuclear neutrophils (PMNs). Linoleic acid, an omega-6 polyunsaturated fatty acid (PUFA), is the principal EFA for humans. α-Linolenic acid, an omega-3 PUFA, also cannot be synthesized in vivo; its metabolic significance in humans continues to be investigated. It might be a conditionally essential fatty acid.

a. Deficiency states of **linoleic acid** are characterized by diarrhea, dermatitis, and hair loss.

b. The currently available lipid emulsions have a high linoleic acid content.

c. Providing 4%-7% of a patient's caloric requirements as linoleic acid from lipid emulsion prevents the development of essential fatty acid deficiency.

4. Vitamins are essential for proper substrate metabolism. Accepted daily allowances for oral administration have been established**. The FDA recently approved a new multivitamin preparation for adults receiving parenteral nutrition (PN).**

a. Vitamin A (fat soluble). Normal stores can last up to 1 year but are rapidly depleted by stress. Vitamin A has essential functions in vision, growth, and reproduction. Recommended oral intake is 2500-5000 IU/day. **The recommended requirement is 3300 IU/day in PN formulations.**

b. Vitamin D (fat soluble). In conjunction with parathormone and calcitonin, vitamin D helps regulate calcium and phosphorous homeostasis. Recommended oral intake is 100-400 IU/day. **The PN requirement is 200 IU/day.**

c. Vitamin E (fat soluble) appears to function as an antioxidant, inhibiting the oxidation of free unsaturated fatty acids. Recommended daily oral allowances are 12-15 IU/day. **The requirement in PN formulations is 10 IU/day.** The presence of polyunsaturated fatty acids increases the requirement for vitamin E, which needs to be considered with the use of lipid system PN.

d. Vitamin K (fat soluble) plays an essential role in the synthesis of clotting factors. The suggested oral intake is 0.7-2.0 mg/day. **The recommended PN requirement is 150** µg**/day.**

e. Vitamin B_1 (thiamine; water soluble) functions as a coenzyme in the phosphogluconate pathway and as a structural component of nervous system membranes. The development of its deficiency state (i.e., acute pernicious beriberi

with high output cardiac failure) is well described in patients on PN receiving inadequate thiamine replacement. A prolonged deficiency state can cause Wernicke encephalopathy. Recommended doses are 0.5 mg/1000 oral calories/day and **6 mg/day in PN formulations.**

f. Vitamin B_2 (riboflavin; water soluble) functions as a coenzyme in oxidative phosphorylation. Essentially, no intracellular stores are maintained. Oral requirements are 1.3-1.7 mg/day. **The requirement in PN formulations is 3.6 mg/day.**

g. Vitamin B_3 (niacin; water soluble) functions as a coenzyme in oxidative phosphorylation and biosynthetic pathways. Pellagra is the well-described deficiency state. Oral requirements are 14.5-19.8 mg/day. **The recommended PN requirement is 40 mg/day.**

h. Vitamin B_5 (pantothenic acid; water soluble). The functional form of vitamin B_5 is coenzyme A, which is essential to all acylation reactions. Oral requirements are 5-10 mg/day. Intravenous (IV) requirements are 10-29 mg/day.

i. Vitamin B_6 (pyridoxine; water soluble) functions as a coenzyme in a variety of enzymatic pathways. Deficiency states are accentuated by some medications, including

isoniazid, penicillamine, and cycloserine. Oral requirements are 1.5-2.0 mg/day. **The recommended PN requirement is 6.0 mg/day.**

j. Vitamin B_7 (biotin; water soluble) functions in carboxylation reactions. It is synthesized by intestinal flora; therefore, deficiency states are rare. **The requirement in PN formulations is 60** µg**/day.**

k. Vitamin B_9 (folic acid; water soluble) is involved in a variety of biosynthetic reactions and amino acid conversions. Folate cofactors are necessary for purine and pyrimidine (DNA) synthesis. Stores usually last 3-6 months; however, rapid depletion is seen with metabolic stress. Deficiency of vitamin B_{12} causes deficiency in folate. A megaloblastic anemia is classic in the deficiency state. Deficiency of folic acid in a pregnant mother can cause neural tube defects in the fetus. Oral requirements are 200-400 µg/day. **The recommended requirement in PN formulations is 600** µg**/day.**

l. Vitamin B_{12} (cyanocobalamin; water soluble) has a variety of metabolic and biosynthetic functions. Because of large stores, deficiency states can take years to develop. Megaloblastic (pernicious) anemia is one manifestation of deficiency. Another manifestation of deficiency is peripheral neuropathy because B_{12} is responsible for biosynthesis of the insulation sheet on nerves called myelin. Oral requirements are 2 µg/day. **The requirement in PN formulations is 5.0** µg**/day.**

5. Trace mineral deficiency may develop during PN because of reduced intake, increased use, decreased plasma binding, or increased excretion.

a. Iron is necessary for hemoglobin and myoglobin production and is a necessary cofactor in a variety of enzymatic reactions. Deficiency is classically demonstrated by a hypochromic, microcytic anemia as well as by the development of immune

deficiency. Oral requirements are 16-18 mg/day. IV requirements are 0.5-1.0 mg/day.

b. Zinc is necessary for DNA and RNA synthesis and is a necessary cofactor in a variety of enzymatic reactions. Zinc deficiency results in impaired wound healing, growth retardation, hair loss, dermatitis, diarrhea, anorexia, and glucose intolerance. Patients at high risk for developing zinc deficiency are those with long-term steroid therapy, malabsorption syndromes, fistulas, sepsis, and major surgery. Oral requirements are 10-15 mg/day. IV requirements are **3.0-5.0 mg/day.**

c. Copper is necessary for heme synthesis, electron transport, and wound healing. Deficiency that develops during PN usually manifests as anemia, leukopenia, and neutropenia. Oral requirements are 30 µg/kg/day**. Intravenous requirements are 0.5-1.5 mg/day.**

d. Manganese is involved in protein synthesis and possibly glucose use. Oral requirements are 0.7-22 mg/day. **Intravenous requirements are 150-300** µg**/day.**

e. Selenium is important in antioxidant reactions. Deficiency during PN has been associated with muscle pain and cardiomyopathy. **Intravenous** requirements are **40-60** µg**/day.**

f. Iodine is a component of the thyroid hormones. Deficiency manifests as a goiter. Recommended intake is 1 µg/kg/day.

g. Chromium is important in glucose use and potentiates the effect of insulin. Signs of deficiency include hyperglycemia and abnormal glucose tolerance. Oral requirements are 70-80 µg/day. Intravenous (IV) maintenance requirements are 0.14-0.2 µg/kg/day (10-15 µg/day). **Suggested IV requirements for deficiency and severe glucose intolerance are 150-200** µg**/day.**

h. Molybdenum is essential to xanthine oxidase. Oral requirements are 2.0 µg/kg/day.

III. METHODS OF SUPPORT

A. PN is also called **total parenteral nutrition (TPN)** and **hyperalimentation.** It is used to meet the patient's nutritional requirements when the enteral route cannot accomplish this.

1. Indications. When the enteral route cannot be used because of dysfunction or disease states (e.g., acute pancreatitis, inflammatory bowel disease, complete bowel obstruction), PN is instituted.

2. Initiation of PN should be undertaken within 1-3 days in moderately to severely malnourished patients when the inadequacy of enteral support is anticipated for more than 5-7

days. In healthy or mildly malnourished patients, PN should be initiated within 5-7 days if enteral support has not been initiated.

3. Routes of administration

a. A central venous route is used with hypertonic PN formulations (i.e., dextrose concentrations > 10%). Most commonly, dextrose concentrations of 25% are used centrally, and the osmolarity exceeds 2000 mOsm/L. Such highly osmolar solutions

must be infused into a large-diameter central vein (e.g., superior vena cava), where they are rapidly diluted by high flow rates.

b. A peripheral venous route can be used when the dextrose concentration is 10% or less.

(1) Solutions with 10% dextrose, amino acids, electrolytes, and trace minerals have a resulting osmolarity of 900-1000 mOsm/L. Higher osmolarity is associated with a higher incidence of thrombophlebitis.

(2) The major reason for use of the central venous PN rather than the peripheral route is the development of thrombophlebitis. Maintaining the osmolality of the peripheral PN solution < 900 mOsm/kg and preferably between 600 and 800 mOsm/kg with intravenous lipid emulsion administered concurrently over 24 hr minimizes the incidence of thrombophlebitis. Also, the development of new peripheral finebore catheters made from polyurethane or silicone has been shown to be significantly less thrombogenic. In addition, the use of low-dose heparin (1 unit/mL) and hydrocortisone (5 mg/L) delivered in the PN solutions has been shown to protect against thrombophlebitis.

(3) Glyceryl trinitrate patches (5 mg), when applied over the area where the tip of the catheter is expected to lie, have been shown to significantly reduce peripheral PN infusion failure caused by phlebitis. With the use of this new catheter technology and new techniques for infusion, it is now feasible to administer peripheral PN in selected patients for short-term therapy (7-10 days) with a low incidence of peripheral vein thrombophlebitis.

4. NPC sources

a. Dextrose monohydrate is the form of dextrose used for parenteral administration. It yields 3.4 kcal/g. It is the component in PN formulas that contributes the most to osmolarity. It is available commercially in concentrations up to 70%.

b. Intravenous lipids are commercially available as 10% or 20% emulsions derived from soybean oil (Intralipid) or a combination of soybean oil and safflower oil (Liposyn II).

(1) Both the 10% and 20% emulsions are isotonic (280 and 340 mOsm/L, respectively) and can be administered via the peripheral vein with a low incidence of phlebitis; these emulsions provide 1.1 and 2.0 kcal/mL, respectively. They contain 1.2% egg yolk phospholipids as the emulsifying agent and 2.25%-2.5% glycerol to make the emulsions isosmotic.

(2) Lipid emulsions can be given as part of the daily NPC requirement or 2-3 times per week to prevent essential fatty acid deficiency. Both types of lipid emulsion contain particles of 0.4-0.5 μm, which prevents the use of 0.22 μm bacterial retention filters.

5. Protein (nitrogen) source. Synthetic crystalline amino acids are currently used as the nitrogen source in PN formulations.

a. These formulations are available commercially without electrolytes and dextrose in concentrations of 5.5% (Travasol), 8.5% (Travasol), 10% (Aminosyn II, Travasol), 15%. (Aminosyn II, Clinisol) and 20% (Prosol).

b. These formulations yield 4 kcal/g.

c. These solutions generally contain a mixture of free essential and nonessential L-amino acids.

d. Specialized amino acid formulations are available for specific disease states.

6. Systems of PN

a. Glucose system PN

(1) Definition. The glucose system PN is a parenteral formulation in which dextrose is used exclusively as the NPC source. Nitrogen is provided as crystalline amino acids. Electrolytes, vitamins, and trace minerals are added to the formulation as needed.

(2) Administration. The glucose system PN formulations usually have dextrose concentrations of 25% or greater and must be administered by the central venous route. These formulations are also referred to as two-in-one formulations because the dextrose and amino acids are usually mixed in one container with electrolytes, vitamins, and trace minerals.

(a) Because of the high dextrose concentration, initial administration should be at low hourly rates (e.g., 50 mL/hr) and increased gradually over 24 hr to avoid hyperglycemia (> 200 mg/dL).

(b) To avoid reactive hypoglycemia (< 70 mg/dL), discontinuation should be gradual over several hours.

(c) Lipid emulsions should be administered for **essential fatty acid replacement** in a dose that provides 4%-7% of required calories as linoleic acid. This can be accomplished by the administration of 250 mL of 20% or 500 mL of 10% emulsion, two to three times weekly.

b. Lipid system PN

(1) Definition. The lipid system PN is a parenteral formulation in which lipid is administered daily to provide a substantial proportion of the NPC. Nitrogen is provided as crystalline amino acids. Electrolytes, vitamins, and trace minerals are added to the formulation as needed.

(2) Administration. The lipid system PN is administered peripherally when the dextrose concentration is less than or equal to 10% and centrally when the dextrose concentration is more than 10%.

(a) Piggyback method. The solution with amino acids, dextrose, electrolytes, trace minerals, and vitamins is infused concurrently with a separate bottle of lipid emulsion through a Y site on the intravenous administration set.

(b) Total nutrient admixture (TNA) **method**—three-in-one, all-in-one. Lipids, amino acids, dextrose, electrolytes, trace minerals, and vitamins are mixed in one container and administered by the central or peripheral route, depending on dextrose concentration.

(i) Advantages include simplification of administration and decreased training time for home PN patients.

(ii) Disadvantages include the inability to inspect for particulate matter in the opaque admixture, the inability to use 0.22-μm bacterial retention filters, and stability problems.

(iii) Because the presence of lipid emulsion in TNAs obscure the presence of a precipitate and may present a life-threatening hazard to patients, the U.S. Food and Drug Administration (FDA) suggests that the piggyback method be used to administer lipid emulsion. If a TNA is deemed medically necessary, then specific admixture guidelines recommended by the FDA should be followed. Also, a particle filter (i.e., 1.2 μ) should be used with TNA administration.

(c) Lipid dosage

(i) Lipid calories should not exceed 60% of total daily calories, including protein calories.

(ii) Maximum dosage of lipids for adults is 2.5 g/kg/day.

(iii) Baseline and weekly serum triglycerides must be monitored in patients on lipid system PN.

(3) Adverse effects of lipids are uncommon. The most frequent adverse effects include fever, chills, sensation of warmth, chest pain, back pain, vomiting, and urticaria (overall incidence < 1%). Severe hypoxemia has been reported with rapid infusion of lipid emulsion.

7. Additives

a. Electrolytes. PN formulations must include adequate amounts of sodium, magnesium, calcium, chloride, potassium, phosphorus, and acetate. The intracellular “anabolic” electrolytes—potassium, magnesium, and phosphate—are essential for protein synthesis. Requirements vary widely, depending on a patient's fluid and electrolyte losses; renal, hepatic, and endocrine status; acid-base balance; metabolic rate; and type of PN formula used. The electrolyte composition of the PN formula must be adjusted to meet the needs of the individual patient.

b. Vitamins and trace minerals. Vitamins are usually added to PN solutions in the form

of commercially available multivitamin preparations. Currently, there is a new adult multiple vitamin infusion formula available (Infuvite Adult, MVI-Adult) that meets the recently amended requirements of the FDA for adult parenteral multivitamins.

(1) The new FDA requirements are based on the prior multivitamin formulation recommended by the Nutrition Advisory Group of the Department of Foods and Nutrition of the American Medical Association (NAG-AMA) but with increased dosages of vitamins B_1, B_6, C, and folic acid and the addition of vitamin K.

(2) The FDA also approved the same multivitamin formulation without vitamin K (MVI-12; multivitamin infusion without vitamin K) for those patients who receive warfarin-type anticoagulant therapy. Because of stability problems, one vial of Infuvite Adult and MVI-Adult contains vitamins A, D, E, B_1, B_2, B_3, B_5, B_6, and K. MVI-12 contains the same vitamins in one vial without vitamin K. The second vial for both preparations contains vitamins B_{12}, biotin, and folic acid.

(3) Trace minerals may be added individually or as a commercially available multielement preparation. Precise requirements for trace minerals have yet to be determined.

c. Insulin may be required for patients receiving PN formulations (especially glucose system PN) to maintain blood glucose levels < 200 mg/dL. If insulin is required, it is best provided by the addition of an appropriate amount of regular insulin to the PN formulation at the time of admixture. Although a small amount of insulin (5-10 U per bag) may be adsorbed to the container and tubing, such losses can be overcome by appropriate titration of the dose. The addition of insulin to the PN formulation has the advantage of changes in the rate of PN infusion being automatically accompanied by appropriate changes in the rate of insulin infusion.

d. Miscellaneous drugs. A number of medications have been successfully admixed with PN formulations for continuous infusion. The H_2-receptor antagonists are the most common drugs used in this way. The routine addition of medications to PN formulations remains controversial because of:

(1) Questions of stability over the wide range of PN component concentrations

(2) Possible **therapeutic inadequacy** or toxicity secondary to PN rate changes and loss of peak and trough levels

(3) Increased **potential for waste** with dose changes

8. Complications with the use of PN can be serious and potentially life-threatening but can be avoided by careful management. Complications can be divided into mechanical, infectious, and metabolic.

a. Mechanical complications generally relate to the central venous catheter or its placement and include pneumothorax, catheter occlusion, and venous thrombosis.

b. Infectious complications usually are related to the central venous catheter. This linerelated sepsis is secondary to multiple catheter manipulations, contamination during insertion, or contamination during routine maintenance. Hyperglycemia and IV lipids also have been implicated. Maintaining blood sugars < 200 mg/dL has been shown to significantly reduce septic complications in certain subsets of patients.

c. Metabolic complications are the most common. These include hyperglycemia, hypoglycemia, hypokalemia, hypomagnesemia, hypophosphatemia, metabolic acidosis, respiratory acidosis, prerenal azotemia, and zinc deficiency. A transient self-limited hepatic dysfunction is also seen with long-term PN.

B. Enteral nutrition (EN). Use of the GI tract to achieve total nutritional support or partial support in combination with the parenteral route should be attempted whenever possible in the face of inadequate oral intake. Theoretical advantages include maintenance of normal digestion, absorption, and gut mucosal barrier function.

1. Contraindications to EN include complete intestinal obstruction, high-output intestinal fistulas, severe acute pancreatitis, severe acute inflammatory bowel disease, and severe diarrhea.

2. Routes of administration. Tube feedings can be administered via nasogastric, nasoduodenal, nasojejunal, gastrostomy, and jejunostomy tubes.

3. EN formulations can be classified as being standard (complete) or modular.

a. Standard formulas generally contain carbohydrates, fats, vitamins, trace minerals, and a nitrogen source. They are further classified according to their nitrogen source.
P.1282

(1) Monomeric formulas contain crystalline amino acids as their nitrogen source. These formulas are usually marketed commercially for specific indications (e.g., ileus, pancreatitis, hepatic coma).
(2) Short-chain peptide formulas contain dipeptides and tripeptides from hydrolyzed protein or de novo synthesis as their nitrogen source. They are currently marketed for the metabolically stressed patient.
(3) Polymeric formulas contain either intact proteins or protein hydrolysates as their nitrogen source. Most patients can be managed with these formulas.
b. Modular formulas consist of separate modules of specific nutrients that can be combined or administered separately. They are used for supplemental use or to custom design an EN formula to meet a specific clinical situation.
(1) Carbohydrate modules differ in the type of carbohydrate present (e.g., polysaccharides, disaccharides, monosaccharides).
(2) Protein modules contain either intact protein, hydrolyzed protein, or crystalline amino acids.
(3) Fat modules contain either long-chain triglycerides (LCTs) prepared from vegetable oils or medium-chain triglycerides (MCTs) prepared from coconut oil. MCTs are more water soluble and more easily absorbed than LCTs. (Bypassing the intestinal lacteal and lymphatic system, MCTs are transported directly to the portal system.) MCTs are, however, relatively expensive and contain no essential fatty acids.
4. Complications. The two **most common** complications of EN are diarrhea and improper tube placement.
a. Diarrhea in patients receiving EN is usually secondary to concomitant administration of medication (e.g., antibiotics and sorbitol-containing liquids). Infectious causes should be eliminated (e.g., *Clostridium difficile*), after which antidiarrheal medications may be beneficial. Reducing the rate or concentration may also be effective.
b. A **feeding tube improperly placed** into the tracheobronchial tree can have disastrous consequences. Tube feedings should never be initiated without radiological verification of tube position.
c. Aspiration

IV. MONITORING SUPPORT

A. PN. In addition to appropriate general medical and nursing care, patients receiving PN initially require daily and weekly laboratory monitoring to assess nutritional progress and metabolic status.
1. Electrolytes

a. Initially, **potassium, sodium,** and **chloride** should be determined daily. Potassium is used intracellularly; thus hypokalemia is not an uncommon finding.
b. Calcium, magnesium, and **phosphate** are primarily intracellular electrolytes, serum levels of which become depleted during protein synthesis. Serum levels generally do not fall as rapidly as potassium; therefore, monitoring two to three times a week is recommended initially until the patient is stabilized, then weekly thereafter.
c. Bicarbonate should be monitored to assess acid-base balance. Hyperchloremic metabolic acidosis may develop in patients on PN. This imbalance can be corrected by providing the potassium and sodium as acetate (converted to bicarbonate in the serum) rather than as the chloride salt. After initial correction, provision of one half the sodium and potassium requirements as the acetate salt and one half as the chloride salt may be beneficial.
2. Serum glucose should be monitored daily, particularly in central glucose systems. Maintaining a blood glucose concentration between 100-200 mg/dL is generally recommended.
3. Weights obtained on a daily or every other day basis track optimum lean body weight gain of 0.25-0.50 lb/day. Weight gain in excess of 0.5 lb/day generally indicates fluid overload or fat deposition.
4. Visceral proteins (e.g., albumin, prealbumin, transferrin) are important indicators of the adequacy of nutritional support.

a. Albumin is useful in the initial assessment of nutritional status, but its long half-life (18-21 days) limits its utility as a short-term marker of nutritional repletion.
b. Prealbumin has a short half-life (2-3 days) and is a more sensitive and early indicator of the adequacy of nutritional support. Its serum value is falsely elevated in renal failure.
c. Transferrin has an intermediate half-life (7-10 days), which makes weekly monitoring useful. Transferrin may be falsely elevated in iron-deficiency states.
d. Retinol-binding protein has an ultra-short half-life (12 hrs). Values are affected by injury and metabolic stress.
5. Serum creatinine and **blood urea nitrogen (BUN)** should be obtained at least weekly. Evidence of renal impairment may require modification of the PN formula. Elevation of the BUN in the absence of renal impairment may be secondary to the PN formula (e.g., excess nitrogen, low NPC:N ratio) and appropriate adjustments need to be made.
6. Liver function tests—aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, lactate dehydrogenase (LDH), and bilirubin—require baseline and periodic monitoring because of potential toxicity from the PN formulation (i.e., fatty infiltration of the liver). Abnormal liver function studies may necessitate changes in the PN formulation.
7. Serum triglycerides should be measured for a baseline and weekly thereafter for patients on lipid system PN. It is not necessary to monitor triglycerides on a weekly

basis for patients receiving lipids two to three times per week for essential fatty acid replacement.

8. A 24-hr UUN should be obtained weekly to determine nitrogen balance for patients in whom nitrogen requirements are uncertain. These are usually highly stressed, severely ill, or injured patients in an intensive care unit (ICU) setting.

9. Serum iron levels should be obtained weekly to determine deficiency and to allow appropriate interpretation of serum transferrin levels.

B. EN generally requires less intense laboratory monitoring. Specific laboratory guidelines for monitoring EN support vary from institution to institution.

V. SUPPORT OF SPECIFIC STATES

A. Conditionally essential nutrients

1. Glutamine. Because of its instability, glutamine is currently not a component of commercially available standard PN amino acid solutions and is found in free form in relatively few EN formulas. A relative deficiency has been shown to occur in critical illness. It is known to be used as a primary fuel source by enterocytes and may exert a trophic effect on the gut mucosa. It is most widely used as a PN component for bone marrow transplant patients and short gut syndrome. Glutamine-containing dipeptides that are stable and highly soluble are being investigated as a source of glutamine in PN. At present, glutamine must be added to the PN solution at the time of compounding. Increasing evidence supports glutamine supplementation in critical illness, however optimum route, timing and dosing have yet to be definitively determined.

2. Arginine has been shown experimentally and clinically to enhance immune function. EN formulas enriched with arginine are available commercially. Recently the efficacy of exogenously administered arginine to subsets of critically ill patients has come into question. Optimum dosing in other patient populations is still undetermined.

3. Antioxidant formulations. Oxidant production occurs as part of the normal inflammatory response and has been implicated in reperfusion injury. The body also produces antioxidant defenses to limit oxidant damage to healthy tissue. These defenses rely on adequate intake of dietary nutrients, such as the sulfur-containing amino acids, vitamin E, vitamin C, selenium, and zinc. Several investigators believe provision of these nutrients should be an early priority in critically ill patients. Optimum doses remain controversial.

4. Tyrosine, cysteine, and **taurine** are either absent or present in low concentrations in commercially available PN formulas. They are believed to be conditionally essential amino acids by some investigators.

5. Omega-3 polyunsaturated fatty acids are derived from fish oils and are currently found in some EN formulations. These fatty acids have been shown experimentally to enhance immune response, protect against tumor growth, and inhibit some of the proinflammatory effects of omega-6 fatty acids. In addition, they

have been shown to lower cardiovascular risk factors by decreasing platelet activation, lowering blood pressure, and reducing triglycerides. However, well-controlled clinical trials in humans are needed to confirm the beneficial effects of immunomodulation seen in animal models.

B. Nutritional support for renal failure. The goal of nutritional support in acute renal failure (ARF) is to meet the patient's NPC requirements while minimizing volume, protein load, and potential electrolyte imbalance.

1. PN formulations used in ARF are low-nitrogen, high-caloric density formulas (e.g., 2% amino acid/47% dextrose), resulting in NPC:N ratios of approximately 500:1.

2. Commercial renal failure formulations (e.g., NephrAmine, RenAmin, Aminosyn RF), containing primarily essential amino acids, have shown no clinical advantage over less expensive, low-concentration standard amino acid formulations.

3. Standard glucose system formulations (4.25% amino acid/25% dextrose) can generally be used in renal failure patients who are being dialyzed on a regular basis. This formulation is particularly useful in severely malnourished patients because it can provide adequate protein to attain positive nitrogen balance, which is not possible with renal failure PN.

4. Monitoring transferrin is a more sensitive and accurate visceral protein marker compared to albumin and prealbumin for assessing nutritional progress in these patients.

5. Enteral formulations that are low in nitrogen and calorie dense (1.7-2.0 NPC/mL) are available for patients with renal failure.

C. Nutritional support for hepatic failure. Patients with hepatic failure have altered protein metabolism, resulting in decreased serum levels of branched-chain amino acids (i.e., leucine, isoleucine, valine) and increased levels of aromatic amino acids (i.e., phenylalanine, tyrosine, tryptophan), methionine, and glutamine. A similar amino acid profile can exist in the cerebrospinal fluid (CSF) and is thought to contribute to hepatic encephalopathy. Fluid and electrolyte disturbances are frequently associated with hepatic failure as well.

1. PN formulations enriched in branched-chain amino acids (36%) and low in aromatic amino acids (e.g., HepatAmine) improve mental status in patients with altered serum amino acid profiles and hepatic encephalopathy. However, studies have not demonstrated definitive clinical differences in morbidity and mortality with these expensive formulations compared to standard formulas.

2. Adequate NPC with a 20-40 g/day protein load (e.g., 2% amino acid/25% dextrose) is an alternative approach to the use of hepatic failure amino acid formulations. Protein load can be liberalized slowly as long as mental status does not deteriorate.

3. EN formulations (e.g., Hepatic-Aid II) enriched with branched-chain amino acids and low in aromatic amino acids are commercially available for patients with hepatic failure.

D. Nutritional support for respiratory failure. The type and amount of substrate administered as NPC can have an effect on a patient's ventilatory status. Overfeeding with resultant lipogenesis and increased carbon dioxide production can

be a cause of respiratory acidosis and/or increased minute ventilation and, therefore, should be avoided. Even in the presence of appropriate amounts of NPC administered as carbohydrate, the normal carbon dioxide load generated by glycolysis may be excessive for the patient with underlying pulmonary dysfunction—for example, chronic obstructive pulmonary disease (COPD).

1. PN lipid system formulations (e.g., 4.25% amino acid/15% dextrose with daily lipid emulsion), where the lipid component constitutes 40%-50% of the total NPC, may be beneficial in reducing the ventilatory demands in respiratory failure patients because lipolysis generates less carbon dioxide than glycolysis.

2. EN formulations containing similar amounts of fat can be prepared from standard EN formulas with the use of lipid modules (i.e., MCT oil, corn oil). More expensive commercial pulmonary formulas are also available.

3. Oxepa, a low-carbohydrate enteral formula containing antioxidants, eicosapentaenoic acid, and γ-linolenic acid, is currently available for adult respiratory distress syndrome (ARDS). It modulates the phospholipid fatty acid composition of inflammatory cell membranes, decreases the synthesis of the proinflammatory eicosanoids of lung injury, and attenuates endotoxin-induced increases in pulmonary microvascular protein permeability. Limited studies have shown some improvement in cardiopulmonary hemodynamics and respiratory gas exchange in ARDS.

E. Nutritional support for cardiac failure. The goal in these patients is to meet metabolic needs while restricting fluid and sodium intake.

1. PN formulations that provide protein and calories in as high a concentration as possible is the goal of nutritional therapy. This can be accomplished with both central glucose or lipid system PN formulations (e.g., 5% amino acid/35% dextrose; 7% amino acid/21% dextrose/20% lipid emulsion).

2. Serum electrolyte monitoring and **adjustment** are imperative in cardiac failure patients receiving PN, particularly when potent diuretics are used concurrently.

3. EN formulations with high nutrient density are available for oral supplementation or tube feedings. Infusion of enteral tube feedings should begin at one third to one half the strength, with a gradual increase in concentration, while maintaining a slow infusion rate (30-50 mL/hr) to avoid rapid increases in fluid load, cardiac output, heart rate, and myocardial oxygen consumption.

F. Nutritional support in pancreatitis. Severe acute pancreatitis is a hypercatabolic state that without nutritional support renders the patient a poor surgical candidate and at increased risk of infection. The goal of nutritional support in severe acute pancreatitis is to rest the pancreas by limiting exocrine stimulation while providing adequate nutrition.

1. PN is generally favored over EN to achieve this goal in the early phases of pancreatitis. Lipid system PN has been shown to be safe and effective when administered to these patients, provided there is no concurrent hyperlipidemia; in fact, it may be valuable in the patient with recalcitrant hyperglycemia.

2. EN, using chemically defined (elemental), low-fat formulas administered into the jejunum, results in minimal pancreatic stimulation and has been used safely in these patients.

G. Nutritional support in stress/critical care. In hypermetabolic critically ill patients, alterations in substrate use, the development of conditional nutrient deficiencies, and modulation of the immune response provide the rationale for specific nutritional formulations.

1. In critical illness, branched-chain amino acids (i.e., isoleucine, leucine, valine) are released from skeletal muscle for protein synthesis and as an energy substrate. PN formulations enriched in branched-chain amino acids (45%)—for example, FreAmine HBC, BranchAmin, Aminosyn-HBC—have been made available with the rationale that, being the preferred fuel source in this patient population, it would enhance protein synthesis, decrease protein catabolism, and improve the patient's clinical outcome. However, these more expensive branched-chain amino acid formulations have not been shown to favorably influence clinical outcomes in critically ill patients.

2. Enteral formulations are currently being produced (e.g., Impact, Perative) with various amounts of the conditionally essential nutrients of critical illness and immunomodulatory substrates (e.g., omega-3 polyunsaturated fatty acids, arginine, glutamine). Clinical studies of the ability of these formulas to improve outcomes in critical illness have been mixed.

3. Hyperglycemia and **insulin resistance** are common occurrences in critically ill patients. Recent data involving mechanically ventilated patients in the surgical intensive care unit who received intensive insulin therapy to maintain blood glucose levels between 80 and 110 mg/dL showed a significant reduction in mortality when compared to more conventional therapy of maintaining blood glucose levels between 180 and 200 mg/dL. The greatest reduction in mortality was associated with deaths caused by multiple organ failure with a proven septic focus. These data point out the importance of striving for a tight glucose control in critically ill patients on PN while avoiding the complications of hypoglycemia.

4. Thermal injury is one of the most hypermetabolic conditions observed in the critical care setting.

a. Methods for estimating the calorie requirements in this patient population are conflicting owing to differences in bias and precision. One of the more accurate unbiased methods reported for estimating energy requirements in thermal injury is

Kcal = (1000 kcal × BSA) + (25 × %BSAB)

where BSA is body surface area and BSAB is body surface area burned.

b. Protein requirements in thermally injured patients are high at 2-2.5 g/kg/day because of the significant degree of catabolism associated with this injury.

c. The increased dermal losses of nitrogen from their burn wounds renders the use of the conventional nitrogen balance formulas less accurate in assessing nitrogen requirements especially with thermal injuries > 40% of BSA. The UUN plus the

insensible loss factor can differ significantly from total nitrogen losses in this patient population.

H. Nutritional support in pregnancy. Nutritional support in pregnancy can have a significant affect on fetal outcome. Weight gain throughout pregnancy is the primary indicator of the adequacy of the nutritional state of mother and child. A weight gain of 11.5-16.0 kg should be the desired goal in women with normal prepregnancy body mass index. PN and EN have both been used successfully during pregnancy, with both modalities demonstrating adequate maternal weight gain, appropriate fetal growth, and term delivery. The calories required to achieve appropriate weight gain throughout the entire pregnancy per the World Health Organization recommendations are an additional 300 kcal/day above the estimated basal energy expenditure (based on the pregravid weight) during all trimesters. The recommended daily protein intake during a normal pregnancy is approximately 1 g/kg/day. This amount represents the normal recommended daily allowance for females plus an additional 10 g/day. In pregnant patients with moderate to severe stress, both calories and protein requirements need to be adjusted in the same manner as for other hypermetabolic nonpregnant patients.

1. PN glucose system and lipid system formulations can both be used successfully to meet the nutrient requirements of pregnant patients. PN is most commonly used during pregnancy in patients with severe hyperemesis gravidarum.

2. Essential fatty acids (EFAs) are required by both mother and fetus. They are necessary for prostaglandin synthesis and normal fetal lipid development. The provision of at least 4.5-7.0% of calorie requirements as EFAs has been estimated to meet the minimum requirements during pregnancy.

3. The **daily vitamin requirements** in a normal pregnancy based on the 1999 dietary reference intakes (DRI) can be met with the parenteral vitamin infusion Infuvite Adult and MVI-Adult. If MVI-12 is used as the parenteral vitamin preparation, an additional 65 ug of vitamin K needs to be added to the daily PN formulation to meet the daily DRI requirements.

4. Prealbumin appears to be the preferred biochemical marker to assess protein status in pregnancy because albumin is falsely depressed and transferrin is falsely elevated in pregnant patients.

5. EN may be useful during pregnancy for patients with less severe hyperemesis gravidarum. The composition of polymeric formulas should be adequate for meeting the nutritional requirements of most pregnant patients.

6. Blood glucose levels should be kept at approximately 100 mg/dL during prolonged continuous PN or EN infusion because chronically elevated maternal glucose levels can result in fetal anomalies, increased risk of miscarriages, and stillbirth.

I. Nutritional support in inflammatory bowel disease (IBD). IBD is associated with weight loss, hypoalbuminemia, anemia, electrolyte imbalance, and vitamin/mineral deficiencies (especially zinc)

1. PN has no role as primary therapy

2. PN has a role with high output fistulae

3. Polymeric and elemental enteral formulas seem equally tolerated.

J. Nutritional support in short bowel syndrome (SBS). A loss of bowel from resection or dysfunction can result in reduced absorption of fluid, electrolytes, macro and micronutrients. Specific deficiencies are related to the regions of lost absorption (e.g., free water and iron deficiency are associated with jejunal loss, vitamin B12, bile salt and fat soluble vitamin deficiency are associated with ileal loss). Complications include dehydration; weight loss; deficiencies of electrolytes, mineral and trace elements; metabolic bone disease; cholelithiasis; nephrolithiasis; gastric acid hypersecretion and D-lactic acidosis. Intestinal adaptation begins to occur after resection and is promoted by enteral feeding.

1. PN not uncommonly required for the short term, and is usually required for the long term in massive small bowel resection.

2. Hypersecretion of gastric acid should be treated with H2-blockers.

3. D-lactic acidosis is caused by fermentation of an increased carbohydrate load delivered to the colon. Treatment is aimed at decreasing enteral carbohydrates.

4. Fat soluble vitamins should be monitored and replaced.

5. Stool volume should be monitored and treated with anti-diarrheal agents if greater than 2 liters/day.

6. Oral calcium and magnesium supplementation needed when enteral feeding achieved.

7. Intestinal adaptation in patients with massive resection may be hastened/improved by the provision of glutamine (enteral and/or parenteral) recombinant human growth hormone and high-carbohydrate, low-fat feeds.

K. Nutritional support in bariatric surgery. Bariatric surgeries are divided into restrictive (vertical banded gastroplasties and silastic ring vertical gastroplasties), restrictive/malabsorptive (Roux-en-Y gastric bypass) and malabsorptive procedures (biliopancreatic diversion). Since restrictive procedures retain the use of the entire gastrointestinal tract, nutritional deficiencies are less common than in malabsorptive procedures. The primary nutrients affected by bariatric surgery include:

1. Iron—one of the most frequent deficiencies after bariatric surgery. Occurs in both restrictive and malabsorptive procedures. Deficiency is secondary to reduced areas of absorption in the small bowel with malabsorptive procedures and reduced production of hydrochloric acid in the stomach for both types of bariatric procedures. The result is a reduction in iron reduced to the absorbable ferrous state. Prevention/treatment is with oral iron supplementation combined with ascorbic to acidify the stomach and facilitate absorption.

2. Vitamin B12 deficiency—common after gastric bypass surgery. Absorption is dependent on intrinsic factor produced in the parietal cells of the stomach and hydrochloric acid is required to cleave vitamin B12 from protein foodstuffs in the stomach. Prevalence after Roux-en-Y procedure is estimated at 12% to 33%. Prevention/treatment: oral B 12 formulations of 350-1000 mcg/day or monthly injections of 2000 mcg in those patients who do not respond to the oral supplements.

3. Folate deficiency—less frequent than B12 deficiency. Folate absorption occurs preferentially in the proximal intestines but with adaptation after gastric bypass surgery absorption can occur throughout the small bowel. Prevention/treatment: 1 mg folate PO/day.
4. Thiamine deficiency—uncommon. Seen with postoperative hyperemesis syndromes. Prevention: 50-100 mg IV or IM thiamine at 6 weeks postop in patients with hyperemesis.
5. Zinc—depends on fat absorption. Deficiency observed with malabsorptive surgery. Standard daily supplementation of zinc is recommended after malabsorptive surgery.
6. Selenium deficiency and a life-threatening cardiomyopathy have been reported in patients after malabsorptive surgery. Supplementation of selenium at 40-80mcg/day is recommended in patients undergoing malabsorptive bariatric surgery.
7. Fat soluble vitamins (A,D,E,K)—Malabsorptive bariatric surgery results in a high incidence of vitamin A,D and K deficiency with altered calcium metabolism (vitamin E, to a lesser extent). Patients undergoing malabsorptive surgery require long-term annual measurements of fat-soluble nutrients. There is no proven regimen for vitamin supplementation after malabsorptive surgery but life-long daily supplementation of fat soluble vitamins has been recommended at the following dosages: 10,000 IU vitamin A; 1200 IU vitamin D; 300 mcg vitamin K, and 1800 mg calcium citrate.

VI. TECHNICAL ASPECTS OF PN PREPARATIONS

A. PN formula preparation is performed **aseptically** in the pharmacy under a laminar flow hood that filters the air, removing airborne particles and microorganisms.
B. Compatibility of the various components of PN formulations is determined by several factors, including their concentration, solution pH, temperature, and the order of admixture. The **most common** compatibility concern is in regard to the addition of calcium and phosphate salts to PN solutions.
C. After admixture of the various components, the PN solution should be **visually inspected** for precipitate or particulate matter. After labeling and final checking, the PN solution should be refrigerated until delivery to the nursing unit.
D. A statistically valid, continuous **sterility testing program** should be an essential component of quality control in preparing PN solutions.

VII. HOME PARENTERAL NUTRITION (HPN)

has become a widely accepted and useful technique for provision of complete nutritional requirements in the home setting. When used appropriately, this modality benefits the patient medically and psychologically, with a decreased cost to the healthcare system.
A. Indications for HPN include short bowel syndrome, severe inflammatory bowel disease, radiation enteritis, enterocutaneous fistulae, and selected malignancies.

B. Candidate selection requires a multidisciplinary approach to determine if the patient and family can assume the responsibility and training needed for safe and successful HPN.

C. Administration. HPN is infused through a central venous Silastic catheter (e.g., Hickman, Broviac), which allows for prolonged PN with low clotting and infection rates. The PN solution is generally infused over a 12- to 15-hr period at night. This type of cycling program allows the patient to be free from the infusion pump during the day, allowing for a more normal lifestyle.

D. Clinical monitoring and follow-up are done periodically, depending on the needs of the individual patient. Long-term HPN patients generally are seen by the physician on a monthly basis after initial stabilization.

VIII. MISCELLANEOUS

A. Soluble fiber is present in some commercially available EN formulas. This fiber is fermented by normal large intestinal flora to short-chain fatty acids that are used by colonocytes as a fuel source. These short-chain fatty acids also seem to have a trophic effect on the large intestinal mucosa.

B. Growth factors. The use of recombinant human growth hormone, insulin-like growth factor, and anabolic steroids, in combination with nutritional support to improve nitrogen balance and reduce hospital length of stay in select patient populations, is currently under investigation. To date, recombinant growth hormone (Humatrope) is available for nutritional support in children with cystic fibrosis, sickle cell anemia, and thalassemia and in adults with AIDS-related cachexia. Oxandrolone is a synthetic anabolic steroid with FDA approval for increasing weight gain in patients with chronic infection, major surgery, and severe trauma. It also has established efficacy in alcoholic cirrhosis (improved survival and liver function), burns (improved nitrogen balance, wound healing, and weight gain), and in AIDS cachexia (improved weight gain). Usual dose is 2.5-20 mg orally (80 mg in alcoholic cirrhosis) in divided doses daily for up to 4 weeks.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 32-year-old well-nourished man involved in a motor vehicle accident was admitted to the surgical intensive care unit with multiple long bone fractures and abdominal injuries with no nutritional support for 4 days. This patient is most likely

(A) suffering from moderate to severe kwashiorkor malnutrition.

(B) at low risk for hospital-acquired infection and other complications.

(C) not suffering from protein or calorie malnutrition.

(D) suffering from severe marasmus malnutrition.

(E) not a candidate for aggressive nutritional support.

View Answer***1. The answer is A[see].*****2. A patient in the intensive care unit on a ventilator was placed on a glucose system parenteral nutrition (PN) formulation providing 2040 kcal/day and 98 g protein/day. A measured energy expenditure (MEE) of 2038 kcal and a respiratory quotient (RQ) of 1.1 were subsequently obtained. Which of the following is correct based on this information?**

(A) The patient is receiving adequate glucose calories, and an adjustment in the program is not necessary.

(B) The daily protein intake has to be decreased to reduce the patient's RQ.

(C) The PN formulation should be switched to a lipid system formulation to reduce the carbon dioxide load.

(D) The patient is retaining oxygen from the glucose calories in the PN formulation.

(E) Lipid emulsion should be added to the current PN formulation to enhance lipogenesis.

View Answer***2. The answer isC [see].*****3. Total nutrient admixture (TNA)**

(A) is more complicated to administer for home parenteral nutrition (PN) patients.

(B) should be filtered with a 1.2-μ filter.

(C) consists of glucose, amino acids, electrolytes, and trace minerals mixed in one container.

(D) is the method recommended by the U.S. Food and Drug Administration (FDA) to administer lipid system PN.

(E) can be visualized for particulate matter.

View Answer***3. The answer is B[see III.A.6.b.(2)(b).(iii)].*****4. The calorie requirements of a moderately hypermetabolic hospitalized patient are best estimated by using the**

(A) nomogram method.

(B) nitrogen balance method.

(C) estimated energy expenditure (EEE) method.

(D) prognostic nutritional index (PNI).

(E) subjective global assessment method.

View Answer***4. The answer is C[see].*****5. Lipid system parenteral nutrition (PN)**

(A) can be administered by peripheral vein if the glucose concentration is less than 15%.

(B) requires daily serum triglyceride monitoring.

(C) is contraindicated in patients with elevated carbon dioxide levels.

(D) requires daily lipid administration to provide a portion of the patient's nonprotein calorie requirements.

(E) can be administered with a maximum lipid dosage of 4.5 g/kg/day.

View Answer***5. The answer is D[see].*****6. Commercial parenteral nutrition (PN) formulations for hypermetabolic critically ill patients**

(A) are enriched in branched-chain amino acids and contain low concentrations of aromatic amino acids.

(B) contain primarily essential amino acids.

(C) have not demonstrated a positive clinical outcome benefit in this patient population.
(D) are the preferred PN formulation used in this clinical setting.
(E) are enriched with arginine to enhance immune function.

View Answer***6. The answer is C[see].*****7. Which of the following methods of parenteral nutritional support would be most appropriate in a severely protein calorie malnourished patient with acute renal failure?**
(A) 2% amino acid/47% dextrose.
(B) 4.25% amino acid/25% dextrose.
(C) 4% essential amino acid/47% dextrose.
(D) 4.25% amino acid/25% dextrose with dialysis on a regular basis.
(E) 2% amino acid/47% dextrose/20% lipid emulsion.

View Answer***7. The answer is D[see].***P.1290

8. Which of the following statements regarding the monitoring of nutritional support is true?
(A) Prealbumin is not the optimal marker to follow for short-term nutritional progress.
(B) Transferrin is falsely depressed in patients with iron deficiency.
(C) Albumin is falsely elevated in renal failure.
(D) A positive nitrogen balance of 3-6 g of nitrogen daily is optimal.
(E) A weight gain of 1.5-2 lb/day indicates optimal lean body weight gain.

View Answer***8. The answer is D[see].*****9. Patients with end-stage liver disease**
(A) generally have increased levels of branched-chain amino acids and decreased levels of aromatic amino acids.
(B) should be placed on a low-branched chain, high aromatic amino acids parenteral nutrition (PN) solution.
(C) can tolerate 20-40 g protein/day with a 2% standard amino acid PN solution.
(D) require glutamine-enriched amino acid solutions.
(E) can tolerate standard glucose system formulations 4.25% amino acid/25% dextrose with regular dialysis.

View Answer***9. The answer is C[see].*****For questions 10-12:** A 67-year-old white female presented to the attending physician with a 3-month history of progressive difficulty swallowing and a 10-kg weight loss. She is currently 160 cm tall and weighs 50 kg. She has just undergone a distal esophagectomy and proximal gastrectomy for distal esophageal cancer. At the time of surgery, she had a feeding jejunostomy tube inserted.
10. The dieticians who are adept at using the Harris-Benedict equation have gone home for the day, and the surgeon calls you for your best guess at what the hourly goal rate for this patient should be using isotonic enteral formula, which provides 0.85 nonprotein calories (NPCs)/mL**. Your answer should be**
(A) 65 mL/hr.
(B) 75 mL/hr.

(C) 85 mL/hr.
(D) 95 mL/hr.
(E) 50 mL/hr.

View Answer***10. The answer is B[see].*****11. The enteral formulation the surgeon has selected is enriched with fish oils. He is hoping this additive will**
(A) prevent diarrhea.
(B) prevent dermatitis.
(C) prevent hyperglycemia.
(D) improve immune function.
(E) improve neurological function.

View Answer***11. The answer is D[see V.A.5].*****12. On the 5th postoperative day, the feeding jejunostomy tube becomes clogged and unusable. The patient will be** NPO **an additional 5 days to ensure the integrity of her surgical anastomosis. The most appropriate course at this time is**
(A) start the patient on a lipid-based peripheral parenteral nutrition program.
(B) keep the patient NPO and without parenteral nutritional support.
(C) have a central venous catheter inserted, and initiate a lipid-based parenteral nutrition program.
(D) start the patient on a glucose-based peripheral parenteral nutritional program.
(E) have a central venous catheter inserted, and start the patient on a high branched-chain amino acid parenteral program.

View Answer***12. The answer is A[see].*****For questions 13-14:** RJ is a 28-year-old pregnant woman. She is in the 9th week of her pregnancy and is diagnosed with hyperemesis gravidarum. Her pregravid weight was 57 kg, and her height is 5 ft., 5 in. She has lost 7 kg (12.3%) during her pregnancy. She was placed on a central glucose PN program.

13. Which one of the following represents the best estimate of her daily caloric requirements?
(A) 1675 kcal
(B) 1790 kcal
(C) 2261 kcal
(D) 2062 kcal
(E) 1925 kcal

View Answer***13. The answer is A[see].*****14. MVI-12 is used as the parenteral vitamin preparation in the PN formulation. Which of the following vitamin(s) need to be supplemented in the daily PN formulation to meet the daily requirements during pregnancy?**
(A) vitamin K
(B) thiamine (B_1)
(C) folic acid
(D) A and C
(E) pyridoxine (B_6)

View Answer***14. The answer is A[see].***

For questions 15-17: A 55-year old male with multiple traumatic injuries and type II diabetes was admitted to the surgical ICU. He was placed on mechanical ventilation and initiated on glucose system PN. After 3 days of PN therapy his blood glucose levels have ranged from 250 to 285 mg/dL over the past 24 hr with 80 U of insulin/L in his PN formulation. He is on no other insulin supplementation at this time.

15. The nutritional support service recommends an insulin drip with the goal of achieving a blood glucose level of

(A) 180-225 mg/dL.
(B) 200-215 mg/dL.
(C) 80-110 mg/dL.
(D) 65-100 mg/dL.
(E) 70-105 mg/dL.

View Answer***15. The answer is C[see].*****16. What parenteral trace mineral therapy may be an effective adjunct if the insulin drip fails to achieve the glucose level goal?**

(A) 20-40 mg zinc/day
(B) 150-200 µg chromium/day
(C) 0.5-1.5mg copper/day
(D) 150-400mcg manganese/day
(E) 40-60 µg selenium/day

View Answer***16. The answer is B[see].*****17. Appropriate insulin control in this patient setting has been shown to provide which of the following clinical outcomes?**

(A) decreased length of time on the ventilator
(B) significant reduction in mortality
(C) decreased duration of PN therapy
(D) a decrease in multiple organ failure with a proven septic focus
(E) B and D

View Answer***17. The answer is E[see].*****For questions 18-19:** A 35 year old female with severe morbid obesity (BMI = 51 kg/m2) of more than 12 years' duration and refractory to conventional obesity treatment was entered into a bariatric surgery program. The patient underwent a Roux-en Y-procedure without any major post-operative complications.

18. The patient was re-admitted to the hospital three months after discharge with intolerance to solid and liquid foods and persistent hyperemesis. She also presented with generalized parathesia, ataxis and mental confusion. Which of the following nutrients is most likely deficient in this patient?

(A) Selenium
(B) Vitamin D
(C) Calcium
(D) Thiamine
(E) Vitamin E

View Answer***18. The answer is D[see].*****19. This patient should be placed on which of the following nutrient supplementations to prevent potential cardiomyopathy.**

(A) Folate (1 mg/day)
(B) Vitamin B12 (350-1000 mcg/day)
(C) Selenium (40-80 mcg)
(D) Vitamin A (10,000 IU/day)
(E) Vitamin K (300 mcg/day)

View Answer***19. The answer is C[see].***P.1292

ANSWERS AND EXPLANATIONS

1. The answer is A *[see* I.B.3*].*
A hypermetabolic state (e.g., trauma, infection) combined with protein deprivation can rapidly develop into a severe kwashiorkor malnutrition characterized by hypoalbuminemia, edema, and impaired cellular immune function.
2. The answer is *C [see* V.D.1*].*
Even in the presence of appropriate amounts of NPCs administered as carbohydrate, the normal carbon dioxide load generated by glycolysis may be excessive for the patient with underlying pulmonary dysfunction. PN lipid system formulations, in which the lipid component constitutes 40%-50% of the total NPCs, may be beneficial in reducing the ventilatory demands in respiratory failure patients because lipolysis generates less carbon dioxide than glycolysis.
3. The answer is B *[see* III.A.6.b.(2)(b).(iii)*].*
A particle filter (i.e., 1.2 µ) should be used with TNA administration.
4. The answer is C *[see* II.B.1*].*
Energy requirements are determined as nonprotein calories by indirect calorimetry, estimated energy expenditure, and the simple nomogram method. The nomogram method is the least accurate method of estimating caloric requirements.
5. The answer is D *[see* III.A.6.b.(1)*].*
The lipid system PN is a formulation in which lipid is administered daily to provide a substantial portion of the NPCs.
6. The answer is C *[see* V.G.1*].*
PN formulations enriched in branched-chain amino acids have been made available with the rationale that, being the preferred fuel source in this patient population, it would enhance protein synthesis, decrease protein catabolism, and improve the patient's clinical outcome. However, these more expensive branched-chain amino acid formulations have not been shown to favorably influence clinical outcomes in critically ill patients.
7. The answer is D *[see* V.B.3*].*
Standard glucose system formulations (4.25% amino acid/25% dextrose) can generally be used in renal failure patients who are being dialyzed on a regular basis. This formulation is particularly useful in severely malnourished patients because it can provide adequate protein to attain positive nitrogen balance, which is not possible with renal failure PN.
8. The answer is D *[see* II.B.2.a.(4)*].*
A positive nitrogen balance of 3-6 g is the goal.

9. The answer is C *[see* V.C.2*].*
Adequate NPCs with a 20-40 g/day protein load (e.g., 2% amino acid/25% dextrose) is an alternative approach to the use of hepatic failure amino acid formulations.
10. The answer is B *[see* II.B.1.c*].*
Use the nomogram of 30 kcal/kg to determine the NPCs/day, and divide that by the NPCs/mL of the enteral formula to determine the volume of formula per day, which is divided by 24 hr to yield the hourly goal rate.
11. The answer is D *[see V.A.5].*
Omega-3 polyunsaturated fatty acids are derived from fish oils and are currently found in some enteral formulations. These fatty acids have been shown experimentally to enhance immune response.
12. The answer is A *[see* III.A.3.b*].*
With the use of new catheter technology and new techniques for infusion, it is now feasible to administer peripheral PN in selected patients for short-term therapy (7-10 days) with a low incidence of peripheral vein thrombophlebitis. This method of PN administration avoids the potential of more serious complications associated with central venous route administration.

13. The answer is A *[see* V.H*].*
The estimated basal energy expenditure is calculated using the pregravid weight in the Harris-Benedict equation. An additional 300 kcal/day is added to the basal energy expenditure to provide the required calories per day during pregnancy.
14. The answer is A *[see* V.H.3*].*
An additional 65 µg of vitamin K needs to be added to the daily PN formulation when MVI-12 is used as the parenteral vitamin preparation to meet the daily requirements during pregnancy.
15. The answer is C *[see* V.G.3*].*
Recent data involving critically ill, mechanically ventilated patients in the surgical intensive care unit indicate intensive insulin therapy to maintain blood glucose levels between 80 and 110 mg/dL.
16. The answer is B *[see* II.B.5.g*].*
Suggested IV requirements of chromium for deficiency and severe glucose intolerance are 150-200 µg/day.
17. The answer is E *[see* V.G.3*].*
The greatest reduction in mortality in patients maintained on tight insulin control was associated deaths owing to multiple organ failure with a proven septic focus.
18. The answer is D *[see* V.K.4*].*
Thiamine deficiency is not common after bariatric surgery but is seen in patients with post-operative hyperemesis syndromes.
19. The answer is C *[see* V.K.6*].*
Selenium deficiency and a life threatening cardiomyopathy have been reported in patients after malabsorptive surgery. Supplementation of selenium at 40-80 mcg/day is recommended in patients undergoing malabsorptive surgery.

60

Immunosuppressive Agents in Organ Transplantation

David I. Min

I. ORGAN TRANSPLANTATION

A. Definition: Replacement of a diseased vital organ with a viable organ from a living or cadaver donor. Solid organ transplantation has become the therapy of choice for many patients with end-organ failure (i.e., heart, liver, lung, and kidney disease). However, it generally requires immunosuppression to overcome the immunological barrier between donor and recipient, except in syngenic (i.e., twins) or autologous transplantation.

B. Classification

1. Solid organ transplantation

a. Life-saving transplantation (e.g., heart, heart-lung, lung, and liver transplantation). There is no alternative life-sustaining method available

b. Non-life-saving transplantation (i.e., kidney, pancreas, and cornea transplantation). There are alternative life-sustaining methods available, such as dialysis or external insulin injection. In these cases, transplantation will improve the patient's quality of life or long-term survival significantly.

2. Hematopoietic stem cell (bone marrow) transplantation is used mainly for hematological malignancy or aplastic anemia.

II. GRAFT REJECTION

A. Transplant immunology (see Chapter 8)

1. Graft rejection. The body's immune system recognizes the allograft (transplanted organ) as a foreign antigen, and it initiates the immune response to remove or destroy the transplanted graft. This reaction is called “rejection.” The degree of the reaction depends on the genetic similarities or differences between the organ of the donor and the immune system of the recipient.

2. Histocompatibility. The antigen determining the compatibility between the donor and the recipient is called a **histocompatibility antigen,** the gene being located on chromosome 6. In many transplants (e.g., bone marrow or kidney transplant), this histocompatibility matching is an important factor for determining the long-term survival of the graft. However, more selective, potent immunosuppression may alleviate the importance of tissue matching between donor and recipient (exception: in hematopoietic stem cell transplantation, the tissue matching is still important).

3. Other factors. Another group of substances that also plays an important role is the **ABO blood group system** of red blood cells. The donor and recipient must be ABO-compatible; otherwise, immediate graft destruction occurs. Some patients may have preformed antibody for unspecified donors because of multiple blood transfusions or other reason. In this case, patients may destroy the transplanted organ immediately. To detect the preformed antibody, the recipient's serum will be tested immediately before the transplantation (cross-match).

B. Types of graft rejection

1. Types of graft rejection according to the time course

a. Hyperacute rejection. Immediate destruction (within minutes or hours) of the transplant organ by a preformed antibody or complement system. Today, this is extremely rare. It occurs only in an ABO-mismatched organ or a cross-match positive (preformed antibody) organ. There is no adequate treatment available.

b. Acute rejection occurs within a few days to several months after transplantation. It is mediated mainly by T-lymphocyte (acute cellular rejection), but occasionally, it is mediated by antibody (antibody mediated rejection) and this rejection can be reversible by steroids or antibody therapy such as muromonab/CD3 or antithymocyte globulin (acute cellular rejection) or intravenous immunoglobulin (IVIG) (antibody mediated rejection).

c. Chronic rejection occurs several months to several years after transplantation. The exact mechanism of this reaction is unknown, but it is thought to be mediated by B-lymphocyte (antibody), and there is no adequate treatment available.

2. Graft versus host, host versus graft. In most solid organ transplants, rejection occurs as the host immune system rejects or attacks the transplant organ (host versus graft). However, in hematopoietic stem cell (bone marrow) transplant, the host is generally immune deficient and the transplanted graft is immune competent, which attracts host tissues (graft versus host).

III. PROPHYLAXIS AND TREATMENT OF GRAFT REJECTION (Table 60-1)

A. Calcineurin inhibitors

1. Cyclosporine (Neoral®, Sandimmune®, Gengraf®, others)

a. Mechanism of action. Cyclosporine binds an intracellular receptor, cyclophiline. This complex inhibits calcineurin, an intracellular phosphatase, which involves activation of the promoter region for the gene-encoding cytokine, such as interleukin-2. This results in inhibiting T-cell activation in the early stage of immune response to a foreign antigen such as a graft.

b. Dosing and monitoring. Cyclosporine pharmacokinetics is unpredictable, and many factors such as age, time after transplant, different oral formulation (Neoral® or Sandimmune®), or drugs affect it. Oral bioavailability is about 30%. Generally, 8 mg/kg/day of oral cyclosporine as two divided doses is used in solid organ transplantation and adjusted according to the blood levels. Serum creatinine should be monitored with the blood levels of cyclosporine. The blood levels are useful in the clinical monitoring.

c. Side effects. Nephrotoxicity is the major side effect. Neurotoxicity and hepatotoxicity are also common. Hirsutism and gingival hyperplasia are also cumbersome side effects. Numerous drug interactions have been reported (Table 60-2).

2. Tacrolimus (Prograf®)

a. Mechanism of action. It is very similar to cyclosporine (III.A.1.a).

b. Dosing and monitoring. Tacrolimus pharmacokinetics is also variable, and oral bioavailability is about 25%. Blood levels are useful in clinical monitoring.

c. Side effects. Nephrotoxicity is the major side effect. Neurotoxicity and posttransplant diabetes are more common than with cyclosporine.

B. Antimetabolites

1. Azathioprine (Imuran®)

a. Mechanism of action. It is converted to 6-mercaptopurine in the body and is a nonspecific purine synthesis inhibitor. It interferes with DNA and RNA synthesis so that it may reduce both cell-mediated and humoral immune responses.

b. Dosage and monitoring. An initial dose of 3-5 mg/kg/day is administered preoperatively. Immediately after transplantation, the dose is usually tapered to a maintenance dose of 1-3 mg/kg/day or titrated to the patient's white blood cell (WBC) count. The WBC count is generally maintained greater than 3000/mm^3.

c. Side effects. Bone marrow suppression (leukopenia, thrombocytopenia) is the major side effect. In addition, xanthine oxidase inhibitor allopurinol inhibits azathioprine metabolism. When these drugs are used concurrently, the azathioprine dose should be reduced by 80%. Otherwise, the patient may develop severe leukopenia due to azathioprine overdose.

2. Mycophenolic acid (CellCept®, Myfortic®)

a. Mechanism of action. Two forms are available. Mycophenolate mofetil (Cellcept®) is a prodrug, which is converted to mycophenolic acid in the body, which is the active form. Myfortic® is an enteric formulation of mycophenolic acid. In the body, mycophenolic acid inhibits de novo purine synthesis pathway by inhibiting inosine dehydrogenase. As a result, it inhibits DNA and RNA synthesis in the immune cells such as lymphocytes.

Table 60-1. Current Immunosuppressive Agents Used in Organ Transplantation

Classification	Drug	Usual Initial Dose	Major Side Effects	Monitoring
Calcineurin inhibitors	Cyclosporine(Neoral®, Sandimmune®)	8 mg/kg/day	Nephrotoxicity	Blood concentrations and serum creatinine concentrations
			Neurotoxicity	
	Tacrolimus (Prograft®)	0.1-0.3 mg/kg/day		

Antimetabolites	Azathioprine (Imuran®)	1.5-3 mg/kg/day	Bone marrow suppression	WBC count
	Mycophenolate mofetil (Cellcept®)	1 g twice daily	Same as above	Same as above
	Mycophenolic acid sodium (Myfortic®)	720 mg twice daily		
	Methotrexate (Rheumatrex®)	15 mg/m^2 on day 1, 10 mg/m^2/day on days 3, 6, and 11	Same as above	Same as above
mTOR inhibitor	Sirolimus (Rapamune®)	6-15 mg loading dose and 2-5 mg once daily	Hyperlipidemia, leukopenia and thrombocytopenia	Blood concentrations and WBC, platelet, and lipid profile
Alkylating agent	Cyclophosphamide (Cytoxan®)	3-4 mg/kg/day for 4 days, followed by reduction to 1 mg/kg/day for treatment of rejection	Hemorrhagic cystitis	WBC count

Antibody products	Muromonab/CD3 (Orthoclone OKT3®)	5 mg daily for 7-14 days	Cytokine release syndromes (flu-like syndrome)	Signs and symptoms, CD3 + cell count
	Antithymocyte globulin (Atgam®, Thymoglobulin®)	15-20 mg/kg/day for 7-14 days (Atgam) or 1.5 mg/kg/day for 7-14 days (Thymoglobulin)	Leukopenia and thrombocytopenia	T-cell count
	Daclizumab (Zenapax®)	1 mg/kg (max. 100 mg), on day 0, and every 2 weeks for a total of 5 doses	No significant side effects reported	No special monitoring required
	Basiliximab (Simulect®)	For adults, 2 doses of 20 mg each (day 0 and day 4)	No significant side effects reported	No special monitoring required
Corticosteroids	Prednisone (Deltasone®) or methylprednisolone (Solumedrol®)	500 mg IV on the day of surgery and rapidly tapering to 10 mg daily at 1	Fluid retention, psychosis, cataracts, osteonecrosis	Signs and symptoms

		month		

Table 60-2. Major Drug Interactions of Cyclosporine and Tacrolimus with Other Drugs and Their Management

Drugs	Mechanism	Effects	Management
Antiepileptic drugs	Increased metabolism by inducing cytochrome P450 enzyme	Cyclosporine or tacrolimus trough levels drop within 48 hr after initiation of these drugs	Increase cyclosporine dose or tacrolimus with frequent monitoring of blood levels. Valproic acid does not interfere cyclosporin or tacrolimus levels
Phenytoin			
Phenobarbital			
Carbamazepine			
Rifampin or rifabutin	Same as above	Same as above	Increase cyclosporine dose or tacrolimus with frequent monitoring of blood levels.
Nevirapine, efavirenz			

St. John's Wort	Same as above	Same as above	Avoid St. John's wort
Azole antifungal agents	Inhibition of liver cytochrome P450 enzyme by these drugs	Significant increase of cyclosporine or tacrolimus levels	Reduce cyclosporine or tacrolimus dose with frequent monitoring of levels
Ketoconazole			
Fluconazole			
Itraconazole			
Voriconazole			
Macrolide antibiotics	Inhibition of liver and GI cytochrome P450 enzyme	Increase AUC (×2) and cyclosporine or tacrolimus trough levels (×2-3)	Same as above.
Erythromycin			
Clarithromycin			
Calcium-channel blockers	Same as above	Same as above	Reduce cyclosporine or tacrolimus dose, or use nifedipine or isradipine
Verapamil			
Diltiazem			
Nicardipine			
Antiviral agents	Same as above	Same as above	Reduce cyclosporine or tacrolimus dose
Indinavir			
Ritonavir			

	Saquinavir			
	Grapefruit juice	Inhibition of GI cytochrome P450 enzyme	Increase AUC and peak concentrations of cyclosporine and possibly tacrolimus, and increase variability of blood levels	Avoid grapefruit juice

b. Dosing and monitoring. A dose of 2 g/day (Cellcept®) or 1440 mg/day (Myfortic®) is administered as two divided doses. The WBC and GI symptoms should be monitored.

c. Side effects. Bone marrow suppression (leukopenia, thrombocytopenia) is the major side effect, as in azathioprine. In addition, GI side effects are more common than with azathioprine.

3. Methotrexate. This agent is used mainly in autoimmune disease and preventing graft versus host disease in hematopoietic stem cell transplant patients.

a. Mechanism of action. It prevents dihydrofolic acid from converting to tetrahydrofolic acid by inhibiting the enzyme dihydrofolate reductase. As a result, DNA and protein synthesis are inhibited.

b. Dosing and monitoring. Dosage regimens in BMT patients usually consist of 15 mg/m2/day on day 1 after transplant and 10 mg/m2/day on days 3, 6, and 11 with other agents such as cyclosporine.

c. Side effects. Bone marrow suppression (leukopenia, thrombocytopenia) is the major side effect as in azathioprine. In addition, diarrhea and mucositis are common.

C. mTOR (mammarian Target of Rapamycin) inhibitor is the alkylating agent mainly used for BMT patients. Rarely is it used as a substitute agent for azathioprine in solid organ transplantation.

1. Sirolimus (Rapamune®)

a. Mechanism of action. Sirolimus binds intracellular receptor, FKBP-12 (FK binding protein-12). This complex inhibits the mTOR, which is a key regulatory kinase. This results in inhibiting T-cell activation in a later stage of immune response to foreign antigen such as a graft.

b. Dosing and monitoring. A dose of 2-10 mg/day is administered as a once-daily dose. Usually, a loading dose of 6-15 mg with a maintenance dose of 2-5 mg once

daily is used. Blood levels are useful in clinical monitoring. The serum lipid profile, WBC count, and GI symptoms should be monitored.

c. Side effects. Hyperlipidemia is the major side effect. In addition, leukopenia, thrombocytopenia, and GI side effects are common.

D. Alkylating agent. Cyclophosphamide is the alkylating agent mainly used for hematopoietic stem cell transplant patients. Rarely, it is used as a substitute agent for azathioprine in solid organ transplantation.

1. Mechanism of action. It is converted to the active metabolite phosphoramide mustard in the liver, which inhibits the cross-linking of DNA, leading to cell death.

2. Dosing and monitoring. Doses of cyclophosphamide up to 3-4 mg/kg/day for 4 days followed by a reduction to 1 mg/kg/day to treat graft rejection. The dosage should be titrated to maintain a WBC count greater than 4000/mm^3.

3. Side effects. Hemorrhagic cystitis and **bone marrow suppression** (leukopenia, thrombocytopenia). In addition, nausea, vomiting, and diarrhea are common.

E. Antibody products

1. Muromonab CD3 (Orthoclone OKT3®) is the first therapeutic mouse monoclonal antibody produced for use in humans.

a. Mechanism of action. OKT3 is a mouse IgG2α immunoglobulin that binds to the CD3 structure on T-lymphocytes. Once OKT3 is bound to the CD3 region of T cells, they lose the antigen recognition function and cannot initiate the rejection process.

b. Dosing and monitoring. The dosage is 5 mg/day intravenously for 7-14 days for prevention or treatment of rejection. The CD3 + lymphocyte counts are monitored, and it is desirable that CD + cell be maintained at less than 30/mm^3. Generally, premedications such as acetaminophen, diphenhydramine and corticosteroid are required to reduce the infusion related side effects (i.e., fever, chills).

c. Side effects. With the first few doses, the patient will develop severe flu-like symptoms such as fever, chills, nausea, vomiting, and headache. The OKT3 stimulates T cells, and these symptoms are caused by abrupt release of cytokines such as interleukin-1, tumor-necrosis factor-a, and interleukin-6 from opsonized T cells (cytokine release syndrome). It requires premedications such as acetaminophen, diphenhydramine, and corticosteroids to reduce these side effects before OKT3 injection.

2. Antithymocyte globulin (Thymoglobulin®, Atgam®)

a. Mechanism of action. It is a purified polyclonal immunoglobulin from rabbits (Thymoglobulin®) or horses (Atgam®), which binds to the human T cells. However, it may have cross-reactivity against the red blood cells, platelets, and granulocytes.

b. Dosing and monitoring. The dosage is 1.5 mg/kg (Thymoglobulin®) or 15-20 mg/kg (Atgam®) infusion daily through a central line for 7-14 days for prevention or treatment of rejection. The T-lymphocyte counts are monitored and maintained less than 100/mm^3. Generally, premedications such as acetaminophen, diphenhydramine and corticosteroid are required to reduce the infusion related side effects (i.e., fever, chills). For the infusion of these drugs, the central venous line is a preferred route rather than peripheral vein.

c. Side effects. Antithymocyte globulin may cause fever, chills, erythema, leukopenia, thrombocytopenia, and anaphylactic reaction or serum sickness.

3. Daclizumab (Zenapax®)

a. Mechanism of action. It is a molecularly engineered humanized immunoglobulin active against interleukin-2 receptor (CD25, or Tac) that binds to block the interleukin-2 receptor on the surface of activated T-lymphocytes, thus preventing T-cell activation and proliferation.

b. Dosing and monitoring. It is indicated only for the prevention of acute rejection. The usual recommended dosage is 1 mg/kg (max. 100 mg) within 24 hours posttransplantation and every 2 weeks up to 8 weeks (a total of 5 doses).

c. Side effects. Based on results of clinical trials, no specific safety monitoring is required with daclizumab.

4. Basiliximab (Simulect®)

a. Mechanism of action. It is a chimeric (murine/human) monoclonal antibody (IgG1), produced by recombinant DNA technology, that binds to block the interleukin-2 receptor on the surface of activated T lymphocytes, and as a result, it prevents T-lymphocyte activation, thus preventing acute rejections.

b. Dosing and monitoring. It is indicated only for the prevention of acute rejection. The usual recommended dosage for the adult patient is 2 doses of 20 mg each at day 0 and day 4 after kidney transplantation. No special monitoring is required.

c. Side effects. Based on results of clinical trials, no cytokine release syndromes have been noticed.

5. Other antibody agents

Alemtuzumab (Campath-1H®) or retuximab (Rituxan®) are indicated for hematologic maliganancy and not approved for the organ transplantation, but are occasionally used in the organ transplantation for prevention of acute rejection or intractable antibody mediated rejection.

F. Corticosteroids. Prednisone (Deltasone®) and **methylprednisolone** (Solumedrol®) are the major corticosteroid products used for transplant patients.

1. Mechanisms of action. Corticosteroids have multiple pharmacological effects in various cells. Corticosteroids bind with intracellular glucocorticoid receptors, which results in altering DNA and RNA translation. As a result, corticosteroids cause a rapid and profound drop in circulating T lymphocytes. They have potent anti-inflammatory effects by inhibiting arachidonic acid release and macrophage phagocytosis.

2. Dosing and monitoring. They are used in both preventing and treating graft rejection and acute graft versus host disease. In general, prophylactic doses in solid organ transplantation are in the range of 1-2 mg/kg/day and tapered over months to 0.1-0.3 mg/kg/day. In the case of treatment, the dosage is 500 mg of methylprednisolone IV for 3-5 days or 1-2 mg/kg/day of oral prednisone, which should be tapered rapidly.

3. Side effects. In the long-term, corticosteroids cause more troubling side effects. They include psychological disturbances (i.e., euphoria, depression), adrenal axis

suppression, hypertension, sodium and water retention, myopathy, impaired wound healing, increased appetite, osteoporosis, hyperglycemia, and cataracts.

IV. COMPLICATIONS OF IMMUNOSUPPRESSION

A. Infections

1. Risk. Transplant patients have a high risk of acquiring an infection due to patient factors such as diabetes mellitus, hepatitis, or uremia. In addition, immunosuppressive agents can cause various effects, such as leukopenia, lymphopenia, or T-cell dysfunction, which inhibit adequate immune response to the infection.

2. Time course. The risk of infection is greatest during the first 3 months after transplantation, when higher doses of immunosuppression are used, and again after a rejection episode is treated. This risk correlates with the overall level of immunosuppression.

3. Types of infections include bacterial, fungal, viral, and protozoan.

4. Prevention

a. Trimethoprim-sulfamethoxazole (Bactrim® and others). One single- or double-strength tablet daily for 6 months significantly reduces *Pneumocystis carinii* pneumonia and bacterial urinary tract infection. After 6 months, three times a week is effective.

b. Herpes and Cytomegalovirus (CMV) infection. Oral acyclovir (200 mg bid for normal renal renal function, with doses adjusted accoridn to renal function) for herpes prophylaxis. For CMV prophylaxis, various prophyxis can be used. High doses of acyclovir (800 mg qid for normal renal function, with doses adjusted according to renal function), oral ganciclovir (1 g tid for normal renal function, with doses adjusted according to renal function), valganciclovir (Valcyte®) 900 mg daily, or high-titer CMV immunoglobulin are effective in reducing the incidence of CMV infection and invasive CMV disease.

c. Nystatin solution, clotrimazole troche or fluconazole reduces oral candidiasis (thrush).

B. Increased risk of malignancy

1. Cause. Continuous immunosuppression interferes with normal immune surveillance and function for malignancy. In addition, some of the immunosuppressive drugs may be directly carcinogenic or activate oncogenic virus, such as Epstein-Barr virus (EBV).

2. Characteristics. Cancers that occur most frequently in the general population (e.g., lung, breast, colon) are not increased among transplant patients. However, various cancers uncommon in the general population are often more prevalent in transplant patients: lymphomas, squamous cell carcinomas of the lip and skin, Kaposi's sarcoma, other sarcoma.

3. Posttransplant lymphoproliferative diseases (PTLDs). The incidence of lymphoma appears to correlate with the intensity of immunosuppression. It is

especially well documented that T-cell specific agents, including OKT3, cyclosporine, and tacrolimus, increase the incidence of lymphoproliferative diseases.

4. Treatment. In case of nonvital organ transplant, immunosuppression should be reduced or stopped. If EBV-related lymphoma occurs, acyclovir or ganciclovir therapy appears to be effective; the B-cell-specific monoclonal antibody, rituximab (Rituxan®), is also used.

C. Hypertension. Many immunosuppressive agents cause hypertension. Cyclosporine and tacrolimus clearly increase the arterial blood pressure and steroids may exacerbate hypertension after transplantation from fluid and sodium retention. Treatment usually requires the use of multiple agents, including diuretics and calcium-channel blockers.

D. Posttransplant diabetes mellitus. Many immunosuppressive agents increase blood glucose levels. Corticosteroids, cyclosporine and tacrolimus increase blood glucose. Some patients develop a new onset diabetes after transplantation, which increases morbidity, mortality and reduces graft and patient survivals. Careful monitoring of blood glucose and patient counselling are essential.

STUDY QUESTIONS

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completion of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. S.M., a 38-year-old, received her living related kidney transplant 2 months ago. At her clinic visit today, she complained of tiredness, shortness of breath and pedal edema. Her serum creatinine and BUN showed the following: serum creatine 2.2 mg/dL**, BUN 43 mg/**dL **(1.2 mg/**dL **and 24 mg/**dL **4 weeks ago) and tacrolimus levels 3 ng/**mL **(therapeutic range 5-15 ng/**mL**). She was diagnosed as acute graft rejection. She was admitted to the hospital and was treated by thymoglobulin. Which of the following regarding thymoglobulin is (are) true?**

I. It is a horse serum against human B cells.

II. It is an IL-2 receptor antagonist against human T-cells.

III. It is a rabbit immunoglobulin against human T-cells.

(A) I only

(B) III only

(C) I and II

(D) II and III

(E) I, II and III

View Answer***1. The answer is B[III E 2].*****2. After 7-day course of thymoglobulin therapy, S.T's renal function improved by thymoglobulin treatment. Her thymoglobulin was completed and her blood tacrolimus level was 8 ng/**mL**. She was discharged to her home. Several days later, she developed diabetic coma and seizures. Her seizures were controlled by IV**

diazepam and the local physician wanted to start phenytoin 200 mg daily as a maintenance therapy. Which is (are) appropriate advice(s) upon this prescription?

(A) Phenytoin will reduce tacrolimus metabolism, so please reduce the tacrolimus dose by 100% and check cyclosporine level twice a week.

(B) Phenytoin will increase tacrolimus metabolism, so please switch tacrolimus to cyclosporine.

(C) Phenytoin will increase tacrolimus metabolism, so please switch pheytoin to valproic acid.

(D) Phenytoin will not affect tacrolimus metabolism, so continue same dose of tacrolimus.

(E) Phenytoin will reduce tacrolimus metabolism, so please monitor tacrolimus level more frequently.

View Answer***2. The answer is C[].*****3. Six month later, her renal function was good with creatinine 1.6 mg/**dL **and BUN 28 mg/**dL**. Today her** BP **was 160/105. Which of the following medication (s) contribute(s) to her hypertension?**

I. Tacrolimus

II. Prednisone

III. Mycophenolate mofetil

(A) I only

(B) III only

(C) I and II

(D) II and III

(E) I, II and III

View Answer***3. The answer is C[].*****4. The physician asked you whether an immunosuppressant, daclizumab (Zenapax®) is useful in treating this patient's acute rejection. Which of the following is an appropriate response?**

(A) It is a humanized IgG product against IL-2 receptor and it is useful only in preventing acute rejection.

(B) It is a useful agent to treat rejection, but chest x-ray and monitoring of patient's fluid status are required before this therapy.

(C) It is useful, but patient's weight gain should be less than 3% from the dry weight before therapy

(D) It is a chimeral IgG with specificity against IL-2 receptor and it is useful only for prevention of rejection.

(E) It is a humanized horse serum against T-cells and it is a new agent useful for prevention and treatment of rejection.

View Answer***4. The answer is D[].*****5. All of the following are correct regarding infection prophylaxis in an organ transplant patient EXCEPT**

(A) Trimethoprime-sulfamethoxazole for *Pneumocytis carinii* pneumonia prophylaxis

(B) Nystatin for fungal infection

(C) Oral acyclovir for herpes simplex

(D) Clotrimazole troche for oral thrush

(E) Levofloxacin for urinary tract infection

View Answer***5. The answer is E[].***P.1302

6. A 16-year-old girl who had received her transplant 2 years ago complained of hair growth on her face and did not want to take her medications any more. Which of the following is (are) likely cause of her problem?

(A) cyclosporine

(B) tacrolimus

(C) prednisone

(D) azathioprine

(E) mycophenolic acid

View Answer***6. The answer is A[].***P.1303

ANSWERS AND EXPLANATIONS

1. The answer is B *[*III E 2*].*

Thymoglobulin is an antibody from rabbit against the human thymocytes. This drug can be used as a rejection prevention agent or a treatment agent for on-going rejection. The dose for rejection treatment is 1.5 mg/kg daily for 7-10 days. Atgam is a horse antibody against the human thymocytes. Daclizumab (Zenopax) or basiliximab (Simulect) is an monoclonal antibody against an IL-2 receptor.

2. The answer is C *[*Table 58-2*].*

Phenytoin is a potent cytochrome P450 enzyme inducer, which increases tacrolimus metabolism. When tacrolimus is used concurrently with phenytoin, it is necessary to increase tacrolimus dose by 500% in order to maintain the therapeutic levels, which is very costly. Valproic acid is another antiepileptic agent, which does not interact with tacrolimus. So it is a good alternative for phenytoin in this case.

3. The answer is C *[*III.A.1, F*].*

Tacrolimus and prednisone increase the blood pressure. Tacrolimus (Prograf®) promotes the vasoconstriction and causes renal dysfunction, which contributes to hypertension. Prednisone (Deltasone®) increases fluid and sodium retention, which contributes to hypertension. Mycophenolate mofetil (Cellcept®) is an antimetabolite inhibiting DNA synthesis and cell proliferation. Its side effects include leukopenia and thrombocytopenia and does not cause hypertension.

4. The answer is D *[*III.E.4.c*].*

Daclizumab (Zenapax®) is a humanized monoclonal antibody that directs to the interleukin-2 (IL-2) receptor on the T cells. The binding site of this antibody (10%) is originated from mouse, but the other part is humanized IgG (90%). Interleukin-2 is T-cell growth factor, which initiates T-cell proliferation. The basiliximab opsonizes this IL-2 receptor, which prevents T-cell growth and proliferation, which is essential for the graft rejection process. Unlike OKT3 or antithymocyte globulin, it does not show any serious side effects, so it does not require premedications such as acetominophen, diphenhydramine, and corticosteroids before its administration.

5. The answer is E *[*IV.A*].*

All except for levofloxacin are correct. Levofloxacin is a broad spectrum oral quinolone antibiotic, which is not appropriate for a long term prophylactic regimen.

6. The answer is A *[*III.A.1*].*

Facial hair growth (hirsutism) is one of the cumbersome side effects of cyclosporine, which may discourage the patient's compliance.

Outcomes Research and Pharmacoeconomics

Peter K. Wong

Alan H. Mutnick

I. GENERAL CONCEPTS

A. Outcomes research (OR) is the study of healthcare interventions (treatment modalities such as drug therapies, surgery, and palliative therapy), care delivery processes, and healthcare quality that are evaluated to measure the extent to which optimal and desirable outcomes can be reached. Normally, the purpose of OR is to assess the value of a program or therapy in question.

1. The **Economic, Clinical, Humanistic Outcome (ECHO) model** provides a framework for comprehensive evaluation of outcomes. Three areas of outcomes identified by Kozma and Reeder (1998) are economic outcomes, clinical outcomes, and humanistic outcomes.

2. Outcomes research methodologies include retrospective chart review, prospective clinical trials, observational studies, and computer modeling studies.

3. Examples of outcomes measures

a. Economic outcomes include acquisition costs associated with care, labor costs associated with care, costs to treat adverse drug reactions, costs of treatment failure, costs of hospital readmission, and costs of emergency room and clinic visits.

b. Clinical outcomes include length of hospital stay, adverse drug reactions, hospital readmission, and death.

c. Humanistic outcomes include patient satisfaction, functional status as measured by a validated instrument, and quality-of-life assessment.

B. Pharmacoeconomics (PE), a division of health economics, is designed to provide decision makers with information about the value of the different pharmacotherapies. According to Bootman, Townsend, McGhan (2006), PE research identifies, measures, and compares the costs (resources consumed) and consequences (clinical, economic, and humanistic) of pharmaceutical products and services.

II. COST

A. Definitions

1. Total cost. All expenses that are directly and indirectly necessary to provide a product or service

2. Average cost. The average cost per unit of output (total cost divided by quantity)

3. Fixed cost. Costs that do not vary with the quantity of output for a short-run production (e.g., rent, fixtures, fixed salary, depreciation, administrative costs)

4. Variable cost. Costs that vary with the level of output (e.g., wages, supplies)
5. Marginal cost. The extra cost of producing *one extra* unit of output
6. Incremental cost. Additional costs when comparing one alternative to another
7. Direct cost. Costs directly related to producing/providing a specific quantity of services or output (e.g., salary, drug cost and supply cost for the provision of pharmacy services)

8. Indirect cost. Costs that are allocated to the area(s) that produce/provide a specific quantity of services or output (e.g., overhead cost)
9. Allowable cost. A cost that is eligible to claim for purposes of reimbursement as necessary and relevant to the delivery of a unit of output
10. Opportunity cost. The cost of the benefit of pursuing an alternative course of action
11. Operating cost. Any cost that supports the operations to provide the output

B. Cost and charge

1. The meaning of the term *cost* depends on the perspective for the analysis. The following examples show differing perspectives.
2. Providers may include hospitals, physician offices, or ambulatory surgery centers, and the term *cost* means the total costs for providing the specific service(s).
3. Payors may include insurance companies, Medicare, or Medicaid, and the term *cost* means the price that they have to pay to obtain the service (i.e., charges by providers).
4. Charges do not equal the payment to providers. Depending on the contractual terms, many providers receive only a percentage of the charges for payment. These are called discounted charges. Many providers today receive a lump sum amount of dollars for each episode of care, e.g., diagnosis-related groups (DRGs) or case rate payment. This may also apply to both inpatient and outpatient treatments.
5. Contractual terms are rarely reviewed and vary with different insurance carriers. This creates additional confusion as to the costs associated for various services or therapies.
6. A recognizable way to resolve these hurdles is to use the cost to charge (RCC) ratio for the cost estimation. Multiply the RCC by the patient's charge to yield the estimated cost. RCC can be obtained from the individual hospital's Centers for Medicare and Medicaid Services (CMS) yearly cost report.

C. Basic steps in assessing cost

1. Define the units of service or output

2. Determine the number of service or output units provided
3. Determine cost drivers of these units of service or output
4. Calculate total costs, direct or indirect, related to the provision of this output or service
5. Calculate the average cost and incremental cost

III. ELEMENTS OF A GOOD STUDY

A. Sound objective(s). The study has well-defined objective(s) and answerable question(s).
B. Perspective(s). There is a defined perspective for analysis (e.g., patient, payor, provider, society). In many cases, study perspective determines the cost-effectiveness of an intervention. Most of the published PE guidelines suggest that societal perspective be considered as an additional perspective for analysis.
C. Patient population chosen must be within the scope of analysis. Patient selection criteria that are too stringent pose a threat to external validity. Patient selection criteria that are too liberal are a threat to internal validity. Consideration is also given to comorbidity and multiple treatment modalities.
D. Possible comparators and their effectiveness. All relevant alternatives for comparison are identified. Chosen comparator(s) should be reasonable and is the current preferred standard treatment. In some instances no treatment (placebo) is considered as an alternative.

E. Metrics for costs and consequences. Measures chosen for costs and consequences can affect the results of the analysis. Biases can be introduced into the analysis if units of measures are not clearly defined. This may pose a problem with a multicountry study in the aggregation of the final costs and consequences because currency exchange rates may fluctuate from time to time.
F. Inclusion of relevant costs and consequences in the analysis are based on the perspective chosen. The computation of costs and consequences should be transparent to readers. The key is reproducibility. Readers should be able to use the published computation methods with the local data to validate the findings.
G. A valid data source. Depending on the design of the study, data can come from clinical trials, observational studies, healthcare claim databases, chart reviews, and epidemiological data. Each of the sources of these data were designed for some other purpose than economic analysis. Limitations are listed in VIII.
H. Discounting for costs and consequences. Much discussion has been devoted to the appropriateness of discounting costs and consequences as well as the discount rate. The consensus at this time is to discount both

costs and consequences. The discount rate normally is the opportunity cost of using resources. Many researchers have used the government bond rate. Regardless, the researcher must offer the justification for the chosen discount rate(s).

I. Incremental analysis provides an insight on the comparison for cost generated from one alternative to another alternative, and the additional benefit yielded from the increased cost.

J. Sensitivity analysis should include all the plausible values and their justification for the key parameters.

K. Time horizon of the analysis covers the full duration of treatment for the disease process. For example, the time horizon for the cholesterol-lowering agent's treatment should be the life span from the start day of treatment to the end of life.

L. Appropriateness and comprehensiveness of presentation and discussion of the study results. Similar to the clinical studies, the presentation of study results should not be biased. Interventional alternatives and study limitations must be addressed. Generalizability and applicability are also discussed.

IV. PHARMACOECONOMIC METHODOLOGIES

A. Cost of illness (COI) is the evaluation and assessment of the resources used in treating an illness. This technique is used to obtain the baseline cost information before the introduction of a new intervention. Costs are measured in terms of dollars. Like any PE analysis, the evaluator needs to define the analysis perspective. A different perspective will change the cost structure. For example, from a patient's perspective, the cost of illness will include the transportation to and from the treatment site. Time duration of the disease can be critical in determining the cost and may be a source of bias. No comparison is made in this type of analysis.

B. Cost-benefit analysis (CBA) is a tool used to determine priority for the resource allocation. The technique can be applied to the comparison of healthcare programs and with non-healthcare programs, such as social welfare programs. For example, one can compare the costs and benefits of a coronary risk factor reduction program and the childhood immunization program and the domestic violence prevention program. This technique consists of identifying all of the benefits that accrue from the program and converting them into dollars in the year that they occur. The stream of costs and benefits are then discounted to present value at the selected discount rate. Net benefit is computed for each program and can then be compared with other programs.

C. Cost-minimization analysis (CMA). The underlying assumption for this type of analysis assumes that consequences are equivalent. Therefore, only cost is compared. The cheapest

intervention will be chosen for implementation. Equivalent outcomes may not necessarily be equal. One needs to determine the key outcome of each comparator. For example, two drugs may have the equivalent therapeutic value but different side effect profiles. In such cases, consequences may not be equivalent, and this technique is not appropriate. CEA should be used instead.

D. Cost-effectiveness analysis (CEA) is a technique to assist the decision maker in identifying a preferred choice among possible alternatives within similar consequences (e.g., same therapeutic category) in terms of health improvement created (e.g., life year gained, clinical cures). It is not to be used to compare different consequences for each alternative, such as blood pressure reduction to degree of cholesterol lowering. Consequences can be intermediate outcomes or surrogate outcomes such as the reperfusion time of the vessel after thrombolytic therapy. Generally, the incremental cost of a program or an intervention from a specified perspective is compared to the incremental health effects. An example is the cost per unit of blood pressure reduction with each antihypertensive agent compared. The results of the analysis normally are stated in terms of cost per unit of effectiveness.

E. Cost-utility analysis (CUA). Unlike CEA, CUA measures the consequences in terms of the quality-adjusted life year (QALY) gained. The results of the analysis are normally expressed as a cost per QALY. The metric of QALY incorporates both the improvement in quantity of life, quality of life, and the preference (utility value) of the health state. There are three sources of obtaining utility values for health states in CUA: judgment to estimate the utility values, values from the literature, or values elicited from a sample of subjects. Common techniques for eliciting utility values are rating scale (visual analog scale), standard gamble, and time tradeoff. Five circumstances have been summarized that detail when CUA may be the appropriate technique to apply.

1. When quality of life is the only outcome

2. When quality and quantity of life are health outcomes

3. When the intervention affects both mortality and morbidity and a combined unit of outcome is desired

4. When the intervention being compared has a wide range of potential outcomes and a common unit of outcome is needed

5. When the objective is to compare a gold standard intervention that already has the cost per QALY. QALY is calculated by multiplying the utility values obtained for the specific health state with the quantity of life years spent in that specific health state. Comparison can then be made for the program and intervention.

F. Multiattribute utility theory (MAUT) or analysis (MAUA) is another technique frequently used in assessing utilities. In this situation, several attributes can be included, such as clinical effect and financial effect as

well as quality of life. It is possible to preferentially weigh the decision based on what the priorities are for the decision maker and then apply the weights to identify the most preferable therapy, service, and so on. As evidenced from the following three examples, the individual's perspective will have a major effect on the final decision made, based on the levels of priority chosen for evaluation.

1. A physician may view clinical outcome to represent 70% of the decision, followed by patient's quality of life (20%), and last the costs (10%).

2. A hospital administrator may view the financial outcomes (70%) as a major priority, followed by the clinical outcome (20%), and last the quality of life (10%).

3. A patient with health insurance might view the clinical outcome (45%) and quality of life (45%) as the top priorities and have minimal concern for the financial outcomes (10%) of such a decision.

G. Willingness to pay (WTP) technique is used to assess the perceived value or benefit of a product and service. The WTP values can be obtained through two approaches:

1. Indirect measurement, which examines in actual payments previous real-world decisions that involve trade-offs between money and expected outcomes

2. Direct measurement, which uses survey methods to elicit stated dollar on the perceived benefits. In this second approach, researchers are seeking to provide sufficient background information to create within the respondent's mind a hypothetical market in which the person provides a judgment of the value of the proposed service.

3. The challenge of using contingent valuation is to present within the questionnaire sufficient, clearly organized information to allow this judgment to occur. Basic facts need to be given at the appropriate time. Unlike CBA, WTP takes into consideration the psychological aspects of the illness as well as the physical deterioration. The use of WTP as an outcome measure is theoretically consistent with welfare economics. It also provides a means to assign dollar values to health outcomes.

V. DECISION ANALYSIS

is a systematic approach to decision making under conditions of uncertainty. It is a tool for helping the decision makers identify options that are available, predict the consequences and value of each option based on the probabilities assigned to each option, and choose the option that has the best payoff. Decision analysis can be incorporated into the pharmacoeconomics evaluation. Steps in performing a decision analysis are as follows:

A. Identify and bound the decision. All the ground rules such as analysis perspective, comparators selection, time span, and decision rules are identified and clarified.

B. Develop a decision tree (Figure 61-1). The decision maker will structure the decision in the form of a tree with branches from left to right. Each branch is a segment of a path that leads to an outcome. The process of setting up the tree helps the decision maker put thoughts on paper and provides an evaluation for each option that occurs.

C. Assess and assign probabilities. Probability related to each branch is assessed and assigned. Probabilities can be obtained from the published literature, an expert panel, or clinical trials.

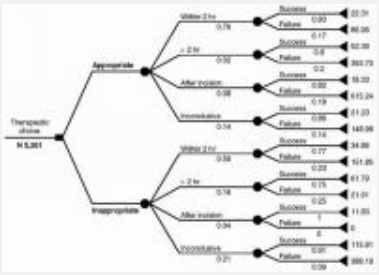

Figure 61-1. Decision tree with probabilities included.

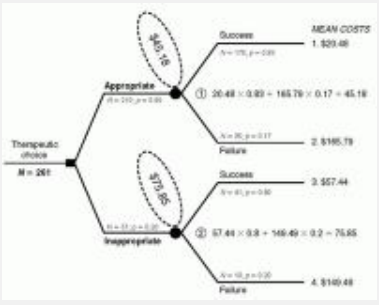

Figure 61-2. Completed decision tree after averaging out and folding back.

D. Value outcomes. For each of the outcome possibilities, assign a value. This can be in the form of monetary or utility values.

E. Calculate the expected value. Using the averaging-out and folding-back method, start from the right and work backward to the left, and calculate the expected value by multiplying the outcome value to each assigned probability (Figure 61-2).

F. Choose the preferred course of action. Depending on the ground rules set in the beginning of either optimization or minimization, choose the best course of action.

G. Perform a sensitivity analysis. Assign different values to all plausible outcomes and resolve the decision tree to identify the robustness of the data and/or results.

VI. PATIENT-REPORTED OUTCOMES (PRO).

PRO refers to any outcomes based on data provided by patient or patient proxy. It includes health-related quality of life data. PRO data can be collected during the clinical trial. Examples of PRO data include patient satisfaction with treatment and providers, functional status, psychosocial well-being, treatment compliance/adherence, and disease symptoms. There is a growing amount of interest in adding PRO data into the drug-review and evaluation process.

A. Health-related quality of life (HRQOL). Although quality of life focuses on all aspects of life, HRQOL focuses only on a patient's nonclinical information such as functional status, well-being, perception of health, return to work from an illness, and other health outcomes that are directly affect by health status. Standardized questionnaires are used to capture HRQOL data in a variety of research settings. Data are obtained either by telephone interview, self-administration, personal face-to-face interview, observation, or mail-in survey. Such standardized questionnaires can also be divided into general health status instruments—for example,, Short-Form 36 (SF-36), Short-Form 12, SF-10 for Children, SF-8 Health Surveys, sickness impact profiles (SIP)—or disease-specific instrument (e.g., McGill Pain Inventory, Beck Depression Scale, Functional

Living Index—Cancer). The general health status instruments measure the global health status, whereas the disease-specific instruments target the disease-specific issues.

B. Short form surveys are the most frequently used general health status instruments. There are a variety of dimensions available, depending on the chosen short form instrument. The original SF-36 includes physical functions, social functions, emotional role, physical role, bodily pain, mental health, general health, and vitality. Other survey instruments may contain only some of these dimensions. Interested readers can explore the the following Web site: www.qualitymetric.com for more information.

C. Psychometric properties. Before using any instrument, the researcher must understand the psychometric properties of the chosen instrument. The

psychometric properties consist of the reliability and validity information of the instrument. In addition, the sensitivity and specificity of the instrument are also important.

1. Reliability is a measure of consistency. Can we reproduce the same score under the same conditions with the same individual? Statistical methods of measuring reliability are Cronbach's α, Pearson's *r* coefficient, and the κ statistic.

2. Validity is a measure of accuracy. Is the instrument measuring what it is supposed to measure? Types of validity are content validity, construct validity, criterion validity, and convergent/divergent validity.

3. Use of the instrument. The psychometric properties preclude "mixing and matching" sections of established questionnaires or selection of a section of an established questionnaire for administration without recalibrating the instrument's psychometric properties.

VII. MODELING STUDIES.

Mathematical modeling is widely used today in the economic evaluation of medications and healthcare technologies.

A. The goal for modeling is to assemble evidence of costs and outcomes in a form that can project long-term consequences. Model-based evaluations are great tools for healthcare decision makers.

B. Mathematical models provide the cost-consequence estimates that cannot be revealed by randomized control trials or epidemiological studies because of the duration required for long-term studies (10-20 years).

C. Results derived from modeling assist decision makers in making informed decisions. However, the quality of the decision is based completely on the truthfulness of the projected results, which in turn depends on the input information and assumptions imposed for each model.

D. The International Society of Pharmacoeconomics and Outcomes Research (ISPOR) recommends the following criteria for assessing the quality of models: model structure, data used as inputs for the model, and model validation.[1]

VIII. 1997 FDA MODERNIZATION ACT, SECTION 114, HEALTH CARE ECONOMIC INFORMATION

A. "Health care economic information provided to a formulary committee, or other similar entity, in the course of the committee or entity carrying out its responsibilities for the selection of drugs for managed care or other similar organizations, shall not be considered to be false or misleading under this paragraph if the health care economic information directly relates to an indication approved ... for such drug and is based on competent and reliable scientific evidence." (From the FDA's Modernization Act of 1997, http://www.fda.gov/cder/guidance/s830enr.txt)

B. Health economic information means any analysis that identifies, measures, or compares the economic consequences including the costs of the represented health outcomes, or the use of a drug to the use of another drug, or to another healthcare intervention, or to no intervention.

C. Key concepts of the act

1. A venue for the pharmaceutical industry to provide OR and/or PE research studies to decision makers

2. Economic information can be provided in the form of CMA, CBA, CUA, COI, and costquality of life.

3. Competent and reliable scientific information pertaining to an approved indication

4. Standard of competent and reliable scientific information has not been addressed.

IX. PRACTICAL ISSUES IN INTERPRETING OUTCOMES RESEARCH AND PHARMACOECONOMIC STUDIES

A. Comparisons between economic study and randomized clinical trials (RCTs)

1. Economic studies are carried out in an observational environment, whereas RCTs depend on rigorous experimental design with strict inclusion/exclusion criteria.

2. RCTs rely on highly controlled and artificial clinical settings to demonstrate clinical efficacy. Clinical and economic end points of the study may not be the same. In addition, RCTs tend to have additional protocol costs (e.g., extra tests) and inflated benefits (e.g., medication compliance, appropriateness of utilization).

3. Economic studies have large sample sizes, whereas RCTs are limited to a relatively small sample size.

4. Economic studies are generalizable to the broader patient population, whereas RCTs are limited to those included within the stringent entry criteria, which might not represent the typical patient receiving the tested therapy.

B. Multiple countries' OR and PE studies

1. There are significant differences in physician practice patterns and care-delivery systems among different countries.

2. Different methods of funding healthcare and allocating health expenditures make it almost impossible to calculate costs.

3. Patients' concerns and beliefs are different.

C. Budgetary constraints. Decision making should not be solely based on the information from the PE analysis because most published PE studies do not impose budgetary constraint as part of the analysis. *Cost-effective* does not equal *affordable.* In addition, one should also consider the implementation costs of the program. In many instances, implementation costs may exceed the benefits or effectiveness of the program.

D. Reproducibility

1. Often, owing to journal space limitation, lengthy cost computations are eliminated from the published article. Such practice creates an impossible auditing mechanism

for the derivation and computation of costs. Critical assessment of this section of the published article is necessary to ensure the validity and reliability of the results.
2. Modeling is an appropriate method when the disease and treatment in question has a lengthy time span and ethical dilemma of withdrawing treatment. However, assumptions and input values to these models are not transparent to readers.
P.1312

3. Both issues make it almost impossible to reproduce the study results using the local data.
E. Limitations of claim data studies. Claim data are designed for billing purposes. There is no differentiation between comorbid conditions and complications in coding data. This can pose a problem in quality benchmark studies. In addition, coding practice may be different from one institution to another, a threat to reliability.
P.1313

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The underlying assumption of cost-minimization analysis (CMA) is

(A) calculation of cost minimization ratio.
(B) consequences are equivalent.
(C) costs are equivalent.
(D) no more than two comparators in any analysis.

View Answer***1. The answer is B[see].*****2. Which one of these statements is *not* true for the differences between economic studies and randomized clinical trials (RCTs)?**

(A) Generalizability and applicability of the results differ between economic studies and RCTs.
(B) Clinical end point and economic end point are identical.
(C) RCTs tend to have inflated benefits and additional protocol-driven costs.
(D) Sample size of the economic study is normally larger than in the RCT.

View Answer***2. The answer is B[see].*****3. In choosing an instrument to measure the health-related quality of life (HRQOL), attention should be paid to**

(A) reliability and validity of the instrument.
(B) sensitivity and specificity of the instrument.
(C) length of the instrument.
(D) All of the above

View Answer***3. The answer is D[seeand].*****4. In choosing a study perspective, the current pharmacoeconomic (PE) guidelines have suggested which one of the following perspectives to be included?**

(A) society

(B) payors
(C) patients
(D) providers

View Answer***4. The answer is A[see].*****5. When interpreting a multination economic clinical trial, what issue needs special attention?**

(A) cost computations
(B) healthcare funding and cost-allocating mechanisms?
(C) patients' variations and beliefs
(D) All of the above

View Answer***5. The answer is D[seeand].*****6. Which one of these pharmacoeconomic (PE) techniques does not address both cost and consequences?**

(A) cost-benefit analysis
(B) cost-effectiveness analysis
(C) cost-utility analysis
(D) cost of illness

View Answer***6. The answer is D[see].*****7. Which of the following is an example of a clinical outcome indicator?**

(A) dollars spent treating acute myocardial infarction
(B) resources used in diagnosing the presence of medical errors
(C) duration of hospitalization and mortality versus discharge rate for ventricular fibrillation patients treated with amiodarone
(D) functional capacity of patients treated with ramipril in the presence of cardiovascular risk factors

View Answer***7. The answer is C[see].***P.1314

ANSWERS AND EXPLANATIONS

1. The answer is B *[see* IV.C*].*

CMA assumes all consequences compared are equivalent. For this reason, only the cost of each alternative is compared. The least expensive alternative will be chosen.

2. The answer is B *[see* IX.A*].*

Clinical and economic end points are generally not equal. In the sequence of the study events, efficacy should come before effectiveness.

3. The answer is D *[see* VI.C.1, 2 *and* 3*].*

All of the characteristics listed require attention.

4. The answer is A *[see* III.B*].*

The societal perspective must be included. It is critical in the healthcare environment to identify the perspective from which a decision is being made because that perspective directly affects the final decision. The decision to add a high-cost, moderately effective therapy for the treatment of hospitalized septic patients might be different if viewed from a hospital formulary committee (in-house

budgetary concerns) than from the local community (saving lives at whatever expense).

5. The answer is D *[see* IX.B.1, 2 *and* 3*].*

All of the issues stated need special attention and play a major role in developing multination economic evaluations to avoid carrying out a study, which when completed cannot be generalized to the broad patient population.

6. The answer is D *[see* IV.A*].*

The cost of illness methodology is carried out as an assessment of the necessary resources, which will be used to treat a designated illness. Resources are measured in terms of dollars, and there are no comparator groups in the evaluation.

7. The answer is C *[see* I.A.3.*].*

Clinical outcomes include the following: length of hospital stay, adverse drug reactions, hospital readmission, and death. These are definable measures of a patient's response to a given treatment, such as amiodarone used for the treatment of ventricular fibrillation.

Appendix A

Prescription Dispensing Information and Metrology

Prescriptions

PARTS OF THE PRESCRIPTION

A prescription is an order for medication for use by a patient that is issued by a physician, dentist, veterinarian, or other licensed practitioner who is authorized to prescribe medication or by their agent via a collaborative practice agreement. A prescription is usually written on a single sheet of paper that is commonly imprinted with the prescriber's name, address, and telephone number. A medication order is similar to a prescription, but it is written on the patient chart and intended for use by a patient in an institutional setting.

All prescriptions should contain accurate and appropriate information about the patient and the medication that is being prescribed. In addition, a prescription order for a **controlled substance** must contain the following information:

- Date of issue
- Full name and address of the patient
- Drug name, strength, dosage form, and quantity prescribed
- Directions for use
- Name, address, and Drug Enforcement Agency (DEA) number of the prescriber
- Signature of the prescriber

A written prescription order is required for substances listed in **Schedule II.** Prescriptions for controlled substances listed in **Schedule II** are **never** refillable. Any other prescription that has no indication of refills is not refillable.

Prescriptions for medications that are listed in Schedules III, IV, and V may be issued either in writing or orally to the pharmacist. If authorized by the prescriber, these prescriptions may be refilled up to five times within 6 months of the date of issue. If the prescriber wishes the patient to continue to take the medication after 6 months or five refills, a new prescription order is required.

THE PRESCRIPTION LABEL

In addition to the name of the patient, the pharmacy, and the prescriber, the prescription label should accurately identify the medication and provide directions for its use.

The label for a prescription order for a controlled substance must contain the following information:

- Name and address of the pharmacy
- Serial number assigned to the prescription by the pharmacy
- Date of the initial filling

- Name of the patient
- Name of the prescriber
- Directions for use
- Cautionary statements as required by law*

AUXILIARY LABELS

Auxiliary, or cautionary, labels provide additional important information about the proper use of the medication. Examples include “Shake Well” for suspensions or emulsions; “For External Use Only” for

topical lotions, solutions, or creams; and “May Cause Drowsiness” for medications that depress the central nervous system. The information contained on auxiliary labels should be brought to the attention of the patient when the medication is dispensed. The pharmacist should place only appropriate auxiliary labels on the prescription container because too many labels may confuse the patient.

BEFORE DISPENSING THE PRESCRIPTION

Double-check the accuracy of the prescription. Provide undivided attention when filling the prescription.

- Check the patient information (e.g., name, address, date of birth, telephone number).
- Check the patient profile (e.g., allergies, medical conditions, other drugs, including over-the-counter medications).
- Check the drug (e.g., correct drug name, correct spelling, appropriate drug for the patient's condition), and verify that there are no known drug interactions. **Always verify the name of the drug. Beware of drug names that look alike (see** table**).**
- Check the dosage, including the drug strength, the dosage form (e.g., capsule, liquid, modified release), the individual dose, the total daily dose, the duration of treatment, and the units (e.g., mg, mL, tsp, tbsp).
- Check the label. Compare the drug dispensed with the prescription. Verify the National Drug Code (NDC) number. Ensure that the information is accurate, that the patient directions are accurate and easily understood, and that the auxiliary labels are appropriate.
- **Provide patient counseling. Be sure that the patient fully understands the drug treatment as well as any precautions.**

Examples of Drugs with Similar Names

Brand name	Celebrex	Cerebyx	Celexa
Generic name	Celecoxib capsules	Fosphenytoin sodium injection	Citalopram HCl
Manufacturer	Searle	Parke-Davis	Forest
Indication	Osteoarthritis and rheumatoid arthritis	Prevention and treatment of seizures	Major depression

Dangerous or Confusing Abbreviations

Numerous common abbreviations and symbols have been associated with errors. Detailed lists of these can be found at the websites of the Institute for Safe Medication Practices (ISMP) and Joint Commission for the Accreditation of Healthcare Organizations (JCAHO) at:
http://www.ismp.org/Tools/abbreviationslist.pdf.
http://www.jcaho.org/accredited + organizations/patient + safety/06_dnu_list.pdf.
The JCAHO has created a “Do Not Use” list of abbreviations that its accredited organizations should not allow to be used.
[black right-pointing arrowhead]**“U” or “IU” for units:** the “U” has been misinterpreted as various numbers such as zero, four; serious harm has occurred with insulin and heparin as a result of confusion. For example, a patient received 66 units of insulin instead of 6 units. The order was written for “6u” of regular insulin but was misinterpreted. The word “units” should be written out in full.
[black right-pointing arrowhead]**“QD, Q.D, qd,** q.d.**”**: common abbreviations for daily have been misinterpreted as “QID” or “qid” and overdoses have occurred. “Daily” should be written out in full.
[black right-pointing arrowhead]**“Q.O.D, QOD, qod”**: common abbreviations for every other day have been misinterpreted as QID (four times daily). This should be written out completely as “every other day.”

[black right-pointing arrowhead]**Trailing zero**: when a dose is ordered and followed with a decimal point and a zero, such as 2.0 mg or 25.0 mg, errors can occur. The decimal point may be missed and an overdose can occur. For example, Warfarin 2.0 mg may be misinterpreted as 20 mg. Trailing zeros should be avoided and the dose written without the additional zero, for example Warfarin 2 mg rather than 2.0 mg.
[black right-pointing arrowhead]**Lack of leading zero**: a drug's dose may be less than 1 mg, such as Digoxin. Often the dose may be written without a leading zero,

such as Digoxin .25 mg, rather than as Digoxin 0.25 mg. Errors have occurred because the decimal point is missed. For example, Warfarin .5 mg may be interpreted as Warfarin 5 mg. Leading zeroes should be included, so the dose is written as “Digoxin 0.25 mg or Warfarin 0.5 mg.”

▸**MS, MSO4, $MgSO_4$: Abbreviations for morphine sulfate (MS, MSO_4) have been confused with Magnesium sulfate ($MgSO_4$). It is recommend to write out each name in full rather than using abbreviations: morphine sulfate or magnesium sulfate.**

In addition to the above abbreviations, there are numerous other hazardous symbols and abbreviations which should be reviewed with caution when used on prescriptions. Examples include:

▸**“cc”**: Often used instead of “mL.” This has been misinterpreted as a “0” (zero). Use “mL.”

[black right-pointing arrowhead]**“µg”**: Used for “micrograms,” for example, Levothyroxine 250 µg. daily. The symbol has been mistaken for “mg.” and overdoses have occurred. Best to use “mcg.” Or write out “micrograms.”

[black right-pointing arrowhead]**“<” or “ >”**: Symbols for “less than” (<) or “greater than” (>) have been mistaken for each other or misinterpreted as numbers. Best to write out as “less than” or “greater than.”

[black right-pointing arrowhead]**“HCT”**: An abbreviation for “hydrocortisone” has been misinterpreted as “hydrochlorothiazide.” Best to write name out completely.

[black right-pointing arrowhead]**“HCl”**: An abbreviation for “hydrochloric acid” has been misinterpreted as “KCl” (potassium chloride). Best to write out name completely.

Common Abbreviations

Considerable variation occurs in the use of capitalization, italicization, and punctuation in abbreviations. The following list shows the abbreviations that are most often encountered by pharmacists.

Metrology

THE METRIC, APOTHECARY, AND AVOIRDUPOIS SYSTEMS

Metric system

1. Basic units

Mass	=	g or gram
Length	=	m or meter
Volume	=	L or liter
		1 cc (cubic centimeter) of water is approximately equal to 1 mL and weighs 1 g.

2. Prefixes

kilo-	10^3, or 1000 times the basic unit
hekto-	10^2, or 100 times the basic unit
deka-	10^1, or 10 times the basic unit
deci-	10^{-1}, or 0.1 times the basic unit
centi-	10^{-2}, or 0.01 times the basic unit

milli-	10^{-3}, or 0.001 times the basic unit
micro-	10^{-6}, or one-millionth of the basic unit
nano-	10^{-9}, or one-billionth of the basic unit
pico-	10^{-12}, or one-trillionth of the basic unit

Examples of these prefixes include milligram (mg), which equals one-thousandth of a gram, and deciliter (dL), which equals 100 mL, or 0.1 L.

Apothecary system

1. Volume (fluids or liquid)

60 minims ()	=	1 fluidrachm or fluidram (f ℥) or (℥)
8 fluidrachms (480 minims)	=	1 fluidounce (f ℥ or ℥)
16 fluidounces	=	1 pint (pt or 0)
2 pints (32 fluidounces)	=	1 quart (qt)
4 quarts (8 pints)	=	1 gallon (gal or C)

2. Mass (weight)

20 grains (gr)	=	1 scruple (℈)
3 scruples (60 grains)	=	1 drachm or dram (ʒ)
8 drachms (480 grains)	=	1 ounce (℥)
12 ounces (5760 grains)	=	1 pound (lb)

Avoirdupois system

1. Volume

1 fluidrachm	=	60 min.
1 fluid ounce	=	8 fl. dr.
	=	480 min.
1 pint	=	16 fl. oz.
	=	7680 min.
1 quart	=	2 pt.
	=	32 fl. oz.
1 gallon	=	4 qt.
	=	128 fl. oz.

2. Mass (weight)

The grain is common to both the apothecary and the avoirdupois systems.

437.5 grains (gr) = 1 ounce (oz)

16 ounces (7000 grains) = 1 pound (lb)

CONVERSION

Exact equivalents

Exact equivalents are used for the conversion of specific quantities in pharmaceutical formulas and prescription compounding.

1. Length

1 meter (m)	=	39.37 in.
1 inch (in)	=	2.54 cm.

2. Volume

1 ml	=	16.23 minims ()
1	=	0.06 mL
1 f	=	3.69 mL
1 f	=	29.57 mL
1 pt	=	473 mL
1 gal (U.S.)	=	3785 mL

3. Mass

1 g	=	15.432 gr
1 kg	=	2.20 lb (avoir.)
1 gr	=	0.065 g or 65 mg
1 oz (avoir.)	=	28.35 g
1 ℥ (apoth.)	=	31.1 g
1 lb (avoir.)	=	454 g
1 lb (apoth.)	=	373.2 g

4. Other equivalents

1 oz (avoir.)	=	437.5 gr
1 ℥ (apoth.)	=	480 gr
1 gal (U.S.)	=	128 fl ℥
1 fl ℥ (water)	=	455 gr
1 gr (apoth.)	=	1 gr (avoir.)

Approximate equivalents

Physicians may use approximate equivalents to prescribe the dose quantities using the metric and apothecary systems of weights and measures, respectively. Household units are often used to inform the patient of the size of the dose. In view of the almost universal practice of using an ordinary household teaspoon to administer medication, a teaspoon may be considered 5 mL. However, when accurate measurement of a liquid dose is required, the USP recommends the use of a calibrated oral syringe or dropper.

1 fluid dram	=	1 teaspoonful
	=	5 mL
4 fluidounces	=	120 mL
8 fluidounces	=	1 cup
	=	240 mL
1 grain	=	65 mg
1 kg	=	2.2 pounds (lb)

Appendix B

Common Prescription Drugs and Over-the-Counter Products

The FDA Approved Drug Products With Therapeutic Equivalence Evaluation: The *Orange Book*

The United States Food and Drug Administration (FDA) publishes the book, *Approved Drug Products With Therapeutic Equivalence Evaluation,* often known as the *Orange Book.* An electronic version of the *Orange Book* is available on the Internet at http://www.fda.gov/cder/ob/. This book is also reproduced by the United States Pharmacopeial Convention, Inc., in the publication, USP DI, Volume III, *Approved Drug Products and Legal Requirements.*

The texts, which are published annually, identify the prescription and nonprescription products that are formally approved by the FDA on the basis of safety and effectiveness. They also provide the FDA's therapeutic equivalence evaluations for approved multiple-source prescription drug products.

The *Orange Book* is a drug product selection guide for pharmacists to use when dispensing a generic drug product as a substitute for the brand-name equivalent. A few drug products that were on the market before 1938 received a “grandfathered” FDA approval. These products are assumed to be safe and effective because of their long usage (e.g., digoxin tablets, phenobarbital tablets). These older products do not have therapeutic equivalence ratings at this time.

The *Orange Book* uses various codes to indicate therapeutic equivalence. The first letter “A” designates drug products that the FDA considers therapeutically equivalent to a pharmaceutically equivalent drug product. These products can be safely substituted. The first letter “B” designates drug products that, for various reasons, the FDA does not consider bioequivalent to the pharmaceutically equivalent drug product.

Therapeutic Equivalence Evaluation Codes

A Codes

Drug products that the FDA considers therapeutically equivalent to other pharmaceutically equivalent products

AA	Products in conventional dosage forms that do not present bioequivalence problems
AB	Products that meet necessary bioequivalence requirements
AN	Solutions and powders for aerosolization
AO	Injectable oil solutions
AO	Injectable aqueous solutions, and in certain instances, intravenous nonaqueous solutions
AT	Topical products

B Codes

Drug products that the FDA does not consider therapeutically equivalent to other pharmaceutically equivalent products at this time

P.1322

B*	Drug products that require further FDA investigation and review to determine therapeutic equivalence
BC	Extended-release dosage forms (capsules, injectables, and tablets)
BD	Active ingredients and dosage forms that have documented problems with bioequivalence
BE	Delayed-release oral dosage forms
BN	Products in aerosol-nebulizer drug-delivery systems
BP	Active ingredients and dosage forms that have potential problems with bioequivalence

BR	Suppositories or enemas that deliver drugs for systemic absorption
BS	Drug products that have drug standard deficiencies
BT	Topical products that have bioequivalence issues
BX	Drug products for which the data are sufficient to determine therapeutic equivalence

Top 200 Prescription Drugs by Trade Name and Generic Namea

Rank	Trade Name	Generic Name
1	Lortab	Hydrocodone/acetaminophen
2	Synthroid	Levothyroxine
3	Xanax	Alprazolam
4	Potassium Chloride	Potassium Chloride
5	Glucophage	Metformin
6	Zestril/Prinivil	Lisinopril
7	Ultram	Tramadol

8	Lasix	Furosemide
9	Lipitor	Atorvastatin
10	Percocet	Oxycodone/acetaminophen
11	Tenormin	Atenolol
12	Toprol-XL	Metoprolol succinate
13	Lopressor	Metoprolol tartrate
14	Hydrochlorothiazide	Hydrochlorothiazide
15	Coumadin	Warfarin
16	Norvasc	Amlodipine
17	Amoxil	Amoxicillin
18	OxyContin	Oxycodone ER
19	Zithromax and Zmax	Azithromycin
20	Darvocet	Propoxyphene/acetaminophen
21	Zoloft	Sertraline
22	Zantac	Ranitidine
23	Zocor	Simvastatin
24	Lexapro	Escitalopram

25	Nexium	Esomeprazole
26	Seroquel	Quetiapine
27	Proventil	Albuterol
28	Singulair	Montelukast
29	Plavix	Clopidogrel
30	Deltasone	Prednisone
31	Effexor XR	Venlafaxine
32	Elavil	Amitriptyline
33	Ativan	Lorazepam
34	Neurontin	Gabapentin
35	Glucotrol and Glucotrol XR	Glipizide
36	Naprosyn and EC-Naprosyn	Naproxen
37	Wellbutrin (SR, XL)	Bupropion
38	Desyrel	Trazodone
39	Prilosec	Omeprazole
40	Dyazide	Triamterene/hydrochlorothiazide

41	Flexeril	Cyclobenzaprine
42	Duragesic	Fentanyl transdermal system
43	Prozac	Fluoxetine
44	Fosamax	Alendronate
45	Vasotec	Enalapril
46	Prevacid	Lansoprazole
47	Lantus	Insulin glargine
48	Premarin	Conjugated estrogens
49	Lanoxin	Digoxin
50	Valium	Diazepam
51	Keflex	Cephalexin
52	Paxil CR	Paroxetine
53	Reglan	Metoclopramide
54	Cardizem CD	Diltiazem
55	Ambien	Zolpidem
56	Celexa	Citalopram
57	Advair	Fluticasone/salmeterol

58	Zestoretic	Lisinopril/hydrochlorothiazide
59	Vytorin	Simvastatin/ezetimibe
60	Zyrtec	Cetirizine
61	Fioricet	Butalbital/acetaminophen/caffeine
62	Diflucan	Fluconazole
63	Ortho Tri-Cyclen	Ethinyl estradiol/norgestimate
64	Depakote ER	Divalproex
65	Adderall XR	Dextroamphetamine/amphetamine
66	Celebrex	Celecoxib
67	Diovan	Valsartan
68	Lotrel	Amlodipine/benazepril
69	Allegra	Fexofenadine
70	Klonopin	Clonazepam
71	Augmentin XR	Amoxicillin/clavulanate
72	Cymbalta	Duloxetine
73	Risperdal	Risperidone
74	Levaquin	Levofloxacin

75	Aldactone	Spironolactone
76	Lyrica	Pregabalin
77	Zyloprim	Allopurinol
78	Protonix	Pantoprazole
79	Actos	Pioglitazone
80	Dilantin	Phenytoin
81	Kenalog	Triamcinolone
82	Motrin	Ibuprofen
83	Altace	Ramipril
84	Coreg	Carvedilol
85	Isoptin and Isoptin SR	Verapamil
86	Estrace	Estradiol
87	Catapres	Clonidine
88	Soma	Carisoprodol
89	Zetia	Ezetimibe
90	Amaryl	Glimepiride
91	Flomax	Tamsulosin

92	Diovan-HCT	Valsartan/hydrochlorothiazide
93	Humalog	Insulin lispro
94	Flonase	Fluticasone propionate
95	Tylenol with Codeine	Acetaminophen/codeine
96	Aricept	Donepezil
97	Mevacor	Lovastatin
98	Accupril	Quinapril
99	Miralax	Polyethylene glycol 3350
100	MS Contin	Morphine sulfate
101	Cozaar	Losartan
102	Ditropan	Oxybutynin
103	Detrol	Tolterodine
104	TriCor	Fenofibrate
105	Combivent	Ipratropium/albuterol
106	Zyprexa	Olanzapine
107	Crestor	Rosuvastatin
108	Remeron	Mirtazapine

109	Procardia and Procardia XL	Nifedipine
110	Imdur	Isosorbide mononitrate
111	Topamax	Topiramate
112	Actonel	Risedronate
113	Atrovent	Ipratropium
114	Medrol	Methylprednisolone
115	Tessalon	Benzonatate
116	Ultracet	Tramadol/acetaminophen
117	Sinequan	Doxepin
118	Ritalin SR and LA	Methylphenidate
119	Avandia	Rosiglitazone
120	Cipro XR	Ciprofloxacin
121	Bactrim or Septra	Sulfamethoxazole/trimethoprim
122	Folic Acid	Folic acid
123	Phenergan	Promethazine
124	Macrodantin and Macrobid	Nitrofurantoin

125	Pyridium	Phenazopyridine
126	Hyzaar	Losartan/hydrochlorothiazide
127	Dilacor XR	Diltiazem
128	Vibramycin/Vibra-Tabs	Doxycycline hyclate
129	Capoten	Captopril
130	Tegretol	Carbamazepine
131	Concerta	Methylphenidate
132	Trileptal	Oxcarbazepine
133	Evista	Raloxifene
134	Glucovance	Glyburide/metformin
135	Namenda	Memantine
136	Cardura	Doxazosin
137	NovoLog	Insulin aspart
138	Flagyl	Metronidazole
139	Nasonex	Mometasone furoate
140	Restoril	Temazepam
141	Micronase	Glyburide

142	Xopenex	Levalbuterol
143	Xalatan	Latanoprost
144	Mycostatin	Nystatin
145	Benicar	Olmesartan
146	Alesse	Ethinyl estradiol/levonorgestrel
147	Abilify	Aripiprazole
148	DuoNeb	Ipratropium/albuterol
149	Armour Thyroid	Thyroid, dessicated
150	Ziac	Bisoprolol/hydrochlorothiazide
151	Lotensin	Benazepril
152	Phenobarbital	Phenobarbital
153	Cleocin	Clindamycin
154	Theophylline	Theophylline
155	Pravachol	Pravastatin
156	Lamictal	Lamotrigine
157	Voltaren	Diclofenac
158	Spiriva	Tiotropium

159	Cogentin	Benztropine mesylate
160	Mobic	Meloxicam
161	Strattera	Atomoxetine
162	Yasmin	Ethinyl estradiol/drospirenone
163	Ortho-Novum 7/7/7	Ethinyl estradiol/norethindrone
164	Hytrin	Terazosin
165	Avapro	Irbesartan
166	Veetids	Penicillin V
167	Lopid	Gemfibrozil
168	Skelaxin	Metaxalone
169	Inderal	Propanolol
170	Zovirax	Acyclovir
171	Benicar-HCT	Olmesartan/hydrochlorothiazide
172	Adipex-P	Phentermine
173	Bactroban	Mupirocin
174	AcipHex	Rabeprazole
175	Pepcid	Famotidine

176	Imuran	Azathioprine
177	Bentyl	Dicyclomine
178	Clozaril	Clozapine
179	Biaxin XL	Clarithromycin
180	Methadone	Methadone
181	Provera	Medroxyprogesterone
182	Requip	Ropinirole
183	Prempro	Conjugated estrogens/medroxyprogesterone
184	Lithonate & Lithotabs	Lithium carbonate
185	Buspar	Buspirone
186	Omnicef	Cefdinir
187	Lunesta	Eszopiclone
188	Relafen	Nabumetone
189	Allegra-D	Fexofenadine/pseudoephedrine
190	Niaspan	Niacin
191	Bumex	Bumetanide
192	Demadex	Torsemide

193	Lotrisone	Clotrimazole/betamethasone
194	Lomotil	Diphenoxylate/atropine
195	Lactulose	Lactulose
196	Monopril	Fosinopril
197	Guaifenex PSE	Guaifenesin/pseudoephedrine
198	Flovent	Fluticasone propionate
199	Imitrex	Sumatriptan
200	Antivert	Meclizine

[a]This table contains the top 200 prescription drugs dispensed through independent, chain, food store, mass merchandiser, and deep discount pharmacies. All forms of the same generic equivalent drug are grouped together and listed under the brand name when appropriate. Rankings are based on total number of prescriptions for August 2004 to August 2005, as measured by SFI's Prescription Drug Audit. Insulin products are included in the tally. Adapted with permission from Prescription Drug Cards, 23rd ed. SFI Medical Publishing, 2007.

Top Over-the-Counter (OTC) Drugs[a]

Trade Name	Drug Use
Abreva®	Cold sore medication
Actifed®	Allergy and cold relief
Advil®	Analgesic
Afrin®	Nasal decongestant
Aleve®	Analgesic
ALternaGEL®	Antacid
Anbesol®	Oral cavity analgesic
Anusol®	Hemorrhoidal agent
Azo Standard®	UTI analgesic
Bayer® Aspirin	Analgesic
Benadryl® Oral	Allergy and cold relief
BEN-GAY®	Topical analgesic
Betadine®	Antiseptic
Bonine®	Motion sickness medication
Bufferin®	Analgesic
Caladryl®	Topical antipruritic
Carmex®	Cold sore medication

Cepastat®	Oral cavity analgesic
Chlor-Trimeton®	Allergy and cold relief
Chloraseptic®	Oral cavity analgesic
Citrucel®	Laxative
Claritin®	Allergy and cold relief
Claritin-D®	Allergy and cold relief
Colace®	Stool softener
COLD-EEZE®	Cold relief
Compound W®	Keratolytic
Cortaid®	Topical antipruritic
Debrox®	Ear wax removal aid
Delsym®	Cough suppressant
Dramamine®	Motion sickness medication
Dulcolax®	Laxative
Duofilm®	Keratolytic
Emetrol®	Antiemetic
Estroven®	Menopause support

Excedrin®	Analgesic
FiberCon®	Laxative
Fungi-Nail®	Topical antifungal
Gas-X®	Antiflatulent
Gyne-Lotrimin®	Vaginal antifungal
Herpecin-L®	Cold sore medication
Imodium A-D®	Antidiarrheal
Ivy Dry®	Topical antipruritic
Lactaid®	Digestive aid
Lactinex®	Antidiarrheal
Lamisil® AT	Antifungal
Listerine®	Oral cavity antiseptic
Lotrimin AF®	Topical antifungal
Maalox® & Maalox® Plus	Antacid
Metamucil®	Laxative
Midol® & Midol® PMS	Analgesic
Monistat® Vaginal	Vaginal antifungal

Motrin® IB	Analgesic
Mucinex® (Adult)	Expectorant
Mylanta®	Antacid
Mylicon® Drops	Antiflatulence
Myoflex®	Topical analgesic
Naphcon® A	Ophthalmic anti-allergy
NasalCrom®	Allergy and cold relief
Neo-Synephrine®	Nasal decongestant
Neosporin®	Topical anti-infective
NicoDerm® CQ	Smoking cessation aid
Nicorette®	Smoking cessation aid
Nix®	Pediculicide
Nizoral® Shampoo	Topical antifungal
NoDoz®	Analeptic
NyQuil®	Cough and cold relief
Ocean®	Nasal decongestant
Opcon-A®	Ophthalmic anti-allergy

Orabase®	Oral cavity analgesic
OralBalance®	Oral moisturizer
Os-Cal®	Essential mineral
Pamprin®	Analgesic
PediaCare®	Cough and cold relief
Pepcid® Complete	Acid reducer
Pepcid-AC®	Acid reducer
Pepto Bismol®	Antidiarrheal
Peri-Colace®	Stool softener plus laxative
Phillips' MOM®	Laxative/antacid
Pin-X®	Anthelmintic
Preparation H®	Hemorrhoidal agent
Prilosec® OTC	Acid reducer
RID®	Pediculicide
Robitussin® (Adult)	Cough relief
Rogaine®	Hair growth stimulant
Salivart®	Saliva substitute

Senokot®	Laxative
Similasan Earache Relief®	Earache relief
Slow-Mag®	Essential mineral
Sominex®	Sleeping aid
Sudafed®	Allergy and cold relief
Tagamet HB 200®	Acid reducer
Tavist®	Allergy and cold relief
Tears Naturale®	Artificial tears
Triaminic® Oral	Cough and cold relief
Tums®	Antacid
Tylenol®	Analgesic
Tylenol® Allergy & Sinus	Allergy and cold relief
Tylenol® Cold & Flu (Adult)	Allergy and cold relief
Tylenol® PM	Analgesic
Unisom®	Sleeping aid
Zantac® OTC	Acid reducer
Zicam® Cold Remedy	Cold relief

Zilactin® and Zilactin-B®	Cold sore medication
Zostrix®	Topical analgesic

Appendix B

Common Prescription Drugs and Over-the-Counter Products

The FDA Approved Drug Products With Therapeutic Equivalence Evaluation: The *Orange Book*

The United States Food and Drug Administration (FDA) publishes the book, *Approved Drug Products With Therapeutic Equivalence Evaluation,* often known as the *Orange Book.* An electronic version of the *Orange Book* is available on the Internet at http://www.fda.gov/cder/ob/. This book is also reproduced by the United States Pharmacopeial Convention, Inc., in the publication, USP DI, Volume III, *Approved Drug Products and Legal Requirements.*

The texts, which are published annually, identify the prescription and nonprescription products that are formally approved by the FDA on the basis of safety and effectiveness. They also provide the FDA's therapeutic equivalence evaluations for approved multiple-source prescription drug products.

The *Orange Book* is a drug product selection guide for pharmacists to use when dispensing a generic drug product as a substitute for the brand-name equivalent. A few drug products that were on the market before 1938 received a “grandfathered” FDA approval. These products are assumed to be safe and effective because of their long usage (e.g., digoxin tablets, phenobarbital tablets). These older products do not have therapeutic equivalence ratings at this time.

The *Orange Book* uses various codes to indicate therapeutic equivalence. The first letter “A” designates drug products that the FDA considers therapeutically equivalent to a pharmaceutically equivalent drug product. These products can be safely substituted. The first letter “B” designates drug products that, for various reasons, the FDA does not consider bioequivalent to the pharmaceutically equivalent drug product.

Therapeutic Equivalence Evaluation Codes

A Codes

Drug products that the FDA considers therapeutically equivalent to other pharmaceutically equivalent products

AA	Products in conventional dosage forms that do not present bioequivalence problems
AB	Products that meet necessary bioequivalence requirements
AN	Solutions and powders for aerosolization
AO	Injectable oil solutions
AO	Injectable aqueous solutions, and in certain instances, intravenous nonaqueous solutions
AT	Topical products

B Codes

Drug products that the FDA does not consider therapeutically equivalent to other pharmaceutically equivalent products at this time

P.1322

B*	Drug products that require further FDA investigation and review to determine therapeutic equivalence
BC	Extended-release dosage forms (capsules, injectables, and tablets)
BD	Active ingredients and dosage forms that have documented problems with bioequivalence
BE	Delayed-release oral dosage forms
BN	Products in aerosol-nebulizer drug-delivery systems
BP	Active ingredients and dosage forms that have potential problems with bioequivalence

BR	Suppositories or enemas that deliver drugs for systemic absorption
BS	Drug products that have drug standard deficiencies
BT	Topical products that have bioequivalence issues
BX	Drug products for which the data are sufficient to determine therapeutic equivalence

Top 200 Prescription Drugs by Trade Name and Generic Namea

Rank	Trade Name	Generic Name
1	Lortab	Hydrocodone/acetaminophen
2	Synthroid	Levothyroxine
3	Xanax	Alprazolam
4	Potassium Chloride	Potassium Chloride
5	Glucophage	Metformin
6	Zestril/Prinivil	Lisinopril
7	Ultram	Tramadol

8	Lasix	Furosemide
9	Lipitor	Atorvastatin
10	Percocet	Oxycodone/acetaminophen
11	Tenormin	Atenolol
12	Toprol-XL	Metoprolol succinate
13	Lopressor	Metoprolol tartrate
14	Hydrochlorothiazide	Hydrochlorothiazide
15	Coumadin	Warfarin
16	Norvasc	Amlodipine
17	Amoxil	Amoxicillin
18	OxyContin	Oxycodone ER
19	Zithromax and Zmax	Azithromycin
20	Darvocet	Propoxyphene/acetaminophen
21	Zoloft	Sertraline
22	Zantac	Ranitidine
23	Zocor	Simvastatin
24	Lexapro	Escitalopram

25	Nexium	Esomeprazole
26	Seroquel	Quetiapine
27	Proventil	Albuterol
28	Singulair	Montelukast
29	Plavix	Clopidogrel
30	Deltasone	Prednisone
31	Effexor XR	Venlafaxine
32	Elavil	Amitriptyline
33	Ativan	Lorazepam
34	Neurontin	Gabapentin
35	Glucotrol and Glucotrol XR	Glipizide
36	Naprosyn and EC-Naprosyn	Naproxen
37	Wellbutrin (SR, XL)	Bupropion
38	Desyrel	Trazodone
39	Prilosec	Omeprazole
40	Dyazide	Triamterene/hydrochlorothiazide

41	Flexeril	Cyclobenzaprine
42	Duragesic	Fentanyl transdermal system
43	Prozac	Fluoxetine
44	Fosamax	Alendronate
45	Vasotec	Enalapril
46	Prevacid	Lansoprazole
47	Lantus	Insulin glargine
48	Premarin	Conjugated estrogens
49	Lanoxin	Digoxin
50	Valium	Diazepam
51	Keflex	Cephalexin
52	Paxil CR	Paroxetine
53	Reglan	Metoclopramide
54	Cardizem CD	Diltiazem
55	Ambien	Zolpidem
56	Celexa	Citalopram
57	Advair	Fluticasone/salmeterol

58	Zestoretic	Lisinopril/hydrochlorothiazide
59	Vytorin	Simvastatin/ezetimibe
60	Zyrtec	Cetirizine
61	Fioricet	Butalbital/acetaminophen/caffeine
62	Diflucan	Fluconazole
63	Ortho Tri-Cyclen	Ethinyl estradiol/norgestimate
64	Depakote ER	Divalproex
65	Adderall XR	Dextroamphetamine/amphetamine
66	Celebrex	Celecoxib
67	Diovan	Valsartan
68	Lotrel	Amlodipine/benazepril
69	Allegra	Fexofenadine
70	Klonopin	Clonazepam
71	Augmentin XR	Amoxicillin/clavulanate
72	Cymbalta	Duloxetine
73	Risperdal	Risperidone
74	Levaquin	Levofloxacin

75	Aldactone	Spironolactone
76	Lyrica	Pregabalin
77	Zyloprim	Allopurinol
78	Protonix	Pantoprazole
79	Actos	Pioglitazone
80	Dilantin	Phenytoin
81	Kenalog	Triamcinolone
82	Motrin	Ibuprofen
83	Altace	Ramipril
84	Coreg	Carvedilol
85	Isoptin and Isoptin SR	Verapamil
86	Estrace	Estradiol
87	Catapres	Clonidine
88	Soma	Carisoprodol
89	Zetia	Ezetimibe
90	Amaryl	Glimepiride
91	Flomax	Tamsulosin

92	Diovan-HCT	Valsartan/hydrochlorothiazide
93	Humalog	Insulin lispro
94	Flonase	Fluticasone propionate
95	Tylenol with Codeine	Acetaminophen/codeine
96	Aricept	Donepezil
97	Mevacor	Lovastatin
98	Accupril	Quinapril
99	Miralax	Polyethylene glycol 3350
100	MS Contin	Morphine sulfate
101	Cozaar	Losartan
102	Ditropan	Oxybutynin
103	Detrol	Tolterodine
104	TriCor	Fenofibrate
105	Combivent	Ipratropium/albuterol
106	Zyprexa	Olanzapine
107	Crestor	Rosuvastatin
108	Remeron	Mirtazapine

109	Procardia and Procardia XL	Nifedipine
110	Imdur	Isosorbide mononitrate
111	Topamax	Topiramate
112	Actonel	Risedronate
113	Atrovent	Ipratropium
114	Medrol	Methylprednisolone
115	Tessalon	Benzonatate
116	Ultracet	Tramadol/acetaminophen
117	Sinequan	Doxepin
118	Ritalin SR and LA	Methylphenidate
119	Avandia	Rosiglitazone
120	Cipro XR	Ciprofloxacin
121	Bactrim or Septra	Sulfamethoxazole/trimethoprim
122	Folic Acid	Folic acid
123	Phenergan	Promethazine
124	Macrodantin and Macrobid	Nitrofurantoin

125	Pyridium	Phenazopyridine
126	Hyzaar	Losartan/hydrochlorothiazide
127	Dilacor XR	Diltiazem
128	Vibramycin/Vibra-Tabs	Doxycycline hyclate
129	Capoten	Captopril
130	Tegretol	Carbamazepine
131	Concerta	Methylphenidate
132	Trileptal	Oxcarbazepine
133	Evista	Raloxifene
134	Glucovance	Glyburide/metformin
135	Namenda	Memantine
136	Cardura	Doxazosin
137	NovoLog	Insulin aspart
138	Flagyl	Metronidazole
139	Nasonex	Mometasone furoate
140	Restoril	Temazepam
141	Micronase	Glyburide

142	Xopenex	Levalbuterol
143	Xalatan	Latanoprost
144	Mycostatin	Nystatin
145	Benicar	Olmesartan
146	Alesse	Ethinyl estradiol/levonorgestrel
147	Abilify	Aripiprazole
148	DuoNeb	Ipratropium/albuterol
149	Armour Thyroid	Thyroid, dessicated
150	Ziac	Bisoprolol/hydrochlorothiazide
151	Lotensin	Benazepril
152	Phenobarbital	Phenobarbital
153	Cleocin	Clindamycin
154	Theophylline	Theophylline
155	Pravachol	Pravastatin
156	Lamictal	Lamotrigine
157	Voltaren	Diclofenac
158	Spiriva	Tiotropium

159	Cogentin	Benztropine mesylate
160	Mobic	Meloxicam
161	Strattera	Atomoxetine
162	Yasmin	Ethinyl estradiol/drospirenone
163	Ortho-Novum 7/7/7	Ethinyl estradiol/norethindrone
164	Hytrin	Terazosin
165	Avapro	Irbesartan
166	Veetids	Penicillin V
167	Lopid	Gemfibrozil
168	Skelaxin	Metaxalone
169	Inderal	Propanolol
170	Zovirax	Acyclovir
171	Benicar-HCT	Olmesartan/hydrochlorothiazide
172	Adipex-P	Phentermine
173	Bactroban	Mupirocin
174	AcipHex	Rabeprazole
175	Pepcid	Famotidine

176	Imuran	Azathioprine
177	Bentyl	Dicyclomine
178	Clozaril	Clozapine
179	Biaxin XL	Clarithromycin
180	Methadone	Methadone
181	Provera	Medroxyprogesterone
182	Requip	Ropinirole
183	Prempro	Conjugated estrogens/medroxyprogesterone
184	Lithonate & Lithotabs	Lithium carbonate
185	Buspar	Buspirone
186	Omnicef	Cefdinir
187	Lunesta	Eszopiclone
188	Relafen	Nabumetone
189	Allegra-D	Fexofenadine/pseudoephedrine
190	Niaspan	Niacin
191	Bumex	Bumetanide
192	Demadex	Torsemide

193	Lotrisone	Clotrimazole/betamethasone
194	Lomotil	Diphenoxylate/atropine
195	Lactulose	Lactulose
196	Monopril	Fosinopril
197	Guaifenex PSE	Guaifenesin/pseudoephedrine
198	Flovent	Fluticasone propionate
199	Imitrex	Sumatriptan
200	Antivert	Meclizine

Duofilm®	Keratolytic
Emetrol®	Antiemetic
Estroven®	Menopause support

Excedrin®	Analgesic
FiberCon®	Laxative
Fungi-Nail®	Topical antifungal
Gas-X®	Antiflatulent
Gyne-Lotrimin®	Vaginal antifungal
Herpecin-L®	Cold sore medication
Imodium A-D®	Antidiarrheal
Ivy Dry®	Topical antipruritic
Lactaid®	Digestive aid
Lactinex®	Antidiarrheal
Lamisil® AT	Antifungal
Listerine®	Oral cavity antiseptic
Lotrimin AF®	Topical antifungal
Maalox® & Maalox® Plus	Antacid
Metamucil®	Laxative
Midol® & Midol® PMS	Analgesic
Monistat® Vaginal	Vaginal antifungal

Motrin® IB	Analgesic
Mucinex® (Adult)	Expectorant
Mylanta®	Antacid
Mylicon® Drops	Antiflatulence
Myoflex®	Topical analgesic
Naphcon® A	Ophthalmic anti-allergy
NasalCrom®	Allergy and cold relief
Neo-Synephrine®	Nasal decongestant
Neosporin®	Topical anti-infective
NicoDerm® CQ	Smoking cessation aid
Nicorette®	Smoking cessation aid
Nix®	Pediculicide
Nizoral® Shampoo	Topical antifungal
NoDoz®	Analeptic
NyQuil®	Cough and cold relief
Ocean®	Nasal decongestant
Opcon-A®	Ophthalmic anti-allergy

Orabase®	Oral cavity analgesic
OralBalance®	Oral moisturizer
Os-Cal®	Essential mineral
Pamprin®	Analgesic
PediaCare®	Cough and cold relief
Pepcid® Complete	Acid reducer
Pepcid-AC®	Acid reducer
Pepto Bismol®	Antidiarrheal
Peri-Colace®	Stool softener plus laxative
Phillips' MOM®	Laxative/antacid
Pin-X®	Anthelmintic
Preparation H®	Hemorrhoidal agent
Prilosec® OTC	Acid reducer
RID®	Pediculicide
Robitussin® (Adult)	Cough relief
Rogaine®	Hair growth stimulant
Salivart®	Saliva substitute

Senokot®	Laxative
Similasan Earache Relief®	Earache relief
Slow-Mag®	Essential mineral
Sominex®	Sleeping aid
Sudafed®	Allergy and cold relief
Tagamet HB 200®	Acid reducer
Tavist®	Allergy and cold relief
Tears Naturale®	Artificial tears
Triaminic® Oral	Cough and cold relief
Tums®	Antacid
Tylenol®	Analgesic
Tylenol® Allergy & Sinus	Allergy and cold relief
Tylenol® Cold & Flu (Adult)	Allergy and cold relief
Tylenol® PM	Analgesic
Unisom®	Sleeping aid
Zantac® OTC	Acid reducer
Zicam® Cold Remedy	Cold relief

Zilactin® and Zilactin-B®	Cold sore medication
Zostrix®	Topical analgesic

[a]This table contains the top OTC drugs by pharmacist recommendation in specific therapeutic classes.

[a] Costs are approximate and are based on 2007 figures. Costs vary depending upon selection of format site versus individual license fees, concurrent users, number of beds in facility, or number of students enrolled. Institutional subscriptions are more expensive than individual subscriptions. It is important to have the appropriate site license.

45

Seizure Disorders

Azita Razzaghi

I. INTRODUCTION

A. Definitions

1. Seizures are characterized by an excessive, hypersynchronous discharge of cortical neuron activity, which can be measured by the electroencephalogram (EEG). In addition, there may be disturbances in consciousness, sensory motor systems, subjective well-being, and objective behavior; seizures are usually brief, with a beginning and an end, and may produce postseizure impairment.

2. Epilepsy is defined as a chronic seizure disorder, or group of disorders, characterized by seizures that usually recur unpredictably in the absence of a consistent provoking factor. The term *epilepsy* is derived from the Greek word meaning “to seize upon” or “taking hold of.” It was first described by Hughlings Jackson in the 19th century as an intermittent derangement of the nervous system due to a sudden, excessive, disorderly discharge of cerebral neurons.

3. Convulsions are violent, involuntary contractions of the voluntary muscles. A patient may have epilepsy or a seizure disorder without convulsions.

B. Classification. An alternative seizure classification is being developed that is purely symptom based. This consists of four categories: sensorial (auras), consciousness, autonomic, and motor. Also, the international league against epilepsy is establishing a four-level descriptive seizure classification based on symptoms, apathophysiological seizure, an epileptic syndrome, and functional disability. At present, there are two systems of classification of seizure disorder: one is based on the seizure type and characteristics (Table 45-1), and the other is based on the

characteristics of the epilepsy (including age at onset, etiological factors, and frequency) and characteristics of the seizure (Table 45-2).

Table 45-1. International Classification of Epileptic Seizures

I.	**Partial seizures** (seizures beginning locally)				
	A.	**Simple partial seizures** (consciousness not impaired)			
		1.	With motor symptoms		
		2.	With somatosensory or special sensory symptoms		
		3.	With autonomic symptoms		
		4.	With behavioral symptoms		
	B.	**Complex partial seizures** (with impairment of consciousness)			
		1.	Beginning as simple partial seizures and progressing to impairment of consciousness		
			a.	Without automatisms	
			b.	With automatisms	
		2.	With impairment of consciousness at onset		
			a.	With no other features	
			b.	With features of simple partial seizures	
			c.	With automatisms	
	C.	**Partial seizures** (simple or complex), secondarily generalized			
II.	**Generalized seizures** (bilaterally symmetric, without localized onset)				

	A.	**Absence seizures**	
		1.	**True absence seizures (petit mal)**
		2.	**Atypical absence seizures**
	B.	**Myoclonic seizures**	
	C.	**Clonic seizures**	
	D.	**Tonic seizures**	
	E.	**Tonic-clonic seizures (grand mal)**	
	F.	**Atonic seizures**	
III.	**Unclassified seizures**		

Reprinted from Commission on Classification and Terminology of the International League against Epilepsy. Proposal for classification of epilepsies and epileptic syndromes. Epilepsia 1985;26:268-278.

1. Partial seizures are the most common seizure type, occurring in approximately 80% of patients with epilepsy.

Table 45-2. Classification of Epilepsies and Epileptic Syndromes

I.	**Localized-related (focal, local, partial) epilepsies and syndromes**		
	A.	**Idiopathic** (with age-related onset)	
		1.	Benign childhood epilepsy with centrotemporal spikes (rolandic epilepsy)
		2.	Childhood epilepsy with occipital paroxysms

	B.	**Symptomatic**	
		1.	Chronic progressive epilepsia partialis continua of childhood
		2.	Syndromes characterized by specific modes of precipitation
		3.	Temporal lobe epilepsies
		4.	Frontal lobe epilepsies
		5.	Parietal lobe epilepsies
		6.	Occipital lobe epilepsies
	C.	**Cryptogenic**	
II.	**Generalized epilepsies and syndromes**		
	A.	**Idiopathic** (with age-related onset)	
		1.	Benign neonatal familial convulsions
		2.	Benign neonatal convulsions
		3.	Benign myoclonic epilepsy in infancy
		4.	Childhood absence epilepsy (pyknolepsy)
		5.	Juvenile absence epilepsy
		6.	Juvenile myoclonic epilepsy

		7.	Epilepsy with generalized tonic-clonic seizures on awakening	
		8.	Other generalized idiopathic epilepsies not defined above	
		9.	Epilepsies with seizures precipitated by specific modes of activation	
	B.	**Cryptogenic or symptomatic** (in order of age)		
		1.	West syndrome (infantile spasms)	
		2.	Lennox-Gastaut syndrome	
		3.	Epilepsy with myoclonic-astatic seizures	
		4.	Epilepsy with myoclonic absences	
	C.	**Symptomatic**		
		1.	**Nonspecific etiology**	
			a.	Early myoclonic encephalopathy
			b.	Early infantile epileptic encephalopathy with suppression burst
			c.	Other symptomatic generalized epilepsies not defined above
		2.	**Specific syndromes and generalized seizures complicating other disease states**	
III.	**Epilepsies and syndromes undetermined whether focal or generalized**			

	A.	**With both focal and generalized seizures**	
		1.	Neonatal seizures
		2.	Severe myoclonic epilepsy in infancy
		3.	Epilepsy with continuous spike waves during slow-wave sleep
		4.	Acquired epileptic aphasia (Landau-Kleffner syndrome)[a]
		5.	Other undetermined epilepsies not defined above
	B.	**Without unequivocal generalized or focal features**	
IV.	**Special situations**		
	A.	Febrile convulsions	
	B.	Isolated seizures or isolated status epilepticus	
	C.	Seizures occurring only when there is an acute metabolic or toxic event due to such factors as alcohol, drugs, eclampsia, and nonketotic hyperglycemia	

[a] Believed to be a localized-related epilepsy.

Reprinted with permission from Bleck TP. Convulsive disorders: the use of anticonvulsant drugs. Clin Neuropharmacol 1990;1:198-209.

a. Clinical and EEG changes indicate initial activation of a system of neurons limited to part of one cerebral hemisphere that may spread to other or all brain areas. Manifestations of the seizures depend on the site of the epileptogenic focus in the brain.

b. Partial seizures are subclassified as **simple** (usually unilateral involvement) or **complex** (usually bilateral involvement). Impairment of consciousness is a feature of complex seizures. Consciousness is defined as the degree of awareness and responsiveness of the patient to externally applied stimuli.

(1) Simple partial seizures generally do not cause loss of consciousness. **Signs and symptoms** of simple partial seizures may be primarily motor, sensory, somatosensory, autonomic, or behavioral. These signs and symptoms may help pinpoint the site of the abnormal brain discharge, for example, localized numbness or tingling reflects a dysfunction in the sensory cortex, located in the parietal lobe.

(a) Motor signs include convulsive jerking, chewing motions, and lip smacking.

(b) Sensory and somatosensory manifestations include paresthesias and auras.

(c) Autonomic signs include sweating, flushing, and pupil dilation.

(d) Behavioral manifestations, which are sometimes accompanied by impaired consciousness, include déjà vu experiences, structured hallucinations, and dysphasia.

(2) Complex partial seizures are accompanied by impaired consciousness; however, in some cases, the impairment precedes or follows the seizure. These seizures have variable manifestations.

(a) Purposeless behavior is common.

(b) The affected person may have a glassy stare, may wander about aimlessly, and may speak unintelligibly.

(c) Psychomotor (temporal lobe) epilepsy may lead to aggressive behavior (e.g., outbursts of rage or violence).

(d) Postictal confusion usually persists for 1-2 min after the seizure ends.

(e) Automatism (e.g., picking at clothes) is common and may follow visual, auditory, or olfactory hallucinations.

2. Generalized seizures are diffuse, affecting both cerebral hemispheres.

a. Clinical and EEG changes indicate initial involvement of both hemispheres.

(1) Consciousness may be impaired, and this impairment may be the initial manifestation.

(2) Motor manifestations are bilateral.

(3) The ictal EEG patterns initially are bilateral and presumably reflect neuronal discharge, which is widespread in both hemispheres.

b. There are three **types** of generalized seizures.

(1) Idiopathic epilepsies have an age-related onset, typical clinical and EEG characteristics, and a presumed genetic origin.

(2) Symptomatic epilepsies are considered the consequence of a known or suspected underlying disorder of the central nervous system (CNS).

(3) Cryptogenic epilepsy refers to a disorder for which the cause is hidden or occult; it is presumed to be symptomatic, but the causal factors are unknown. It is age related, but often does not have well-defined clinical and EEG characteristics.

c. Signs and symptoms of generalized seizures may be minor or major.

(1) Absence (petit mal) seizures present as alterations of consciousness (absences) lasting 10-30 sec.

(a) Staring (with occasional eye blinking) and loss or reduction in postural tone are typical. If the seizure takes place during conversation, the individual may break off in midsentence.
(b) Enuresis and other autonomic components may occur during absence seizures.
(c) Some patients experience 100 or more absences daily.
(d) Onset of this seizure type occurs from age 3 to 16 years; in most patients, absence seizures disappear by age 40.
(2) Myoclonic (bilateral massive epileptic myoclonus) seizures present as involuntary jerking of the facial, limb, or trunk muscles, possibly in a rhythmic manner.
(3) Clonic seizures are characterized by sustained muscle contractions alternating with relaxation.
P.986

(4) Tonic seizures involve sustained tonic muscle extension (stiffening).
(5) Generalized (grand mal) tonic-clonic seizures cause sudden loss of consciousness.
(a) The individual becomes rigid and falls to the ground. Respirations are interrupted. The legs extend, and the back arches; contraction of the diaphragm may induce grunting. This tonic phase lasts for about 1 min.
(b) A clonic phase follows, marked by rapid bilateral muscle jerking, muscle flaccidity, and hyperventilation. Incontinence, tongue biting, tachycardia, and heavy salivation sometimes occur.
(c) During the postictal phase, the individual may experience headache, confusion, disorientation, nausea, drowsiness, and muscle soreness. This phase may last for hours.
(d) Some patients with epilepsy have serial grand mal seizures, regaining consciousness briefly between attacks. In some cases, grand mal seizures occur repeatedly with no recovery of consciousness between attacks (**status epilepticus**); this disorder is discussed in III.A.
(6) Atonic seizures (drop attacks) are characterized by a sudden loss of postural tone so that the individual falls to the ground. They occur primarily in children.
C. Epidemiology
1. Most common neurological disorder
2. Epilepsy has a prevalence of approximately 1% (i.e., 500,000 cases per 50 million persons worldwide).
3. In the United States, the prevalence of epilepsy is 6.42 cases per 1000 people.
4. The onset of seizures is greatest during the 1st year of life; this probability decreases each decade after the 1st year until age 60. Approximately 1 of 50 children and 1 of 100 adults are affected.
5. Approximately 70% of people with epilepsy have only one seizure type; the remainder have two or more seizure types.
D. Cause. Some seizures arise secondary to other conditions. However, in most cases, the cause of the seizure is unknown.

1. Primary (idiopathic) seizures have no identifiable cause.

a. This type of seizure affects about 75% of people with epilepsy.

b. The onset of primary seizures typically occurs before age 20.

c. Birth trauma, hereditary factors, and unexplained metabolic disturbances have been proposed as possible causes.

2. Secondary seizures (symptomatic or acquired seizures) occur secondary to an identifiable cause.

a. Disorders that may lead to secondary seizures include

(1) Intracranial neoplasms

(2) Infectious diseases, such as meningitis, influenza, toxoplasmosis, mumps, measles, and syphilis

(3) High fever (in children)

(4) Head trauma

(5) Congenital diseases

(6) Metabolic disorders, such as hypoglycemia and hypocalcemia

(7) Alcohol or drug withdrawal

(8) Lipid storage disorders

(9) Developmental abnormalities

b. Age at seizure onset is associated with specific causes (Table 45-3).

E. Pathophysiology. Seizures reflect a sudden, abnormal, excessive neuronal discharge in the cerebral cortex. Any abnormal neuronal discharge could precipitate a seizure (Figure 45-1).

1. Normal firing of neurons, which usually originate from the gray matter of one or more cortical or subcortical areas, requires the following elements:

a. Voltage-dependent ion channels are involved in action-potential propagation or burst generation.

Table 45-3. Probable Causes of Recurrent Seizures by Age Group

Age at Seizure Onset	Probable Cause of Seizure
Birth-1 month	Birth injury or anoxia, congenital hereditary diseases, and metabolic disorders
1-6 months	As above, plus infantile spasms
6 months-2 years	Infantile spasms, febrile convulsions, birth injury or anoxia, meningitis, and head trauma

3-10 years	Birth injury or anoxia, meningitis, cerebral vessel thrombosis, and idiopathic epilepsy
10-18 years	Idiopathic epilepsy and head trauma
18-25 years	Idiopathic epilepsy, trauma, neoplasm, and withdrawal from alcohol or drugs
35-60 years	Trauma, neoplasm, vascular disease, and withdrawal from alcohol or drugs
> 60 years	Vascular disease, neoplasm, degenerative disease, and trauma

b. Neurotransmitters control neuronal firing, including excitatory neurotransmitters, acetylcholine, norepinephrine, histamine, corticotropin-releasing factors (CRFs), inhibitory neurotransmitters, γ-aminobutyric acid (GABA), and dopamine; therefore, normal neuronal activity requires adequate ions (e.g., sodium, potassium, calcium); excitatory and inhibitory neurotransmitters; and glucose, oxygen, amino acids, and adequate systemic pH.

c. People with epilepsy may be **genetically** predisposed to a **lower seizure threshold.**

d. A diencephalic nerve group that normally suppresses excessive brain discharge may be deafferentated, hypersensitive, and vulnerable to activation by various stimuli in individuals with epilepsy.

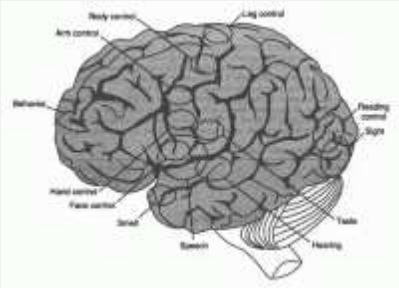

Figure 45-1. Gross anatomy of the brain. Clinical manifestation of seizures depends on the area of the cortex that is affected and its function, the degree of irritability, and the identity of the impulse.

e. During seizures, there is an increased use of energy, oxygen, and, consequently, an increased production of carbon dioxide. Because of the limited capacity to increase the blood flow to the brain, the blood supply may be **oxygen deficient.** The ratio of supply to demand decreases when the seizure episode is prolonged, leading to increased ischemia and neuronal destruction. Thus it is crucial to diagnose seizures and treat them as soon as possible.

2. Abnormal electrical brain activity occurring during a seizure usually produces **characteristic changes on the EEG.** Each part of the cortical area has its own function, and the clinical presentation of a seizure depends on the site, the degree of irritability of the area, and the intensity of the impulse.

3. Seizure activity may include three major **phases.**

a. A prodrome may precede the seizure by hours or days.

(1) Changes in behavior or mood typically occur during the prodrome.

(2) This phase may include an aura—a subjective sensation, such as an unusual smell or flashing light.

b. The **ictal phase** is the seizure itself. In some cases, its onset is heralded by a scream or cry.

c. The **postictal phase** takes place immediately after the seizure.

(1) Extensor plantar reflexes may appear.

(2) The patient typically exhibits lethargy, confusion, and behavioral changes.

F. Clinical evaluation

1. History includes an evaluation of the seizure, including interviews of the patient's family and eyewitness accounts to establish

a. The frequency and duration of the episodes

b. Precipitating factors

c. The times at which episodes occur

d. The presence or absence of an aura

e. Ictal activity

f. Postictal state

2. Physical and neurological examinations are the tools with which to identify an underlying cause to rule out diseases that manifest as seizures (Table 45-4).

3. Laboratory tests may also identify an underlying cause.

a. Liver and kidney function tests, complete blood count (CBC), urinalysis, and serum drug levels (e.g., antidepressants and amphetamines may precipitate seizures) are necessary.

b. Lumbar puncture may be required for evidence of cerebrospinal fluid (CSF) infection for patients with a fever who have seizures.

Table 45-4. Disorders That Mimic Epilepsy

Gastroesophageal reflux		Movement disorders	
Breath-holding spells			Shuddering attacks
Migraine			Paroxysmal choreoathetosis
	Confusional		Nonepileptic myoclonus
	Basilar		Tics and habit spasms
	With recurrent abdominal pain and cyclic vomiting	Psychological disorders	
	Sleep disorders (especially parasomnias)		Panic disorder
Cardiovascular events			Hyperventilation attacks
	Pallid infantile syncope		Pseudoseizures
	Vasovagal attacks		Rage attacks
	Vasomotor syncope		
	Arrhythmias		

4. Neurological imaging studies, including MRI and/or CT, complement electrophysiological studies and can identify structural brain disorders (anatomical abnormalities).

a. An MRI can detect cerebral lesions related to epilepsy and should be used in all cases, especially in patients with partial seizure, to exclude brain abnormalities.
b. Positron-emission tomography (PET), single-photon emission CT (SPECT), and stable xenon-enhanced x-ray CT offer functional views of the brain to detect hypometabolism or relative hypoperfusion. PET and SPECT scans are not available in all institutions.
c. EEG studies measure the electrical activity of the brain. These studies help identify functional cerebral changes underlying structural abnormalities and are useful with MRI for patients considered for epilepsy surgery.
(1) An EEG is useful for classifying the seizure or as an additional diagnostic tool, but the EEG by itself cannot rule seizures in or out, because some patients with normal interictal EEGs have seizure disorders.
(2) The best time to obtain an EEG is *during* a seizure episode. EEG recordings done while the patient is asleep can often record the abnormal activity; therefore, EEGs performed during a sleep-induced state under normal conditions or in a sleepdeprived state can be more sensitive for making a diagnosis.

G. Treatment objectives

1. To prevent or suppress seizures or reduce their frequency through drug therapy
2. To control or eliminate the factors that cause or precipitate seizures
3. To prevent serious consequences of seizures, such as anoxia, airway occlusion, or injury, by protecting the tongue and placing a pillow under the victim's head
4. To encourage a normal lifestyle and prevent the patient from feeling like or being treated as an invalid
5. Short- and long-term side effects
6. Drug interactions

II. THERAPY

A. Principles of drug therapy

1. Seizure control. Approximately 50% of patients with epilepsy achieve complete seizure control through drug therapy. In another 25%, drugs reduce the frequency of seizures. People with epilepsy generally require continuous drug therapy for at least 2 seizure-free years before the drug discontinuation can be considered.

2. Initial treatment

a. Before anticonvulsive drug treatment is instituted, treatable underlying causes of the seizure activity should be excluded.
b. A single primary drug that is most appropriate for the seizure type must be selected. If there is more than one appropriate primary drug, then age, sex, and compliance of the patient must be considered.
c. For patients with newly diagnosed epilepsy, administer low doses for a few days. Patients may respond to a dosage that is lower than that traditionally prescribed initially by their physicians, and this may have important implications in terms of limiting adverse effects. The incidence of adverse effects increases with increasing drug levels, even when the plasma concentrations are maintained within the so-called therapeutic or optimal range.

d. Between one fourth and one third of the maintenance dose of a single medication is used to begin therapy; it is then increased over 3-4 weeks. The exceptions are phenytoin and phenobarbital, which can be started with the loading or maintenance dose. The dose should be titrated until seizure control or intolerable side effects occur.
e. With the initiation of therapy, blood concentrations of medications should be measured:
(1) To establish therapeutic ranges and dosage regimens based on symptomatic toxicity or seizure frequency
(2) To assess the patient's compliance with therapy
(3) To control the correlation among the dose, blood levels, and clinical therapeutic levels or toxicity
(a) Phenytoin follows nonlinear kinetics, as drug levels increase dramatically (more than onefold) with only a small increase in the dose. However, before this twofold

increase in drug level with a small increase in dose, there is a predictable linear increase with dose increases; for this reason, it is recommended to increase the dose in small increments to be able to predict when the drug follows the nonlinear kinetic. When this happens, that means the maximum rate of hepatic enzyme clearance is reached and the body can no longer clear the drug as it is introduced into the body.
(b) If physical examination reveals a new onset of nystagmus (except with phenytoin, in which nystagmus develops before clinical intoxication), ataxia, and unsteady wide gait, the next dose increase should be minimal.
(c) There is no justification for increasing drug dosage when a patient's seizures are fully controlled, even if the plasma concentration is below the lower limit of the therapeutic range. If the patient continues to have seizures without any evidence of adverse effects at a plasma concentration near the toxic range, there are two approaches:
(i) Some clinicians increase the dosage according to clinical response up to the highest tolerated limit.
(ii) Some clinicians do not increase the dosage because of the likelihood of producing adverse effects.
(d) Carbamazepine has an autoinduction metabolism property, which means that if the dose is increased twofold, blood levels increase less than twofold because of increased metabolism.
(4) To determine the free drug level, which is helpful in patients who are in the therapeutic range but have side effects or no response. The plasma protein binding may be altered in these patients by some other disease state or medication. Because of this alteration, there is more free drug available in the system than the total level shows, especially with phenytoin, valproic acid, and carbamazepine.
3. Paradoxical intoxication occurs when a high concentration of a single drug causes an increased frequency of seizures without classical adverse events. This is common with hydantoins and carbamazepine. The proposed reason is that their

effect on the cerebellum is blocked at high concentrations. Management usually requires no more than withholding enough doses of the drug to allow the concentration to drift down.

4. When seizures cannot be controlled, there are two options.

a. The initial drug can be substituted with another agent. This is accomplished by gradually discontinuing the initial drug while simultaneously increasing the dosage of the second agent. Then the dosage of the second agent is titrated up to the maintenance level as the initial agent is gradually discontinued. There are three main advantages of gradual substitution:

(1) It allows evaluation of the effects of individual drugs

(2) It reduces the risk of toxicity

(3) It reduces the risk of adverse drug interactions

b. A second drug can be added. Combination therapy is reserved for patients with severe epilepsy to rapidly control the seizures. Rapid control can be important for psychosocial reasons as well as for the possibility of a more favorable prognosis.

5. Long-term drug treatment. Most physicians review the patient's condition when the patient has been seizure free for 2 years. This has important implications in children because early termination of treatment has better remission rates compared with adults. It is recommended to gradually decrease the dose, over at least 6 months. The age of onset of epilepsy, the presence of an underlying neurological condition, and any abnormal EEGs should be considered.

6. Diseases and conditions that alter antiepileptic drug-protein bindings

a. Liver disease

b. Hypoalbuminemia

c. Burns

d. Pregnancy

e. High protein-binding drugs or antiepileptic agents. (Most important interactions are discussed under individual agents.)

7. Medications. Some medications decrease levels of phenytoin, carbamazepine, phenobarbital, and primidone by enhancing their metabolism. These drugs also cause false decreases in thyroid function tests.

a. Oral contraceptives

b. Oral hypoglycemics

c. Glucocorticoids

d. Tricyclic antidepressants

e. Azathioprine

f. Cyclosporine

g. Quinidine

h. Theophylline

i. Warfarin

j. Doxycycline

k. Levodopa

8. Overview of drug therapy in seizure disorder

a. Monotherapy. Start the drug therapy as single agent.

b. Dosage treatment. Use a low dose for a few days. Patients with newly diagnosed epilepsy may respond to dosages that are lower than those prescribed initially by their physicians, and this may have important implications in terms of adverse effects. The incidence of adverse effects increases with increasing drug dosage, even when the plasma concentration is maintained within the so-called therapeutic or optimal range.

c. Drug monitoring. There is no justification for increasing drug dosage when a patient is fully controlled, even if the plasma concentration is below the lower limit of the therapeutic range. If the patient continues to have seizures without any evidence of adverse effects at a plasma concentration near the toxic range, there are two approaches:

(1) Some clinicians increase the dosage according to clinical response up to the highest tolerated limit.

(2) Some clinicians do not increase the dosage because of the likelihood of producing adverse events.

9. Adverse effects of anticonvulsive drugs

a. Alternation in cognition and mentation

(1) Sedation and depression are the most common symptoms of overdose of anticonvulsive drugs, but they are difficult to assess. For example, barbiturates commonly cause depression, with primidone being the worst offender; diazepam and clorazepate are less likely to cause depression. Barbiturates, clonazepam, and trimethadione commonly cause cognitive impairment, ranging from sensation to confusion.

(2) Excitation can be a paradoxical effect of barbiturates with younger children and the elderly. For example, felbamate can cause restlessness and hyperactivity.

b. Deterioration of motor performance and primary coordination includes trembling hands, staggering when rounding corners, and mild limb ataxia. Drugs associated with these effects include hydantoins, methsuximide, carbamazepine, and primidone. These effects are less common with barbiturates and lamotrigine and are rarely seen with gabapentin.

c. Gastrointestinal symptoms include nausea and vomiting. Two purposed mechanisms include

(1) A local effect on the stomach, as in the case of valproic acid; divalproex acid, however, has less incidence compared with valproic acid. These symptoms decrease in incidence if the drug is given with meals.

(2) A brainstem effect, as in the cases of felbamate and carbamazepine. Nausea and vomiting caused by these drugs are associated with brainstem involvement; therefore, drug levels play a role in these symptoms. Administration in smaller, more frequent doses decreases the incidence of these symptoms by lowering the transient peak concentration.

d. Appetite and body weight. Few anticonvulsants affect appetite separate from nausea and vomiting, including anorexia or increased appetite.

(1) Drugs that cause anorexia are felbamate, and to a lesser extent, carbamazepine, ethosuximide, and valproic acid.
(2) Drugs that cause increased appetite are valproic acid, and to a lesser extent, carbamazepine.
e. Headache and dizziness
(1) Diffuse headaches may be caused by ethosuximide and, to a lesser extent, by methsuximide and felbamate.

(2) Dizziness seen in association with anticonvulsants is caused by a combination of ataxia and loss of eye movement coordination, which is part of motor coordination symptoms.
B. Specific antiseizure agents. Table 45-5 lists the uses of antiepileptic medications based on seizure type. Table 45-6 lists classifications of anticonvulsive drugs. Table 45-7 lists dosage characteristics of antiepileptic medications.
1. Carbamazepine (Tegretol)
a. Mechanisms of action. Carbamazepine is chemically related to tricyclic antidepressants. Its mechanism of action is unknown in the treatment of seizure disorders, but it is thought to act by reducing polysynaptic responses and blocking the posttetanic potentiation.
b. Administration and dosage (Table 45-7)
(1) Adults and children > 12 years of age receive an initial oral dose of 200 mg twice daily. This may be increased gradually to 800-2000 mg daily (usually given in divided doses).
(2) Children < 12 usually receive 10-20 mg/kg daily in two or three divided doses.
c. Precautions and monitoring effects
(1) Carbamazepine should be used with caution in patients with bone marrow depression. A CBC should be obtained and platelets measured to determine baseline levels before therapy, and levels should be monitored during therapy. Aplastic anemia and agranulocytosis have been reported.
(2) Tricyclic antidepressants should be avoided if there is a history of hypersensitivity to tricyclics. Monoamine oxidase (MAO) inhibitors should be discontinued 2 weeks before carbamazepine therapy.
(3) Carbamazepine should be used cautiously in patients with glaucoma because of its mild anticholinergic effects.
(4) Carbamazepine is an enzyme inducer; therefore, the half-life ($t_{1/2}$) decreases over 3-4 weeks ($t_{1/2}$ 18-54 hr; $t_{1/2}$ 10-25 hr); for maximal enzyme induction, levels should be rechecked to avoid breakthrough seizures.
(5) Carbamazepine is metabolized in the liver to 10-11 epoxide, which also has anticonvulsant activity; carbamazepine may induce its own metabolism.
(6) Potential for drug interaction in elderly patients.
(7) Adverse effects. The physician should be notified if any of the following adverse effects occur: jaundice, abdominal pain, pale stool, darkened urine, unusual bruising and bleeding, fever, sore throat, or an ulcer in the mouth. The most

common side effects are dizziness, drowsiness, unsteadiness, nausea, and vomiting.

Table 45-5. Uses of Antiepileptic Medications Based on Seizure Type

	Drug Therapy			
Seizure Type	**Choice 1**	**Choice 2**	**Choice 3**	**Choice 4**
Simple partial	Carbamazepine (alone or combination)	Phenytoin	Primidone Lamotrigine Oxcarbazepine	Gabapentin, levetiracetam Zonisamide
Complex partial	Carbamazepine Lamotrigine	Phenytoin	Phenobarbital Zonisamide Oxcarbazepine	Valproic acid Primidone Topiramate Tiagabine
Primary generalized Tonic-clonic	Valproic acid Lamotrigine	Carbamazepine	Phenytoin Valproic acid	Phenobarbital Topiramate Tiagabine
Absence	Lamotrigine,[a] ethosuximide	Zonisamide, valproic acid		
Myoclonic atonic	Valproic acid Valproic acid	Clonazepam Clonazepam	Zonisamide[a]	Felbamate[a] (alone or in combination)
Status epilepticus	Diazepam	Phenytoin	Phenobarbital	

Psychomotor	Phenytoin			

[a] Also indicated for treatment of Lennox-Gastaut syndrome in children.

Table 45-6. Anticonvulsive Drug Classification

Barbiturates	Hydantoins	Succinimides	Sulfonamides	Oxazolidinediones	Benzodiazepine	Miscellaneous
Phenobarbital	Phenytoin	Ethosuximide	Zonisamide	Paramethadione	Clonazepam	Lamotrigine
Primidone	Mephenytoin	Methsuximide	Trimethadione	Diazepam	Felbamate	Gabapentin
Mephobarbital	Ethotoin	Phensuximide		Lorazepam	Clorazepate dipotassium	Pregabalin
	Fosphenytoin				Carbamazepine	Oxcarbazepine
					Valproic acid	

					Topiramate	
					Tiagabine	
					Levetiracetam	

Table 45-7. Dosages Characteristic of Antiepileptic Medications

Drug	Enzyme Inducer	Enzyme Inhibitor	Loading Dose	Usual Adult Dose (mg/day)	Half-life (hr)	Therapeutic Range of Total Plasma Concentration (µg/mL)	Major Mode of Elimination	Protein-Binding Level (%)
Carbamazepine	+/-	-	No	800-2000	11[a]-22	4-12	Hepatic	75-80
Phenytoin	+/-	-	Yes	300-700	22-72 1-2 (free)	5-20	Hepatic	90
Phenobarbital	+/-	-	Yes	90-300	100	15-40	Hepatic > renal	40-60

Primidone	+/-	-	No	750-3000	15[a],[b]	5-12	Hepatic	20-25
Valproic acid	+/-	+	Yes	1000-3000	15-20	50-150	Hepatic	75-90
Ethosuximide	+/-	-	No	750-1000	30-60[c]	40-100	Hepatic > renal	0
Felbamate	+/-	+	No	2400	20-23	30-100	Hepatic > renal	22-25
Gabapentin	-	-	Yes	900-1000	5-7	5-7	Renal	< 3
Lamotrigine	+/-	-	No	200-400	25 12.6[d] 70[e]	2-6	Hepatic > renal	5 5
Topiramate	+/-	-	No	200-400	15-23	n/a	Renal > hepatic	9-15
Tiagabine	-	-	No	32-56	6-8	n/a	Hepatic	9 6

Levetiracetam	-	-	Yes	500-3000	7	n/a	Renal	<10
Zonisamide	-	-	No	100-600	24-50	n/a	Hepatic	40-60
Oxcarbazepine	+/-	+	No	900-1800	4-9	n/a	Hepatic	40-60

[a] The half-life decreases autometabolism after chronic use.

[b] Metabolized in part to phenobarbital.

[c] Lower range in children and higher range in adults.

[d] Receiving other enzyme-inducing drugs.

[e] Valproic acid slows the metabolism.

(a) CNS effects. These include dizziness, ataxia, and diplopia. If diplopia and ataxia are common and occur after a dose, the schedule could be adjusted to include more frequent administration or a larger proportion of the dose at night. CNS side effects may decrease with chronic administration.

(b) Gastrointestinal (GI) effects. These most commonly include nausea, vomiting, and anorexia.

(c) Metabolic effects. Hyponatremia occurs after several weeks to months of therapy, and the incidence increases with age. The antidiuretic hormone (ADH) level may be low. Levels of 125-135 mEq/L without symptoms should be monitored. Fluid restriction should be instituted when levels decrease to < 125 mEq/L with or without symptoms. Another agent should be used if fluid dose reduction does not help or the seizures recur.

(d) Hematopoietic effects. Aplastic anemia is rare. Thrombocytopenia and anemia have a 5% incidence, and they respond to a cessation of drug therapy. Leukopenia is the most common hematopoietic side effect: 10% of cases are transient, and

about 2% of patients have persistent leukopenia but do not seem to have increased infections even with white blood cell (WBC) counts of 3000/mL.

(e) Dermatological effects. Pruritic and erythematous rashes, the Stevens-Johnson syndrome, and lupus erythematosus have been reported.

d. Significant interactions

(1) Antiepileptic drugs, such as **phenytoin, primidone,** and **phenobarbital,** decrease the level of carbamazepine (increase metabolism).

(2) Valproic acid increases the level of carbamazepine (decreases metabolism).

(3) Other medications such as **erythromycin, isoniazid, cimetidine, propoxyphene, diltiazem,** and **verapamil** increase the level of carbamazepine (decrease metabolism).

(4) Carbamazepine decreases levels of **calcium channel blockers,** increasing its own level.

(5) Carbamazepine decreases the effect of warfarin.

(6) Antibiotics increase the level of carbamazepine.

(7) Carbamazepine decreases tricyclic antidepressant levels.

2. Phenytoin (Dilantin)

a. Mechanism of action

(1) Phenytoin inhibits the spread of seizures at the motor cortex and blocks posttetanic potentiation by influencing synaptic transmission. There is an alternation of ion fluxes in depolarization, repolarization, and membrane stability phase and alternating calcium uptake in presynaptic terminals.

(2) Phenytoin is effective for the treatment of generalized tonic-clonic (grand mal) seizures and for partial seizures, both simple and complex. It is not effective for absence seizures.

b. Administration and dosage (Table 45-7)

(1) The usual daily dose for **adults** is 300-700 mg, with adjustments made as needed.

(a) Regular daily doses above 500 mg are poorly tolerated.

(b) A loading dose of 900 mg to 1.5 g may be given intravenously (IV). The infusion rate should not exceed 50 mg/min. (Alternatively, an oral loading dose may be given.)

(2) The usual daily dose for **children** is 4-7 mg/kg divided every 12 hr. An IV loading dose of 15 mg/kg may be given.

(3) Phenytoin sodium is available as capsules and parenteral solution. Phenytoin is available as tablets and oral suspension.

c. Precautions and monitoring effects

(1) IV phenytoin should not be used in patients with sinus bradycardia, sinoatrial block, second- and third-degree atrioventricular (AV) block, or Adams-Stokes syndrome.

(2) Phenytoin should be used cautiously in patients with myocardial insufficiency and hypotension.

(3) Elimination of phenytoin converts from first-order elimination (proportional to its concentration) to zero-order elimination (a fixed amount per unit time), usually at high therapeutic levels. The daily dose of phenytoin can be increased 100 mg daily

until therapeutic blood levels are attained, after which increases of 30-50 mg will avoid twofold to threefold increases in blood levels.
P.996

(4) It is necessary to measure free drug levels or correct the total level when aluminum levels are abnormal or the patient has renal failure.
(5) Potential for drug interaction in elderly patients.
(6) Adverse effects. The physician should be notified if any of the following adverse effects occur: swollen or tender gums, skin rash, nausea and vomiting, swollen glands, bleeding, jaundice, fever, or sore throat (i.e., signs of infection or bleeding).
(a) CNS effects include ataxia (limiting side effect), dysarthria, and insomnia. Transient hyperkinesia may follow IV phenytoin infusion. Alcoholic beverages should be avoided while on this medication.
(b) GI **effects** most commonly include nausea and vomiting. Phenytoin should be taken with food to enhance absorption and decrease GI upset.
(c) Dermatological effects include maculopapular rashes sometimes with fever, Stevens-Johnson syndrome, and lupus erythematosus. Gingival hyperplasia may be reduced by frequent brushing and appropriate oral care.
(d) Connective tissue disorders include a coarsening of the facial features.
(e) Hematopoietic effects include thrombocytopenia, leukopenia, and granulocytopenia.
(f) Miscellaneous effects include hyperglycemia and increased body hair.
d. Significant interactions
(1) Antiepileptic drugs, such as **carbamazepine, valproic acid, clonazepam,** and **phenobarbital,** decrease the level of phenytoin (increase metabolism).
(2) Phenytoin increases the **conversion of primidone to phenobarbital** (increases metabolism).
(3) Other medications such as **disulfiram, isoniazid, chloramphenicol,** and **propoxyphene** increase the level of phenytoin (decrease metabolism).
(4) Drugs whose efficacy is impaired by phenytoin include **corticosteroids, digitoxin, doxycycline, estrogens, furosemide, oral contraceptives, quinidine, rifampin, theophylline, vitamin D,** and **enteral nutritional therapy.**
(5) Coumarin and **warfarin** anticoagulants increase the serum phenytoin levels and prolong the serum half-life of phenytoin by inhibiting its metabolism.
(6) Phenytoin decreases **tricyclic antidepressant** levels.
(7) Phenytoin interacts with **diabetes and arthritis medications.**
3. Fosphenytoin (Cerebyx)
a. Mechanism of action
(1) Water-soluble prodrug of phenytoin. It is converted to phenytoin by the bloodstream phosphatases, with a half-life of about 8 min in both adults and children.
(2) It is indicated for patients who cannot take oral drugs, and in the acute treatment for status epilepticus.

(3) Administered via IV or intramuscular (IM) injection
(4) A dose conversion table should be used to convert the phenytoin dose to fosphenytoin.
(5) Characteristics similar to phenytoin
(6) Advantages
(a) Fosphenytoin is an aqueous solution, unlike phenytoin, which is an alkaline solution; therefore, there is no need to add propylene glycol and ethanol to the solution.
(b) Fosphenytoin causes less soft-tissue injury at the site of injection. When administered by IM injection, it is completely absorbed and has more predictable serum concentration than IM-injected phenytoin.

4. Valproic acid (Depakote)

a. Mechanism of action
(1) Increases levels of GABA
(2) Potentiates a postsynaptic GABA response by inhibiting the enzymatic response for the catabolism of GABA
(3) Affects the potassium channel, creating a direct membrane-stabilizing effect

b. Administration and dosage (Table 45-7)
(1) For **adults,** valproic acid is administered orally in a usual dose of 1000-3000 mg daily in divided doses.

(2) For **children,** valproic acid is administered orally in a dose of 15-60 mg/kg daily, divided into two or three doses.
(3) Medication should be taken with food to reduce GI upset.
(4) Tablets or capsules should be swallowed, not chewed, to avoid irritation of the mouth and throat.
c. Precautions and monitoring effects. There are some reports of hepatotoxicity and increased liver function tests, which are mostly reversible. The severity and incidence of hepatotoxicity increase when the patient is younger than 2 years of age.
d. Adverse effects. Contact the physician if abdominal pain, nausea, vomiting, or anoxia occurs; these could be symptoms of pancreatitis.
(1) CNS effects include tremor, ataxia, diplopia, lethargy, drowsiness, behavioral changes, and depression.
(2) GI **effects** include nausea and increased appetite. Enteric-coated divalproex sodium may reduce these side effects.
(3) Dermatological effects include alopecia and petechiae.
(4) Hematopoietic effects include thrombocytopenia, bruising, hematoma, and bleeding.
(5) Hepatic effects include minor elevations of aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactate dehydrogenase (LDH).
(6) Endocrine effects include decreased levels of prolactin, resulting in irregular menses, and secondary amenorrhea.

(7) Pancreatic effects include acute pancreatitis.

(8) Metabolic effects include hyperammonemia owing to renal origin. Discontinuation may be considered if lethargy develops.

e. Significant interactions

(1) Antiepileptic drugs

(a) Primidone decreases valproic acid clearance (increases metabolism).

(b) Phenobarbital and **phenytoin** displace protein binding, resulting in an increased total phenytoin level and an increase or no change of free phenytoin.

(c) Clonazepam increases CNS toxicity in patients on valproic acid.

(2) Other medications

(a) Aspirin increases the level of valproic acid.

(b) Warfarin inhibits the secondary phase of platelet aggregation.

(c) Antacids increase the level of valproic acid.

(3) Laboratory tests

(a) False-positive urine ketone tests may result in patients taking valproic acid; thus patients with diabetes must use caution when using urine tests.

(b) Thyroid function tests may be altered by antiepileptic drugs.

5. Phenobarbital (Luminal)

a. Mechanism of action. Phenobarbital increases the seizure threshold by decreasing postsynaptic excitation by stimulating postsynaptic GABA-A receptor inhibitor responses as a CNS depressant.

b. Administration and dosage (Table 45-7)

(1) For **adults,** phenobarbital is administered orally at 90-300 mg daily (in three divided doses or as a single dose at bedtime).

(2) Children typically receive 3-6 mg/kg daily in two divided doses. Adjustment is made as needed.

c. Precautions and monitoring effects

(1) Phenobarbital produces respiratory depression, especially with parenteral administration.

(2) Phenobarbital should be used with caution in patients with hepatic disease who may need dose adjustments.

(3) Phenobarbital has sedative effects in adults and produces hyperactivity in children.

(4) Abrupt discontinuation of phenobarbital produces withdrawal convulsions. If the drug must be discontinued, another GABA-A agonist (e.g., benzodiazepine, paraldehyde) should be substituted.

(5) Potential for drug interaction in elderly patients.

(6) Adverse effects. The physician should be notified if any of the following adverse effects occur: sore throat, mouth sores, easy bruising or bleeding, and any signs of infection.

(a) CNS effects include agitation, confusion, lethargy, and drowsiness. Patients should avoid alcohol and other CNS depressants.

(b) Respiratory effects include hypoventilation and apnea.
(c) Cardiovascular effects include bradycardia and hypotension.
(d) GI **effects** include nausea, diarrhea, and constipation. If GI upset is experienced, phenobarbital should be taken with food.
(e) Hematological effects include megaloblastic anemia after chronic use (a rare side effect).
(f) Miscellaneous effects include osteomalacia and Stevens-Johnson syndrome, both of which are rare.

d. Significant interactions

(1) Antiepileptic drugs, such as **valproic acid** and **phenytoin,** increase the level of phenobarbital (decrease metabolism).
(2) Other drugs such as **acetazolamide, chloramphenicol, cimetidine,** and **furosemide** increase the level of phenobarbital (decrease metabolism).
(3) Rifampin, pyridoxine, and **ethanol** decrease the level of phenobarbital (increase metabolism).

6. Primidone (Mysoline)

a. Mechanism of action. Primidone is a metabolite of phenobarbital and phenylethylmalonamide (PEMA), which has some anticonvulsive effects. It has drug characteristics similar to phenobarbital, with some differences in dose and half-life.

b. Administration and dosage (Table 45-7)

(1) Primidone has a short half-life of 7 hr, which may require three-times daily dosing.
(2) Primidone is tolerated better if started at 50 mg at night for 3 days until the target daily dose is reached.

7. Ethosuximide (Zarontin)

a. Mechanism of action

(1) Ethosuximide may inhibit the sodium-potassium adenosine triphosphatase (Na^+/K^+ ATPase) system and the reduced form of nicotinamide adenine dinucleotide phosphate (NADPH) linked aldehyde reductase (which is necessary for the formation of γ-hydroxybutyrate, which is associated with the induction of absence seizures).
(2) Ethosuximide reduces or eliminates the EEG abnormality; however, absence seizures are the only seizures in which the normal EEG has clinical value (i.e., when the EEG abnormality is corrected, the seizures are also controlled).
(3) Ethosuximide is a relatively benign anticonvulsant with minimum protein binding.

b. Administration and dosage (Table 45-7). Ethosuximide is usually given orally in an initial dose of 500 mg daily in **adults and older children** and 250 mg daily in **children ages 3-6 years.** The dose may be raised by 250 mg every week to a maximum of 1.5 g daily in adults.

c. Precautions and monitoring effects

(1) Blood dyscrasias have been reported, making periodic blood counts necessary.
(2) There have been reports of hepatic and renal toxicity; thus periodic renal and liver function monitoring is necessary.
(3) Cases of systemic lupus erythematosus have been reported.

d. Adverse effects

(1) GI **effects** include nausea and vomiting. Small doses may lessen these effects. Ethosuximide should be taken with food if GI upset occurs.
(2) Hematopoietic effects include eosinophilia, granulocytopenia, leukopenia, and lupus.
(3) CNS effects include drowsiness, blurred vision, fatigue, lethargy, hiccups, and headaches. Alcoholic beverages should be avoided with this medication.
(4) Psychiatric-psychological effects include confusion and emotional instability.
(5) Dermatological effects include pruritus, photosensitivity, urticaria, and Stevens-Johnson syndrome.
(6) Genitourinary effects include increased frequency of urination, vaginal bleeding, renal damage, and hematuria.
(7) Miscellaneous effects include periorbital edema and muscle weakness. Patients should also be advised of the risks of exposure to sunlight and ultraviolet light.

e. Significant interactions.
(1) Antiepileptic drugs, such as **carbamazepine,** decrease the level of ethosuximide (increases metabolism).
(2) Valproic acid increases the level of ethosuximide (decreases metabolism).
8. Clonazepam (Klonopin)
a. Mechanism of action. Clonazepam is a potent GABA-A agonist, but its efficacy decreases over several months of treatment.
b. Administration and dosage
(1) For **adults,** clonazepam is an oral agent that may be given in an initial dose of 1.5 mg daily divided two or three times. The dose may be increased to a maximum of 20 mg daily.
(2) Children should receive 0.01-0.03 mg daily in two or three doses. The dosage may be increased to a maximum of 0.2 mg/kg daily.
c. Precautions and monitoring effects
(1) Patients with psychoses, acute narrow-angle glaucoma, and significant liver disease should use this medicine cautiously.
(2) Adverse effects
(a) CNS effects include drowsiness, ataxia, and behavior disturbances in children; these may be corrected by dose reduction.
(b) Respiratory effects include hypersalivation and bronchial hypersecretion.
(c) Miscellaneous effects include anemia, leukopenia, thrombocytopenia, respiratory depression, anorexia, and weight loss.
d. Significant interactions
(1) Antiepileptic drugs, such as **phenytoin,** increase the level of clonazepam (decrease metabolism).
(2) Other drugs. Clonazepam decreases the efficacy of **levodopa** and increases the serum level of **digoxin.**
9. Felbamate (Felbatol)

a. Mechanism of action. A proposed mechanism of action is that the drug interacts with glycine modulatory site on *N*-methyl-D-aspartate (NMDA) receptors. Blockade of NMDA may contribute to neuroprotective effects of felbamate. Felbamate is used as monotherapy or adjunctive therapy or without secondary generalization in adults and generalized seizures associated with Lennox-Gastaut syndrome in children. The U.S. Food and Drug Administration (FDA) recommended that use of felbamate be restricted to only those patients who are refractory to other medications and in whom the risk-benefit relationship warrants its use, because of severe hepatotoxicity.

b. Administration and dosage (Table 45-7)

(1) Adults and children > 14 years of age

(2) Monotherapy, initially 1.2 g in three to four doses daily. The dosage may be increased in 600-mg increments every 2 weeks to 2.4 g daily based on clinical response and, thereafter, 3.6 g daily if necessary.

(3) Adjunctive therapy, 1.2 g in three to four doses daily, with reduction of the dosage of other antiepileptic drugs by 20%-33%. The dosage of felbamate may be increased in increments of 1.2 g at weekly intervals to a maximum of 3.6 g daily.

(4) Conversion to monotherapy initially 1.2 g daily in three to four doses, with reduction of the dosage of other antiepileptic drugs by 33% at week 3. The felbamate dosage may be increased to 3.6 g daily, and other antiepileptic drugs discontinued or dosage further reduced in stepwise fashion.

(5) Children 2-14 years of age with Lennox-Gastaut syndrome, as adjunctive therapy, initially 15 mg/kg daily in three to four doses. The dosage of other antiepileptic drugs is reduced by 20%. The amount of felbamate may be increased in increments of 15 mg/kg at weekly intervals to 45 mg/kg daily. Further reduction in the dosage of other antiepileptic drugs may be necessary.

c. Precaution and monitoring effects. There are two very serious toxic effects, aplastic anemia and liver failure, which lead to death for some patients.

(1) For aplastic anemia, the onset range from 5 to 30 weeks of initiation of therapy. Weekly or biweekly CBCs are recommended initially.

(2) For liver, toxicity time between initiation of treatment and diagnosis of these cases ranges from 14 to 257 days. It is recommended that liver function tests be performed before initiation of therapy to identify patients who have evidence of preexisting

liver damage. Liver function tests should also be performed weekly or biweekly. The FDA recommends that this drug be used only in patients who are refractory to other medications and in whom the risk-benefit relationship warrants its use.

(3) Photoallergy or phototoxicity may occur; patients should take protective measures against exposure to ultraviolet light or sunlight.

(4) Instruct patients to store medication in its own tightly closed container at room temperature away from excessive heat, direct sunlight, and moisture.

(5) Adverse effects. Contact the physician if signs of infection (e.g., bleeding or bruising) occur.

(a) This drug has the potential to cause aplastic anemia (bone marrow).
(b) The patient should be monitored for these toxicities by CBCs and liver function tests weekly or biweekly until discontinuation of any sign of these toxicities occurs.
(c) CNS effects are insomnia, headache, anxiety, hyperactivity, and fatigue.
(d) Cardiovascular effects are peripheral edema, vasodilation, hypotension, and hypertension.
(e) Ocular effects are diplopia and blurred vision.
(f) GI **effects** are anorexia, weight decrease, and nausea.
(g) Hematological effects may include lymphadenopathy, leukopenia, and thrombocytopenia.
(h) Metabolic/nutrition effects may include hypokalemia and hyponatremia.
d. Significant interactions
(1) Felbamate and phenytoin. Felbamate causes an increase in phenytoin plasma concentration. Phenytoin doubles felbamate clearance, resulting in 45% decrease in felbamate levels.
(2) Felbamate and carbamazepine. Felbamate causes a decrease in carbamazepine levels and an increase in carbamazepine metabolites. In addition, carbamazepine causes a 50% increase in felbamate clearance, resulting in a 40% decrease in steady-state trough levels.
(3) Felbamate and valproic acid. Felbamate causes an increase in valproic acid levels, but valproic acid does not affect felbamate levels.
(4) Adverse effects. Signs and symptoms associated with increased plasma level and toxicity are anorexia, nausea, vomiting, insomnia, and headache.
10. Gabapentin (Neurontin)
a. Mechanism of action. It is an analog of GABA. It increases GABA turnover, but it does not bind to GABA or any other established neurotransmitter receptor. Its mechanism of action is currently unknown, although it binds to a specific receptor in the brain and inhibits voltage-dependent sodium currents. It has been shown to be effective as an add-on drug in patients with partial seizure with or without secondary generalization.
b. Administration and dosage (Table 45-7)
(1) Patients **> 12 years** receive 900 mg to 1.8 g daily, administered as adjunctive therapy in three divided doses. Titrating to an effective dose normally can be achieved within 3 days by initiating therapy with 300 mg and then increasing the dose in 300-mg increments over the next 2 days to establish a dosage of 900 mg daily in three doses. If necessary, the dosage may be increased to 1.8 g daily. To minimize potential side effects, especially somnolence, dizziness, or fatigue, the first dose on day 1 may be administered at bedtime.
(2) Patients 3-12 years of age should receive 10-15 mg/kg/day in 3 divided doses up to 25-50 mg/kg/day.
(3) The drug is primarily excreted renally; therefore, the dosage should be adjusted for patients who have compromised renal function.
(4) The drug does not bind to plasma protein. There are no significant pharmacokinetic interactions with other commonly used antiepileptic drugs.

(5) If gabapentin is discontinued or an alternate anticonvulsant medication is added, it should be done gradually over a minimum of 1 week.

c. Precautions and monitoring effects

(1) The value of monitoring blood concentration has not been established and would not alter blood concentration of other antiepileptic drugs when used together.

(2) It has a low level of toxic side effects, which include somnolence, dizziness, ataxia, and minimal interaction with other drugs.

(3) Gabapentin is useful in patients who are taking other medications for epilepsy or other chronic diseases. It may be especially useful for elderly patients.

(4) Gabapentin is well absorbed orally; it can be taken with or without food. However, patients who have GI problems might have problems with absorption.

(5) Adverse effects. Common side effects are somnolence, dizziness, ataxia, fatigue, weight gain and nystagmus.

(a) CNS effects are somnolence, dizziness, ataxia, and fatigue.

(b) GI **effects** include dyspepsia, dryness of mouth, constipation, and increased appetite.

(c) Ocular effects are diplopia, blurred vision, and nystagmus.

d. Significant interactions

(1) Antacids and gabapentin. Antacids reduce the bioavailability of gabapentin by 20%; gabapentin could be taken 2 hr after antacid use.

(2) Cimetidine and gabapentin. Cimetidine decreases the renal excretion of gabapentin by 14% and consequently increases gabapentin plasma levels (however, this amount is not clinically significant).

(3) Oral contraceptives and gabapentin. Oral contraceptives increase the level of norethindrone by 13%; this amount may not be clinically significant.

11. Lamotrigine (Lamictal)

a. Mechanism of action. Its antiepileptic effect is similar to that of phenytoin. Its effect may be the result of inhibition of voltage-dependent sodium currents and reduction of sustained repetitive neuronal activity. It is indicated for the treatment of partial seizures and secondary generalized tonic-clonic seizures that are not controlled with other drugs. It is also used to treat Lennox-Gastaut syndrome. Lamotrigine is broad spectrum, as well tolerated as monotherapy, and probably the least teratogenic of the first-line agents. It may aggravate severe myoclonic epilepsy.

b. Administration and dosage (Table 45-7)

(1) Adults (> 16 years), initially 50 mg/day in two divided doses (patients taking valproic acid should be given 25 mg every other day), up to 100 mg/day (up to 25 mg daily with valproic acid treatment).

(2) Children 2-12 years 0.6 mg/kg/day in two divided dosed (0.15 mg/kg/day on valproic acid treatment), up to 1.2 mg/kg/day (up to 0.3 mg/kg/day with valproic acid treatment).

(3) The smallest available chewable dispersible tablet is 5 mg. Then, after 2 weeks, increase by 0.3 mg/kg/day in one to two divided doses, up to 200 mg/day.
(4) Swallow chewable dispersible tablet whole, chewed, or in dispersing water or diluted fruit juice. If chewed, consume a small amount of water or dilute fruit juice to aid in swallowing. To disperse, add the chewable dispersible tablet to a small amount of liquid (1 teaspoon or enough to cover the medication). Approximately 1 min later, when the tablet is completely dispersed, swirl the solution and consume the entire quantity immediately.
(5) For patients taking valproic acid, the initial dose is 50 mg daily for 2 weeks, followed by maintenance doses of 100-200 mg daily in two divided doses.
(6) Reduced clearance in the elderly necessitates dosage reduction.
(7) Patients with hepatic impairment may require dosage reduction because of reduction in metabolism.

c. Precautions and monitoring effects

(1) The value of monitoring plasma concentration has not been established.
(2) Caution should be used for patients taking this drug. It may adversely affect the patient's metabolism or complicate the elimination of the drug because of renal, hepatic, or cardiac impairment.
(3) Lamotrigine binds to melanin and can accumulate in melanin-rich tissue over time. Periodic ophthalmological monitoring is recommended.
(4) Photosensitization (photoallergy and phototoxicity) patients should take protective measures against exposure to ultraviolet light or sunlight.
(5) Serious rashes requiring hospitalization have been reported. The incidence of rashes, including Stevens-Johnson syndrome, is approximally 1% in patients < 16 years old and 0.3% in adults. Rare cases of toxic epidermal necrolysis or rash-related death have occurred. Most rashes occur within 2-8 weeks of initial treatment.

(6) Adverse effects. The most common side effects are dizziness, diplopia, ataxia, blurred vision, nausea, dose-related rash and vomiting.
(a) CNS effects are headache, dizziness, and ataxia tics (in children).
(b) GI **effects** are nausea, vomiting, diarrhea, and dyspepsia.
(c) Ocular effects are diplopia, blurred vision, and vision abnormality.
(d) Dermatological effects are pruritus, and a rash may form similar to that found when using phenytoin and carbamazepine. In many cases, the rash disappears during continued therapy, but 1%-2% of patients with the rash represent a more serious allergic reaction. Occasionally, patients have developed the Stevens-Johnson syndrome. Concomitant use with valproic acid may increase the likelihood of serious rash. The occurrences of life-threatening rash that were reported developed within 2-8 weeks following therapy; other cases of rash have been reported developing up to 6 months after therapy. The incidence of rash is higher in children than in adults.
(e) Monotherapy during pregnancy found no teratogenic effect.

d. Significant interactions

(1) Carbamazepine decreases lamotrigine concentration by 70% and increases carbamazepine levels.

(2) Phenobarbital or primidone decreases lamotrigine concentration by 40%.

(3) Valproic acid decreases the metabolism of lamotrigine and extends its half-life to 60 hr, which necessitates a dose reduction.

12. Topiramate (Topamax)

a. Mechanism of action. Topiramate is a derivative of fructose. It decreases rapid hippocampal neuronal firing, possibly because of sodium- or calcium-channel inhibition. It is also a weak carbonic anhydrase inhibitor and a sodium-channel blocking agent. Topiramate potentiates the activity of GABA. It has been shown to be effective adjunctive therapy for partial seizure treatment in adults, tonic-clonic seizure, infantile spasms, and Lennox-Gastaut syndrome.

b. Administration and dosage (Table 45-7)

(1) Adults 17 years and older, 25-50 mg/day, up to 400 mg/day in two divided doses. **Children** 2-16 years, 1-3 mg/kg/day, up to 5-9 mg/kg/day in two divided doses.

(2) Topiramate is 80% bioavailable, and food does not affect its bioavailability.

(3) Dose adjustment is necessary for patients with renal or hepatic impairments.

(4) Enzyme-inducing anticonvulsive drugs can decrease topiramate levels, but topiramate has a significant effect on metabolism of other anticonvulsive drugs.

(5) Initial treatment is 50 mg daily, followed by titration to an effective dosage. More than 400 mg daily has not been shown to improve response.

c. Precaution and monitoring effects

(1) Increased incidence of kidney stones (renal calculus) in older patients who received this drug. Patients should be advised to increase intake of fluids while taking topiramate.

(2) Paresthesia is a common side effect of anhydrase inhibitors.

(3) Adverse effects

(a) The physician should be notified if any of the following adverse effects occur:

(i) Breast pain in females

(ii) Nausea or tremor, which are dose-related side effects.

(iii) Back pain, chest pain, dyspepsia, or leg pain

(b) CNS effects mostly seen in 600 mg/day dose include psychomotor slowing, difficulty with concentration and speech, somnolence, fatigue, asthenia, weight loss, cognitive disturbances and difficulties, tremors, dizziness, ataxia, and headache.

(c) GI **effects** include upset, such as nausea, vomiting, and gastroenteritis.

(d) Genitourinary effects include renal calculi nephro.

(e) Cardiovascular effects include chest pain, palpitation, and vasodilation.

(f) Ocular effects include abnormal vision, eye pain, diplopia, and open angle glaucoma.

(g) Hematological effects include anemia, epistaxis, leukopenia, and aplastic anemia.

(h) Other: metabolicacidosis, hypohidrosis (in children)

d. Significant interactions

(1) Phenytoin and carbamazepine will increase clearance.

(2) Topiramate increases the clearance of other drugs that are cleared by cytochrome P450.

13. Tiagabine (Gabitril)

a. Mechanism of action. Tiagabine is designed to act on the inhibitory action of GABA by blocking its uptake, thereby prolonging its action after synaptic release. It is indicated as adjunctive therapy for partial seizures and secondary generalized tonic-clonic seizures.

b. Administration and dosage (Table 45-7)

(1) Starting dose of 4 mg daily for 2 weeks may be increased 4-8 mg weekly thereafter, to a maintenance dose of 32-56 mg daily.

(2) Maximum recommended dosage for **children** is 32 mg daily; maximum recommended dosage for **adults** is 56 mg daily.

(3) A high-fat meal decreases the rate of tiagabine absorption but does not affect the extension of absorption. Tiagabine should be taken with food.

c. Precautions and monitoring effects

(1) Moderately severe to severe **generalized weakness** has been reported. It resolves in all cases after reduction in dose or discontinuation of therapy.

(2) Ophthalmic effects, as indicated by animal studies, include the possibility for residual binding to retina and melanin binding; this finding, however, has not been confirmed in human studies. Periodic ophthalmological monitoring is necessary.

(3) Dermatological effects include the possibility of severe rash to Stevens-Johnson syndrome, as reported in clinical studies.

(4) Adverse effects

(a) CNS effects are confusion, dizziness, and fatigue.

(b) GI **effects** are upset stomach, nausea, mouth ulceration, and anorexia.

d. Significant interactions. Phenobarbital, phenytoin, and carbamazepine will increase tiagabine clearance.

14. Zonisamide (Zonegran)

a. Mechanism of action. It is not well known. It may block the sensitive sodium channels and T-type calcium channels. It is an effective agent for refractory partial seizure, generalized seizure indicated for adjunct therapy for partial seizure for adults, infantile spasm, mixed seizure types of Lennox-Gastaut syndrome, myoclonic, and generalized tonic-clonic seizure.

b. Administration and dosage (Table 45-7)

(1) Adults and children > 16 years of age, 100 mg daily; within 2 weeks, increase to 200 mg/daily in 2-week bases, up to 600 mg daily.

(2) Can be taken with or without food.

c. Precautions and monitoring effects

(1) May increase mean concentration of serum creatinine and blood, urea, nitrogen; renal function should be monitored periodically.

(2) May increase serum alkaline phosphatase.

(3) May produce drowsiness.
(4) Side effects. The physician should be contacted if sudden pain or abdominal pain occurs or if blood in urine is detected; these symptoms could indicate a **kidney stone.** Increase fluid intake to decrease the risk of stone formation. Also, contact the physician if fever, sore throat, oral ulcer, or easy bruising is seen; these symptoms could be the result of a **hematological complication.**
(5) Most commonly reported adverse events are **somnolence, anorexia, dizziness, headache, nausea, allergic reactions, agitation,** and **weight loss.**
(a) CNS effects are ataxia, confusion, tremor, and abnormal thinking.
(b) Cardiovascular effects are palpitation, tachycardia, and vascular insufficiency.
(c) Dermatologic effects are maculopapular rash, acne alopecia, and photosensitivity.
(d) Other effects are bladder calculus, leukopenia, and hypohidrosis (children).
d. Significant interactions
(1) Zonisamide induces **liver enzymes** by increasing metabolism and through clearance of zonisamide and decreases half-life.
(2) Food will delay absorption but will not affect the bioavailability of the drug.

15. Levetiracetam (Keppra)
a. Mechanism of action. It is a pyrrolidone derivative and is chemically unrelated to other antiepileptic drugs. It displays inhibitory properties in the kindling model in rats. It is used as adjunctive therapy in the treatment of partial seizure in adult patients.
b. Administration and dosage (Table 45-7). Starting dose of 1000 mg/day given in two divided doses may be increased every 2 weeks, to a maximum of 3000 mg/day.
c. Precautions and monitoring effects
(1) Hematological effects are minor, but there is a statistically significant decrease compared to placebo in total mean RBC count, mean hemoglobulin, and mean hematocrit.
(2) Decrease in WBC count and neurophil count
(3) It also causes drowsiness.
(4) Side effects. Most commonly reported adverse events are **somnolence, weakness (asthenia), infection,** and **dizziness.**
(a) CNS effects are somnolence, dizziness, depression, and nervousness.
(b) Cardiovascular effects are palpitation, tachycardia, and vascular insufficiency.
(c) Respiratory effects are pharyngitis, rhinitis, and increased cough.
(d) Miscellaneous effects are weakness, headache, and infection.
e. Significant interactions. Levetiracetam does not influence the **plasma concentration** of existing antiepileptic drugs, and other **antiepileptic drugs** do not influence the pharmacokinetic effects of levetiracetam.
16. Oxcarbazepine (Trileptal)
a. Mechanism of action. This drug produces blockade of voltage-sensitive sodium channels, resulting in stabilization of hyperexcited neural membranes, inhibition of

repetitive neuronal firing, and diminution of propagation of synaptic impulses. These actions are thought to be important in the prevention of seizure spread in the intact brain. In addition, increased potassium conductance and modulation of high-voltage activated calcium channels may contribute to the anticonvulsant effects of the drug.

b. Administration and dosage (Table 45-7)

(1) Children 4-16 years, 8-10 mg/kg/day to 600 mg/day as adjunctive therapy and 8-10mg/kgday as monotherapy.

(2) Adults, 600mg/day as adjunctive therapy and 1200mg/day as monotherapy. A dosage adjustment is needed for patients with renal failure; no dosage adjustment is needed for patients with mild to moderate hepatic impairment.

(3) Can be taken with or without food.

c. Precaution and monitoring effects

(1) Clinically significant **hyponatremia** (sodium < 125 mmol/L) can develop during therapy.

(2) Side effects

(a) Use of this product have been associated with **CNS effects** such as cognitive symptoms (psychomotor slowing, difficult concentrating).

(b) May reduce the efficacy of oral contraceptive.

(3) Adverse effects

(a) CNS effects are dizziness, somnolence, headache, ataxia, fatigue, and vertigo.

(b) GI **effects** are vomiting, nausea, and abdominal pain.

(c) Neuromuscular and skeletal effects are abnormal gait and tremor.

(d) Ocular effects are Diplopia, nystagmus, and abnormal vision.

(e) Endocrine and metabolic effects common in elderly include hyponatremia (low level of sodium in the blood).

(f) Dermatologic: rash.

d. Significant interactions

(1) Oxcarbazepine inhibits **cytochrome P450 2C19** and induces **cytochrome P450 3A4/5** with potentially important effects on plasma concentrations of other drugs.

(2) Serum concentrations of **phenytoin** and **phenobarbital** are increased.

(3) It decreases **oral contraceptive** effects, benzodiazepine, and calcium channel blockers.

(4) Cross-sensitivity with **carbamazepine** (25%-30%).

17. Less common drugs are listed in Table 45-8.

Table 45-8. Less Common Drugs Used in Practice

Drug	Labeled Indication	Half-Life (hr)	Total Plasma Concentration (mg/L)	Therapeutic Range of Adult Dose (mg/day)	Usual Mode of Elimination	Major Protein Binding Level
Mephobarbital	• Grand mal • Petit mal • Gets converted to phenobarbital • Indicated when phenobarbital must be decreased because of excessive drowsiness • Hyperexcitability • Mood disturbances	11-67	n/a	400 - 600	Liver	40-60
Mephenytoin	• Tonic-clonic • Psych	95 (active	n/a	200 - 600	Liver > rena	90

	omotor • Status epilepticus • Used with phenytoin; together more sedative compared to phenytoin alone	metabolite)			l	
Ethotoin	• Tonic-clonic • Psychomotor • Used as second-line therapy; less toxic and less effective than phenytoin (alone or combined)	3-9[a]	15-50	2000-3000	Liver	N/A

Methsuximide	• Absence • Does not precipitate tonic-clonic (compared to other succinimides)	2-40[b]	n/a	1200	Liver	n/a
Phensuximide	• Absence • Less toxic and less effective compared to other succinimides	8[b]	n/a	1000-3000	Urine, bile	n/a
Parameth adione[c]	• Absence • Useful when other seizures exist with absence seizure	n/a	n/a	900-2400	Liver > renal	n/a

	• *Note:* Do not use with mephenytoin					
Trimethadione[c]	• Absence • Useful when other seizures exist with absence seizure • *Note:* Do not use with mephenytoin	6-13 days	≥ 700	900 - 2400	Liver	0
Pregabalin	• Simple partial seizure	6	n/a	150 - 600	Renal	0

[a] At high doses, nonlinear kinetic like phenytoin.

[b] Active metabolite.

[c] Possible fetal malformation if used during pregnancy.

18. Vagus nerve stimulation (VNS)

a. It is used as adjunctive therapy for adults and children >r 12 years of age whose partial seizures are refractory to antiepileptic medications.

b. A programmable signal generator that is implanted in the patient's left upper chest has a bipolar VNS lead that connects the generator to the left vagus nerve in the neck, a programming wand that uses radio-frequency signals to communicate noninvasively with the generator, and handheld magnets used by the patient or caregiver to manually turn the stimulator on or off.

c. The implantation procedure usually lasts 1 hr under general anesthesia. Once programmed, the generator will deliver intermittent stimulation at the desired setting until any additional programming is entered.

C. Surgery. If seizures do not respond to drug therapy, surgery may be performed to remove the epileptogenic brain region. The most common is cortical excision (lobectomy). Between 70% and 80% of patients who have anterior temporal lobectomy have fewer seizures. Between 30% and 40% patients who have frontal lobectomy have fewer seizures.

1. Indications for surgery are intractable or disabling seizures recurring for 6-12 months. Should be considered for patients with medically refractory seizures.

2. In **stereotaxic surgery,** the surgeon uses three-dimensional coordinates to guide a needle through a hole drilled in the skull, then destroys abnormal pathways via small intracerebral incisions.

3. Other surgical approaches include temporal lobe resection, removal of the temporal lobe tip, and cerebral hemispherectomy.

III. Complications

A. Convulsive status epilepticus. This disorder is characterized by rapid repetition of generalized tonic-clonic seizures with no recovery of consciousness between seizures. This life-threatening condition may persist for hours or even days; if it lasts longer than 1 hr, severe permanent brain damage may result.

1. Causes of status epilepticus include poor therapeutic compliance, intracranial infection or neoplasm, alcohol withdrawal, drug overdose, and metabolic imbalance.

2. Management

a. A patent airway must be maintained.

b. If the cause of the condition is unknown, dextrose 50% in water (25-30 mL) is given via IV in case hypoglycemia is the cause.

c. If the seizures persist, **diazepam** (10 mg) is administered via IV at a rate not exceeding 2 mg/min until the seizures stop or 20 mg has been given.

d. Phenytoin or fosphenytoin is then administered via IV no faster than 50 mg/min to a maximum dose of 11-18 mg/kg. Blood pressure is monitored to detect hypotension.

e. If these measures do not stop the seizures, one of the following drugs is given.

(1) Diazepam is given as an IV drip of 50-100 mg diluted in 500 mL dextrose 5% in water, infused at 40 mL/hr until the seizures stop.

(2) Phenobarbital is given as an IV infusion of 8-20 mg/kg no faster than 100 mg/min.

f. If seizures continue despite these measures, one of the following steps is then taken.

(1) Paraldehyde is given via IV in a dosage of 0.10-0.15 mL/kg diluted to a 4% solution in normal saline solution.

(2) Lidocaine is given in an IV loading dose of 50-100 mg, followed by an infusion of 1-2 mg/min.

(3) General anesthesia is induced with ventilatory assistance and neuromuscular junction blockade.

B. Nonconvulsive status epilepticus. This condition presents as repeated absence seizures or complex partial seizures. The patient's mental state fluctuates; confusion, impaired responses, and automatisms are prominent. **Initial management** typically involves intravenous diazepam. Complex partial status epilepticus may also necessitate administration of such drugs as phenytoin or phenobarbital.

IV. Seizure Disorder and Pregnancy

A. Epidemiology. About 0.5% of all pregnancies occur in women with epilepsy.

B. Preconception counseling. The risks for mother and fetus should be discussed, including the risks of fetal malformation associated with antiepileptic drugs and other genetic factors.

C. Drug therapy

1. If the patient is seizure free for at least 2 years, withdrawal of the drug should be considered. If antiepileptic drug therapy is necessary, a switch to monotherapy should be made if possible.

2. Five antiepileptic medications have been used or studied in pregnant patients: carbamazepine, phenobarbital, phenytoin, primidone, and valproic acid. Monotherapy of lamotrigine during pregnancy found no teratogenic effect. Congenital malformations associated with these drugs include craniofacial abnormalities, cardiac defects, and neuronal tube defects. Most of the studies did not consider paternal genetic factors, environmental factors, drug dosing, or combination therapy.

3. Antiepileptic drugs interfere with folate metabolism. Administration of folic acid, 4 mg daily, and multivitamins decreases the risk of malformation, especially of the neuronal tube.

4. Vitamin K, 10 mg per day for the last 1-2 months of gestation, will help prevent neonatal hemorrhage, especially in cases of phenytoin or phenobarbital use.

5. Seizure disorder and oral contraceptives. Gabapentin, lamotrigine, levetiracetam, ethosuximide, valproate, zonisamide and tiagabine do not affect the efficacy of oral contraceptives.

6. Seizure disorder and the elderly population. The new generation of antiepileptic drugs such as levetiracetam and gabapentin may be more useful owing to low levels of protein binding and safer side effects. Also, the newer agents have less potential for drug interactions than agents eliminated from the liver.

D. Monitoring

1. Free serum antiepileptic drug levels should be monitored monthly, immediately before the next dose; and the dose should be adjusted to the lowest dose providing adequate control.

2. Serum α-fetoprotein levels should be checked, and ultrasonography should be performed at 16 weeks of gestation to evaluate for fetal neuronal tube defects. An alternative to these tests is amniocentesis, especially if the mother is taking valproate or carbamazepine.

3. Comprehensive ultrasonography should be performed at 18 and 22 weeks of gestation for patients taking antiepileptic drugs that cause cardiac anomalies.

4. Intrapartum plans should include IV administration of a short-acting benzodiazepine. If there is concern about fetal or maternal respiratory depression, administering intravenous phenytoin or intramuscular phenobarbital should be considered. Clotting studies should be performed, and 1 mg vitamin K should be given to the infant. Nurses and physicians should be alerted for possible hemorrhage of the infant and apprised that the infant may experience antiepileptic drug withdrawal.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Phenytoin is effective for the treatment of all of the following types of seizures *except*

(A) generalized tonic-clonic.

(B) simple partial.

(C) complex partial.

(D) absence.

(E) grand mal.

View Answer***1. The answer is D[see].*****2. Which of the following anticonvulsants is contraindicated in patients with a history of hypersensitivity to tricyclic antidepressants?**

(A) phenytoin

(B) ethosuximide

(C) acetazolamide

(D) carbamazepine

(E) phenobarbital

View Answer***2. The answer is D[see].*****3. Which anticonvulsive drug requires therapeutic monitoring of phenobarbital serum levels as well as its own serum level?**

(A) phenytoin

(B) primidone

(C) clonazepam

(D) ethotoin

(E) carbamazepine

View Answer***3. The answer is B[seeand].*****4. Which anticonvulsive drug treatment has a higher incidence of kidney stones?**

(A) phenytoin

(B) carbamazepine

(C) topiramate

(D) tiagabine

View Answer***4. The answer is C[see*****5. What are the most common adverse effects of anticonvulsive drugs?**

(A) headache and dizziness

(B) gastrointestinal symptoms

(C) alternation of cognition and mentation

(D) adverse effects on appetite and body weight

(E) all of the above

View Answer***5. The answer is E[see-9]*****6. Which antiepileptic drug has the least effect on the efficacy of oral contraceptives?**

(A) phenytoin

(B) tiagabine

(C) gabapentin

(D) lamotrigine

(E) C and D

View Answer***6. The answer is E[see*****7. Which of the following drugs could cause hyponatremia?**

(A) carbamazepine

(B) phenytoin

(C) oxcarbazepine

(D) felbamate

(E) topiramate

(F) A, C, and D

View Answer***7. The answer is F[see].***P.1009

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* I.B.2.c.(1)*].*

Phenytoin (diphenylhydantoin) is the most commonly prescribed hydantoin for seizure disorders. It is one of the preferred drugs for generalized tonic-clonic (grand

mal) seizures and for partial seizures, both simple and complex. However, phenytoin is not effective for absence (petit mal) seizures.

2. The answer is D *[see* II.B.1.c.(2)*].*

Carbamazepine is structurally related to the tricyclic antidepressants (e.g., amitriptyline, desipramine, imipramine, nortriptyline, protriptyline) and should not be administered to patients with hypersensitivity to any of the tricyclic antidepressants.

3. The answer is B *[see* II.B.5 *and* 6*].*

Primidone's antiseizure activity may be partly attributable to phenobarbital. In patients receiving primidone, serum levels of both primidone and phenobarbital should be measured.

4. The answer is C *[see* II.B.12]

There is a higher incidence of kidney stones (renal calculus) with topiramate administration.

5. The answer is E *[see* I.B.1, 2-*9]*

Alternation in cognition and mentation, gastrointestinal symptoms, appetite and body weight, and headache and dizziness are all common adverse effects of anticonvulsive drugs.

6. The answer is E *[see* IV.C.5]

Gabapentin and lamotrigine do not increase the metabolism of oral contraceptives to a clinically significant level; therefore, they could be used with oral contraceptives.

7. The answer is F *[see* II.B.1; II.B.9; II.B.16*].*

Carbamazepine, oxcarbazepine, and felbamate all cause hyponatremia.

46

Parkinson Disease

Azita Razzaghi

I. DISEASE STATE AND PATHOLOGY

A. Definition. Parkinson disease is a slowly progressive degenerative neurological disease characterized by tremor, rigidity, bradykinesia (sluggish neuromuscular responsiveness), and postural instability. Parkinson disease was first described by Dr. James Parkinson in 1817 as “shaking palsy.”

B. Incidence

1. It has a prevalence of 1-2 per 1000 of the general population and 2 per 100 among people >65 years.

2. Onset generally occurs between age 50 and 65; it usually occurs in the 60s.

C. Pathogenesis. Parkinson disease is a neurodegenerative disease associated with **depigmentation of the substantia nigra** and the **loss of dopaminergic input to the basal ganglia** (extrapyramidal system); it is characterized by distinctive **motor disability.** The basal ganglia are responsible for initiating, sequencing, and modulating motor activity.

1. In healthy individuals, dopamine is produced by neurons that project from the substantia nigra to the neostriatum (which include caudate and putamen) and globus pallidus. In these areas, dopamine acts as an inhibitory neurotransmitter.

2. Lewy bodies are widespread but occur especially in the basal ganglia, brainstem, spinal cord, and sympathetic ganglia.

3. In Parkinson disease, the loss of dopamine-producing neurons in the substantia nigra results in an imbalance between dopamine, an inhibitory neurotransmitter, and the excitatory neurotransmitter acetylcholine. Alterations in the concentrations of other neurotransmitters, such as norepinephrine, serotonin, and γ-aminobutyric acid (GABA), are also involved in the pathophysiology of Parkinson disease (Figure 46-1).

D. Cause. Several forms of Parkinson disease have been recognized.

1. Primary (idiopathic) Parkinson disease

a. This is also called classic Parkinson disease or **paralysis agitans.**

b. The cause is unknown; and while treatment may be palliative, the disease is incurable.

c. Most patients suffer from this type of parkinsonism.

d. Hypotheses of neuronal loss in idiopathic Parkinson disease are as follows:

(1) Absorption of highly potent neurotoxins (environmental), such as carbon monoxide, manganese, solvents, and *N*-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), which is a product of improper synthesis of a synthetic heroin-like compound. Exposure to these agents, alone or in combination with the neuronal loss of age, may be the cause of Parkinson disease.

(2) Exposure to the free radicals. Normally, dopamine is catabolized by monoamine oxidase (MAO). Hydrogen peroxide and production of free radicals—both toxic to cells—are products of catabolism. Protective mechanisms, enzymes, and free radical scavengers, such as vitamins E and C, protect cells from damage.

It is proposed that either a decrease in these protective mechanisms or an increase in the production of dopamine causes a destruction of the neurons by free radicals.

e. Genetics factors: Genes that link to Parkinson disease such as alpha-synuclein and Parkin are further being studied in treatment and diagnosis of Parkinson disease.

2. Secondary parkinsonism—from a known cause

a. Only a small percentage of cases are secondary, and many of these are curable.

b. Secondary parkinsonism may be caused by drugs, including dopamine antagonists, such as the following:

P.1011

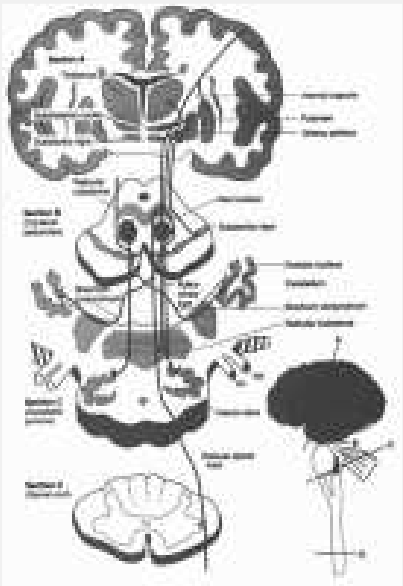

Figure 46-1. Extrapyramidal system involved in Parkinson disease. (Reprinted with permission from Netter F. *Ciba Collection of Medical Illustrations.* West Caldwell, NJ: Ciba Geigy Pharmaceuticals, 1983:69.)

P.1012

(1) Phenothiazines (e.g., chlorpromazine, perphenazine)

(2) Butyrophenones (e.g., haloperidol)

(3) Reserpine

c. Poisoning by chemicals or toxins may be the cause; these include

(1) Carbon monoxide poisoning

(2) Heavy-metal poisoning, such as that by manganese or mercury

(3) MPTP, a commercial compound used in organic synthesis and found (as a side product) in an illegal meperidine analog

d. Infectious causes include

(1) Encephalitis (viral)

(2) Syphilis

e. Other causes include

(1) Arteriosclerosis

(2) Degenerative diseases of the central nervous system (CNS), such as progressive supranuclear palsy
(3) Metabolic disorders, such as Wilson disease

E. Signs and symptoms

1. Tremor

a. Tremor may be the initial complaint in some patients. It is most evident at rest (**resting tremor**) and with low-frequency movement. When the thumb and forefinger are involved, it is known as the **pill-rolling tremor.** Before pills were made by machine, pharmacists made tablets (pills) by hand, hence the name (Figure 46-2).
b. Some patients experience **action tremor** (most evident during activity), which can exist with or before the resting tremor develops.
2. Limb rigidity is present in almost all patients. It is detected clinically when the arm responds with a ratchet-like (i.e., cogwheeling) movement when the limb is moved passively. This is owing to a tremor that is superimposed on the rigidity.
3. Akinesia or bradykinesia. Akinesia is characterized by difficulty in initiating movements, and bradykinesia is a slowness in performing common voluntary movements, including

standing, walking, eating, writing, and talking. The lines of the patient's face are smooth, and the expression is fixed (**masked face**) with little evidence of spontaneous emotional responses (Figure 46-3).

Figure 46-2. Resting (or static) tremors. (Adapted from Bates B. *A Guide to Physical Examination and History Taking.* 5th ed. Philadelphia: Lippincott, 1991:197.)

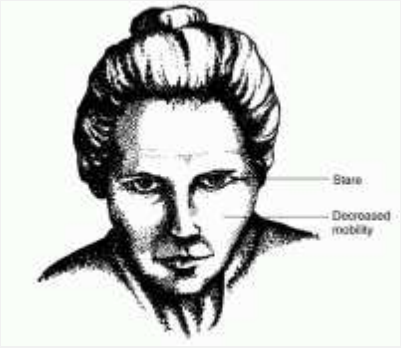

Figure 46-3. Masked face of Parkinson disease. (Adapted from Bates B. *A Guide to Physical Examination and History Taking.* 5th ed. Philadelphia: Lippincott, 1991:197.)

4. Gait and postural difficulties. Characteristically, patients walk with a stooped, flexed posture; a short, shuffling stride; and a diminished arm swing in rhythm with the legs. There may be a tendency to accelerate or festinate (Figure 46-4).

5. Changes in mental status. Mental status changes, including depression (50%), dementia (25%), and psychosis, are associated with the disease and may be precipitated or worsened by drugs.

6. Unified Parkinson disease rating scale (UPDRS)

a. To evaluate the clinical efficacy of antiparkinson drugs and **to monitor disease progression,** most investigators have used the UPDRS.

(1) The disadvantages associated with the use of scales for rating the functional and motor disabilities of patients with Parkinson disease include the potential of interrater variability and imprecision because of the semiquantitative scoring.

(2) The result of testing depends highly on the stage of the disease, whether the patient is being evaluated during an on or off period, and the relative distribution of the improvement across all the items evaluated.

b. Part I of the UPDRS is an **evaluation of mentation, behavior,** and **mood.**

c. Part II is a **self-reported evaluation of the activities of daily living (ADLs)** and includes speech, swallowing, handwriting, ability to cut food, dressing, hygiene, falling, salivating, turning in bed, and walking.

d. Part III is a **clinician-scored motor evaluation.**

(1) Patients are evaluated for speech, rest-tremor facial expression and mobility, action or postural tremor of hands, rigidity, finger taps, hand movements, rapid alternative pronation-supination movement of hands, leg agility, ease of arising from a chair, posture, postural stability, gait, and bradykinesia.

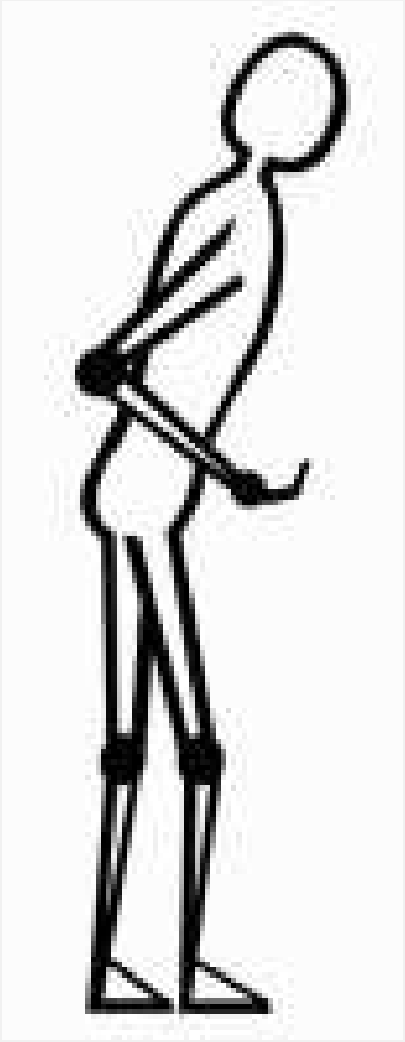

Figure 46-4. Characteristic walk of patients with Parkinson disease. (Adapted from Bates B. A *Guide to Physical Examination and History Taking.* 5th ed. Philadelphia: Lippincott, 1991:553.)

(2) Each item is evaluated on a scale of 0-4.

(a) A rating of 0 on the motor performance evaluation scale indicates **normal performance.**

(b) A rating of 4 on the motor performance evaluation scale indicates **severely impaired performance.**

e. Part IV is the **Hoehn and Yahr** staging of severity of Parkinson disease (Table 46-1).

f. Part V is the **Schwan and England ADL scale.**

Table 46-1. Stages of Parkinson Disease

Stage	Characteristics
0	No clinical signs evident
I	Unilateral involvement, including the major features of tremor, rigidity, or bradykinesia; minimal functional impairment
II	Bilateral involvement but no postural abnormalities
III	Mild to moderate bilateral disease, mild postural imbalance, but still ability to function independently
IV	Bilateral involvement with postural instability; patient requires substantial assistance
V	Severe disease; patient restricted to bed or wheelchair unless aided

Reprinted with permission from Hoehn MM, Yahr MD. Parkinsonism: Onset, progression, and mortality. *Neurology* 1967;17:427.

F. Diagnosis

1. Diagnosis depends on clinical findings.

2. Tests (including imaging) are most often used to rule out an origin of secondary Parkinson disease.

3. New technologies—for example, positron-emission tomography (PET) scan—are used to visualize dopamine uptake in the substantia nigra and basal ganglia. The PET scan measures the extent of neuronal loss in these areas.

4. A specific form of single-photon emission computed tomography (SPECT) can be helpful for diagnosis of parkinsonian syndromes and nonparkinsonism syndromes, particularly essential tremor.

5. Other diseases that are similar to Parkinson disease are multiple system atrophy (striatonigral degeneration, olivopontocerebellar atrophy, shy-dragger syndrome), corticobasal ganglionic degeneration, and progressive supranuclear palsy.

6. Other investigational diagnostic tools: (i) Transcranial ultrasound, (ii) exaime deficits in olfaction, and (iii) detection of oligometric alpla-synucelin in blood of patients with Parkinson disease.

G. Treatment (Figure 46-5)

1. Nondrug treatment

a. Exercise is an important adjunctive therapy and is most beneficial. Although exercise does not help with the symptoms of Parkinson disease, regular focused exercise, stretching, and strengthening activities can have a positive effect on mobility and mood.

b. Nutrition. Patients with Parkinson disease are at increased risk of poor nutrition, weight loss, and reduced muscle mass. Examples of the beneficial effects of proper nutrition in this group of patients include the following:

(1) Sufficient fiber and fluid intake help prevent constipation associated with Parkinson disease and the medications used to treat the disease.

(2) Calcium supplementation helps maintain the existing bone structure.

(3) Excessive dietary protein in the late stages of the disease causes erratic responses to levodopa therapy.

(4) A large body of literature supports the pathophysiological role of antioxidants in the neuroprotective role and decrease in progression in Parkinson disease. Products such as α-tocopherol or vitamin, creatine, coenzyme Q10 act as scavengers of free radical which are harmful to cells.

2. Drug therapy for symptomatic relief. Treatment is divided into two generalized categories: symptomatic therapies and preventive or protective measures. Neuroprotective strategies are used to slow the development and progression of the disorder.

H. Drug treatment: Neuroprotective treatment

1. MAO-B, such as selegiline and tocopherol (vitamin E), acts as a scavenger of free radicals.

2. Dopamine agonists serve as scavengers of free radicals and decrease dopamine turnover, which reduces oxidative stress. During early development of the disease, there are increases in oxidative stress. Four classes of drugs are available:

a. Anticholinergics (for resting tremor)

b. Precursor of dopamine (e.g., carbidopa/levodopa)

c. Direct-acting dopamine agonists (e.g., bromocriptine)

d. Indirect-acting dopamine agonists

(1) Decrease reuptake (e.g., amantadine)

(2) Decrease metabolism (e.g., selegiline)

3. Drug therapy for treating associated symptoms

a. Tricyclic antidepressants are used to treat **depression.** They exhibit some dopaminergic and anticholinergic effects.

b. β-Blockers, especially **propranolol** with its high lipophilicity, **benzodiazepines,** and **primidone,** are medications used for **action tremor.** Usually, patients show a clinical response in low doses.

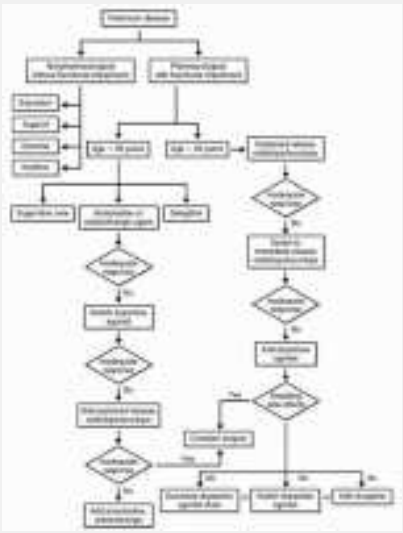

Figure 46-5. Management of Parkinson disease.

P.1017

c. Antihistamines. Diphenhydramine hydrochloride has some mild anticholinergic effects and is used for symptomatic release of mild tremor; because of its adverse reaction in the CNS, it should be used with caution in the elderly.

4. General principles of drug therapy

a. If a patient does not respond to an agent in one class, another class should be tried. Studies show that some patients respond to one agent when they fail to respond to the other.

b. Therapy should be started with a low dose and titrated up. Response usually is seen within a few days after starting therapy.

c. If a second agent is added to the drug therapy, the dose of the first medication should be decreased to minimize side effects.

d. Drug therapy should never be discontinued suddenly because withdrawal may exacerbate the symptoms.

5. Definitions concerning drug therapy

a. Dyskinesias/dystonia are typically oral-facial movements, grimacing, or jerky and writhing movements of the trunk and extremities. They are always reversible with antiparkinsonian medications, and they decrease or diminish with dose reduction. Symptoms of Parkinson disease may reappear by reducing the dose, and it is the clinical judgment of the physician or the preference of the patient whether to continue with the drug regimen or tolerate the side effects. There are three types of dyskinesias/dystonia: peak dose dyskinesia, biphasic dyskinesias, and off-period dystonia. All could benefit from sustained-release preparations.

(1) Peak-dose dyskinesia

(a) Could be corrected with sustained-release preparations.

(b) Decrease L-dopa dose, or add catechol-*O*-methyltransferase (COMT) inhibitor.

(c) Add amantadine.

(d) Perform surgery.

(2) Biphasic dyskinesias

(a) Could be corrected with sustained-release preparations.

(b) Decrease L-dopa dose and increase dopaminergic dose. If symptoms are still present, a COMT inhibitor should be added.

(c) Amantadine may be helpful.

(3) Off-period dystonia

(a) Decrease L-dopa dose.

(b) Increase dopaminergic dose.

b. On-off effect describes oscillations in response (at the receptor site) and sudden changes in mobility from no symptoms to full parkinsonian symptoms in a matter of minutes. No direct relationship between the on-off effect and drug levels has been found. Usually, a second drug is added to the therapy regimen to correct the effect. Reducing the dose of one drug and adding a second drug may also be useful. Could be managed by adding entacapone, dopamine agonist, amantadine, or selegiline.

c. End-dose effect, known also as the **wearing-off effect,** occurs at a latter part of the dosing interval; it happens after a few years of L-dopa therapy. Reduce the single L-dopa dose and spread the total L-dopa dose over a larger number of single doses. Change to a dopamine agonist and use a sustained-release formulation of L-dopa. Could be managed by adding entacapone, dopamine agonist, amantadine, or selegiline.

d. Drug holiday. Long-term levodopa use results in downregulation of dopamine receptors. A drug holiday allows striatal nigra dopamine receptors to be resensitized, although controversy exists regarding the consequences and the outcome of this holiday.

6. Physical rehabilitation restores patients' physical function and independence through physical and occupational therapy. Such therapy helps patients with managing big and small muscle groups by focusing on maintaining coordination, dexterity, flexibility, and range of motions.

7. Psychological rehabilitation provides support for patients and their families. Keep in mind that patients with Parkinson disease have a high incidence of depression and that, in later stages of the disease, they develop dementia (Table 46-2).

8. Secondary effects of Parkinson disease include

a. Cardiovascular effects, including orthostatic hypotension and arrhythmia

b. Gastrointestinal effects, including constipation and hypersalivation

c. Genitourinary effects, including increased urinary frequency and impotence

Table 46-2. Overview of Parkinson Disease Management

Stage	Characteristics	Treatment Considerations	
		Physical	Psychosocial
Early	Fully functional May have unilateral tremor, rigidity	Preventive exercise program	Education Information
Early middle	Symptoms bilateral, bradykinesia, rigidity Mild speech impairment Axial rigidity, stooped posture, stiffness Gait impairment begins	Corrective exercise program	Counseling Support group Monitor for depression
Late middle	All symptoms worse but independent in ADLs May need minor assistance Balance problems	Compensatory and corrective exercise Speech therapy Occupational therapy	Caregiver issues (medications, mobility) Monitor for dementia
Late	Severely disabled, impaired Dependent with ADLs	Compensatory exercise Dietary concerns Skin care Hygiene Pulmonary function	Dementia Depression

ADLs, activities of daily living.

d. Central nervous system effects, including hallucinations, depression, and psychosis. Could be treated with reducing or eliminating amantadine, selegiline, anticholinergics, or dopamine agonists.

9. Late disabilities of Parkinson disease can be divided into two groups.

a. Levodopa-related disabilities, which include motor fluctuation, dyskinesia, neuropsychiatric toxicity, and reduced response

b. Non-levodopa-related disabilities, which include cognitive impairment, instability resulting in more frequent falls, gait disturbance, incontinence, dysphagia, and speech disturbance

c. Late disabilities management therapies include the following:

(1) Motor fluctuation. Altering the levodopa dosage and timing, using alternative means of levodopa administration, delivery, and absorption; using direct-acting dopamine agonists or experimental agonists; altering metabolism of dopamine and levodopa parental agonists; using glutamate antagonists; and performing functional neurosurgery

(2) Miscellaneous late disabilities and management therapies include

(a) Urinary urgency: oxybutynin

(b) Urinary retention: apomorphine

(c) Constipation: fiber, polyethylene glycols

(d) Tenesmus: clonazepam, apomorphine

(e) Hypersalivation: antihistamine, anticholinergic

(f) Dysphagia: liquid levodopa

(g) Sweating crises: β-blockers, anticholinergic agents

(h) Daytime sleepiness: selegiline

(i) Nightmares: amitriptyline, clonazepam

(j) Panic attacks and depression: liquid levodopa, amitriptyline

(k) Orthostatic hypotension: domperidone, desmopressin

(l) Dysphonia: reduce levodopa dosage, speech therapy

(m) Pain: amitriptyline, fluvoxamine

II. INDIVIDUAL DRUGS

A. Anticholinergic agents are used for mild symptoms, predominantly tremors.

1. Mechanism of action. This class of drugs blocks the excitatory neurotransmitter cholinergic influence in the basal ganglia. These drugs are more effective for tremor and rigidity than for bradykinesia and less effective for postural imbalance.

2. Administration and dosage (Table 46-3)

3. Precautions and monitoring effects

a. Anticholinergics should be used with caution in patients with obstructed gastrointestinal (GI) or genitourinary (GU) tracts, narrow-angle glaucoma, or severe cardiac disease. Physicians should be notified if a rapid heartbeat or eye pain are experienced. (Frequent ophthalmological visits are recommended.)

b. The sedative side effects of antihistamines may be beneficial in some patients.

c. Alcohol and other CNS depressants should be used with caution.

d. Adverse effects of anticholinergic therapy include the following:

(1) Peripheral anticholinergic effects include dry mouth (hard candies may be helpful); decreased sweating, resulting in decreased tolerance to heat; urinary retention; constipation (stool softeners may be helpful); increased intraocular tension; and nausea. Because of patients' decreased tolerance to heat, these agents should be used with caution in hot weather. They should also be taken with food to minimize GI upset.

Table 46-3. Dosage Range and Characteristics of Drug Treatment

Drug	Time to Peak Concentration (hr)	Half-Life (hr)	Daily Dosage Range (mg/day)
Anticholinergic agents			
Benztropine	n/a	n/a	1-6
Biperiden	1-1.5	18.4-24.3	2-8
Procyclidine	1.1-2	11.5-12.6	6-20
Trihexyphenidyl	1-1.3	5.6-10.2	2-15
Ethopropazine	n/a	n/a	50-400
Dopamine agents			
Carbidopa/levodopa	1	1-1.75	10/100-200/2000
Carbidopa/levodopa, sustained-release	2	>standard treatment	10/400-25/1000, in 2-3 divided doses
Amantadine	4-8	9.7-14.5	100-400
Bromocriptine	1-3	3-8	2.5-40

Selegiline	0.5-2	2-20.5	5-10
Selegiline Oral Disintegrating table*	1	1-3 hrs	0.5-1 mg
Rasagiline	1	1.3-3hrs	0.5-1mg
Non-ergot dopamine agents			
Pramipexole	1-2 (3-4[a])	8-12[b]	1.5-4.5, in 3 divided doses
Ropinirole	1-2 (3-4[a])	6	3-24, in 3 divided doses
COMT inhibitor	0.5-4	70	0.5-6
Tolcapone	2	2-3	300-600
Entacapone	1	2-3	200-1600
Rotigotine	15-27	5-7 hrs	2-6mg
Apomorphine hydrochloride injection (SC)	1	40 min	2-6mg

[a] With food.

[b] Over 65 years of age.
COMT, catechol-*O*-methyltransferase; *n/a,* not available.

* avoids first pass effect

SC: subcutaneous injection

(2) CNS effects include dizziness, delirium, disorientation, anxiety, agitation, hallucinations, and impaired memory. The incidence of CNS effects increases in elderly individuals.

(3) Cardiovascular effects include hypotension and orthostatic hypotension.

4. Significant interactions

a. Side effects may be potentiated by other drugs with anticholinergic activity such as **antihistamines, antidepressants,** and **phenothiazines.**

b. Anticholinergic agents increase **digoxin** levels.

c. When anticholinergic agents are taken with **haloperidol,** the following occurs:

(1) Schizophrenic symptoms may increase.

(2) Haloperidol levels may decrease.

(3) The severity of (not the risk of) tardive dyskinesia may increase.

d. When **phenothiazines** are taken with anticholinergic drugs, the effects of the phenothiazines decrease and the anticholinergic symptoms increase.

e. Patients on high doses of anticholinergics combined with **levodopa** should be watched for decreased levodopa activity because of a delayed gastric emptying time.

B. Dopamine precursor. Levodopa/carbidopa is the most effective drug for managing Parkinson disease; however, prolonged use decreases its therapeutic effects (there is a decline in efficacy after 3-5 years) and increases adverse drug reactions. Dopamine does not cross the blood-brain barrier; therefore, a precursor is used. Peripheral conversion of levodopa to dopamine causes adverse reactions like nausea, vomiting, cardiac arrhythmias, and postural hypotension. To decrease the peripheral conversion and peripheral adverse effects, a peripheral dopa decarboxylase inhibitor (carbidopa) is added to levodopa.

1. Mechanism of action

a. Levodopa is converted to dopamine by the enzyme dopa decarboxylase, which elevates CNS levels of dopamine.

b. The sustained-release formulation is designed to release the drug over 4-6 hr, thereby inhibiting variation in plasma concentration and decreasing motor fluctuation “off” time or improving overall dose response in patients with advanced disease.

2. Administration and dosage (Table 46-3)

a. It is necessary to give at least 100 mg daily of carbidopa to decrease the incidence of the peripheral conversion of levodopa and GI side effects (e.g., nausea) and increase the bioavailability of levodopa for the CNS.

b. If carbidopa is given in a separate dosage form, the dose of levodopa can be decreased by 75%.

c. If patients still complain of GI side effects after combination levodopa/carbidopa, plain carbidopa can be given.

d. Sustained-release preparations are approximately 30% less bioavailable as compared with levodopa/carbidopa. Because of this lower bioavailability, the daily dosage should be higher. If a patient is receiving a standard preparation and needs to be converted to the sustained-release dose, approximately 10% more levodopa should initially be added to the daily dosage and at least 3 days should pass between increased dosages; then gradually increase the levodopa dose up to 30% of standard preparation.

e. With the sustained-release preparation, the peak plasma concentration is lower and the trough plasma concentration is higher.

f. The sustained-release preparation could be divided in half at the scored point only. The tablet should not be chewed or crushed.

g. When carbidopa is given to patients being treated with levodopa, give the two drugs at the same time, starting with no more than 20% to 25% of the previous daily dosage of levodopa and initiating therapy with carbidopa and levodopa.

h. Long-term treatment could lead to motor fluctuation and dyskinesias, especially at high doses.

3. Precautions and monitoring effects

a. Levodopa must be used with caution in patients with narrow-angle glaucoma.

b. Levodopa may activate a malignant melanoma in patients with suspicious undiagnosed skin lesions or a history of melanoma.

c. The efficacy of levodopa declines with long-term therapy by desensitizing the receptors or because of the decreased number of receptors, resulting from the progression of the disease.

d. Adverse drug reactions

(1) GI **effects** include anorexia, nausea and vomiting, and abdominal distress. Levodopa should be taken with food to minimize stomach upset.

(2) Cardiovascular effects include postural hypotension and tachycardia.

(3) Musculoskeletal effects include dystonia or choreiform muscle movement.

(4) CNS effects include confusion, memory changes, depression, hallucinations, and psychosis. Physicians should be notified if any of these symptoms occur.

(5) Hematological effects include hemolytic anemia, leukopenia, and agranulocytosis (rare).

4. Significant interactions

a. Antacids cause rapid and complete intestinal levodopa absorption (by decreasing gastric emptying time).

b. Hydantoin decreases the effectiveness of levodopa.

c. Methionine increases the clinical signs of Parkinson disease.

d. Metoclopramide increases the bioavailability of levodopa, which decreases the effects of metoclopramide on gastric emptying and on lower esophageal pressure. As a dopamine blocker, it may also precipitate parkinsonian symptoms.

e. False-positive results are seen with the Coombs test.

f. The uric acid test increases with the calorimetric method but not with the uricase method.

g. Hypertensive reactions may occur if levodopa is administered to patients receiving **MAO inhibitors** and **furazolidone.** MAO inhibitors must be discontinued 2 weeks before starting levodopa.

h. Administering **papaverine** may decrease the effect of levodopa.

i. Tricyclic antidepressants decrease the rate and extent of absorption of levodopa; hypertensive episodes have been reported when levodopa is combined with tricyclic antidepressants.

j. Food decreases the rate and extent of absorption and transport to the CNS across the blood-brain barrier. A **protein-restricted diet** may also help minimize the “fluctuations” (i.e., the decreased response to levodopa) at the end of each day or at various times of the day.

C. Direct-acting dopamine agonists are classified as ergot derivatives (such as bromocriptine) and nonergolines (such as pramipexole and ropinirole).

1. These agents mimic dopamine agonist and reduce motor fluctuations.

2. Drugs in this class have a range of half-lives, and the half-life of any particular drug can vary among patients.

3. These drugs are not metabolized by the oxidative pathway and do not produce free-radical metabolites.

4. Dopamine agonists may have a direct antioxidative effect.

5. They take longer than L-dopa to reach effective doses and require supplementary L-dopa for relief of symptoms after a varying period of time.

6. Common side effects are nausea and psychiatric side effects similar to L-dopa such as hallucinations and delusions; dyskinesias are less common.

7. Other adverse effects are headache, nasal congestion, erythromelalgia, pleural and retroperitoneal fibrosis, pulmonary infiltrates, and vasospasm (except with the new, non-ergot derivatives such as ropinirole).

8. Annual chest radiographs have been recommended for patients on high-dose therapy with bromocriptine to detect pleuropulmonary changes.

9. New dopaminergic agonists (non-ergot derivatives) cause postural hypotension, sleep disturbances, peripheral edema, constipation, nausea, dyskinesias, and confusion.

10. Bromocriptine (Parlodel)

a. Mechanism of action. Bromocriptine is responsible for directly stimulating postsynaptic dopamine receptors; it is most commonly used as an adjunct to levodopa therapy in patients:
(1) With a deteriorating response to levodopa
(2) With a limited clinical response to levodopa secondary to an inability to tolerate higher doses
(3) Who are experiencing fluctuations in response to levodopa
b. Administration and dosage (Table 46-3)
(1) Initially, patients are given one half of a tablet twice daily, which is then increased to one tablet twice daily every 2-3 days.
(2) Patients' responses are extremely variable. Many patients show a dopamine antagonist response at both low and high doses, with the desirable agonist response in the midrange.
(3) Because postural hypotension may result from the first few doses of bromocriptine, the first dose should be administered with the patient lying down, and sudden changes in posture should be avoided.
c. Precautions and monitoring effects
(1) Bromocriptine may cause a first-dose phenomenon that can trigger sudden cardiovascular collapse. It should be used with caution in patients with a history of myocardial infarction or arrhythmias.
(2) Early in therapy, dizziness, drowsiness, and fainting may occur, so patients should be cautious about driving or operating machinery. A physician should be notified if these symptoms appear.
(3) Cardiac dysrhythmias. Patients on bromocriptine were found to have significantly more episodes of atrial premature contractions and sinus tachycardia.
(4) Other adverse effects
(a) GI **effects,** including anorexia, nausea, vomiting, and abdominal distress, may be decreased by taking bromocriptine with food.
(b) Cardiovascular effects include postural hypotension (to which tolerance develops) and tachycardia. Blood pressure must be monitored, particularly for patients taking antihypertensive medication.
(c) Pulmonary effects, including reversible infiltrations, pleural effusions, and pleural thickening, may develop after long-term treatment, so pulmonary function should be monitored in patients treated longer than 6 months.
(d) CNS effects, including confusion, memory changes, depression, and hallucinations, as well as psychosis may be exacerbated by bromocriptine; thus patients with psychiatric illnesses must be monitored.
d. Significant interactions
(1) A combination of **antihypertensive drugs** and bromocriptine could decrease blood pressure.
(2) Dopamine antagonists increase the effect of bromocriptine.
D. Indirect-acting dopamine agonists

1. Selegiline (Eldepryl)

a. Mechanism of action

(1) MAO catabolizes various catecholamines (e.g., dopamine, norepinephrine, epinephrine), serotonin, and various exogenous amines (e.g., tyramines) found in foods (e.g., aged cheese, beer, wine, smoked meat) and drugs. Lack of MAO in the intestinal tract causes absorption of these amines, creating a hypertensive crisis. MAO type A is predominantly found in the intestinal tract, and MAO type B in the brain. They differ in their substrate specificity and tissue distribution. This specificity decreases with selegiline as the dose increases. Most patients experience side effects at doses of selegiline higher than 30-40 mg/day.

(2) Selegiline is a selective inhibitor of MAO-B, which prevents the breakdown of dopamine selectively in the brain at recommended doses.

(3) Selegiline is most commonly used as an adjunct with levodopa/carbidopa when patients experience a “wearing-off” phenomenon; it decreases the amount of off time and decreases the dose needed of levodopa/carbidopa by 10% to 30%.

(4) Results of some studies show that selegiline delays the time before treatment with a more potent dopaminergic drug like levodopa is needed; the proposed mechanism

of action is that an oxidation mechanism contributes to the emergence and progression of Parkinson disease.

b. Administration and dosage (Table 46-3). Exceeding the recommended dose of 10 mg/day increases the risk of losing MAO selectivity.

(1) Oral capsule/tablet: 5mg (maximum of 10 mg/day)

(2) Oral disintegrating tablet: 1.25 mg daily may be increased up to 2.5 mg daily. Disintegrating tablets maximum of 2.5 mg daily.

(3) Transdermal: 6 mg/24 h apply upper torsa, high on the outer surface of the upper arm, avoid exposure of application site to external heat resources. Excessive heat will increase absorption

c. Precautions and monitoring effects

(1) Hypertensive crisis (see II.D.1.a.1).

(2) Levodopa-associated side effects may be increased because the increased amounts of dopamine react with supersensitive postsynaptic receptors. Reducing the dose of levodopa/carbidopa by 10% to 30% may decrease levodopa side effects.

(3) Patients should be educated about foods and drugs containing tyramine and the signs and symptoms of hypertensive reactions.

(4) CNS effects include dizziness, confusion, headache, hallucinations, vivid dreams, dyskinesias, behavioral and mood changes, and depression. Patients who experience insomnia should avoid taking the drug late in the day.

(5) Cardiovascular effects include orthostatic hypotension, hypertension, arrhythmia, palpitations, sinus bradycardia, and syncope.

(6) GI **effects** include nausea and abdominal pain and **lead to** GI **bleeding,** weight loss, poor appetite, and dysphagia.

(7) GU effects include slow urination, transient nocturia, and prostatic hypertrophy.

(8) Dermatological effects include increased sweating, diaphoresis, and photosensitivity.
(9) Hepatic effects include mild and transient elevations in liver function tests.
d. CYP2B6 inhibitors may increase level of selegeline. Also selegiline have active metabolite (n-desmethylselegelineand amphetamine) example of such significant interactions are:
(1) MAO inhibitors are contraindicated with **meperidine** and other opioids. Administration with opioids should be avoided. (serotonin syndrome)**. Death has occurred after initiation of selegiline shortly after discontinuation of fluoxetine.** At least 5 weeks should elapse between discontinuation of fluoxetine and initiation of selegiline. (serotonin syndrome)
(2) Rasagiline: similar to selegiline. The different is 5- to 10-fold greater potency, higher oral absorption. Unlike selegiline it is not metabolites to amphetamine derivatives (see Table 46-3)
2. Amantadine (Symmetrel)
a. Mechanism of action. Amantadine is an antiviral agent (used to prevent influenza).
(1) Amantadine increases dopamine levels at postsynaptic receptor sites by decreasing presynaptic reuptake and enhancing dopamine synthesis and release.
(2) It may also have some anticholinergic effects. It decreases tremor, rigidity, and bradykinesia.
(3) It can be given in combination with levodopa as Parkinson disease progresses.
(4) Clinical effects of amantadine can be seen within the first few weeks of therapy, unlike the other antiparkinsonian medications (e.g., carbidopa/levodopa), which need weeks to months to show their full clinical effects.
b. Administration and dosage (Table 46-3)
(1) Amantadine should be started at 100 mg/day. This may be increased to 200-300 mg/day as a maintenance dose.
(2) Patients experiencing a decline in response may benefit from the following:
(a) Discontinuing the drug for a few weeks, then restarting it
(b) Using the drug episodically, only when the patient's condition most needs a therapeutic boost
(3) Amantadine is also available in liquid form for patients with dysphagia.
c. Precautions and monitoring effects
(1) Amantadine should be used with caution in patients with renal disease, congestive heart failure (CHF), peripheral edema, history of seizures, and mental status changes. It may be necessary to modify dosages in patients with renal failure.

(2) Tolerance usually develops within 6-12 months. If tolerance occurs, another drug from a different class can be added, or the dose may be increased.
(3) Patients should be informed about the side-effect profile.
(a) Peripheral anticholinergic effects include those mentioned in II.A.3.d.(1).

(b) CNS effects include seizures as well as those mentioned in II.A.3.d.(2).

(c) Cardiovascular effects. Patients may develop CHF. Periodic blood pressure monitoring and electrocardiograms (ECGs) are necessary in patients with myocardial infarction or arrhythmias.

(d) Dermatological effects include **livedo reticularis,** a diffuse rose-color mottling of the skin, which is reversible on discontinuation of the drug.

(e) Hematological effects. Periodic complete blood counts (CBCs) should be done for patients with long-term therapy.

(4) Renal function impairment. Dose adjustment is necessary in patients with renal function impairment.

d. Significant interactions

(1) Amantadine increases the anticholinergic effects of **anticholinergic drugs,** requiring a decrease in the dosage of the anticholinergic drug.

(2) Hydrochlorothiazide plus **triamterene** decreases the urinary excretion of amantadine and increases its plasma concentration.

E. Nonergot dopamine agonists

1. Pramipexole and ropinirole are indicated for both early and advanced stages of Parkinson disease.

2. Both selectively bind to dopamine receptors and activate the D_2-receptor but have little or no affinity to the D_1-receptor. They have greater affinity for the D_3-receptor than for the D_2-receptor. The incidence of adverse events (such as pleuropulmonary fibrosis and retroperitoneal fibrosis, coronary vasoconstriction, erythromelalgia, and Raynaud phenomenon), is low compared to nonselective dopamine agonists.

3. Non-ergot dopamine agonists have a low potential for the development of motor fluctuations and dyskinesia.

a. Pramipexole (Mirapex)

(1) Mechanism of action

(a) $\mathbf{D_2}$ subfamily of dopamine receptors. Pramipexole fully stimulates the dopamine receptors to which it binds. Its action may be related to its capacity to function as an antioxidant and oxygen free-radical scavenger.

(b) Pramipexole also has antidepressant activity in moderate depression, which may be related to its preferential binding to the dopamine D_1-receptor subtype.

(c) Long-acting dopamine agonists appear to have a lower risk of inducing abnormal movements. Their use as initial treatment in early Parkinson disease seems warranted, particularly for those with disease onset at a younger age.

(2) Administration and dosage

(a) Initial treatment: starting dose of 0.375 mg daily given in three divided doses.

(b) Do not increase more frequently than every 5-7 days.

(c) Maintenance treatment: 1.5-4.5 mg daily in three divided doses with or without levodopa.

(d) When given in combination with levodopa, consider reduction of levodopa dose by an average of 27% from baseline.

(e) Titrate slowly to balance benefits and side effects, such as dyskinesia, hallucinations, somnolence, and dry mouth.

(f) May be taken with food to reduce the occurrence of nausea. Food decreases the rate of absorption but not the extent of absorption.
(g) Dosage adjustment is necessary in patients with renal function impairment.
(h) Weak protein bound 15%
(i) Not extensively metabolized; >90% of the dose is excreted unchanged in urine.
(j) Dose needs to be decreased by 25% in the elderly.
(3) Precautions and monitoring effects
(a) Dose reduction necessary in patients >65 years, and in patients with renal function impairment or failure

(b) Symptomatic hypotension
(i) Dopaminergic agents appear to impair the systemic regulation of blood pressure, which results in orthostatic hypotension.
(ii) Monitoring and education of the patient is necessary, especially during doseescalation periods.
(c) Hallucinatory effects are increased in patients >65 years of age with early or advanced stages of Parkinson disease.
(d) Other effects include nausea, insomnia, constipation, dizziness, somnolence, GI side effects, and visual hallucinations. Sleep attack by falling sleep during activity daily living.
(4) Significant interactions
(a) Cimetidine reduces renal clearance of pramipexole.
(b) No interaction with selegiline, probenecid, or domperidone.
(c) When combined with levodopa, the dosage of levodopa must be decreased by 27%.
b. Ropinirole (Requip)
(1) Mechanism of action is similar to pramipexole.
(2) Administration and dosage
(a) Initial treatment: 0.25 mg three times daily
(b) Titrate weekly increments.
(c) After week 4, if necessary, daily dosage may be increased by 1.5 mg/day on a weekly basis up to 9 mg/day, to a total of 24 mg/day.
(d) Discontinue gradually over a 7-day period. Decrease the frequency of administration from three times to two times daily for 4 days, and then once daily for the remainder of the week.
(e) When given in combination with levodopa, consider reduction of levodopa dose.
(f) May be taken with food to reduce the occurrence of nausea. Food decreases the rate of absorption, but not the extent of absorption.
(g) Metabolized by the liver (cytochrome P450 1A2), and first-pass effect.
(h) Smoking induces the liver metabolism.
(i) Between 30% and 40% protein bound
(3) Precautions and monitoring effects

(a) Syncope. Bradycardia is observed in patients treated with ropinirole. Most cases occur within the first 4 weeks of therapy and are usually associated with a recent increase of dose.
(b) Binds to melanin-containing tissues like the eyes and skin.
(c) Symptomatic hypotension
(i) Dopaminergic agents appear to impair the systemic regulation of blood pressure, which results in orthostatic hypotension.
(ii) Monitoring and education of the patient is necessary, especially during doseescalation periods.
(d) Hallucinatory effects are increased in patients >65 years of age with early or advanced stages of Parkinson disease.
(e) Other side effects include nausea, dizziness, somnolence, headache, fatigue, and abnormal vision. Sleep attack, by falling asleep during activity daily living.
(4) Significant interactions
(a) Smoking induces the liver metabolism, but the affect of smoking on clearance of ropinirole has not been studied.
(b) There is no interaction between levodopa, theophylline, digoxin, or domperidone.
(c) Estrogens decrease the clearance of ropinirole by approximately 36%.
(d) Ciprofloxacin increases ropinirole area under the curve (AUC) by 84% and maximum plasma concentration by 60%.
c. Rotigotine (Neupro)
(1) Mechanism of action: Nonergoline $D_3/D_2/D_1$ dopamine agonist, it stimulates dopamine D_2 receptors within the caudate-putamen in the brain.
(2) Administration and dosage:
(a) Start at 2 mg/24 hours, may be increased weekly by 2 mg/24 hours if tolerated and if additional therapeutic effect is needed.

(b) The lowest effective dose is 4 mg/24 hours.
(c) The highest recommended dose is 6 mg/24 hours.
(3) Precautions and monitoring:
(a) Similar Ropinirole
(b) Weight gain and fluid retention: due to development of peripheral edema (fluid retention)
(c) Application-site reactions: localized erythema, edema, or pruritus limited to the patch area
(d) Sulfite sensitivity: contains a sulfite that may cause allergic-type reactions, including anaphylactic symptoms and life threatening or less severe asthmatic episodes in certain susceptible persons.
(4) Drug interactions. Dopamine agonists (eg, antipsychotics, metoclopramide) may decrease efficacy of rotigotine.
d. Apomorphine Hydrochloride Injection SC (Apokyn)
(1) Mechanism of action:

(a) stimulating of post synaptic dopamine D2-type receptors within Caudate and putamen in brain
(b) Subcutaneous injection is indicated for acute intermittent treatment if hypomobility “off” episodes (end of dose wearing, unpredictable on/off episodes)
(2) Administration and dosage:
(a) Doses more than 6 mg is not recommended
(b) Dose should be started at 2 mg increase to maximum of 6mg.
(c) It should be administrated at “off” state should begin test dose at 2 mg where blood pressure can be monitored. Blood pressure should be monitored predose at 20, 40, and 60 minutes post dose standing up.
(d) If patient developed orthostatic hypotension should not received Apomorphine
(e) Patients who have a significant interruption in therapy (more than a week) should be restarted on a 0.2 mL (2 mg) dose and gradually titrated to effect.
(3) Precautions and monitoring:
(a) Profound hypotension and loss of consciousness when given with 5HT3 antagonist class (including ondansetron, granisetron)
(b) QT prolongation and potential pro-arrhythmia effect. Patient should be monitored for palpitation syncopy and signs for episode of torsades de points.
(c) Sleep attack, falling asleep during daily activities.
(d) Hallucination
(e) Sulfite sensitivity: contains a sulfite that may cause allergic-type reactions, including anaphylactic symptoms and life-threatening or less severe asthmatic episodes in certain susceptible people
(4) Drug interactions:
(a) 5HT3 antagonist such as ondansetron, granisetron, dolasetron, palonosetron) results in hypotension
(b) Antihypertensive medications and vasodilators which may results in hypotension.
(c) Contraindicated when used with other drugs that have potential to prolong QT, QTC interval. It increases risk of life-threatening arrhythmias.
4. COMT inhibitors
a. Tolcapone (Tasmar)
(1) Mechanism of action
(a) Tolcapone is a selective and reversible inhibitor of COMT and is used as an adjunct to levodopa/carbidopa therapy.
(b) Tolcapone inhibits COMT both peripheral and centrally.
(c) COMT is the main enzyme responsible for peripheral and central metabolism of catecholamines, including levodopa. Addition of a COMT inhibitor results in the doubling of the elimination half-life of levodopa and in increased oral bioavailability of levodopa by 40%-50%.
(d) Tolcapone is indicated as an adjunct therapy to carbidopa/levodopa therapy.
(2) Administration and dosage
(a) Starting dose of 100-200 mg, three times daily
(b) Usual daily dose of 200 mg, three times daily

(c) If patient fails to show expected benefit after 3 weeks of treatment, discontinue drug because of associated risk of liver failure. Rapid withdrawal or abrupt reduction

dose could lead to hyperpyrexia and confusion symptoms such as high fever and severe rigidity similar to those in neuroleptic malignant syndrome.

(3) Precautions and monitoring

(a) Liver toxicity. High risk of fatal liver failure has been reported with tolcapone. Discontinue use if substantial benefit is not seen within 3 weeks of commencement of therapy.

(b) Do not use in patients with liver disease or in patients who have two alanine aminotransferase (ALT) or aspartate aminotransferase (AST) values greater than the upper limit of normal.

(c) Advise patient regarding self-monitoring for liver disease (i.e., clay-colored stool, jaundice, fatigue, appetite loss, or lethargy).

(d) Monitor AST and ALT every 2 weeks for the first year, then every 4 weeks for the next 6 months and every 8 weeks thereafter.

(e) MAO and COMT are two major enzyme systems involved in the metabolism of catecholamines; combination of tolcapone with a nonselective MAO inhibitor will result in inhibition of the pathway responsible for normal catecholamine metabolism.

(f) Tolcapone can be taken concomitantly with a selective MAO-B inhibitor, such as selegiline in recommended dose of less or equal to 10 mg/day.

(g) Fibrolic complications, such as retroperitoneal fibrosis, pulmonary infiltrates or effusion or pleural thickening.

(4) Other side effects

(a) Orthostatic hypotension. Tolcapone enhances levodopa bioavailability and, therefore, may increase the occurrence of orthostatic hypotension.

(b) Diarrhea usually manifests within 6-12 weeks after administration of tolcapone, but can develop as early as 2 weeks after administration. Diarrhea normally resolves after discontinuation of the drug.

(c) Hallucinations are sometimes accompanied by confusion, insomnia, and excessive dreaming. Hallucinatory effects usually occur after initiation of tolcapone and are usually resolved by decreasing the dose of levodopa.

(d) Tolcapone may potentiate the dopaminergic side effect of levodopa and may cause or exacerbate preexisting dyskinesia. Decreased doses of levodopa may or may not alleviate the symptoms.

(e) Severe cases of rhabdomyolysis have been reported, which present as fever, alternation of consciousness, and muscular rigidity.

(f) Others. Dyspepsia, abdominal cramping, mild paresthesia of the legs, and temporary discoloration of urine have also been noted but are not considered clinically important.

(g) Drug interactions. Although no drug interaction studies have been conducted, concurrent use of tolcapone and drugs that are metabolized by the COMT system (i.e., methyldopa, dobutamine, apomorphine) should be monitored. Tolcapone also

has affinity for the cytochrome P450 2C9 isoenzyme, similar to warfarin. Coagulation parameters should be monitored when tolcapone is administered with warfarin.

b. Entacapone (Comtan)

(1) Mechanism of action

(a) Entacapone is a selective and reversible inhibitor of COMT and permits additional levodopa to reach the brain. It does not have any anti-Parkinson effect of its own.

(b) It acts only peripherally by inhibiting COMT.

(c) It improves the duration of on time and decreases the duration of off time.

(d) It is indicated as an adjunct to those on levodopa/carbidopa therapy who experience the signs and symptoms of end-of-dose wearing-off.

(2) Administration and dosage

(a) Dosage: 200 mg with each dose of L-dopa up to 8 times daily with a maximum dose of 1600 mg daily.

(b) Rapid withdrawal could lead to emergency signs and symptoms of Parkinson disease such as hyperpyrexia and confusion (symptoms resembling neuroleptic malignant syndrome).

(c) Levodopa + carbidopa and Entacapone: Available in 4 strengths, each in a 1: 4 ratio of carbidopa to levodopa and combined with entacapone 200 mg in a standard-release formulation, 50, 100, 150, and 200 mg of Levodopa.

(3) Precautions and monitoring effects

(a) MAO. COMT and MAO are two major enzymes in the metabolism of catecholamines. Do not use together.

(b) Drugs metabolized by COMT. Drugs that are metabolized by this pathway, such as isoproterenol, epinephrine, norepinephrine, dopamine, and dobutamine, as well as methyldopa, may interact and may result in increased heart rate, arrhythmias, and an excessive increase in blood pressure.

(c) Hepatic function impairment. The majority of the drug is metabolized by the liver; therefore, use caution in patients who have liver function abnormalities.

(d) Fibrotic complication. Cases of retroperitoneal fibrosis, pulmonary infiltrates, pleural effusion, and pleural thickening have been reported. These complications may resolve when the drug is discontinued, but complete resolution may not always occur.

(e) Biliary excretion. Entacapone is excreted by bile; therefore, use caution with drugs known to interfere with biliary excretion, such as probenecid, erythromycin, and ampicillin.

(4) Other side effects. Dyskinesia/hyperkinesia, nausea, urine discoloration (brownish orange), diarrhea, and abdominal pain

(5) Drug interactions. May interact with drugs that are metabolized by the liver cytochrome P450.

III. SURGICAL TREATMENT.

All surgeries require needle insertion into the brain, which in turn increases the risk of hemorrhage.

A. Globus pallidus internus (Gpi) pallidotomy

1. Definition. A pallidotomy entails the surgical resection of parts of the globus pallidus.

2. Advantages. Improves contralateral dyskinesia

3. Disadvantages. Increased risk of damage to other parts of the brain, including optic nerve and internal capsule, and risk of emotional, behavioral, and cognitive deficits

B. Deep-brain stimulation

1. Definition. High-frequency stimulation that induces functional inhibition of target regions of the brain by implanting an electrode into a target site and connecting the lead to a subcutaneously placed pacemaker.

2. Advantages. No destructive lesion is formed. Stimulation parameters can be readjusted at any time to improve efficacy or decrease adverse events.

3. Disadvantages. Side effects associated with equipment (such as lead breaks, infection, skin erosion, mechanical malfunction, and need for battery replacement). Other side effects include paresthesia limb dystonia, ataxia, intracerebral hemorrhage, seizure, and confusion.

C. Fetal nigral transplantation

1. Definition. Implantation of embryonic dopaminergic cells into the denervated striatum to replace degenerated neuronal cells.

2. Advantages. Implanted cells all survive, and innervation of the striatum is accomplished in an organotypic manner. Does not necessitate making a destructive lesion.

3. Disadvantages. Optimal transplant variables and target site not defined. Also clinical studies showed development atypical dyskinesias during off period.

D. Use of genetically engineered viruses (Adeno-associated virus, AAV) to carry levodopa-dopamine converting enzyme aromatic L-amino decarboxylase (AADC) to increase effectiveness of levodopa, as result decrease doses of levodopa and subsequently decrease dyskinesias and other side effects associated with levodopa.

E. Neuronal regeneration: delivering either growth factors or stem cells to produced dopamine producing neurons.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following drugs is a catechol-*O*-methyltransferase (COMT) inhibitor and has reports of fatal liver toxicity with it?

(A) Tolcapone

(B) Entacapone
(C) Rasagiline
(D) Selegiline

View Answer***1. The answer is A[see].*****2. Levodopa is associated with which of the following problems?**

(A) Gastrointestinal side effects
(B) Involuntary movements
(C) Decline in efficacy after 3-5 years
(D) All of the above

View Answer***2. The answer is D[seeand].*****3. Amantadine has which of the following advantages over levodopa?**

(A) More rapid relief over symptoms
(B) Higher success rate
(C) Better long-term effects

View Answer***3. The answer is A[seeand].*****4. Which drug is a non-ergot dopamine agonist and has a side-effect profile different from the rest of the dopaminergic agents?**

(A) Entacapone
(B) Levodopa/carbidopa
(C) Ropinirole
(D) Selegiline

View Answer***4. The answer is C[seeand].*****5. Which of the following medications is indicated as an adjunct to carbidopa/levodopa therapy?**

(A) Pramipexole
(B) Bromocriptine
(C) Amantadine
(D) Tolcapone

View Answer***5. The answer is D[see].***P.1030

ANSWERS AND EXPLANATIONS

1. The answer is A *[see* II.E.4.a.(3).(a)*].*

Severe cases of hepatocellular injury—including fulminant liver failure, which causes death—have been reported. Patients should be monitored and instructed to look for signs of liver disease such as clay-colored stool, jaundice, fatigue, loss of appetite, and lethargy.

2. The answer is D *[see* II.B.3.c *and* d*].*

Levodopa can cause GI side effects such as nausea and vomiting, particularly when starting treatment. Bowel irregularity and gastrointestinal bleeding can also occur. With long-term levodopa therapy, involuntary choreiform movements can develop, and the efficacy of the drug declines. Other unwanted effects of levodopa include tachycardia and cardiac arrhythmias, postural hypotension, and psychiatric disturbances such as confusion or depression.

3. The answer is A *[see* II.D.2.a.(4), II.D.2.c *and* d*].*

Amantadine is most efficacious within the first few weeks, whereas benefits from levodopa may not be seen for weeks to months. Amantadine is more beneficial than the anticholinergics but is less effective than levodopa. Unfortunately, the efficacy of amantadine declines after 6-12 months of therapy. The efficacy of levodopa declines after 3-5 years of therapy.

4. The answer is C *[see* II.E.3.a *and* b*].*

Non-ergot dopamine agonists, such as ropinirole, are indicated for both early and advanced stages of Parkinson disease. These drugs selectively bind to dopamine receptors and activate the D_2-receptor, but have little or no affinity for the D_1-receptor. They have a greater affinity for the D_3-receptor than for the D_2-receptor. The incidence of adverse events (e.g., pleuropulmonary fibrosis and retroperitoneal fibrosis, coronary vasoconstriction, erythromelalgia, and Raynaud phenomenon) is low compared to nonselective dopamine agonists. Non-ergot dopamine agonists have a low potential for the devolvement of motor fluctuations and dyskinesis.

5. The answer is D *[see* II.E.4.a.(1).(d)*].*

Tolcapone is an inhibitor of COMT enzyme used to metabolize catecholamines, including levodopa. It is indicated as an adjunct therapy to carbidopa/levodopa therapy.

47

Schizophrenia

Rebekah R. Arthur Grube

I. INTRODUCTION

A. Schizophrenia is a major psychological disorder affecting approximately 1% of the population.

B. It is a disease that can markedly affect social and occupational functioning, interpersonal relationships, morbidity, and mortality.

1. As many as 45% of the homeless population in the United States suffer from schizophrenia.

2. Mortality rates of patients with schizophrenia are two to four times higher than the general population.

3. Suicide attempt rates for patients suffering from schizophrenia range from 20% to 42%, with a success rate of 10%.

C. The cost of schizophrenia on the U.S. economy is estimated to be $62.7 billion per year. One half of this cost is the result of indirect losses, such as lost work.

II. PATHOPHYSIOLOGY.

The actual cause of schizophrenia is uncertain, however multiple theories exist, each of which provides partial explanations. These include genetic theories, the dopamine theory, the neurodevelopmental theory, and psychosocial theories.

A. Genetic theories. A strong genetic link exists for the development of schizophrenia.

1. Schizophrenia occurs in 1% of the general population; however, this increases to 10% if a first-degree relative has a history of schizophrenia.

2. The risk of developing schizophrenia further increases to 40% when both parents have a history of schizophrenia.

3. Monozygotic twins have demonstrated a 48% risk of both twins developing schizophrenia if one twin has the disease.

4. Studies are ongoing to locate specific genes linked to the development of schizophrenia.

B. Dopamine theory. This theory postulates that dopamine hyperactivity in the brain is responsible for psychotic symptoms present in schizophrenia.

1. While dopamine hyperactivity is present in the mesolimbic pathway, other areas of the brain, such as the prefrontal, frontal, and temporal cortices, have decreased dopamine activity during acute psychosis.

a. Typical antipsychotics block dopamine activity in the brain. Blockade of dopamine with these agents has not resulted in a response for all patients.

b. The dopamine theory has not been found to be a complete explanation for schizophrenia.

2. Other neurotransmitters thought to be involved in schizophrenia include **5-hydroxytryptamine (serotonin; 5-HT)** and **glutamate.**

a. The role of 5-HT is largely evidenced by the blockade of 5-HT with the newer atypical antipsychotics.

b. The role of glutamate is also being evaluated because one of its major functions is to regulate dopamine activity. Glutamate deficiency has been found to cause similar effects to that of dopamine hyperactivity.

C. Neurodevelopmental theory. This theory suggests that schizophrenia occurs as a result of an in utero disturbance during pregnancy. Potential causes of this disturbance include upper-respiratory infections, obstetric complications, and neonatal hypoxia. Studies exist that link

these prenatal conditions with an increased risk of development of schizophrenia; however, this theory continues to be evaluated.

D. Psychosocial theories. These theories propose that situations such as stress, poor interpersonal skills, conflicting family communication, and various socioeconomic influences are linked to the development of schizophrenia. While these theories have been unproved, such situations can serve as triggers for the development of the disease in people with a predisposition.

III. DIAGNOSIS AND CLINICAL FEATURES

A. Schizophrenia is **diagnosed** based on *Diagnostic and Statistical Manual of Mental Disorders,* 4th ed. (DSM-IV-TR) criteria.

1. A patient must have at least two of the following symptoms: delusions, hallucinations, disorganized speech, disorganized or catatonic behavior, and negative symptoms.

2. The symptoms should be present for at least 1 month, with at least 6 months of continuous prodromal or residual symptoms.

3. At least one area of the patient's social or occupational functioning should be significantly affected.

4. Other conditions causing similar symptoms such as schizoaffective disorder, mood disorders, substance abuse, and general medical conditions should be ruled out.

B. Five **types** of schizophrenia exist (Table 47-1).

C. The clinical features of schizophrenia are categorized as **positive, negative,** or **disorganized** symptoms (Table 47-2). The most common symptoms are **hallucinations** and **delusions.**

1. An **hallucination** is a perception disturbance in sensory experiences of the environment. Hallucinations can be auditory, visual, olfactory, or tactile. Auditory hallucinations are most common.

Table 47-1. Types of Schizophrenia

Type	Presentation
Catatonic	Motor symptoms are most notable. The patient may either demonstrate rigid immobility or excessive purposeless movement. The patient may be silent and withdrawn or may become loud and shout. Bizarre voluntary movements such as posturing may also occur. The patient may fluctuate between the two extremes.
Disorganized	The patient tends to have disorganized speech and behavior with a flat affect. Hallucinations and delusions are not well formed and fragmented. The patient may also have bizarre mannerisms and grimacing.
Paranoid	The most common type of schizophrenia. Patients are usually preoccupied with paranoid delusions or auditory hallucinations. Cognitive function is usually preserved; if thought disorder is present, it does not prevent description of delusions or hallucinations.
Residual	The patient does not have acute psychosis, but some symptoms of schizophrenia remain. Largely negative symptoms are seen, such as flat affect, social withdrawal, and loose associations. Prominent delusions or hallucinations are not present.
Undifferentiated	The patient meets the criteria for a diagnosis of schizophrenia but does not meet the criteria for a specific type, or the patient may meet the criteria for multiple types of schizophrenia. No one type appears to be dominant.

Table 47-2. Symptoms of Schizophrenia

Positive Symptoms	Negative Symptoms	Disorganized Symptoms
Delusions	Affective flattening	Disorganized speech
Hallucinations	Alogia	Thought disorder
Combativeness	Anhedonia	Disorganized behavior
Insomnia	Amotivation	Poor attention
	Apathy	
	Asocial behavior	

2. A **delusion** is an incorrect or false belief. Delusions can be religious, paranoid/persecutory, grandiose, somatic, influential, or sexual. Persecutory or paranoid delusions are the most common.

IV. RISK FACTORS.

Risk factors for the development of schizophrenia include a family history of schizophrenia, any potential cause of fetal hypoxic brain damage, history of birth complications, advanced age of mother during pregnancy, birth during winter months, substance abuse, single marital status, lower socioeconomic class, urban environment, and environmental stress.

V. TREATMENT GOALS AND OBJECTIVES.

There is currently no known cure for schizophrenia. Treatment options include **psychotherapy** as well as **pharmacotherapy.** The goals and objectives of treatment are as follows:

A. Minimize symptoms of schizophrenia
B. Improve quality of life and social/occupational functioning
C. Prevent relapse and hospitalization
D. Minimize adverse effects of medications
E. Prevent suicide attempts or self-harm

VI. PHARMACOTHERAPY: ANTIPSYCHOTIC MEDICATIONS

A. Two generations of antipsychotic medications are available for treatment: **first-generation or typical antipsychotics** and **second-generation or atypical antipsychotics.**

1. The choice of an appropriate antipsychotic agent depends on the patient's previous experiences with antipsychotic medications, adverse effects, the patient's

concomitant medical conditions, medication interactions, and the patient's preference.

2. Current American Psychiatric Association (APA) guidelines recommend using an atypical antipsychotic first, owing to less risk for extrapyramidal symptoms (EPS). Patients who prefer or have a history of response to typical antipsychotics may first use typical antipsychotics.

3. Response to medications is not immediate, and maximal treatment response may take 6 months or longer to be seen.

4. After a treatment response is seen, patients should be maintained on the current therapy for a minimum of 6 months. Most patients will require chronic therapy, because 80% of first-episode patients who do not receive antipsychotic treatment will relapse within 5 years.

Table 47-3. Properties of Typical Antipsychotics

Agent	CPZ[a] Equivalent	Dose Range[a] (mg/day)	Sedation	EPS	Anticholinergic Side Effects	Orthostatic Hypotension
Chlorpromazine (Thorazine)	100	300-1000	+++	++	++	+++
Trifluoperazine (Stelazine)	5	5-15	+	+++	+	+
Thioridazine (Mellaril)	100	300-800	+++	+	+++	+++
Perphenazine (Trilafon)	10	16-64	++	++	+	+
Fluphenazine (Prolixin)	2	5-20	+	+++	+	+

Thiothixene (Navane)	5	15-50	+	+++	+	++
Haloperidol (Haldol)	2	5-20	+	+++	+	+
Molindone (Moban)	10	30-100	++	++	+	+
Loxapine (Loxitane)	10	30-100	+	++	+	+

[a] Data from Lehman AF, Lieberman JA, Dixon LB, et al. Practice guideline for treatment of patients with schizophrenia, 2nd ed. Am J Psych 2004;161:1-56.

CPZ, chlorpromazine; *EPS,* extrapyramidal symptoms; +++, high; ++, moderate; +, low.

B. Typical antipsychotic medications (Table 47-3)

1. Mechanism of action. The antipsychotic effect of these medications is primarily mediated through the blockade of dopamine receptors. These agents also have activity at histamine, muscarinic, and α-receptors, although these receptors are not responsible for desired therapeutic activity.

2. Potency. Typical antipsychotic agents are classified by their potency for the dopamine receptor into high-, moderate-, and low-potency antipsychotics. High-potency agents have a higher affinity for the dopamine receptor and are associated with higher risk for the development of EPS. Low-potency agents have less affinity for dopamine receptors; and although they have less risk for causing EPS, they are associated with more adverse effects from their activity at histamine, muscarinic, and α-receptors.

3. Efficacy. When dosed in equivalent doses, the various typical antipsychotics have similar efficacy. Equivalent doses are described using **chlorpromazine (CPZ) equivalents** (Table 47-3). Typical antipsychotics are thought to be as effective as atypical antipsychotics for positive symptoms but are less effective for negative symptoms.

4. Adverse effects. Typical antipsychotics are associated with several adverse effects (Tables 47-3 and 47-4).

a. The activity of the various typical antipsychotics at the dopamine, α-, muscarinic, and histamine receptors are responsible for many of the adverse effects of these medications (Table 47-5).

b. Extrapyramidal side effects can occur with all the typical antipsychotics, especially with high-potency typical antipsychotics. Four types of extrapyramidal side effects have been described: acute dystonia, akathisia, pseudoparkinsonism, and tardive dyskinesia.

(1) Acute dystonia describes sudden muscle spasms that primarily occur in the eye, neck, face, and throat muscles.

(a) Types of acute dystonia include torticollis (a muscle spasm of the neck causing the head to be twisted to the side), retrocollis (a muscle spasm of the neck causing the head to be pulled back), trismus (a muscle spasm of the mouth causing the jaw to be clenched), and oculogyric crisis (a spasm of the eye muscles causing one or both eyes to become fixed in an upward gaze).

Table 47-4. General Adverse Effects of Antipsychotics

Typical Antipsychotics	Atypical Antipsychotics
Sedation	Sedation
Anticholinergic effects	Anticholinergic effects (clozapine, olanzapine)
Blurred vision	Orthostatic hypotension
Constipation	Moderate to severe weight gain
Dry mouth	Diabetes mellitus
Urinary retention	Hypercholesterolemia
Extrapyramidal symptoms	Hyperprolactinemia (risperidone)
Lowered seizure threshold	Lowered seizure threshold
Orthostatic hypotension	QT prolongation
Hyperprolactinemia	Neuroleptic malignant syndrome

Moderate weight gain	Extrapyramidal symptoms
QT prolongation	Sexual dysfunction
Photosensitivity	
Temperature dysregulation	
Neuroleptic malignant syndrome	
Sexual dysfunction	
Elevated liver enzymes	

(b) Acute dystonias can occur within hours of initiating the medication or increasing the dose. This is most common in young men and in patients using high doses of high-potency typical antipsychotics.

(c) Management includes the use of anticholinergic agents like benztropine and diphenhydramine; if ineffective, benzodiazepines can also be used. Prevention of future reactions may be achieved by decreasing the dose of antipsychotic, using oral anticholinergics, or changing therapy to an atypical antipsychotic.

(2) Akathisia is described as motor restlessness associated with internal agitation and feelings of having to move.

(a) Patients with akathisia may pace or be unable to sit still. This may occur within days to a few months after the initiation of therapy or increase in dose.

(b) Treatment of akathisia includes dose reduction of the antipsychotic, lipophilic β-blockers, benzodiazepines, or anticholinergics. Therapy may also be changed to an atypical antipsychotic.

(3) Pseudoparkinsonism clinically appears similar to idiopathic Parkinson disease, and includes symptoms like shuffling gait, mask-like face, cogwheel rigidity, and resting or pill-rolling tremor.

(a) This can occur within 1-3 months after starting therapy or increasing the dose of the antipsychotic agent.

(b) This is treated by changing to an atypical antipsychotic, decreasing the dose, and/or adding an anticholinergic agent.

Table 47-5. Adverse Effects by Receptor Affinities

Receptor Antagonized	Adverse Effects
Histamine	Sedation
	Weight gain
Dopamine	Extrapyramidal symptoms
	Hyperprolactinemia
Muscarinic	Anticholinergic adverse effects
	Cognitive impairment
	Tachycardia
Alpha	Orthostatic hypotension
	Reflex tachycardia
Serotonin	Weight gain

(4) Tardive dyskinesia (TD) usually does not occur until the patient has been taking antipsychotics for a year or more. It is a movement disorder that can occur in various locations of the body, including the face, tongue, hips, and extremities.
(a) Movements can be dystonic (fixed) or choreoathetoid (rhythmic). Common movement disorders include tongue chewing, lip smacking, and rhythmic movements of the trunk.
(b) TD may be irreversible, so patients taking antipsychotics should be monitored closely for the appearance of any movement disorders.
(c) Tools such as the Abnormal Involuntary Movement Scale (AIMS) or Dyskinesia Identification System Condensed User Scale (DISCUS) are available to assist in monitoring patients.
(d) Treatment should include stopping the antipsychotic. Multiple agents have been used to attempt to treat TD, although none has been definitively proven to be effective. These include vitamin E, benzodiazepines, baclofen, and reserpine.

c. Neuroleptic malignant syndrome (NMS) is an uncommon but potentially fatal adverse effect of antipsychotics. Signs and symptoms include fever, severe rigidity, altered mental status, unstable blood pressure, tachycardia, incontinence, elevated creatine kinase, and increased white blood count.

(1) NMS has a sudden onset, and should prompt immediate discontinuation of all antipsychotics.

(2) Treatment includes supportive care and the use of bromocriptine and/or dantrolene.

C. Atypical antipsychotic medications (Table 47-6)

1. Seven atypical antipsychotics are currently on the U.S. market: clozapine (Clozaril), risperidone (Risperdal), olanzapine (Zyprexa), quetiapine (Seroquel), ziprasidone (Geodon), aripiprazole (Abilify), and paliperidone (Invega).

2. The **mechanism of action** for atypical antipsychotics is different from that of the typical antipsychotics. With the exception of aripiprazole, the atypical antipsychotics are dopamine antagonists but also block 5-HT_{2A}-receptors. They block 5-HT to a greater extent than dopamine. Aripiprazole is a partial dopamine and 5-HT_{1A}-agonist and a 5-HT_{2A}-antagonist.

3. Receptor affinity differs for the various atypical antipsychotics. All atypical antipsychotics have activity at the 5-HT_{2A}-receptor and dopamine receptor. Different agents have different activity for histamine, α-, and muscarinic receptors (Table 47-6).

4. Atypical antipsychotics have increased efficacy for negative symptoms compared to typical antipsychotics. With the exception of clozapine, all antipsychotics are thought to have similar efficacy for positive symptoms. Clozapine has demonstrated efficacy for treatment-refractory schizophrenia.

5. Adverse effects. Atypical antipsychotics differ from typical antipsychotics in their adverse effect profile (Table 47-4). Owing to their higher affinity for 5-HT-receptors compared to dopamine receptors, they are associated with less EPS and hyperprolactinemia than typical antipsychotics. However, they have problematic adverse effects, which limit their use (Table 47-6).

a. Atypical antipsychotics have been linked with weight gain, hyperlipidemia, and hyperglycemia. The risk for the development of these metabolic adverse effects differs among agents.

b. A recent meta-analysis of the atypical antipsychotics demonstrated an increased risk of death in patients with dementia. Atypical antipsychotics now carry a **black box warning** cautioning providers **against the use of atypical antipsychotics in the treatment of dementia-related psychosis.** For more information, refer to Schneider LS, Dagerman KS, Insel P. Risk of death with atypical antipsychotic drug treatment for dementia. JAMA 2005;294:1934-1943.

6. Clozapine was the first atypical antipsychotic to be marketed in the United States, is the only antipsychotic with no risk of EPS or TD and is the only antipsychotic with proven efficacy for treatment-refractory schizophrenia. However, clozapine is indicated only in patients who have failed two to three antipsychotics (including typical and atypical antipsychotics) because of its risk of agranulocytosis. Complete blood count (CBC) must be monitored at baseline, every week for the first

6 months of therapy, every other week for the next 6 months, and then every month thereafter. Clozapine may also lower seizure threshold in patients, especially with higher doses. Clozapine should be used with caution in patients at risk for seizures or with a history of a seizure disorder.

Table 47-6. Properties of Atypical Antipsychotics

Medication	Dose Range[a] (mg/day)	Receptor Affinity[a]	Sedation	EPS	Anticholinergic Effects	Orthostatic Hypotension	Weight Gain
Clozapine	150-600	D, 5-HT, M, H_1, α	+++	0	+++	+++	+++
Risperidone	2-8	D, 5-HT, H_1, α	+	+ to +++	0	+	++
Olanzapine	10-30	D, 5-HT, M, H_1, α	++	+	++	+	++++
Quetiapine	300-800	D, 5-HT, H_1, α	++	+	0	++	++

Ziprasidone	120-200	D, 5-HT, H_1, α	0	+	0	0	0
Aripiprazole	10-30	D, 5-HT, H_1, α	+	+	0	0	0
Paliperidone[b]	3-12	D, 5-HT, H1, α	+	+ to + +	0	+	unknown

[a] Data from Lehman AF, Lieberman JA, Dixon LB, et al. Practice guideline for treatment of patients with schizophrenia, 2nd ed. Am J Psych 2004;161:1-56. *5-HT,* 5-hydroxytryptamine (serotonin); α, alpha; *D,* dopamine; *EPS,* extrapyramidal symptoms; H_1, histamine; *M,* muscarinic; +++, high; ++, moderate; +, low.

[b] Data from Invega package insert, 2007. Titusville, NJ, Janssen, L.P.

7. Unique formulations of atypical antipsychotics are available for patients.

a. Orally disintegrating tablets. Risperidone and olanzapine both are available as orally disintegrating tablets, and are manufactured as Risperdal M tablets and Zyprexa Zydis tablets.

b. Parenteral formulations. Ziprasidone and olanzapine are available in parenteral formulations for use in acutely agitated patients with schizophrenia.

(1) Ziprasidone may be given as 10 or 20 mg intramuscularly. The 10-mg dose may be repeated in 2 hr, and the 20 mg dose may be repeated in 4 hr. The maximum daily dose is 40 mg.

(2) Olanzapine may be given as 10 mg intramuscularly. The 10-mg dose may be repeated every 2 hr, up to a maximum of 30 mg daily.

D. Rapid tranquilization is used for acutely psychotic patients with aggression or who are severely agitated. Parenteral typical or atypical agents may be used in these patients. Typical agents available in a parenteral form include chlorpromazine (Thorazine), fluphenazine (Prolixin), and haloperidol (Haldol). As described earlier, available atypical agents include ziprasidone and olanzapine.

E. Noncompliant patients. Those patients with a history of noncompliance or who have frequent hospitalizations secondary to noncompliance may be candidates for a long-acting intramuscular formulation of antipsychotic. Currently three options exist: haloperidol decanoate, fluphenazine decanoate, and long-acting risperidone (Risperdal Consta).

1. Haloperidol decanoate is given intramuscularly every 3-4 weeks. The starting dose should be 10-15 times the total daily dose of oral haloperidol. This equation is only a rough conversion, and the lowest effective dose should be given. The first dose should not exceed 100 mg, and subsequent doses should not exceed 450 mg.

2. Fluphenazine decanoate is administered intramuscularly every 2-3 weeks. The starting dose is 1.2-1.6 times the total daily dose of oral fluphenazine. The maximum dose of fluphenazine decanoate is 100 mg at any one time. The lowest effective dose of this formulation should be used.

3. Long-acting risperidone is administered intramuscularly every 2 weeks. An effective dose of oral risperidone should first be identified before changing to the long-acting formulation. Patients should be started at 25 mg every 2 weeks and covered with oral medications for 3 weeks after initiation. Doses may be increased to a maximum of 50 mg every 2 weeks.

F. Antipsychotic agents may be switched for several reasons, such as lack of efficacy and adverse effects. When switching antipsychotic agents, the original agent should be titrated down while the new agent is titrated up. If changing from a typical antipsychotic to an atypical antipsychotic secondary to EPS, anticholinergic agents may be continued until the typical agent is completely discontinued unless the new agent is clozapine. Clozapine has high anticholinergic effects, thus additional anticholinergic agents would not be indicated.

G. Adjunctive therapy. In patients with partial or no response to therapy after an adequate trial of an antipsychotic, a second antipsychotic should be tried. After the failure of two to three antipsychotics, the patient meets the criteria for clozapine, and its use should be considered. Augmentation is an option for those patients unable to take clozapine or with partial/no response. Clozapine has been studied in combination with typical and atypical antipsychotics. Other options for augmentation include mood stabilizers, such as lithium, valproic acid, and carbamazepine. Antidepressants have also been used in patients suffering from depressive symptoms. Electroconvulsive therapy (ECT) has also been used as an adjunctive therapy in patients with partial or no response to antipsychotics.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

For questions 1-5: DG is a 23-year-old female committed to the inpatient psychiatric ward by her parents. They state that she has recently been under a large amount of stress from college, and they have noticed over the past year that she has become more withdrawn from her friends and social activities. They also state that she angers more easily than she used to as a child, and this morning they found her with a knife trying to slit her wrists. DG states that the voices keep telling her she is bad and that she should kill herself. She does not admit to any visual hallucinations but describes multiple voices (male and female) talking to her continuously telling her that she should harm herself or that people are out to get her. She keeps telling you that her parents are trying to get rid of her, and she wants to leave. She appears to be a healthy young woman although noticeably agitated. Her medical history is significant only for smoking one pack/day since age 16. DG is diagnosed with schizophrenia.

1. Which type of schizophrenia is DG likely experiencing based upon her presenting signs and symptoms?

(A) catatonic

(B) disorganized

(C) paranoid

(D) residual

View Answer***1. The answer is C[see].*****2. Which of the following of DG's symptoms is best described as a negative symptom of schizophrenia?**

(A) social withdrawal

(B) auditory hallucinations

(C) delusions

(D) agitation

View Answer***2. The answer is A[see].*****3. The medical team decides to initiate treatment for DG. Which of the following antipsychotic medications is the best initial treatment for this patient?**

(A) haloperidol

(B) risperidone

(C) thioridazine

(D) clozapine

View Answer***3. The answer is B[see].*****4. Which of the following is *not* a potential adverse effect of the medication selected for DG in question 3?**

(A) weight gain

(B) pseudoparkinsonism

(C) sedation

(D) urinary retention

View Answer***4. The answer is D[see].*****5. DG is stabilized on the medication prescribed and is discharged home. DG is readmitted into the psychiatric ward 1 year later for auditory *and* visual hallucinations secondary to noncompliance**

on her current treatment regimen. Which of the following treatment options is most appropriate for DG at this time?

(A) haloperidol decanoate

(B) long-acting risperidone

(C) clozapine monotherapy

(D) adjunctive clozapine with haloperidol

View Answer***5. The answer is B[seeandand].*****For questions 6-8:** TW is a 52-year-old female with a history of schizophrenia and diabetes mellitus type 2. She has been treated for many years with haloperidol with good response; however, she has recently developed lip smacking and tongue chewing.

6. What type of adverse effect is TW experiencing?

(A) akathisia

(B) acute dystonia

(C) pseudoparkinsonism

(D) tardive dyskinesia

View Answer***6. The answer is D[seeand].*****7. Which of the following medications has been used to treat the adverse effect described in question 6?**

(A) vitamin E

(B) propranolol

(C) diphenhydramine

(D) amantadine

View Answer***7. The answer is A[see].***P.1040

8. Now that TW is experiencing this reaction, her healthcare providers want to change her therapy to a different antipsychotic. Which of the following antipsychotics is the best treatment option for her?

(A) olanzapine

(B) risperidone

(C) quetiapine

(D) fluphenazine

View Answer***8. The answer is C[see].*****9. Which of the following atypical antipsychotics would be the least likely to cause weight gain?**

(A) risperidone

(B) olanzapine

(C) quetiapine

(D) aripiprazole

View Answer***9. The answer is D[see].*****10. Which of the following statements does not describe a way in which atypical antipsychotics differ from typical antipsychotics?**

(A) Atypical antipsychotics have a higher affinity for serotonin receptors than dopamine receptors.

(B) Atypical antipsychotics are more efficacious for positive symptoms than typical antipsychotics.

(C) Atypical antipsychotics are more likely to cause weight gain and hyperlipidemia than typical antipsychotics.
(D) Atypical antipsychotics are less likely to cause extrapyramidal symptoms (EPS) than typical antipsychotics.

View Answer***10. The answer is B[seeand].***P.1041

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* Table 47-1*].*
DG's prominent symptoms include well-formed hallucinations and delusions. These hallucinations and delusions are characteristic of paranoid schizophrenia. DG also does not meet the criteria for any other type of schizophrenia.
2. The answer is A *[see* Table 47-2*].*
Social withdrawal or asocial behavior is a negative symptom of schizophrenia. Hallucinations, delusions, and agitation are all positive symptoms of schizophrenia.
3. The answer is B *[see* VI.A.2; VI.C.1; VI.C.6*].*
The American Psychiatric Association currently recommends using atypical antipsychotics first over typical antipsychotics, unless the patient has a preference. Haloperidol and thioridazine are typical antipsychotics. Clozapine should be used only for treatment refractory patients because of its adverse effect profile.
4. The answer is D *[see* Table 47-4; Table 47-6*].*
Risperidone has been associated with moderate weight gain, low to moderate risk of EPS, and low risk of sedation. It has not been associated with anticholinergics effects such as urinary retention.
5. The answer is B *[see* VI.A.1 *and* 2, VI.E.1, 2 *and* 3*].*
DG has a history of response with risperidone; however, she is experiencing a relapse of symptoms owing to noncompliance. A long-acting formulation is indicated to assist with medication compliance. As she has not failed multiple antipsychotics, DG is not a candidate for clozapine or adjunctive clozapine. Long-acting risperidone is preferred in this patient over haloperidol decanoate owing to the patient's response history and its preferable adverse effect profile.
6. The answer is D *[see* VI.B.4.b.(1), (2), (3) *and* (4)*].*
TW is experiencing lip smacking and tongue chewing of a late onset, which is best described as tardive dyskinesia.
7. The answer is A *[see* VI.B.4.b.(4).(d)*].*
Vitamin E, benzodiazepines, baclofen, and reserpine have all been used in the treatment of tardive dyskinesia, although none has been definitively proven to be effective.
8. The answer is C *[see* Table 47-3; Table 47-6*].*
Because TW is experiencing tardive dyskinesia, her therapy should be changed to an atypical antipsychotic. Her medical history is significant for type 2 diabetes mellitus. Olanzapine is associated with a high risk of causing weight gain, and other metabolic symptoms and should not be used in this patient. Risperidone has a low

to moderate risk of EPS. Other atypical antipsychotics, such as quetiapine, that carry a lower risk of EPS would be preferable.

9. The answer is D *[see* Table 47-6*].*

Olanzapine has a high risk of causing weight gain. Risperidone and quetiapine have a moderate risk of causing weight gain. Aripiprazole is associated with a low risk of weight gain.

10. The answer is B *[see* VI.C.2, 3, 4 *and* 5.a; Table 47-4*].*

Atypical antipsychotics have a higher affinity for serotonin receptors than dopamine receptors, whereas typical antipsychotics have no activity at serotonin receptors. Atypical and typical antipsychotics have similar efficacy for positive symptoms of schizophrenia; however, atypical antipsychotics have increased efficacy against negative symptoms. Atypical antipsychotics are more likely to cause significant weight gain and hyperlipidemia and less likely to cause EPS than typical antipsychotics.

48

Mood Disorders

Rebekah R. Arthur Grube

I. DEFINITION.

Mood disorders are described as an elevation or depression in mood that persists over a period of time and affects the ability of the person to function. These disorders are associated with significant morbidity, mortality, and financial cost. Mood disorders can cause a 10- to 20-fold increase in suicide rates and impair social and occupational functioning. Two common types of mood disorders are **major depression** and **bipolar disorder.**

II. MAJOR DEPRESSION

A. Major depressive disorder is defined as a mood disorder in which the patient has one or more episodes of major depression but has no history of mania, mixed, or hypomania episodes. Major depressive episodes are described in II.D.

B. Epidemiology

1. Depression occurs in 16.2% of the United States population. Results from recent studies indicate that 6.6% of the population has experienced an episode in the prior 12 months.

2. Depression occurs more frequently in women than men, with women having a lifetime risk of 1.7-2.7 times higher than men.

3. The highest risk of depression occurs in adults between the **ages of 25 to 44 years,** although depression may occur at any age.

C. Pathophysiology. The pathophysiology of depression is not completely known, however several theories exist: genetic theories, the biogenic amine theory, and the dysregulation theory.

1. As with many psychiatric disorders, a **genetic link** exists for depression. People who have a parent or sibling with a history of depression have a 1.5-3 times greater risk for developing depression than the general population. Between 8% and 18% of patients with major depression have a parent or sibling with a history of depression.

2. The **biogenic amine theory** was originally described in the 1950s and is the basis for past and current pharmacological treatment options. This theory suggests that depression is associated with **decreased levels of norepinephrine (NE), 5-hydroxytryptamine (serotonin; 5-HT),** and **dopamine (DA) in the brain.**

3. The **dysregulation theory** was developed after the biogenic amine theory and suggests that **impaired homeostasis of NE, 5-HT, and DA in the brain** is associated with depression rather than absolute levels of these neurotransmitters. This theory in part attempts to explain the changes in neurotransmitter receptor sensitivities witnessed in the first few weeks of pharmacotherapy.

D. Diagnosis and clinical features

1. Major depressive episodes are diagnosed using the *Diagnostic and Statistical Manual of Mental Disorders,* 4th ed. (DSM-IV-TR) criteria. To meet the criteria for a major depressive episode, patients should experience at least five or more persistent symptoms for at least 2 weeks. These symptoms include depressed mood,

loss of interest or pleasure in activities, change in appetite, unintentional weight gain or loss, insomnia or excess sedation, psychomotor agitation or retardation, decreased energy or fatigue, feelings of worthlessness or inappropriate guilt, decreased ability to concentrate, and recurrent thoughts of suicide, death, or suicide attempt.[1]

2. Symptoms should impair social or occupational functioning and should not be related to a general medical condition or substance abuse.

3. Patients presenting with excessive sedation (hypersomnia), increased appetite, weight gain, and agitation are classified as experiencing atypical depression.

E. Treatment options. Three treatment options exist for the treatment of depression: **pharmacotherapy, psychotherapy,** and **electroconvulsive therapy (ECT).** The choice of which treatment option or combination of treatment options to use should be patient specific and influenced by the severity of symptoms and patient preference.

1. Pharmacotherapy options (antidepressants). Pharmacotherapy can be used for mild to severe major depression and produces a response in 40%-70% of patients. Antidepressants have similar efficacy; however, they differ in adverse effects, mechanism of action, medication interactions, and cost. Therefore, selection of pharmacologic agents for patients should be based on the specific symptoms the patient is experiencing, adverse effects of the medications, medication interactions, patient preference, and ability of patient to afford the medication. Patients with a history of response to a particular agent may restart that agent if desired.

a. Monoamine oxidase inhibitors (MAOIs) (Table 48-1)

(1) Indications. MOAIs have numerous adverse effects and medication interactions and are indicated only in patients refractory to other antidepressants. These agents also have a role in patients presenting with atypical depression.

(2) Mechanism of action. MOAIs inhibit monoamine oxidase, which is responsible for the breakdown of neurotransmitters such as DA, 5-HT, and NE. By blocking this enzyme, levels of these amines increase in the brain.

(3) Adverse effects. MAOIs have numerous adverse effects that limit their use. These include hypertensive crises, serotonin syndrome, orthostatic hypotension, peripheral edema, weight gain, and sexual dysfunction.

(a) Hypertensive crises can occur when increased levels of sympathetic amines, such as NE, build up in the body, which can be the result of ingestion of tyramine-containing foods like wine and cheese or the administration of sympathomimetic agents (e.g., decongestants). Patients should be counseled regarding the risk for drug and food interactions when taking MAOIs.

(b) Serotonin syndrome can occur when levels of 5-HT become too high, usually as the result of the use of multiple serotonergic agents. MAOIs in combination with selective serotonin-reuptake inhibitors, tricyclic amines, serotonin and norepinephrine reuptake inhibitors, and any other agent with serotonergic activity

can lead to serotonin syndrome. The clinical manifestations of serotonin syndrome are given in Table 48-2.

b. Many **tricyclic amines (TCAs)** are commercially available in the United States and can be classified as tertiary and secondary (Table 48-3).

(1) Indications. Owing to their numerous adverse effects, TCAs are not usually indicated first-line for the treatment of depression.

(a) TCAs may be considered for patients with a history of response to TCAs, patients refractory to other medications, or patients with co-morbidities that might benefit from TCAs, such as neuropathic pain and migraines.

(b) TCAs should not be used in patients with suicidal ideations and should probably be avoided in patients with cardiovascular conditions, closed angle glaucoma, urinary retention, or severe prostate hypertrophy.

Table 48-1. Monoamine Oxidase Inhibitors

Agent	Starting Dose (mg/day)	Dose Range[a] (mg/day)	Anticholinergic Effects	Sedation	Weight Gain
Phenelzine (Nardil)	10	15-90	++	++	+++
Isocarboxazid (Marplan)	20	20-40	++	++	++
Tranylcypromine (Parnate)	10	10-40	++	+	++
Selegiline (Emsam) patch	6	6-12	++	0	+

[a] For normal adults. Doses may need to be adjusted for elderly patients or those with impaired renal or hepatic function.

+++, high; ++, moderate; +, slight.

Table 48-2. Signs and Symptoms of Serotonin Syndrome

Cognitive-Behavioral Dysfunction	Autonomic Nervous System Dysfunction	Neuromuscular Dysfunction
Confusion	Diarrhea	Myoclonus
Hypomania	Shivering	Hyperreflexia
Agitation	Fever	Tremor
	Diaphoresis	Seizure
	Change in blood pressure	Death
	Nausea and vomiting	

(2) Mechanism of action. TCAs produce their antidepressant effect by inhibiting the reuptake of 5-HT and NE. TCAs also have effect at α-adrenergic, histamine, and cholinergic receptors. Individual TCAs have different affinities for these receptors.

(3) Adverse effects. Several adverse effects exist for TCAs and may differ between agents, depending on their affinity for α-adrenergic, cholinergic, and histamine receptors (Table 48-3).

(a) Tertiary TCAs have been associated with a higher risk of causing anticholinergic adverse effects (blurred vision, constipation, urinary retention, dry mouth), sedation, weight gain, and orthostatic hypotension than secondary TCAs.

(b) Additional adverse effects include tachycardia, QT prolongation, cardiac conduction abnormalities, decreased seizure threshold, and sexual dysfunction. TCAs may be lethal when taken as an overdose.

(c) Owing to their activity on serotonin, TCAs have the potential for causing serotonin syndrome when used in combination with other serotonergic agents.

(4) Medication interactions. TCAs are substrates of various cytochrome P450 enzymes and levels can be affected by enzyme inhibitors and inducers.

c. Selective serotonin reuptake inhibitors (SSRIs). Five SSRIs are currently available in the United States for the treatment of depression (Table 48-4): fluoxetine (Prozac), paroxetine (Paxil), sertraline (Zoloft), citalopram (Celexa), and escitalopram (Lexapro). These medications are considered to be first line for the treatment of depression, and many are also

indicated for anxiety, panic disorder, post-traumatic stress disorder, and obsessive-compulsive disorder.

Table 48-3. Tricyclic Amines

Agent	Dose Range[a] (mg/day)	Anticholinergic Effects	Sedation	Orthostatic Hypotension	Cardiac Effects	Weight Gain
Tertiary amine						
Amitriptyline (Elavil)	50-300	++++	+++	++++	++	+++
Doxepin (Sinequan)	50-300	+++	+++	++	++	+++
Imipramine (Tofranil)	50-300	+++	+++	++++	++	+++
Trimipramine (Surmontil)	50-300	++++	+++	+++	++	+++
Secondary amine						
Nortriptyline (Pamelor)	25-150	++	++	+	++	+
Desipramine (Norpramin)	50-300	+	++	++	++	+
Protriptyline (Vivactil)	10-60	++	+	++	+++	+

[a] For normal adults. Doses may need to be adjusted for elderly patients or those with impaired renal or hepatic function.

++++, very high; +++, high; ++, moderate; +, slight.

Table 48-4. Selective Serotonin Reuptake Inhibitors and Serotonin and

Norepinephrine Reuptake Inhibitors

Agent	Starting Dose (mg/day)	Dose Range (mg/day)	Half-Life	CYP450 Isoenzyme Inhibition
Fluoxetine (Prozac)	10-20	20-80; 90 mg weekly[a]	7-9 days[b]	2D6, 2C9/19 (potent); 3A4 (mild)
Paroxetine (Paxil)	10-20	20-60	21 hr	2D6 (potent)
Sertraline (Zoloft)	25-50	50-200	24 hr	2D6 (mild)
Citalopram (Celexa)	10-20	20-60	35 hr	2D6 (mild)
Escitalopram (Lexapro)	5-10	10-20	27-32 hr	2D6 (mild)
Venlafaxine (Effexor)	75	150-375	11 hr	2D6 (mild)
Duloxetine (Cymbalta)	40	40-60	9-19 hr	2D6 (moderate)

[a] Fluoxetine can be given in a once-weekly formulation in patients stabilized on fluoxetine 20 mg daily; should be started 1 week after the last dose of fluoxetine.

[b] Norfluoxetine is an active metabolite of fluoxetine and has a half-life of 7-9 days. The half-life of fluoxetine alone is 2-3 days.

CYP450, cytochrome P450.

(1) Mechanism of action. SSRIs exert their antidepressant effect by blocking the reuptake of serotonin.

(2) Adverse effects

(a) SSRIs have been associated with nausea, vomiting, insomnia, sedation, sexual dysfunction, headache, agitation, and tremor.

(b) Paroxetine has also been associated with anticholinergic adverse effects, such as blurred vision, dry mouth, constipation, and urinary retention.
(c) These agents have been associated with serotonin syndrome when used in combination with other serotonergic agents.
(3) Many SSRIs are substrates and inhibitors of the cytochrome P450 system and may interact with other medications.
(4) Abrupt discontinuation of SSRIs has been associated with **withdrawal symptoms,** such as nightmares, vivid dreams, tremor, anxiety, nausea, and poor concentration. Fluoxetine has little risk of causing syndrome upon discontinuation, likely because of its long half-life. With the exception of fluoxetine, SSRIs should be slowly tapered when discontinued to prevent this syndrome.
d. Serotonin and norepinephrine reuptake inhibitors (SNRIs) (Table 48-4). Two SNRIs are currently available for the treatment of depression: venlafaxine (Effexor) and duloxetine (Cymbalta). Data have shown these medications to have efficacy for the treatment not only of depression but also of painful peripheral neuropathies. Duloxetine carries a U.S. Food and Drug Administration (FDA) indication for the treatment of pain in diabetic neuropathy.
(1) Mechanism of action. SNRIs inhibit the reuptake of 5-HT and NE, thereby increasing their levels. These medications differ from TCAs in that they have little activity for α-adrenergic, cholinergic, or histamine receptors.
(2) Adverse effects. SNRIs have an adverse effect profile similar to that of the SSRIs. Common adverse effects include nausea, headache, somnolence, dry mouth, dizziness, sexual dysfunction, and insomnia. Venlafaxine and duloxetine have also been associated with elevations of diastolic blood pressure, particularly with higher doses.
(3) Medication interactions. Venlafaxine and duloxetine are both substrates for the cytochrome P450 isoenzyme system and are mild to moderate inhibitors of the isoenzyme 2D6 (Table 48-4). SNRIs should not be used with MAOIs or other serotonergic agents owing to risk of serotonin syndrome.
e. Bupropion (Wellbutrin) (Table 48-5).
(1) The **mechanism of action** for bupropion is not completely understood. Bupropion is known to inhibit the reuptake of dopamine and to a smaller extent the reuptake of serotonin and norepinephrine.

Table 48-5. Miscellaneous Antidepressants

Agent	Starting Dose (mg/day)	Dose Range (mg/day)	Cytochrome P450 Isoenzyme Inhibition
Bupropion (Wellbutrin)	75-150	200-450	2D6
Mirtazapine (Remeron)	15	30-45	Does not inhibit
Trazodone (Desyrel)	50-100	150-600	Does not inhibit

(2) In addition to its indication for depression, bupropion is also indicated for smoking cessation.

(3) Common **adverse effects** associated with the use of bupropion include nausea, vomiting, and insomnia.

(a) Bupropion has been associated with less sexual dysfunction than many other antidepressant medications, such as SSRIs.

(b) Bupropion has been associated with an increased risk for seizures and is contraindicated in patients at risk for seizures. This includes patients with the following medical disorders: seizure disorder, history of anorexia or bulimia, or using or withdrawing from medications such as alcohol or benzodiazepines. Doses > 450 mg should not be used, and dose increases should be gradual.

f. Mirtazapine (Remeron) (Table 48-5).

(1) Mirtazapine antagonizes α-adrenergic and $5HT_{2,3}$-receptors, causing an increase in levels of NE and 5-HT. In addition, mirtazapine has activity at histamine(H) receptors.

(2) Adverse effects for mirtazapine include sedation, weight gain, constipation, dry mouth, and increased appetite. Sedation, increased appetite, and weight gain can be problematic, particularly at lower doses. Mirtazapine has a lower risk for causing sexual dysfunction as compared to SSRIs.

g. Trazodone (Desyrel) (Table 48-5).

(1) The **mechanism of action** for trazodone is not completely understood, but is thought to be owing an increase in 5-HT.

(2) Trazodone is indicated for the treatment of depression, although it is not frequently used because of sedation. It is more frequently used in low doses as adjunctive treatment for insomnia in depressed patients.

(3) The most common **adverse effects** of trazodone include sedation, nausea, and orthostatic hypotension. Trazodone has rarely been associated with priapism and QT prolongation.

h. Nefazodone (Serzone). Nefazodone is a medication structurally similar to trazodone. It was considered to be first line for treatment of depression; however,

recent reports of hepatotoxicity have limited its use and led to a **black box warning** for possible liver failure leading to death.

(1) Nefazodone inhibits 5-HT2-receptors and blocks the reuptake of NE and 5-HT.

(2) Adverse effects. Common adverse effects for nefazodone include dry mouth, nausea, constipation, orthostatic hypotension, and sedation. The most severe adverse effect associated with nefazodone is hepatic failure.

(a) Reported rates by the FDA estimate 1 case of liver failure resulting in death or transplant per 250,000-350,000 patient-years.

(b) No known predicators for the development of liver failure are available. If nefazodone is used, liver function enzymes should be monitored routinely.

(c) The generic product is still available, although brand name nefazodone was withdrawn from the U.S. market in 2004.

(3) Nefazodone is highly protein bound and is an inhibitor of cytochrome P450 isoenzyme 3A4, leading to the potential for multiple drug-drug interactions.

2. Duration of treatment. Treatment is divided into three phases: acute phase, continuation phase, and maintenance phase.

a. The **acute phase** begins with the initiation of therapy until remission is reached, typically lasting between 6 and 12 weeks.

b. The **continuation phase** begins after remission is reached and typically lasts between 6 and 9 months. Medication from the acute phase is continued during this phase to prevent relapse of depression.

c. A **maintenance phase** is used in patients with a high risk of recurrence of depression, such as those with a history of multiple episodes of depression, history of suicidal thoughts, and severe depression. These patients should receive maintenance treatment for 2-3 years, and many may receive life-long therapy.

3. Administration and dosage

(a) Antidepressants are usually started at low doses and slowly titrated up to reach target doses over a period of a few weeks to prevent adverse reactions. Clinical response determines if the dose should be further titrated. While full effects may not be seen for 4-6 weeks, often some signs and symptoms of depression such as insomnia may resolve more rapidly. Patients must receive maximum tolerated doses for 4-6 weeks without response to be classified as ineffective.

(b) If patients receive only a partial or no response, other antidepressants may be considered. When changing to another antidepressant agent, caution should be used to prevent serotonin syndrome. These guidelines should be followed if changing to or from a MAOI:

(1) A 2-week washout period should be observed when changing to a MAOI from an antidepressant without a long half-life and when changing from a MAOI to another antidepressant.

(2) A 5-week washout period should be observed when changing to a MAOI from an antidepressant with a long half-life, such as fluoxetine.

4. Augmentation of therapy. When patients fail to fully or partially respond to two or more medications, augmentation of antidepressant therapy with another agent may be considered.

(a) Lithium and thyroid hormone have been used for augmentation of antidepressant medications. Lithium augmentation is currently preferred over thyroid augmentation.

(b) Dual antidepressant augmentation has also been used. Agents that have been used include bupropion, TCAs, and mirtazapine.

5. Suicide risk. Risk of suicide is always a concern in patients suffering from a major depressive episode. In adolescents and children, recent studies have shown a link between antidepressant use and risk of increased suicidal thoughts and actions. Because of this increased risk, the FDA has now issued a **black box warning** for all antidepressants that an increase in suicidal thoughts and actions may occur with therapy and that adolescents and children receiving this therapy should be closely monitored.

III. BIPOLAR DISORDER

A. Definition. Bipolar disorder or manic depression is a syndrome in which patients suffer from episodes of mania and depression. Mania is an unusually elevated mood and is described in greater detail in III.D.1.

B. Epidemiology

1. Bipolar I and II disorders affect 3.7%-3.9% of the U.S. population. In patients presenting with depression, 21%-49% of patients have bipolar disorder.

2. Bipolar I disorder occurs equally in men and women although bipolar II disorder tends to occur more commonly in women.

3. Although patients may present with bipolar disorder at any age, most patients have an average age of onset of 21 years, with peak onset occurring between the ages of **15 and 24 years.**

4. Suicide occurs in 10%-15% of patients with bipolar I disorder.

C. Pathophysiology. As with many psychiatric disorders, the pathophysiology for bipolar disorder is not completely understood, although many theories exist.

1. A positive family history is present in 80%-90% of patients with bipolar disorder. Therefore, **genetics** is believed to play a role in its pathophysiology, although a direct genetic link has not been discovered.

2. Like major depression, bipolar disorder is believed to be caused by an **imbalance of neurotransmitters.** However, in bipolar disorder, the neurotransmitter levels fluctuate and may be similar or reversed, depending on the patient's current clinical presentation.

a. A manic episode is believed to result from elevations in NE.

b. Depression has been associated with a decrease in NE.

3. A dysregulation of **γ-aminobutyric acid (GABA)** may play a role in bipolar disorder. A deficiency in GABA, an inhibitory neurotransmitter, may lead to mania caused by unopposed excitatory neurotransmitters, such as DA and NE.

4. Increased and decreased levels of **calcium** in the cerebrospinal fluid (CSF) have been detected in depressed and manic individuals, respectively. Changes in the extracellular and intracellular calcium levels, which can affect the excitability of neurons, may be a factor in emotional variations and switches from depression to mania.

5. Recent research has focused on **G proteins** and their effects on mood stabilization. G proteins are involved in signal transduction and activation of second messenger systems for various neurotransmitters, like NE, 5- HT, and DA.

a. The current theory proposes that hyperactive G proteins cause mood instability; and by normalizing G proteins, mood stability will occur.

b. G proteins and glutamate may also play a role in the long-term potentiation and cycling of mood disorders.

(1) Glutamate binding to G proteins linked to *N*-methyl-D-aspartate (NMDA) receptors may be involved in long-term potentiation.

(2) Serotonin and NE are involved in bipolar illness, but the cycling and long-term potentiation may be mediated by glutamate and the medications that affect the glutamate system.

6. Psychosocial and physical stressors have been proposed to trigger early episodes of bipolar disorder, although these stressors may or may not trigger later episodes. These later episodes and cyclic episodes are thought to be caused by increased sensitivity or electrophysiologic kindling of the brain.

D. Diagnosis. Bipolar disorder is diagnosed using DSM-IV-TR criteria. The symptoms should impair social or occupational functioning and should not be related to a general medical condition or use of a substance.

1. Mania is described as at least a 1-week period of a continuously elevated or irritable mood, although shorter durations of symptoms are acceptable if the patient is hospitalized. In addition to elevated mood, the patient should experience at least three of the following symptoms: elevated self-esteem or grandiose ideations, reduced need for sleep, pressured speech, racing thoughts or flight of ideas, easily distracted, psychomotor agitation, and excessive involvement in high risk activities.[2]

2. Hypomania has similar symptoms to that of mania; however, symptoms are not as severe. Hypomania is diagnosed by an elevated mood present for at least 4 days, with at least three of the same symptoms as described for mania. These symptoms should not interfere with social or occupational functioning and should not cause hospitalization.

2. A **mixed disorder** is diagnosed when the criteria for both mania and a major depressive episode are met every day for nearly 1 week, affects social and occupational functioning, and is not caused by a general medical condition or substance.

3. Bipolar disorder may be classified into bipolar I disorder, bipolar II disorder, cyclothymia, and rapid cycling.

a. Bipolar I disorder. Patients are classified with bipolar I disorder with a history of at least one mixed or manic episode and at least one major depressive episode.

b. Bipolar II disorder. Patients are classified with bipolar II disorder with a history of at least one episode of hypomania and one major depressive episode but have never experienced mania or a mixed episode.

c. Cyclothymic disorder. Patients are classified with cyclothymic disorder with at least a 2-year history of multiple episodes of hypomania and depressive symptoms. These patients have never met full criteria for a major depressive or manic episode.
d. Rapid cycling. Patients that experience at least four depressive, manic, hypomanic, or mixed episodes within a 12-month period of time are described as rapid cycling.
E. Clinical course. The course of bipolar disorder is variable and patient specific.
1. Patients frequently present with episodes of depression. Patients presenting with depression should always be questioned for a history of signs and symptoms of mania.
2. Episodes vary in length and severity; however, they may last from days to months if untreated.
3. The duration of time between episodes varies. Commonly, 4 years or more may separate the first and second episode but subsequent episodes are more frequent. Untreated patients may experience 10 or more episodes during their life.
4. The management of this disorder can be complicated by mixed episodes, rapid cycling, and substance abuse.
F. Treatment options
1. Pharmacotherapeutic options. Mood stabilizers have historically been the mainstays of therapy for bipolar disorder. Agents include lithium (Eskalith, Lithonate, Lithobid), valproic acid (Depakene, Depakote), and carbamazepine (Tegretol, Carbatrol, Equetro). Recent literature has supported the use of atypical antipsychotics as monotherapy or adjunctive treatments in bipolar mania. Agents for the treatment of depressive episodes in patients with bipolar remains more limited, with recent data emerging for lamotrigine (Lamictal), quetiapine (Seroquel), and olanzapine-fluoxetine (Symbyax). The 2005 Texas Implementation of Medication Algorithms update for the treatment of bipolar I disorder is summarized in Table 48-6.
a. Lithium is a first-line agent for the acute and maintenance treatment of mania and hypomania. It is also first-line for the maintenance treatment of mixed episodes and is useful as adjunctive treatment in depressive episodes.
(1) Lithium is available as lithium carbonate and lithium citrate. Lithium carbonate is available as regular (Eskalith), controlled-release (Eskalith CR), or extended release (Lithobid) tablets and lithium citrate (Lithonate) is available as syrup.
(2) Pharmacokinetics
(a) Between 60% and 100% of lithium is absorbed from the gastrointestinal tract. The extent of absorption is not affected by food. The rate of absorption varies, depending on the formulation.
(i) Lithium citrate syrup reaches peak concentrations in 15-60 min.

(ii) Immediate-release tablets and capsules peak in 1-3 hr.

(iii) Extended-release tablets have peak concentrations in 4-12 hr.

(b) Lithium is distributed into total body water and penetrates many body tissues, such as the thyroid, bone, and brain. Lithium is not highly protein bound.

Table 48-6. Algorithms for Treatment of Bipolar I Disorder

Type of Episode	Monotherapy Options First-Line	Monotherapy Options Second-Line
Acute mania	Lithium, VPA, aripiprazole, quetiapine, risperidone, ziprasidone	Olanzapine, CBZ
Acute mixed	VPA, aripiprazole, quetiapine, risperidone, ziprasidone	Olanzapine, CBZ
Acute depressive	Lamotrigine or lamotrigine plus anti-manic	Quetiapine, olanzapine-fluoxetine
Maintenance mania or mixed	Lithium, VPA, or lamotrigine	Olanzapine
Depression	Lamotrigine plus anti-manic or lamotrigine	

CBZ, carbamazepine; *VPA,* valproic acid.

Adapted from Suppes T, Dennehy EB, Hirschfeld RM, et al. The Texas implementation of medication algorithms: Update to the algorithm for treatment of bipolar I disorder. J Clin Psychiatry 2005;66:870-886.

(c) Lithium is eliminated primarily through the kidneys. It is filtered by the glomeruli in the kidneys and is also cleared by renal tubular reabsorption. Changes in renal function can significantly affect the clearance of lithium.

(3) The **mechanism of action** for lithium is currently unknown, although several theories exist.

(a) Lithium is thought to help correct desynchronized biological rhythms in patients with bipolar disorder.

(b) Lithium may affect membrane stabilization.
(c) Lithium may augment homeostasis by enhancing the function of secondary messenger systems, especially cyclic adenosine monophosphate (cAMP), cyclic guanosine monophosphate (cGMP), and phosphatidylinositol.
(d) Lithium can inhibit NE release and accelerate its metabolism.
(e) Lithium may decrease receptor sensitivity and increase presynaptic reuptake of NE and 5-HT.
(4) Lithium has a **narrow therapeutic index,** with a therapeutic range of 0.5-1.2 mEq/L. Toxicity is associated with levels > 1.5 mEq/L. Patients presenting with acute mania generally require levels in the higher end of the therapeutic range than those on maintenance therapy.
(a) Patients are generally started on 300 mg two to three times daily of lithium and titrated up by 300 mg increments as needed to achieve therapeutic effects and minimize toxicity.
(b) Patient-specific factors should be considered when deciding the appropriate initial dose of lithium, such as age, weight, and renal function.
(c) Serum concentrations may be monitored 3 days after initiation therapy or changing doses. Levels should be obtained 12 hr after the dose, usually in the morning before the first dose of the day.
(5) Clinical response. Clinical response may be seen within 2 weeks after lithium initiation for the treatment of acute mania. When used in depression, responses may not occur for 4-6 weeks.
(6) Precautions and adverse effects
(a) Lithium has an absolute contraindication in patients experiencing acute renal failure or women in their first trimester of pregnancy.
(b) Lithium has the following relative contraindications: renal impairment, cardiovascular disease, dehydration, pregnancy, seizure disorder, and thyroid disease.
(c) Lithium has numerous **adverse effects** (Table 48-7). Certain adverse effects indicate toxicity. If toxicity occurs, lithium should be immediately discontinued, the patient should be properly hydrated, stomach contents should be emptied with gastric lavage, and if severe toxicity occurs (level ≥ 3 mEq/L), hemodialysis may be indicated.
(7) Many medications and disease states may affect lithium levels in the body (Table 48-8).
(a) Use of lithium with antipsychotics or benzodiazepines may increase the risk for CNS toxicity, especially if used together long term.
(b) Use of lithium with medications that can increase 5- HT may cause serotonin syndrome.

Table 48-7. Adverse Effects of Lithium

Early Onset	Long-Term Use	Toxicity
Gastrointestinal upset	Weight gain	Severe drowsiness
Nausea	Altered taste	Coarse hand tremor
Polydipsia	Decreased libido	Muscle twitching
Nocturia	Hypothyroidism	Seizures
Dry mouth	Rash	Choreoathetosis
Hand tremor	Acne	Vomiting
Leukocytosis	Psoriasis	Confusion
Polyuria	Alopecia	Vertigo

Table 48-8. Factors That Change Lithium Concentrations[a]

Increase Lithium Levels	Decrease Lithium Levels
Angiotensin-converting enzyme inhibitors Angiotensin II receptor blockers Nonsteroidal anti-inflammatory drugs Thiazides Dehydration Renal dysfunction Sodium loss Fluoxetine	Acetazolamide Methylxanthines (e.g., theophylline, caffeine) Osmotic diuretics Pregnancy (third trimester) Sodium supplements Urine alkalinizers (ex. sodium bicarbonate)

[a]Not an all-inclusive list.

b. Valproic acid (VPA) is indicated in the acute and chronic treatment of mania, hypomania, mixed disorders, and rapid cycling. It is also used as adjunctive treatment in depressive episodes (Table 48-6).

(1) Mechanism of action. The mechanism of action for VPA is not entirely known. Efficacy for VPA is thought to be related to its ability to increase levels of GABA.
(2) Many formulations exist for VPA. VPA is formulated as valproic acid (Depakene) in capsules and syrup, as divalproex in delayed-release tablets (Depakote) and extended-release tablets (Depakote ER), and as valproate in intravenous solution (Depacon).
(3) VPA is generally initiated at doses of 20 mg/kg/day given in divided doses for inpatients and 250 mg three times daily for outpatients. The current therapeutic range (50-125 μg/mL) was originally described for the treatment of seizure disorders and has not been established for efficacy in bipolar disorder. However, this range can still be useful to minimize toxicities and assess compliance.
(a) Levels may be first obtained after 4-5 days of therapy. These values should be representative of trough values and are frequently obtained in the mornings before the first dose of medication.
(b) Patients that are treated for 4-6 weeks with VPA concentrations of 80-120 μg/mL without clinical response may be classified as failures of VPA therapy.
(4) Adverse effects. Common adverse effects of VPA include nausea, vomiting, dyspepsia, sedation, elevated liver enzymes, hair loss, and tremor. Less frequent adverse effects include thrombocytopenia, leukopenia, pancreatitis, weight gain, and liver failure. VPA has also been associated with polycystic ovarian syndrome in women of child-bearing age.
(a) Gastrointestinal adverse effects may be minimized by lowering the dose or by using divalproex formulations instead of valproic acid or sodium valproate.
(b) Liver function tests and complete blood counts should be monitored at baseline, every month for the first 2 months of therapy, and then every 6-12 months thereafter.
(5) Medication interactions. VPA has the potential for multiple drug interactions. VPA is highly protein bound in the body, thus levels can increase in the presence of another medication that is highly protein bound. VPA is also a substrate and inhibitor of the cytochrome P450 isoenzyme 2C9 and can potentially elevate levels of other medications that are metabolized via this isoenzyme.
c. Carbamazepine (CBZ) is indicated in the treatment of bipolar disorder and is considered to be a second-line agent owing to its numerous adverse effects and medication interactions (Table 48-6).
(1) The **mechanism of action** for CBZ is not completely known; however, its efficacy in bipolar disorder is thought to be the result of its effects on GABA and G proteinlinked second messenger systems, such as cAMP.
(2) CBZ should be initiated at doses of 200-600 mg/day given in divided doses and increased by 200 mg/day to usual doses of 800-1000 mg/day.

(a) A therapeutic range of 4-12 μg/mL has been described for seizure disorders. While correlation between this range and efficacy have not been fully established for bipolar disorder, it is used to minimize adverse effects.

(b) Levels may be obtained 5-7 days after initiating therapy. Levels should continued to be obtained in the following few weeks because CBZ concentrations will decrease in the body once autoinduction occurs.
(c) Patients who are treated for 4-6 weeks with CBZ concentrations of 6-12 µg/mL without clinical response may be classified as failures of CBZ therapy.
(3) Adverse effects. CBZ is associated with numerous adverse effects, many of which are dose related.
(a) Frequent adverse effects include dizziness, drowsiness, ataxia, fatigue, blurred vision, diplopia, nystagmus, confusion, headache, nausea, vomiting, diarrhea, and dyspepsia. The gastrointestinal adverse effects of CBZ are often dose related.
(b) Additional adverse effects include rash, leukopenia, thrombocytopenia, hyponatremia, elevation in liver enzymes, and weight gain.
(c) Severe idiosyncratic reactions may also occur, including agranulocytosis, aplastic anemia, severe thrombocytopenia, liver failure, Stevens-Johnson syndrome, and pancreatitis.
(d) Complete blood counts, liver function tests, thyroid tests, and electrolytes should be monitored at baseline and every 3-6 months.
(4) Medication interactions. CBZ is an inducer of many hepatic enzymes responsible for metabolism of medications and, therefore, has numerous medication interactions. Oral contraceptive levels in the body can be decreased in patients taking CBZ. Alternative forms of contraception should be used in patients taking CBZ. CBZ can also induce its own metabolism (autoinduction). Decreases in CBZ levels in the body may be seen after 3-30 days of therapy. CBZ levels should be monitored and adjusted accordingly.
d. Lamotrigine is indicated in the treatment of bipolar disorder, primarily in patients presenting with depression (Table 48-6).
(1) The **mechanism of action** for lamotrigine is not completely understood. It is currently thought to be related to its ability to decrease release of glutamate and aspartate by blocking sodium channels.
(2) Owing to the risk of rash, lamotrigine should be initiated at low doses (25 mg/day) and slowly increased by 25 mg every 1-2 weeks. Lamotrigine should be administered twice daily in doses > 50 mg. Patients who are taking lamotrigine with VPA should decrease the dose by half owing to a significant medication interaction.
(3) Common **adverse effects** include dizziness, diplopia, nausea, vomiting, rash, photosensitivity, ataxia, headache, and blurred vision. Rashes may be severe and life-threatening such as Stevens-Johnson rash, and patients should immediately discontinue the medication if a rash appears.
e. Atypical antipsychotics have recently been the subject of multiple studies in the treatment of bipolar disorder. These medications are indicated in the treatment of bipolar disorder (Table 48-6). For information regarding dosing, adverse effects, and mechanism of action see Chapter 47. Olanzapine is available in a formulation with fluoxetine (Symbyax) and is approved for depressive episodes in bipolar disorder.
f. Additional anticonvulsants

(1) Gabapentin has been evaluated in two trials for its use in acute mania and has not been shown at this time to improve symptoms. It is not indicated for monotherapy in bipolar disorder but may be used as adjunctive therapy to assist with symptoms such as anxiety.
(2) Oxcarbazepine is a medication structurally similar to carbamazepine but with fewer adverse effects. It is postulated to have similar therapeutic effects in bipolar disorder to carbamazepine; however, studies demonstrating its efficacy are limited. It currently is recommended only in combination with other mood stabilizers.
g. Antidepressants should be used cautiously in patients with bipolar disorder because of the risk of inducing mania. When possible, patients should be receiving mood stabilizers at goal doses before initiating antidepressants and should be cautiously monitored. Bupropion and paroxetine have been associated with less risk of inducing mania than other antidepressants and may be preferable.
2. Treatment duration/phases. The treatment of bipolar disorder is structured similarly to that of depression with acute, continuation, and maintenance phases. Maintenance treatment is

strongly recommended for all patients with bipolar disorder, especially those with a family history.
3. Treatment augmentation
a. Patients with no or partial response to monotherapy may receive combination therapy with two agents. Agents that can be combined include lithium; VPA; and the atypical antipsychotics olanzapine, quetiapine, risperidone, and ziprasidone. Atypical antipsychotics, if used, should be combined with either VPA or lithium and not combined with another atypical antipsychotic.
b. For depressive episodes, lamotrigine may be combined with another mood stabilizer as first-line therapy and the olanzapine-fluoxetine combination product is a second-line option.
4. Treatment options in pregnancy
a. Multiple agents used in the treatment of bipolar disorder have been associated with birth defects.
(1) Lithium, VPA, and CBZ are pregnancy category D medications.
(2) Lithium has been associated with birth defects, primarily in the first trimester.
(3) VPA and CBZ should be used during pregnancy only if the benefits outweigh the risks. If the decision is made to use these medications during pregnancy, folic acid should be given to minimize the risk of defects.
(4) Lamotrigine and oxcarbazepine are pregnancy category C medications.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following statements about depression is true?

(A) The incidence of depression is greater in men than in women.

(B) Depression occurs most frequently in adults between the ages of 60 and 85 years.

(C) Depression has no genetic link.

(D) Depression is diagnosed using the DSM-IV-TR criteria.

View Answer***1. The answer is D[seeand].*****2. A patient with major depression should receive antidepressant therapy for at least**

(A) 2 weeks.

(B) 6 weeks.

(C) 2 months.

(D) 6 months.

View Answer***2. The answer is D[see].*****For questions 3-4:** A 36-year-old woman presents with a 2-month history of depressed mood, anhedonia, increased appetite, weight gain, hypersomnolence, and suicidal ideation. This is the patient's first episode of major depression.

3. Which of the following antidepressants would be most appropriate in the treatment of this patient?

(A) amitriptyline

(B) sertraline

(C) phenelzine

(D) mirtazapine

View Answer***3. The answer is B[seeand].*****4. Which of the following is *not* a potential adverse effect of the medication selected for the patient in question 3?**

(A) sexual dysfunction

(B) nausea

(C) urinary retention

(D) insomnia

View Answer***4. The answer is C[see].*****5. Which of the following medications would most likely exacerbate a preexisting seizure disorder?**

(A) venlafaxine

(B) trazodone

(C) bupropion

(D) paroxetine

View Answer***5. The answer is C[see].*****6. A patient who has received citalopram 40 mg/day for 2 weeks for the treatment of major depression complains that the medication is not working and would like to be switched to another agent. What is the appropriate recommendation?**

(A) Provide the patient with some information on monoamine oxidase inhibitors (MAOIs) and call the physician to recommend switching the patient to phenelzine.

(B) Encourage the patient to continue with the current regimen, and inform him or her that it may take 4-6 weeks before the full response is evident.
(C) Recommend adding lithium to augment the current regimen.
(D) Recommend switching to mirtazapine because of therapeutic failure with citalopram.

View Answer***6. The answer is B[see II.E.3.a-b].***7. **A patient diagnosed with depression was unsuccessfully treated with fluoxetine. Fluoxetine was discontinued, and 14 days later, the patient started therapy with phenelzine. Then, 3 days after phenelzine was started, the patient presented with hyperreflexia, fever, elevated blood pressure, confusion, and diarrhea. What is the most likely cause of this clinical presentation?**
(A) serotonin syndrome
(B) serotonin withdrawal syndrome
(C) hypertensive crisis
(D) neuroleptic malignant syndrome

View Answer***7. The answer is A[see II.E.3.b;].***P.1055

8. A patient presents with pressured speech, inability to sleep for 72 hr, bizarre dress, inappropriate makeup, and grandiose delusions that interfere with social functioning. Which of the following is the most likely diagnosis?
(A) depression
(B) euthymia
(C) hypomania
(D) mania

View Answer***8. The answer is D[see].***9. **Which of the following medications would be considered first-line monotherapy for an acute episode of mania?**
(A) gabapentin
(B) lithium
(C) lamotrigine
(D) haloperidol

View Answer***9. The answer is B[see].***10. **Which of the following is the appropriate therapeutic range for lithium in the treatment of mania?**
(A) 0.4-0.6 mEq/L
(B) 0.6-1.5 mEq/L
(C) 1.0-2.0 mEq/L
(D) 0.5-1.2 mEq/L

View Answer***10. The answer is D[see].***11. **Which of the following mood stabilizers would be most appropriate in a patient with liver disease?**
(A) lithium
(B) valproic acid
(C) carbamazepine
(D) none of the above

View Answer***11. The answer is A[seeand].*****12. A 32-year-old, 70-kg man diagnosed with bipolar I disorder is being treated with valproic acid (VPA). Which of the following is a reasonable loading dose for VPA in this patient?**

(A) 250 mg twice a day

(B) 500 mg twice a day

(C) 250 mg three times a day

(D) 500 mg three times a day

View Answer***12. The answer is D[see].*****13. Which of the following factors may increase lithium concentration?**

(A) caffeine

(B) osmotic diuretics

(C) increased fluid intake

(D) nonsteroidal anti-inflammatory drugs

View Answer***13. The answer is D[see].***P.1056

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* II.B, C *and* D*].*

The DSM-IV-TR criteria provide the diagnostic guidelines for psychiatric disorders. Depression occurs more often in women than in men and in adults between the ages of 25 and 44. A higher incidence of depression occurs among patients with a positive family history, supporting a genetic link.

2. The answer is D *[see* II.E.2*].*

Patients should receive antidepressant therapy through the continuation phase, which is generally 6-9 months.

3. The answer is B *[see* II.E.1.a, b *and* c; II.E.1.f; Table 48-1; Table 48-3*].*

Sertraline, an SSRI, is a good first-line agent, particularly in patients who would benefit from the stimulatory side effects. Amitriptyline and mirtazapine would not be good alternatives because of this patient's hypersomnolence and weight gain. In addition, a TCA (amitriptyline) is not recommended in patients at risk for suicide. Although some aspects of this patient's depression may be considered atypical, an MAOI would not be selected as first-line therapy, given that it is the patient's first episode of depression.

4. The answer is C *[see* II.E.1.c.(2)*].*

Sertraline has been associated with nausea, sexual dysfunction, and insomnia. Sertraline does not express anticholinergic activity and would, therefore, not cause urinary retention. Of the SSRIs, only paroxetine has been associated with causing anticholinergic adverse effects.

5. The answer is C *[see II.E.1.e.(3)(b)].*

Although all antidepressants can lower the seizure threshold, bupropion is contraindicated in patients with seizure disorder. Bupropion is specifically contraindicated in patients with a seizure disorder. Paroxetine was associated with a 0.1% incidence of seizures during clinical trials. Seizure associated with venlafaxine occurs infrequently (1/100 to 1/1000 patients). The overdosage of

trazodone may be associated with seizures; but at normal doses, trazodone is not thought to alter the seizure threshold.

6. The answer is B *[see II.E.3.a-b].*

An antidepressant must be given at the maximum tolerated dose for 4-6 weeks before it is considered a therapeutic failure; therefore, the best recommendation is to continue with the current regimen for at least 2 more weeks. MAOIs are reserved for refractory depressed patients and are not indicated in this patient scenario. Lithium is an appropriate augmentative agent but is not indicated until the patient has failed two or three different antidepressant trials.

7. The answer is A *[see II.E.3.b;* Table 48-2*].*

Serotonin syndrome may result when starting an MAOI immediately after another agent that increases serotonin levels. Generally, a 2-week washout period is recommended; however, fluoxetine requires a 5-week washout period because of norfluoxetine (active metabolite).

8. The answer is D *[see* III.D.1*].*

The clinical presentation described is consistent with mania. Hypomania generally does not impair functioning. Euthymia implies normal mood, whereas depression typically involves more neurovegetative symptoms.

9. The answer is B *[see* Table 48-6*].*

Lithium is considered to be first-line monotherapy for euphoric mania. Gabapentin has demonstrated utility as a mood stabilizer but is considered only an adjunctive therapy. Lamotrigine is an anticonvulsant that currently has data supporting its use in depressive episodes of bipolar disorder, but not as first-line monotherapy for mania. Haloperidol is a traditional antipsychotic that may be used parenterally to manage acute agitation but is not appropriate as first-line monotherapy.

10. The answer is D *[see* III.F.1.a.(4)*].*

The therapeutic range of lithium is 0.5-1.2 mEq/L. When using lithium in the treatment of acute mania, the upper end of the therapeutic range is typically used.

11. The answer is A *[see* III.F.1.a.(6) *and* (7); III.F.1.b.(4); III.F.1.c.(3).(b); Table 48-7*].*

Lithium is not known to cause hepatic dysfunction, nor is it metabolized via the liver. However, both valproic acid and carbamazepine can impair liver function.

12. The answer is D *[see* III.F.1.b.(3)*].*

The appropriate loading dose for VPA in acute mania is 20 mg/kg/day; therefore, in this patient, the appropriate loading dose is 1400 mg/day. This equation approximates the need for the patient, and it is appropriate to round up to available dosage forms.

13. The answer is D *[see* Table 48-8*].* Caffeine, osmotic diuretics, and increased fluid intake all decrease lithium concentrations. Nonsteroidal anti-inflammatory drugs decrease renal blood flow and decrease lithium clearance, resulting in increased lithium concentrations.

49

Asthma and Chronic Obstructive Pulmonary Disease

Roy A. Pleasants

I. ASTHMA

A. Definition. Asthma is a chronic inflammatory disorder of the airways. It involves complex interactions between many cells (e.g. eosinophils, mast cells) and inflammatory mediators (e.g. interleukins, leukotrienes) that result in inflammation, obstruction (partially or completely reversible after treatment or resolves spontaneously), increased airway responsiveness (i.e., hyperresponsiveness), and episodic asthma symptoms (see I.G.1). Neutrophils may play an important role in some asthma exacerbations.

B. Classification. Asthma severity classifications according to the 2007 expert panel report of the National Heart, Lung, and Blood Institute include **mild intermittent asthma** in addition to **mild, moderate,** and **severe persistent asthma** (Table 49-1). The asthma guidelines highlight that disease severity is used to initiate therapy and asthma control should be used to monitor therapy. The 2007 Guidelines have also been modified to incorporate domains of both disease risk and impairment to determine disease severity. The guidelines define impairment as the frequency and intensity of symptoms and functional limitations the patient is currently is experiencing or has recently experienced. Risk is defined as the likelihood of astma exacerbations, progressive decline in lung function (or for children lung growth), or adverse effects from medications. A patient's severity classification plays an important role in determining the most appropriate pharmacotherapeutic approach and is determined by:

1. Symptoms (short-acting B-agonist use, nocturnal symptoms)

2. Interference with normal daily activity

3. Lung function (spirometry to determine FEV1 and FVC)

4. Frequency of exacerbations

C. Incidence. In 2002, according to CDC data, approximately 31 million Americans had ever been told they had asthma during their lifetime. In 2002, 20 million people in the U.S. had asthma (~7% of population).

1. It has been estimated that 8.3% million children age 18 years and younger have asthma.

2. Asthma improves in many children as they age; 50% appear to have “outgrown” asthma by their mid-teens. However, it is incorrect to consider that these individuals no longer have asthma, because many eventually have a return of symptoms.

3. Sixty percent of asthmatics have at least one asthma flare each year

4. Although death from asthma remains uncommon, death rates had been increasing in recent years but appear to have reached a plateau. In 1999, there were 4657 deaths attributed to asthma. The most common cause of death is believed to be inadequate assessment of the severity of airway obstruction by either practitioner or patient, leading to suboptimal therapy.

5. The cost to society of asthma is substantial. In 2000 alone, it is estimated that direct costs related to asthma exceeded $8.1 billion. These costs include $2.4 billion for medications and $3.5 billion for hospitalizations. Indirect costs of asthma are estimated at $4.6 billion. Acute care visits (e.g., hospitalizations) account for the majority of healthcare costs for asthma.

D. Cause. Precipitating factors of an acute asthma exacerbation may include the following:

1. Allergens (e.g., pollen, house dust mite, animal dander, mold, cockroaches, food)

a. Concurrent predisposition to allergy is highly prevalent in patients with asthma, especially children.

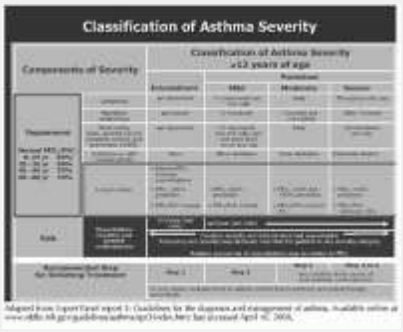

Table 49-1. Classification of Asthma Severity

b. For example, allergic rhinitis is reported in 45% of patients with asthma compared to 20% of the general population.

2. Occupational exposures (e.g., chemical irritants, flour, wood, textile dusts)

3. Viral respiratory tract infections

4. Exercise

5. Emotions (e.g., anxiety, stress, hard laughter or crying)

6. Exposure to irritants (e.g., strong odors, chemicals, fumes)

7. Environmental exposures (e.g., weather changes, cold air, sulfur dioxide, cigarette smoke)

8. Drugs

a. Reactions to drugs may occur as a result of hypersensitivity or as an extension of the pharmacological effect.

b. Problematic drugs include

(1) Aspirin and other nonsteroidal anti-inflammatory drugs such as ibuprofen (note: cyclooxygenase 2 inhibitors are not recommended for use in aspirin-sensitive asthma patients)

(2) Antiadrenergic and cholinergic drugs (e.g., β-adrenergic blockers, bethanechol)

(3) Medications (or foods) that contain tartrazine, sulfites, benzalkonium chloride, and other preservatives
(4) Excipients in inhaled drugs that are derivatives of legumes (soybeans) in peanut allergic patients. E.g. oleic acid
P.1060

E. Pathology. On postmortem examination of patients with asthma, the following characteristics have been identified:
1. Hypertrophy of smooth muscle
2. Airways containing plugs consisting of inflammatory cells and their debris, proteins, and mucus
3. Inflammatory cellular infiltrate with vasodilation, denuded airway epithelium, and microvascular leakage
4. Vasodilation of the vasculature
5. Denuded airway epithelium
6. Microvascular leakage
7. Collagen deposition in basement membranes
F. Pathophysiology (Figure 49-1)
1. Major contributing processes
a. Inflammatory cells (i.e., mast cells, eosinophils, activated T cells, macrophages, and epithelial cells) secrete mediators and influence the airways directly or via neural mechanisms.
b. Airway obstruction is responsible for many of the clinical manifestations of asthma.
(1) Severity of obstruction is variable and believed to be a result of bronchoconstriction, airway wall edema, mucus plug formation, airway remodeling, smooth muscle hypertrophy, and hyperplasia.
(2) Airway obstruction reduces ventilation to some lung regions, which causes a ventilation/perfusion (V/Q) imbalance that leads to hypoxemia. This is reflected by a
P.1061

reduction in the partial pressure of arterial oxygen (PaO_2) observed in moderate to severe exacerbations.

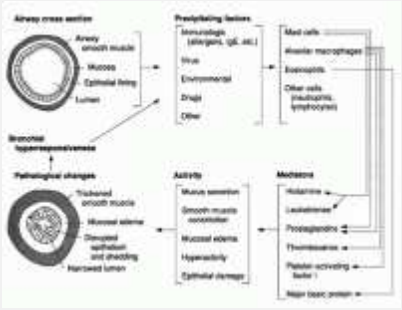

Figure 49-1. The pathophysiology of asthma.

c. Hyperresponsiveness, an exaggerated response to certain stimuli, is an important feature of asthma and appears to correlate with clinical severity and medication requirements. Increased levels of inflammatory mediators and infiltration by inflammatory cells are thought to be the primary mechanisms responsible for airway hyperresponsiveness.

d. Airway inflammation is crucial to development of asthma and contributes to airway hyperresponsiveness, airflow obstruction, respiratory symptoms, and disease chronicity. Inflammatory cells and their mediators are responsible for altered mucociliary function, epithelial disruption ranging from minor ciliary loss to severely denuded epithelium, increased airway permeability (to inhaled allergens, irritants, and inflammatory mediators), and reduced clearance of inflammatory mediators.

(1) Acute inflammation is associated with early recruitment of cells to the airway.

(2) Subacute inflammation is associated with recruited and resident cell activation, resulting in more persistent inflammation.

(3) Chronic inflammation is associated with persistent cell damage and ongoing repair, resulting in airway abnormalities that may become permanent.

e. Alteration in **autonomic neural control** also contributes to obstruction.

(1) Elevated parasympathetic tone and reflex bronchoconstriction may occur as a result of increased cholinergic sensitivity or a change in muscarinic receptor function.

(2) Increased smooth muscle responsiveness may be the result of smooth muscle hypertrophy. Exposure of the nerve endings, caused by inflammation, may also contribute.

f. Airway remodeling can result from persistent inflammation from chronic asthma. The resulting damage can yield permanent airway abnormalities because of subbasement membrane collagen deposition and fibrosis. Hypertrophy of the airway smooth muscle is another form of tissue remodeling in asthma. These events may occur even in the face of mild disease but airway remodeling does not necessarily occur in all asthma patients.

2. Sequencing of events in asthma

a. Triggering. In an allergic asthma patient, after exposure to an allergic trigger, the antigen binds to immunoglobulin E (IgE), which is attached to activated mast cells. Nonallergic factors (e.g., aspirin, viral infections) may also function as triggers. Viral infections serve as an important cause of worsened asthma.

b. Early and late responses

(1) The **early asthmatic response** begins within 30 min of trigger exposure (usually only several minutes after exposure) and resolves within 2 hr. This results in constriction of the airway smooth muscles, bronchospasm, and subsequently asthma symptoms. This response can be blocked by the administration of short-acting β-agonists (albuterol [Ventolin, Proventil], bitolterol [Maxair] or levalbuterol [Xopenex]).

(2) The **late asthmatic response** involves a second decline in lung function typically 4-8 hr after the initial trigger exposure. The early asthma response does not necessarily progress into the late asthmatic response. The late asthmatic response, principally an inflammatory response, is characterized by persistent airflow obstruction, airway inflammation, and bronchial hyperresponsiveness. The response may last several days, and bronchial hyperreactivity may persist for several weeks. This response can be blocked by the administration of corticosteroids—inhaled steroids such as budesonide (Pulmicort) and leukotriene modifiers such as montelukast (Singulair) or cromones (i.e., cromolyn sodium (Intal) or nedocromil (Tilade).

G. Clinical evaluation

1. Physical findings

a. In asymptomatic patients, physical findings of asthma are often not present.

b. Physical findings depend on the severity of the underlying disease and the severity of the exacerbation. Regardless of the underlying disease severity, patients can have mild, moderate, or severe exacerbations (Table 49-2).

c. Patients with **chronic, poorly controlled, severe asthma** may have evidence of chronic hyperinflation, including barrel chest and decreased diaphragmatic excursion, similar to chronic obstructive pulmonary disease

d. Acute exacerbations may have a sudden or gradual onset. Symptoms are frequently nocturnal or occur in the early morning hours.

Table 49-2. Stages of Severity of an Acute Asthmatic Attack

Stage	Symptoms	FEV_1 or FVC	Arterial pH	Pao_2	$Paco_2$
I Mild	Breathlessness while walking, speaks in sentences, moderate wheezing	> 70% of normal	Normal or ↑	Normal or ↓	Normal or ↓
II Moderate	Dyspnea while at rest, talks in phrases, loud wheezing throughout expiration	40%-69% of normal	↑	> 60 mmHg	< 42 mmHg
III Severe	Breathlessness while at rest, speaks in words, loud wheezing, coughing difficulty speaking, accessory chest muscle use, and chest hyperinflation	< 40% of normal	Normal or ↓	< 60 mmHg	> 42 mmHg

IV Respiratory failure	Severe respiratory distress, confusion, lethargy, cyanosis, disappearance of breath sounds, and pulsus paradoxus >12 mm Hg	< 25% of normal	↓↓	↓	↑↑

FEV_1, forced expiratory volume in 1 sec; *FVC,* forced vital capacity; *P*ao_2; partial pressure of arterial oxygen; $Paco_2$; partial pressure of arterial carbon dioxide; ↑, increased; ↓, decreased; ↑↑, markedly increased; ↓↓, markedly decreased.

(1) Common findings in an acute exacerbation include

(a) Shortness of breath

(b) Wheezing (usually occurs at the end of exhalation but may be heard throughout inspiration and exhalation in more severe asthma)

(c) Chest tightness

(d) Cough

(e) Tachypnea and tachycardia (moderate to severe exacerbations)

(f) Pulsus paradoxus (severe exacerbations)

(2) Between acute asthma exacerbations, the patient may be asymptomatic.

2. Diagnostic test results

a. Pulmonary function tests determine the degree of airway obstruction and may be normal between exacerbations. The 2007 NHLBI Asthma Guidelines recommend spirometry in all asthma patients >5 y.o. to determine that airway obstruction is at least partially reversible. Breathing tests include spirometry and peak flow meter testing.

(1) Forced expiratory volume in 1 second (FEV_1) and forced vital capacity (FVC) both decrease during an acute exacerbation. The spirometer is used to generate the FEV_1 and FVC.

(2) Residual volume (RV) and total lung capacity (TLC) may increase in asthma because of **air trapping** and subsequent **lung hyperinflation.**

(3) Peak expiratory flow rate (PEFR), obtained through the patient forcefully breathing out into a **peak flow meter,** correlates well with FEV_1. However, PEFR measurement is not used in making the diagnosis of asthma. PEFR measurement can be used to monitor control of asthma.

(a) Uses of PEFR monitoring at home include assessment of therapy, trigger identification, and assessment of the need for referral to emergency care.

(b) PEFR monitoring at home is recommended for patients who have had severe exacerbations, who are poor perceivers of asthma symptoms, and who have moderate to severe disease.
(c) PEFR is best measured in early morning, before medication administration. More frequent monitoring over a few weeks may also be indicated to identify specific patterns and to identify a patient's personal best PEFR measurement. In this case,

measurements are taken before medications are taken in the morning (i.e., on awakening).
(4) Provocation testing with **histamine or methacholine challenge** may be performed to assess hyperresponsiveness and to rule out asthma in a patient who has had normal pulmonary function test results but in whom asthma is still suspected.
b. Blood analysis, although not typically undertaken in asthma, typically shows a slightly increased white blood cell (WBC) count during an acute exacerbation; eosinophilia also may be present. Leukocytosis may be present because of WBC demargination that occurs when patients receive systemic corticosteroids.
c. Pulse oximetry is a noninvasive means of assessing the degree of hypoxemia during an acute exacerbation. The oximeter measures oxygen saturation in arterial blood (SaO_2) and pulse.
d. Arterial blood gas measurements may be required to help gauge the severity of the asthma exacerbation (Table 49-2).
(1) In the early stages of an asthma exacerbation, **hyperventilation** results in a decrease in the partial pressure of arterial carbon dioxide ($PaCO_2$). If the exacerbation progresses and the airways remain narrowed, respiratory muscles may fatigue and the $PaCO_2$ level increases.
(2) Respiratory acidosis is a poor prognostic sign. It develops if hypoxemia worsens and the patient's respiratory rate is not maintained owing to respiratory fatigue. This results in a rising $PaCO_2$ level.
e. An **electrocardiogram (ECG)** may show sinus tachycardia. An ECG may be particularly useful in an older patient.
f. A **chest radiograph** may be normal or could detect accompanying pneumothorax, atelectasis, or pneumonia. Evidence of hyperinflation may be present in acute asthma and in chronic, poorly controlled asthma. A chest radiograph may also be needed to exclude other causes of the patient's symptoms.
3. Signs of respiratory distress include
a. Use of accessory muscles
b. Inability to speak in sentences or ambulate owing to dyspnea
c. Declining mental status
d. PEFR <50% of predicted (or personal best)
e. Cyanosis
f. Suprasternal retractions
g. Absence of respiratory sounds
h. Increasing $PaCO_2$

i. Unable to sleep for extended time because of shortness of breath

4. Patients with **potentially fatal asthma** should be quickly identified and aggressively managed. These patients have the following characteristics:

a. History of severe exacerbations, particularly exacerbations that develop suddenly

b. Poor self-perception of asthma symptoms and severity

c. History of intubation or intensive care unit (ICU) admission for asthma

d. Two or more hospitalizations or three or more visits to the emergency department for asthma within 1 year

e. Hospitalization or treatment in the emergency department for asthma with in the last month

f. Frequent β-agonist use (i.e., more than two canisters per month), current systemic steroid treatment, or recent systemic steroid withdrawal

g. Concurrent conditions (e.g., cardiovascular or psychiatric disease, substance abuse, low socioeconomic status [particularly in urban areas])

H. Therapy

1. Treatment objectives

a. The goal of therapy is to provide symptomatic control with normalization of lifestyle and to return pulmonary function as close to normal as possible.

b. The treatment goals listed in the 2007 NHLBI's expert panel update report include the following:

(Reduce Impairment)

(1) Prevent chronic and troublesome symptoms day or night

(2) Maintain normal pulmonary function

(3) Maintain normal activity levels including exercise and attendance at work or school

(4) Minimal use of short-acting inhaled β_2-agonist (<2 times per week) for quick relief of symptoms (not including use prior to exercise)

(5) Meet patient and family expectations

(Reduce Risk)

(1) Prevent recurrent exacerbations and minimize need for ED visits of hospitalizations

(2) Prevent loss of lung function

(3) Provide optimal pharmacotherapy and with minimal or no adverse effects from medications

2. Management of acute asthma exacerbations

a. Home-based treatment of an acute asthma exacerbation (Figure 49-2)

b. Treatment of an acute asthma exacerbation in the **hospital or emergency department** (Figure 49-3)

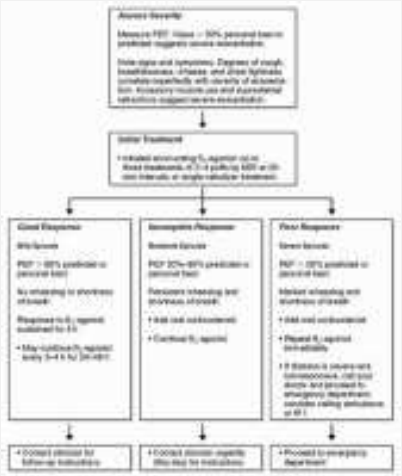

Figure 49-2. The NIH treatment algorithm for the home-based management of asthma exacerbations. (NIH highlights of the expert panel report 3; Guidelines for the diagnosis and management of asthma. NIH Publication No 80-4051 August 2007, Figure 5-4.)

P.1065

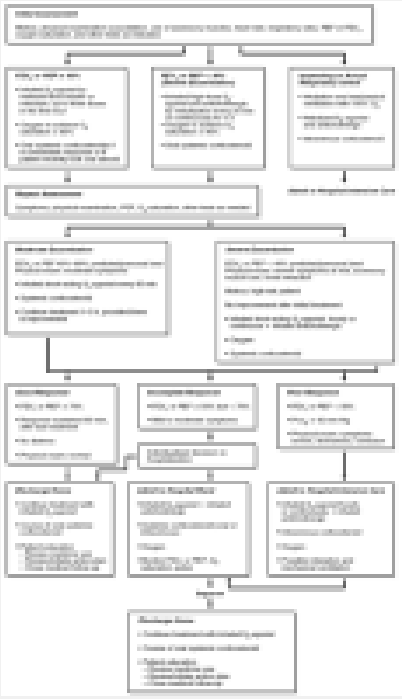

Figure 49-3. NIH treatment algorithm for management of asthma exacerbations in the emergency department and hospital. FEV1, forced expiratory volume in 1 sec; PEF, peak expiratory flow; PCO2, partial pressure of carbon dioxide. (From NIH highlights of the expert panel report 3: Guidelines for the diagnosis and management of asthma [NIH Publication No. 08-4051]. August 2007, Figure 5-6.)

P.1066

3. Management of persistent asthma

a. A stepwise approach to pharmacological therapy is recommended to gain and maintain control of asthma in both the impairment and risk domains (Table 49-3). The type, amount, and scheduling of medication is dictated by asthma severity for initiating therapy and the level of asthma control for adjusting therapy.

b. At each step, patients should control their environment to avoid or control factors, when possible, that make their asthma worse (e.g., allergens, irritants). This requires specific diagnosis and education.

c. Inhaled steroids are considered to be first-line anti-inflammatory agents in asthma.

d. Combination products for asthma are formoterol/budesonide (Symbicort) and fluticasone/salmeterol (Advair). These products are indicated for moderate or severe persistent asthma. The 2007 NHLBI Asthma Guidelines give equal weight to increasing the dose of the inhaled steroid compared to adding a long-acting B2-agonist to the inhaled steroid in uncontrolled chronic asthma. In the U.S., Advair is available as an MDI and DPI (Diskus), Symbicort is available as an MDI.

e. Inhaled β-agonists such as albuterol and levalbuterol are used as needed for acute symptoms for all levels of severity.

(1) Daily or increasing use of a short-acting inhaled β_2-agonist suggests the need for additional long-term controller (i.e., anti-inflammatory) therapy.

(2) Pretreatment with either an inhaled β-agonist, montelukast, cromolyn sodium, or nedocromil may be used before exercise or allergen exposure.

f. A rescue course of systemic corticosteroid (e.g., prednisone) may be needed at any time and at any step.

4. Prevention and treatment of exercise-induced bronchospasm (EIB)

a. Steps to prevent EIB should be implemented in all patients with asthma.

b. Patients should be advised that a warmup period might be helpful in preventing EIB.

c. EIB can usually be prevented with one of the following options.

(1) Short-acting β-agonists (e.g., albuterol) should be administered 15 min before exercise. These are considered the drug of choice for EIB.

(2) Long-acting β-agonists—salmeterol (Serevent) and formoterol (Foradil)—should be administered 30-60 min before exercise. When salmeterol is used chronically for EIB, some patients may lose protection toward the end of the 12-hr dosing interval. Because of its rapid onset, formoterol may be dosed 15 min before exercise. Generally, short-acting agents are preferred over long-acting β-agonists.

(3) Cromolyn sodium and nedocromil may be used to prevent EIB and exacerbations related to exposure to other asthma triggers. Cromolyn and nedocromil should be administered no more than 1 hr before exercise or exposure.

(4) Leukotriene modifiers given daily help with EIB but should not be used on a as-needed basis just before exercise.

d. Regardless of the prophylactic approach, all patients who experience EIB should have a short-acting β-agonist available for treatment of breakthrough symptoms.

5. Concurrent diseases

a. Allergic rhinitis, sinusitis, gastroesophageal reflux disease frequently coexist with asthma. Other notable comorbidities in asthma include vocal cord dysfunction (VCD) and obstructive sleep apnea.

b. GERD is frequent in persons with obstructive lung disease. Management of GERD with proton pump inhibitors (PPIs), such as pantoprazole (Protonix) can improve

asthma symptoms and in some patients' breathing tests. H_2-antagonists, such as ranitidine (Zantac) are less effective than PPIs in this situation.

c. Asthma control has been shown to improve if these conditions are adequately controlled.

I. Therapeutic agents

1. β-Agonists—albuterol, formoterol, arformoterol, levalbuterol, metaproterenol (Metaprel), pirbuterol, salmeterol

a. Short-acting β-agonists (albuterol, levalbuterol, pirbuterol, metaproterenol) are best reserved for worsening symptoms, treatment of acute exacerbations, and prophylaxis for EIB. Assessing the frequency of short-acting β-agonist use for rescue therapy can help determine the patient's level of asthma control. Those requiring regular use (e.g., every day), of short-acting β-agonists have uncontrolled disease and should receive more aggressive controller therapy.

P.1067

Table 49-3. Medications Recommended for Long-term Control of Asthma

Step	Age 0-4 Years[a]	Age 5-11 Years[a]	Age ≥ 12 Years[b]
1 (intermittent asthma)	Short-acting inhaled β_2-agonist taken as needed to treat symptoms	Short-acting inhaled β_2-agonist taken as needed to treat symptoms	Short-acting inhaled β_2-agonist taken as needed to treat symptoms; short-acting inhaled β_2 agonist, cromolyn, or nedocromil taken shortly before exercise in patients known to have exercise-induced bronchospasm
2 (persistent asthma)	Inhaled corticosteroid (low dose) daily; cromolyn or montelukast is an alternative (but not	Inhaled corticosteroid (low dose) daily; cromolyn, leukotriene-receptor antagonist, nedocromil, or	Inhaled corticosteroid (low dose) daily; cromolyn, leukotriene-receptor antagonist, nedocromil, or

	preferred)	theophylline is an alternative	sustained-release theophylline is an alternative (but not preferred)
3 (persistent asthma)	Inhaled corticosteroid (medium dosage)	Inhaled corticosteroid (low dosage) plus long-acting β_2-agonist, leukotriene-receptor antagonist, or theophylline; or inhaled corticosteroid (medium dosage)	Inhaled corticosteroid (low dosage) and long-acting β_2-agonist; *or* inhaled corticosteroid (medium dosage); inhaled corticosteroid (low dosage) plus either leukotriene-receptor antagonist, theophylline, or zileuton is an alternative (but not preferred)
4 (persistent asthma)	Inhaled corticosteroid (medium dosage) plus either long-acting β_2-agonist or montelukast	Inhaled corticosteroid (medium dosage) and long-acting β_2-agonist; inhaled corticosteroid (medium dosage) plus either leukotriene-receptor antagonist or theophylline is an alternative (but not preferred)	Inhaled corticosteroid (medium dosage) and long-acting β_2-agonist; inhaled corticosteroid (medium dosage) plus leukotriene-receptor antagonist, theophylline, or zileuton is an alternative (but not preferred)

5 (persistent asthma)	Inhaled corticosteroid (high dosage) plus either long-acting β_2-agonist or montelukast	Inhaled corticosteroid (high dosage) and long-acting β_2-agonist; inhaled corticosteroid (high dosage) plus either leukotriene-receptor antagonist or theophylline is an alternative (but not preferred)	Inhaled corticosteroid (high dosage) and long-acting β_2-agonist; omalizumab may be considered for patients with sensitivity to relevant perennial allergens
6 (persistent asthma)	Inhaled corticosteroid (high dosage) and oral systemic corticosteroid plus either long-acting β_2-agonist or montelukast	Inhaled corticosteroid (high dosage), oral systemic corticosteroid, and long-acting β_2-agonist; inhaled corticosteroid (high dosage) and oral systemic corticosteroid plus either leukotriene-receptor antagonist or theophylline is an alternative (but not preferred)	Inhaled corticosteroid (high dosage), oral systemic corticosteroid, and long-acting β_2-agonist; omalizumab may be considered for patients with sensitivity to relevant perennial allergens

[a] For all six steps, a short-acting β_2-agonist should be used as needed to relieve symptoms of asthma.

[b] For all six steps, a short-acting β_2-agonist—up to three treatments at 20-minute intervals—should be used as needed to relieve symptoms of asthma. Short-course therapy with an oral systemic corticosteroid may be needed.

Adapted from: Expert Panel report 3: Guidelines for the diagnosis and management of asthma. Available online at www.nblbi.nih.gov/guidelines/asthma/epr3/index.htm; last accessed April 10, 2008.

b. Indications for long-acting β-agonists

(1) Maintenance treatment of moderate and severe persistent asthma in combination with inhaled corticosteroids, particularly for patients with frequent nocturnal symptoms.

(a) Long-acting β_2-agonists (salmeterol, formoterol, arformterol) should not be used as sole therapy for an acute asthma exacerbation in lieu of short-acting agents.

(b) Research indicates that rather than increasing the dose of the inhaled corticosteroid in uncontrolled chronic asthma, adding a long-acting β-agonist results in a greater improvement in symptoms and breathing tests.

(c) Recent warnings have been placed in the package inserts for long-acting β_2-agonists regarding an increased risk of asthma death. This has led to the 2007 NIH Asthma Guidelines giving higher priority to increasing the dose of inhaled steroids as compared to adding a long-acting B2-agonist to current inhaled steroid dose to manage uncontrolled chronic asthma.

(2) Prophylaxis of EIB

(3) Patients with asthma and concurrent chronic obstructive pulmonary disease (COPD)

c. Therapeutic effects. These sympathomimetic agents relieve bronchoconstriction during acute asthma exacerbations as well as during chronic therapy and prevent exacerbations from occurring during exercise.

d. Mechanism of action

(1) β_2-Agonists stimulate β_2-receptors, activating adenyl cyclase, which increases intracellular production of cyclic adenosine monophosphate (cAMP).

(a) Increased intracellular cAMP and activation of cAMP result in bronchodilation, improved mucociliary clearance, and reduced inflammatory cell mediator release.

(b) Stimulation of β_2-receptors in skeletal muscle accounts for tremor.

(2) β-Agonists differ in their affinity for the β_1- and β_2-receptors. Agents with greater β_1-receptor affinity are more likely to cause cardiac effects.

e. Administration and dosage

(1) Whenever possible, agents should be administered via **inhalation** to minimize systemic exposure and adverse reactions. **Systemic** administration should be reserved for patients who cannot use inhalation therapy.

(2) Regimens with long-acting β_2-agonists should also include a concurrent inhaled corticosteroid, unless it is being used only to prevent EIB. All regimens containing long-acting agents should also include a short-acting agent for treatment of acute symptoms.

(3) Dosage information is provided in Table 49-4.

Adapted from National Institutes of Health, National Heart, Lung, and Blood Institute. National Asthma Education and Prevention Program expert panel report 2: Guidelines for the diagnosis and management of asthma [NIH Publication 97-4051] July 1997:91, Figure 3-5d (NIH ERR-2, Fig. 35d)

f. Precautions and monitoring effects

(1) Common adverse effects of β-agonists include tremor, palpitation, tachycardia, nervousness, and headache. Leg cramps may occur with high doses owing to hypokalemia.

(2) Nonselective β-agonists (e.g., isoproterenol (Isuprel) may induce myocardial ischemia, myocardial necrosis, and arrhythmias because of excessive cardiac stimulation. Use of β_2-selective agents (e.g., albuterol, bitolterol) is preferred.

(3) Tachyphylaxis (form of tolerance) can occur with regular use of inhaled or oral β-agonists. Suggested mechanisms include

(a) A decrease in the number of active β-receptors owing to movement of receptors from the cell surface into the cell (**downregulation**)

(b) A decreased sensitivity in the β-receptors to stimuli, making them unable to activate adenyl cyclase

(i) The clinical significance of this effect is unclear with normal doses of β-agonists.

(ii) This effect may be lessened by adding corticosteroids to the regimen.

(4) Hypokalemia may occur in some patients, particularly those receiving concurrent medications that cause hypokalemia (e.g., diuretics, amphotericin) and high doses, including inhaled agents.

(5) Paradoxical bronchoconstriction found with β-agonists may be the result of a “cold-Freon effect” or the use of additives such as benzalkonium chloride in the formulation.

(6) Unlike albuterol, which is a racemic mixture of albuterol's R-and S-isomers, levalbuterol HCl (Xopenex) is composed of the active R-enantiomer.

(7) Systemic adverse reactions when the recommended starting dose of levalbuterol is used appear to be similar to or *slightly less frequent* than the effects of albuterol. When the dose of levalbuterol is increased to 1.25 mg, however, the incidence of adverse reactions is similar to the corresponding dose of albuterol.

(8) It is important to be aware of **significant drug-drug interactions.**

(a) Concomitant use of systemic β-agonists with **monoamine oxidase inhibitors, tricyclic antidepressants,** or **methyldopa** may infrequently lead to severe hypertension. The risk with aerosolized agents may be smaller.
(b) β-Adrenergic blockers (especially nonselective agents as propranolol) precipitate bronchospasm and increase the dose of β-agonist necessary to achieve bronchodilation. The risk of bronchospasm should be weighed against the potential benefits of β-blockers. β_1-Selective agents such as metoprolol (Toprol XL) may be used carefully (e.g., in the hospital), in asthma patients when the risk-benefit ratio indicates such, as in an acute myocardial infarction.
(c) β-Agonists should not be combined with other sympathomimetic agents because of additive cardiovascular effects. Vasoconstrictor and vasopressor effects of epinephrine are antagonized by **β-adrenergic blocking agents** (e.g., phentolamine).
(9) The effects of β-agonists should be closely monitored in the elderly and in patients with a history of hyperthyroidism, diabetes, seizures, arrhythmias, and coronary artery disease.

2. Corticosteroids

a. Therapeutic effects. Corticosteroids suppress the inflammatory response and decrease airway hyperresponsiveness.
b. Mechanism of action. Corticosteroids bind to glucocorticoid receptors on the cytoplasm of cells. The activated receptor **regulates transcription** of target genes.
(1) Corticosteroids reduce inflammation via:
(a) Inhibition of transcription and release of inflammatory genes
(b) Increased transcription of anti-inflammatory genes that produce proteins that participate in or suppress the inflammatory process
(2) Clinical effects include
(a) Reduced production of inflammatory mediators
(b) Enhanced β-adrenergic receptor expression (thus making the β_2-agonist work better)
(c) Decreased mucus production
(d) Prevention of endothelial and vascular leakage
(e) Partial reversal of tissue-remodeling

c. Administration and dosage

(1) There is no significant difference in the clinical efficacy of the corticosteroid agents currently available. The **route of administration** is determined by the condition of the patient.
(2) Systemic corticosteroids are used for rapid response during an exacerbation. Improvement in pulmonary function may begin within 1-3 hr; however, the maximum effect is not achieved until 6-9 hr, or longer, after administration. Supplemental doses should be administered to patients who are already taking systemic corticosteroids when they experience an exacerbation, even if the exacerbation is mild.

(3) Intravenous corticosteroids (e.g., methylprednisolone (Solu-Medrol) are administered to patients who are unable to take oral medications in severe exacerbations. Large doses (e.g. methylprednisolone 60 mg or 125 mg intravenously [IV]) can be quickly administered; however, patients can usually be switched to oral therapy as soon as they show clinical improvement and can tolerate oral medication.
(4) Oral corticosteroids are acceptable as emergency treatment if the patient can tolerate the oral route and is not believed to be in imminent danger of respiratory arrest. **Prednisone** and **prednisolone (Prelone)** are the most frequently used oral corticosteroids.
(a) Prednisone and prednisolone are frequently administered in short “bursts” over 3-10 days [see I.I.2.c.(2).(b)] to treat acute exacerbations in the outpatient setting and in the emergency department. This type of regimen may also be used to rapidly achieve asthma control.
(b) During burst therapy, these agents may be administered for 3-10 days in one or two daily doses and then discontinued. When used in this fashion, tapering is not usually necessary, but is often done by physicians. However, if a patient's condition appears to worsen after the last dose has been administered, it is reasonable to reinstitute the corticosteroid and then begin a tapering regimen.
(5) Because **inhaled corticosteroids** are least likely to produce adverse reactions, the inhaled route should be used whenever possible for chronic treatment.
(a) Inhaled corticosteroids should not be used alone to treat serious acute exacerbations.
(b) Inhaled steroids are the preferred anti-inflammtory therapy for chronic asthma.
(c) In milder outpatient flares, doses of the inhaled steroids may be increased temporarily (although this is controversial).
(d) The number of corticosteroids available for inhalation therapy is increasing. The most recent addition is mometasone (Asmanex).
(e) Dosages of inhaled corticosteroids are provided in Table 49-5. When asthma control is achieved, attempts should be made to use the lowest effective dose to maintain control (step-down therapy). Side effects of inhaled steroids (and systemic steroids) are dose dependent.
(f) Inhaled corticosteroids are considered first-line anti-inflammatory therapy for mild to severe persistent asthma in both adults and children.
(2) Treatment of asthma exacerbation in adults
(a) For treatment of a severe exacerbation, prednisone may be given at a dose of 2 mg/kg (maximum of 60 mg/day). For intravenous treatment, methylprednisolone is given at a dosage of 120-180 mg/day in three or four divided doses for 48 hr or until the patient can tolerate oral medications. The dosage is then reduced to 60-80 mg/day until PEFR reaches 70% predicted (or personal best).
(b) For outpatient burst therapy, the dosage of prednisone is 1-2 mg/kg/day (maximum of 60 mg/day) in one or two divided doses for 3-10 days.
(3) Treatment of asthma exacerbation in children
(a) For inpatient treatment of a severe exacerbation, prednisone, methylprednisolone, or prednisolone is given at a dosage of 1 mg/kg every 6 hr for

48 hr. The dosage is then reduced to 1-2 mg/kg/day (maximum of 60 mg/day) in two divided doses until PEFR is 70% predicted (or personal best).

(b) For outpatient burst therapy, the dosage of prednisone is 1-2 mg/kg/day (maximum of 60 mg/day) in one or two divided doses for 3-10 days.

d. Precautions and monitoring effects

(1) Systemic corticosteroids

(a) Careful monitoring is necessary in patients with diabetes (steroids commonly increase blood sugar), hypertension, adrenal suppression, congestive heart failure

(fluid retention owing to mineralocorticoid effects), peptic ulcer disease, candidiasis, immunosuppression, osteoporosis, chronic infections, cataracts, glaucoma, myasthenia gravis, and psychiatric diseases (e.g., depression, psychosis). Some of these side-effects begin shortly after beginning systemic steroids (e.g., hyperglycemia), whereas others (e.g., osteoporosis) only occur with long-term use.

Table 49-5. Estimated Comparative Daily Dosages for Inhaled Corticosteroids[a]

	Low Daily Dose		Medium Daily Dose		High Daily Dose	
Drug	**Adult**	**Child**	**Adult**	**Child**	**Adult**	**Child**
Beclomethasone						
CFC: 42 or 84 µg/puff	168-504 µg	84-336 µg	504-840 µg	336-672 µg	>840 µg	>672 µg
HFA: 40 or 80 µg/puff	80-240 µg	80-160 µg	240-480 µg	160-320 µg	>480 µg	>320 µg
Budesonide						
DPI: 200 µg/inhalation	200-600 µg	200-400 µg	600-1200 µg	400-800 µg	>1200 µg	>800 µg

Inhalation suspension for nebulization (child dose)		0.5 mg		1.0 mg		2.0 mg
Flunisolide						
250 µg/puff	500-1000 µg	500 - 750 µg	1000 - 2000 µg	1000 - 1250 µg	>2000 µg	>1250 µg
Fluticasone						
MDI:[b] 44, 110, or 220 µg/puff	88-264 µg	88-176 µg	264-660 µg	176-440 µg	>660 µg	>440 µg
DPI: 50, 100, or 250 µg/inhalation	100-300 µg	100 - 200 µg	300-600 µg	200-400 µg	>7600 µg	>400 µg
Mometasone						
DPI: 200 ug/inhalation (not approved for persons < 12 yo)	200 µg	NA	400 µg	NA	>400 µg	NA
Triamcinolone						
100 µg/puff	400-1000 µg	400 - 800 µg	1000 - 2000 µg	800-1200 µg	>2000 µg	>1200 µg

[a]In all cases, the lowest dose to maintain control should be used. Some doses

are outside package labeling.

[b] MDI doses are actuator doses (i.e., amount leaving actuator).

CFC, chlorofluorocarbons; *DPI,* dry-powder inhaler; HFA, hydrofluoroalkanes; *MDI,* metered dose inhaler.
Modified from National Asthma Education and Prevention Program expert panel report guidelines for the diagnosis and management of asthma—NHLBI Asthma Guidelines 2007. August 2007.

(b) If a prolonged course of systemic therapy is necessary to maintain asthma control, interference with the hypothalamic-pituitary-adrenal axis is lessened by a single morning dose (i.e., 6-8 AM) or alternate-day therapy. For alternate-day therapy, the dose is twice that of the single morning dose.
(c) Patients on regular systemic therapy should be closely monitored and should receive regular ophthalmological evaluations and osteoporosis screening, and preventative therapy (e.g., calcium, vitamin D, bisphosphonates) if indicated.
(2) Inhaled corticosteroids
(a) Local effects associated with inhaled corticosteroids include hoarseness (dysphonia), and fungal infection (candidiasis) of the mouth and throat. Local side effects can be lessened through mouth rinsing, use of a spacer, and use of certain inhaled steroid products.
(b) The U.S. Food and Drug Administration (FDA) recently revised the warning labels on inhaled corticosteroid products to include dose-related slowing of growth velocity in children (approximately one third in. per year). Shortly after

the labeling was revised, two major publications demonstrated short-term growth suppression of approximately 1 cm in the first year of budesonide treatment, but without long-term effects on final adult height. However, children should be treated with the lowest effective dose and should be reminded that poorly controlled asthma also slows growth.
(c) Large doses of inhaled corticosteroids may result in systemic effects, such as reduced bone density, changes in adrenal function, skin changes, adrenal suppression, and cataract formation. Further study is needed to fully understand these effects and to determine their clinical significance. However, patients receiving high doses of inhaled corticosteroids should be closely monitored and should receive regular ophthalmological evaluations and osteoporosis screening and treatment (e.g., calcium, vitamin D) if indicated.
(d) Spacers (e.g. AeroChamber) are generally prescribed for patients who receive moderate to high doses of inhaled corticosteroids via metered dose inhalers (MDIs).

Patients should also gargle, rinse their mouth and throat, and expectorate after administration. Both of these interventions minimize oropharyngeal drug deposition, local adverse reactions, and gastrointestinal absorption.

(i) Steroids in dry-powder inhalers (Pulmicort Flexhaler) generally have a lower incidence of local side effects.

(ii) A new form of beclomethasone (Qvar) MDI also has a low incidence of local side effects.

(3) Significant interactions

(a) Concurrent use of **hepatic microsomal enzyme inducers** (e.g., rifampin, barbiturates, hydantoins) causes enhanced corticosteroid metabolism, reducing therapeutic efficacy.

(b) Concurrent use of **estrogens, oral contraceptives, itraconazole (Sporanox),** or **macrolide antibiotics** (e.g., erythromycin, clarithromycin [Biaxin]) may decrease corticosteroid clearance.

(c) Cyclosporine may increase the plasma concentration of corticosteroids.

(d) Administration of **potassium-depleting diuretics** (e.g., thiazides, furosemide) or other potassium-depleting drugs (e.g., amphotericin) with corticosteroids causes enhanced hypokalemia. Serum potassium should be closely monitored, especially in patients on **digitalis glycosides.**

3. Leukotriene modifiers are the newest agents with anti-inflammatory properties to be approved for use in asthma. Leukotrienes are important participants in asthma pathophysiology. Cellular effects of leukotrienes include enhanced migration of eosinophils and neutrophils, increased adhesion of leukocytes, and increased monocyte and neutrophil aggregation. Leukotrienes also increase capillary permeability and cause smooth muscle contraction.

a. Leukotriene modifiers currently available in the United States include montelukast, zafirlukast (Accolate), zileuton (Zyflo).

(1) Therapeutic effects

(a) Leukotriene modifiers have anti-inflammatory and bronchodilator activity. They may allow reduction in corticosteroid doses in some patients.

(b) Because they may be less effective anti-inflammatory agents than inhaled corticosteroids, they are considered second-line agents.

(c) In children, for whom administration of inhaled drugs is challenging, oral leukotriene receptor antagonists may be particularly useful.

(d) They may be useful in patients with concurrent allergic rhinitis and asthma.

(2) Mechanism of action. The leukotriene receptor antagonists are selective cysteinyl leukotriene 1 (cys-LT-1) receptor antagonists; therefore, they prevent leukotrienes from interacting with their receptors. Zileuton, a leukotriene modifier, blocks the effects of 5-lipo-oxygenase and ultimately blocks leukotriene production.

(3) Administration and dosage

(a) The dosage of **zafirlukast** in children >12 years and adults is 20 mg twice daily. Food reduces bioavailability, so zafirlukast should be taken at least 1 hr before or 2 hr after meals. Children 5-11 years of age should receive 10 mg twice daily.

(b) The dosage of **montelukast** in adolescents 15 years of age or older and adults is one 10-mg tablet once every evening. The dosage for children 6-14 years of age is one 5-mg chewable tablet once every evening. Children ages 2-5 should

receive one 4-mg chewable tablet once every evening. Food does not appear to change bioavailability.

(4) Precautions and monitoring effects

(a) Adverse reactions to montelukast are uncommon and include headache, dizziness, and dyspepsia.

(b) Adverse reactions associated with zafirlukast include headache, dizziness, nausea, and diarrhea.

(c) Churg-Strauss syndrome, a form of eosinophilic vasculitis, has rarely been associated with zafirlukast, montelukast, and pranlukast (available in Japan). It has usually, but not always, occurred in patients whose chronic steroid regimens were tapered and discontinued. At-risk patients should be monitored for vasculitic rash, eosinophilia, and increasing pulmonary, cardiac, and neuropathic symptoms.

(d) Significant drug-drug interactions may occur.

(i) Aspirin increases zafirlukast levels.

(ii) Erythromycin, theophylline, and **terfenadine** decrease zafirlukast concentrations.

(iii) Zafirlukast may increase the anticoagulant effect of **warfarin** and levels of dofetilide.

(iv) Drug interactions appear to be less significant with montelukast. Patients who are receiving montelukast with **hepatic enzyme inducers** (e.g., rifampin, phenobarbital) should be monitored closely.

(v) The chewable forms of montelukast (4- and 5-mg tablets) contain aspartame and should be avoided in patients with **phenylketonuria.**

b. The only **lipoxygenase inhibitor** approved by the FDA is **zileuton (Zyflo).** Zileuton may allow reduction in corticosteroid doses in some patients.

(1) Therapeutic effects. Lipoxygenase inhibitors have anti-inflammatory and bronchodilator activity.

(2) Mechanism of action. Lipoxygenase inhibitors prevent the formation of leukotrienes. Zileuton blocks 5-lipoxygenase, the enzyme responsible for leukotriene formation.

(3) Administration and dosage. In adults and children 12 years of age and older, the dosage of zileuton is 600 mg four times daily. It may be taken without regard to meals. A new formulation, Zileuton CR, may be dosed twice daily.

(4) Precautions and monitoring effects

(a) Zileuton is contraindicated in patients with hepatic function impairment and should be monitored closely in patients who drink large quantities of alcohol.

(b) Adverse effects include headache, abdominal pain, asthenia, nausea, dyspepsia, and myalgia. Drug therapy was discontinued in almost 10% of patients owing to side effects, although this was similar to placebo.

(c) Significant drug-drug interactions may occur.

(i) Zileuton increases concentrations of **propranolol, terfenadine,** and **theophylline.**
(ii) The anticoagulant effect of **warfarin** is increased by zileuton.
(d) Hepatic enzymes (e.g., alanine aminotransferase [ALT]) may become elevated during therapy, with most occurrences during the first several months of therapy. Symptomatic hepatitis has been reported. Therefore, the manufacturer recommends that serum ALT be checked before initiation of treatment, monthly for 3 months, and every 2-3 months for the rest of the first year. ALT should be checked periodically thereafter.
(i) Patients should be monitored closely for signs or symptoms of liver dysfunction (e.g., right upper quadrant abdominal pain, flu-like symptoms, fatigue, nausea, lethargy, itching, jaundice).
(ii) If ALT increases to more than five times the upper limit of normal, therapy should be discontinued and the patient should be monitored until enzymes normalize.

4. Cromolyn sodium and nedocromil sodium

a. Therapeutic effects. Cromolyn sodium and nedocromil sodium are nonsteroidal drugs with anti-inflammatory properties. These medications are less effective in their anti-inflammatory properties than the inhaled corticosteroids; however, because of their excellent safety profile, they are sometimes used in children.

(1) When used prophylactically, cromolyn sodium and nedocromil sodium prevent the early and late response of asthma.
(2) When used as maintenance therapy for asthma, these medications suppress nonspecific airway reactivity.
b. Mechanism of action. Cromolyn sodium and nedocromil sodium are believed to act locally by stabilizing mast cells and thereby inhibiting mast cell degranulation.
c. Administration and dosage
(1) Cromolyn sodium is available as an MDI (800 mg per inhalation), and a nebulizer solution (20 mg/2 mL). The required dosage is two puffs of the MDI or 20 mg of nebulizer solution. Because of the dosage needed to achieve asthma control, the nebulizer is preferred.
(2) Nedocromil sodium is available as an MDI (1.75 mg per inhalation). The required dosage is two inhalations four times a day.
(3) When used for prophylaxis of EIB, cromolyn sodium and nedocromil sodium should be administered 1 hr before exercise.
(4) After administration, initial improvement is seen within 1-2 weeks; however, the maximum effect may take longer.
d. Precautions and monitoring effects
(1) Cromolyn sodium and nedocromil sodium are **not effective during an acute asthma exacerbation.** They should be used only for maintenance therapy of persistent asthma or for prevention of EIB.

(2) Both drugs are well-tolerated, although paradoxical bronchospasm, wheezing, coughing, nasal congestion, and irritation or dryness of the throat may occur.

5. Theophylline compounds (methylxanthines)

a. Indications

(1) Theophylline compounds may be considered if β-agonists and corticosteroids fail to control an acute asthma exacerbation.

(2) Theophylline is an alternative to long-acting β-agonists in the treatment of persistent asthma.

(3) Theophylline is most beneficial as an adjuvant to inhaled corticosteroids in patients with nocturnal or early morning symptoms.

b. Therapeutic effects

(1) Theophylline compounds produce bronchodilation to a lesser extent than β-agonists.

(2) Nonbronchodilator effects include reduced mucus secretion, enhanced mucociliary transport, improved diaphragmatic contractility, and possibly reduced fatigability.

(3) There may also be notable degree of anti-inflammatory activity

c. Mechanism of action. Theophylline-induced phosphodiesterase inhibition results in increased levels of cAMP.

d. Administration and dosage

(1) Oral therapy (e.g., sustained-release theophyllines) allows for a longer dosing interval and improves compliance. Compliance to oral theophylline also may be better than that of inhaled bronchodilators and corticosteroids.

(a) Because theophylline does not distribute well into fatty tissue, dosages should be calculated using lean body weight.

(b) The initial dose of theophylline for adults and children > age 1 is 10 mg/kg/day (maximum of 300 mg/day) given in divided doses. Usual dosage should be adjusted to achieve serum theophylline concentration of 5-15 μg/mL (5-10 μg/mL acceptable).

(c) The dosage can be titrated slowly upward and the serum level monitored until a therapeutic level is obtained.

(d) The usual maximal daily dose in adults is 800 mg/day.

(e) The maximum recommended dosage in children < age 1 is 0.2 × (age in weeks) + 5 = mg/kg/day and in children ≥1 year is 16 mg/kg/day, given in divided doses.

(f) Ultra-sustained release theophylline formulations (Theo-24 and Uniphyl) may be dosed once daily.

(g) In addition to theophylline, other methylxanthine compounds are available (e.g., oxtriphylline, dyphylline) but infrequently used. Dosing of these compounds is based on theophylline content (Table 49-6).

Table 49-6. Theophylline Content of Theophylline-Containing Products

Preparation	Theophylline Content (%)	Equivalent Dose (mg)
Theophylline anhydrous (most oral solids)	100	100
Theophylline monohydrate (oral solutions)	91	110
Aminophylline anhydrous	86	116
Aminophylline hydrous	79	127
Oxtriphylline	64	156

(2) Intravenous therapy. Although frequently used in the past, IV administration is now uncommon. IV administration is generally used only in hospitalized patients for whom oral therapy is not possible (e.g., vomiting, nothing by mouth).

(a) The usual **loading dose** for adults and children not previously receiving a methylxanthine is 5 mg/kg of theophylline administered over 20-30 min at a rate not exceeding 25 mg/min.

(b) The usual **maintenance infusion** rate of theophylline in healthy nonsmoking adults on no interacting drugs is 0.4 mg/kg/hr. This rate should be adjusted for factors that affect theophylline metabolism and serum levels (see Table 49-7).

d. Precautions and monitoring effects

(1) Theophyllines are contraindicated in patients with hypersensitivity to xanthine compounds and should be used cautiously in patients with a history of peptic ulcer or untreated seizure disorder.

(2) Adverse effects include nausea, vomiting, diarrhea, anorexia, palpitations, dizziness, restlessness, nervousness, insomnia, seizures, reduced lower esophageal sphincter tone, and reduced control of gastroesophageal reflux disease. Patients who experience adverse gastrointestinal effects should be evaluated to rule out theophylline toxicity versus local gastrointestinal effect.

(3) Theophylline clearance can be altered by several factors and drug interactions (Table 49-7). Close drug-level monitoring is required for patients with factors that alter theophylline clearance.

(4) Careful monitoring is required in patients with hepatic disease, hypoxemia, hypertension, congestive heart failure, alcoholism, and in the elderly. Because of developmental changes in the neonate and child, dosing must be carefully established and monitored in these populations as well.

(5) Therapeutic drug monitoring of serum levels, adverse reactions, and concomitant drug use is essential for long-term therapy owing to theophylline's age- and condition-specific clearance.
(a) Therapeutic effect is achieved and toxicity minimized by keeping drug concentrations at 5-15 µg/mL.
(b) Drug levels should be assessed at steady state (typical half-life 8 hr, up to 24 hr in severe heart and liver failure),
(c) During oral therapy, trough drug levels should be obtained at steady state.
(d) Dyphylline serum levels should be monitored during therapy because serum theophylline levels will not measure dyphylline. The minimal effective therapeutic concentration of dyphylline is 12 µg/mL.
6. Anticholinergics. Bronchodilation occurs when these drugs block postganglionic muscarinic receptors in the airway. Response to anticholinergics is most pronounced in patients with fixed airway obstruction (e.g., COPD).
a. Ipratropium bromide (Atrovent) is a quaternary ammonium compound.
(1) Indications
(a) Ipratropium bromide is recommended for use in combination with β-agonists for the treatment of an acute asthma exacerbation in the emergency department or hospital settings. However, benefits in the chronic management of asthma have not been established.
(b) Ipratropium bromide may be particularly useful in older patients and patients with coexisting COPD.

Table 49-7. Factors That Alter Theophylline Clearance

Factors that increase theophylline clearance (decrease levels)		
	Age 1-9 years	
	Drugs	
		Carbamazepine
		Phenobarbital
		Phenytoin
		Rifampin

	Fever	
	Food (may delay or reduce absorption of some sustained-release products)	
	High-protein diet	
	Smoking (marijuana and tobacco)	
Factors that decrease theophylline clearance (increase levels)		
	Age	
		Elderly
		Premature neonates
		Term infants <6 months
	Cor pulmonale	
	Congestive heart failure, decompensated	
	Drugs	
		Allopurinol
		β-Blockers (nonselective)
		Calcium channel blockers
		Cimetidine
		Fluoroquinolones (ciprofloxacin)

		Influenza virus vaccine
		Macrolides (clarithromycin, erythromycin)
		Oral contraceptives
		Ticlopidine
		Zafirlukast
	Fever/viral illness	
	Fatty foods (may increase rate of absorption of some products)	
	High-carbohydrate diet	
	Liver dysfunction (e.g., cirrhosis)	

(c) Ipratropium should not be used alone to treat an asthma exacerbation.
(d) Ipratropium bromide is an alternative bronchodilator in some patients who cannot tolerate β-agonists and in patients who present with bronchospasm induced by a β-blocker.
(2) Administration and dosage
(a) Closed-mouth MDI technique or the use of a spacer is recommended for patients receiving anticholinergic therapy via MDI.
(b) The starting dose of the MDI is two inhalations four times a day. When administered via nebulizer, the dose is 500 µg (2.5 mL) four times a day.
(3) Precautions and monitoring effects
(a) If the anticholinergic spray contacts the eye, intraocular pressure may increase.
(b) The onset of action (approximately 15 min) and peak effect (1-2 hr) are more delayed than for β-agonists.
b. Aerosolized **atropine** is used rarely now that ipratropium bromide nebulization solution is available owing to atropine's high incidence of systemic adverse effects.
7. Antihistamines are useful for patients with coexisting allergic rhinitis; however, their role in the treatment of asthma remains unclear. Antihistamines compete with histamine for H_1-receptor sites on effector cells and thus help prevent the histamine-mediated responses that influence asthma.
8. Antibiotics are generally not used for the treatment of asthma, unless other signs of infection are present.

9. Magnesium sulfate, administered intravenously, may be useful in some patients because of its modest ability to cause bronchodilation. When administered intravenously, it also improves respiratory muscle strength in hypomagnesemic patients. Research has suggested that magnesium may reduce admission rate and improve FEV_1 in severe, acute asthma exacerbations and in stable, chronic asthma.
10. Immunotherapy (allergy shots) improves asthma control in some patients and is ineffective in others. A recent meta-analysis demonstrated that immunotherapy may improve lung function, reduce symptoms, and decrease medication requirements in a significant number of patients.
11. Mucus may contribute to airway obstruction in asthma. However, because some inhaled mucolytics such as acetylcysteine may precipitate bronchospasm, they should not be used for the treatment of patients with asthma.
12. Omalizumab (Xolair) is an anti-IgE compound used for severe asthma and concurrent allergies. It is usually administered twice monthly as an injection in a specialty physician's office. Life-threatening anaphylaxis has rarely been reported with this medication.

J. Drug delivery options

1. MDIs

a. When administered with good technique and a spacer, the efficacy of MDIs is similar to that of nebulizers, despite the lower doses administered with an MDI and spacer. The only MDI that comes with a built-in spacer is the Azmacort (triamcinolone) inhaler.
b. For small children to be able to use an MDI, a spacer with a face mask must be used.
c. MDIs can be difficult to use. Steps for properly using an MDI are outlined in Table 49-8.
d. MDIs can be administered to patients on mechanical ventilation with the use of an attachment device designed for the mechanical ventilator circuit. Higher doses of the β_2-agonist are often used in this setting.
e. Breath-actuated MDIs (e.g., Maxair Autohaler) require the patient to use a closed-mouth technique. When inhalation is begun, the medication is released automatically. This type of inhaler is useful for a patient who is having problems coordinating actuation and inhalation.

2. Spacers and holding chambers (e.g., AeroChamber, AeroVent, Ellipse, InspirEase, Opti-Chamber)

a. Spacers and holding chambers reduce the amount of drug deposited in the oral cavity.
b. The use of spacers and holding chambers may minimize local and systemic adverse reactions.
c. Addition of a spacer in a patient with poor MDI technique may improve pulmonary delivery of the agent.

d. Spacers should be considered in all patients who are receiving medium to high doses of inhaled corticosteroids.

Table 49-8. Procedure for the Proper Use of Metered Dose Inhalers (MDIs)

Assemble MDI, if necessary.	
Remove cap and inspect mouthpiece for foreign objects.	
Attach MDI to spacer (if applicable).	
Shake MDI (with spacer).	
Tilt head back slightly and exhale fully.	
Position inhaler:	
	Wrap lips around spacer mouthpiece.
	Position inhaler 1-2 in. from open mouth.
	Wrap lips around inhaler mouthpiece.
Just as you begin to inhale, depress canister once to release medication.	
Continue inhaling slowly (over 3-5 sec) until lungs are full.	
Hold breath for 5-10 sec.	
Wait 1 min before repeating steps to deliver additional puffs.	
Rinse mouth out after use of inhaled steroids.	

e. They are especially beneficial for patients with poor hand-lung coordination, such as very young and old.

f. Devices vary in construction and efficacy. The presence of a one-way mouthpiece valve, inhalation rate whistle, size, and durability are all factors that should be considered when selecting a particular spacer for a patient. Some new spacers have anti-static interiors to minimize adherence of aerosol particles to the interior of the spacer.

3. Nebulizers

a. Compared to MDI and spacer administration, nebulizers require less patient coordination during administration of multiple inhalations.

b. Disadvantages of nebulizers include cost, preparation and administration time, size of the device, and drug delivery inconsistencies among devices.

c. Despite the disadvantages, nebulization is recommended for delivery of high-dose β-agonists and anticholinergics in severe exacerbations and for delivery of cromolyn sodium to children.

4. Dry-powder inhalers

a. Dry-powder inhalers (DPIs) are coming to the market as a result of the international move to avoid the use of chlorofluorocarbon (CFC) propellants. They are also being used more frequently because many patients find them easier to use than an MDI.

b. Dry-powder inhalers require the user to:

(1) First load the dose into the delivery chamber

(2) Exhale fully

(3) Inhale rapidly or slowly, depending on the device (versus only slow inhalation required for MDI administration)

(4) Use the closed-mouth technique

(5) Avoid exhaling into the mouthpiece before inhalation.

c. Spacers are not used with dry-powder inhalers.

d. Patients should be advised to keep these devices away from moisture.

K. Nonpharmacological treatment

1. Humidified oxygen is administered to all patients with severe, acute asthma to reverse hypoxemia. Although the fraction of inspired oxygen (FIO_2) administered is based on the patient's arterial blood gas status, 1-3 L/min is generally given via face mask or nasal cannula. The goal is to keep the SaO_2 >90% (>95% if the patient is pregnant or has heart disease).

2. Heliox is a mixture of helium and oxygen that has a lower density than air. Because of its decreased airflow resistance, heliox may increase ventilation during acute asthma exacerbations. Because conflicting information has been published in studies using heliox, its role in asthma is unclear.

3. Intravenous fluids and electrolytes may be required if the patient is volume depleted.

4. Environmental control and allergen avoidance are important in the management of a patient with asthma.

a. Available data suggest that avoidance of known allergens can improve asthma control.

b. Some measures include use of allergen-resistant mattress and pillow encasements, use of high-filtration vacuum cleaners, removal of carpets and draperies, and avoidance of furry pets.

5. Vaccines (e.g., influenza virus, polyvalent pneumococcals) are recommended to prevent infection, which may precipitate an exacerbation.

II. CHRONIC OBSTRUCTIVE PULMONARY DISEASE

A. Definitions. The 2001 National Heart, Lung, and Blood Institute/World Health Organization (NHLBI/WHO) Global Initiative for Chronic Obstructive Lung Disease (GOLD) definition of COPD is "a disease state characterized by airflow limitation that is not fully reversible. The airflow limitation is usually both progressive and associated with an abnormal inflammatory response of the lungs to noxious particles or gases." The American Thoracic Society definition is similar: a disease state characterized by the presence of airflow limitation owing to chronic bronchitis or emphysema; the airflow obstruction is generally progressive, may be accompanied by airway hyperreactivity, and may be partially reversible. The two major forms of COPD—**chronic**

bronchitis and **emphysema**—frequently coexist. COPD also coexists with asthma. These guidelines have been updated annually.

1. Chronic bronchitis is characterized by excessive mucus production by the tracheobronchial tree, which results in airway obstruction as a result of edema and bronchial inflammation. Bronchitis is considered chronic when the patient has a cough producing more than 30 mL of sputum in 24 hr for at least 3 months of the year for 2 consecutive years and other causes of chronic cough have been excluded.

2. Emphysema is marked by permanent alveolar enlargement distal to the terminal bronchioles and destructive changes of the alveolar walls. There is a lack of uniformity in airspace enlargement, resulting in loss of alveolar surface area. The collapse of these small airways results in airflow limitation that is independent of exertion.

B. Incidence. Approximately 17 million Americans have COPD. COPD is the fourth leading cause of death in the United States and the leading cause of hospitalization in the older population. It is most commonly diagnosed in older men; however, the incidence is increasing in women owing to an increasing population of women smokers. Women may be more likely to have more rapidly progressive COPD than men.

C. Cause. Various factors have been implicated in the development of COPD, including the following:

1. Cigarette smoking is the primary causal factor for the development of COPD, present in >90% of patients.

a. One mechanism suggests that pulmonary hyperreactivity secondary to smoking results in persistent airway obstruction.

b. There is also an increased risk of COPD in people who have α1-antitrypsin (AAT) deficiency. One in three people with genetic AAT deficiency develop emphysema, usually as young adults.
(1) AAT is a serine protease inhibitor, and it is also an acute-phase reactive protein. The major physiological function of AAT is inhibition of neutrophil elastase.
(2) AAT deficiency should be suspected when emphysema develops early in the absence of a significant smoking history.
2. Exposure to irritants such as sulfur dioxide (as in polluted air), noxious gases, and organic or inorganic dusts
3. A history of respiratory infections or bronchial hyperreactivity
4. Social, economic, and hereditary factors

D. Pathophysiology

1. Chronic bronchitis

a. Respiratory tissue inflammation results in vasodilation, congestion, mucosal edema, and goblet cell hypertrophy. These events trigger goblet cells to produce excessive amounts of mucus.
b. Changes in tissue include increased smooth muscle, cartilage atrophy, infiltration of neutrophils and other cells, and impairment of cilia.
c. Airways become blocked by thick, tenacious mucous secretions, which trigger a productive cough.
d. Normally sterile airways can become colonized with *Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, Staphylococcus aureus,* and *Pseudomonas aeruginosa* species. Recurrent lung infections (viral and bacterial) reduce ciliary and phagocytic activity, increase mucus accumulation, weaken the body's defenses, and further destroy small bronchioles.
e. As the **airways degenerate,** overall gas exchange is impaired, causing **exertional dyspnea.**
f. Hypoxemia results from a V/Q imbalance and is reflected in an increasing arterial carbon dioxide tension (i.e., increasing $PaCO_2$).
g. Sustained hypercapnia (increased $PaCO_2$) desensitizes the brain's respiratory control center and central chemoreceptors. As a result, compensatory action to correct hypoxemia and hypercapnia (i.e., a respiratory rate or depth increase) does not occur. Instead, hypoxemia

serves as the stimulus for breathing. Use of narcotics or benzodiazepines, especially in combination, should be done cautiously in these patients to avoid respiratory failure.

2. Emphysema

a. Anatomical changes are the result of loss of tissue elasticity.
(1) Inflammation and **excessive mucus secretion** (as from long-standing chronic bronchitis) cause air trapping in the alveoli. This contributes to breakdown of the bronchioles, alveolar walls, and connective tissue.
(2) As clusters of alveoli merge, the number of alveoli diminishes, leading to increased space available for air trapping.

(3) Destruction of alveolar walls causes collapse of small airways on exhalation and disruption of the pulmonary capillary beds.
(4) These changes result in V/Q abnormalities; blood is shunted away from destroyed areas to maintain a constant V/Q ratio, unlike the case in chronic bronchitis.
(5) Hypercapnia and respiratory acidosis are uncommon in emphysema because V/Q imbalance is compensated for by an increased respiratory rate.
b. There are **specific regions of the lung** in which characteristic anatomical changes of emphysema occur.
(1) In **centrilobular** (centriacinar) emphysema associated with cigarette smoking, destruction is central, selectively involving respiratory bronchioles. Typically, bronchioles and alveolar ducts become dilated and merge.
(2) In **panlobular** (panacinar) emphysema, all lung segments are involved. The alveoli enlarge and atrophy, and the pulmonary vascular bed is destroyed. This form of emphysema is associated with AAT deficiency.
(3) In **paraseptal** emphysema, the lung periphery adjacent to fibrotic regions is the site of alveolar distention and alveolar wall destruction. This is associated with spontaneous pneumothorax.

E. Clinical evaluation

1. Physical findings

a. Predominant chronic bronchitis typically has an insidious onset after age 45.
(1) A **chronic productive cough** is the hallmark of chronic bronchitis. It occurs first in winter, then progresses to year-round. It is usually worse in the morning. Smoking cessation can help lessen the productive cough.
(2) Exertional dyspnea, the most common presenting symptom, is progressive. However, the severity of this symptom may not reflect the severity of the disease.
(3) Other common findings include obesity, rhonchi and wheezes on auscultation, prolonged expiration, and a normal respiratory rate. As the disease progresses, right ventricular failure is common, which presents as jugular venous distention, peripheral edema, hepatomegaly, and cardiomegaly. Because patients tend to develop cyanosis, the term *blue bloater* is sometimes used to describe patients with chronic bronchitis.
b. Predominant emphysema has an insidious onset, and symptoms occur after age 55.
(1) The **cough** is chronic but less productive than in chronic bronchitis.
(2) Exertional dyspnea is progressive, constant, severe, more characteristic of emphysema than chronic bronchitis.
(3) Other common findings include weight loss, tachypnea, pursed-lip breathing, prolonged expiration, accessory chest muscle use, hyperresonance on percussion, diaphragmatic excursion, and diminished breath sounds. Because patients are able to maintain reasonably good oxygenation because of their tachypnea, the term *pink puffer* is sometimes used to describe patients with emphysema. Note however, that the pink puffer and blue bloater presentations are not specific for the respective diseases.

c. Patients may have elements and physical findings from each of these diseases simultaneously. Comorbidites such as CHF, CAD, stroke, DM, and depression are common in COPD patients.

2. Diagnostic test results

a. COPD patients with characteristic symptoms of cough, dyspnea, sputum production, and/or exposure to known risk factors (e.g., smoking) should be evaluated for a COPD diagnosis. If the patient has FEV_1/FVC <70% and a postbronchodilator FEV_1 <80% predicted, he or she has airflow limitation that is not fully reversible. Patients with a smoking history (e.g. >20 pack year history and >45 years old) should be considered for the diagnosis. Spirometry can be used to help make the diagnosis.

b. Chronic bronchitis

(1) Blood analysis may reveal polycythemia as a result of to erythropoiesis secondary to hypoxemia. With bacterial infection, the WBC count may be increased.

(2) Sputum inspection reveals thick purulent or mucopurulent sputum tinged yellow, white, green, or gray; an acute change in color and/or quantity suggests infection.

(3) Arterial blood gas studies may show a markedly decreased PaO_2 level (45-60 mm Hg), reflecting hypoxemia, and a $PaCO_2$ level that is normal or elevated (50-60 mm Hg), reflecting hypercapnia.

(4) Pulmonary function tests may be normal in the early disease stages. Later, they show a reduced FEV_1/FVC ratio, increased residual lung volume, a decreased vital capacity, and a decreased FEV_1. Unlike emphysema, chronic bronchitis patients tend to have normal diffusing capacity, normal static lung compliance, and normal total lung capacity.

(5) Chest radiograph typically identifies lung hyperinflation, a barrel chest, and increased bronchovascular markings.

(6) An ECG may reveal right ventricular hypertrophy and changes consistent with cor pulmonale.

c. Emphysema

(1) Sputum inspection reveals scanty sputum that is clear or mucoid. Infections are less frequent than in chronic bronchitis.

(2) Arterial blood gas studies typically indicate a reduced or normal PaO_2 level (65-75 mm Hg) and, in late disease stages, an increased $PaCO_2$ level (50-60 mm Hg).

(3) Pulmonary function tests show a reduced FEV_1/FVC ratio, normal or increased static lung compliance, reduced FEV_1 and diffusing capacity, and increased TLC and RV.

(4) Chest radiograph usually reveals bullae, blebs, a flattened diaphragm, lung hyperinflation, vertical heart, enlarged anteroposterior chest diameter, decreased vascular markings in the lung periphery, and a large retrosternal air space.

F. Treatment objectives endorsed by GOLD include the following

1. Prevent disease progression (smoking cessation)

2. Relieve symptoms and improve exercise tolerance (enable the patient to perform normal daily activities)
3. Improve health status
4. Prevent and treat exacerbations
5. Prevent and treat complications
6. Reduce mortality

G. Therapy

1. Pharmacological treatment. Therapy is based on disease staging, which is determined by spirometry (Table 49-9).

a. Short-acting anticholinergics and β-agonists, alone or in combination, are the most commonly used initial agents. Long-acting bronchodilators, such as salmeterol, formoterol, tiotropium (Spiriva), and theophylline are added to the short-acting agents. Methylxanthines are usually added when the response to other agents is inadequate. In addition to bronchodilation, these agents can decrease dyspnea, improve exercise capacity, improve quality of life, and decrease the frequency and severity of exacerbations, especially tiotropium.

b. Bronchodilators are the most important therapy for symptoms in COPD. Figure 49-4 indicates a strategy of use.

c. Inhaled corticosteroids, such as fluticasone and budesonide, have shown small benefits in FEV_1; the majority of their benefit occurs in reducing the severity of exacerbations, not the number of exacerbations.

d. Anticholinergics (e.g., ipratropium bromide, tiotropium bromide, atropine)

(1) Indications. Anticholinergics may be used as first-line bronchodilators or in conjunction with β-agonists in the treatment of COPD because these agents are the most potent bronchodilators for the condition.

Table 49-9. Therapy at Each Stage of COPD

Old	**0: At Risk**	**I: Mild**	**II: Moderate IIA**	**IIB**	**III: Severe**
New	**0: At Risk**	**I: Mild**	**II: Moderate**	**II: Severe**	**IV: Very Severe**
Characteristics	Chronic symptoms	$FEV_1/FVC<70\%$	$FEV_1/FVC<70\%$	$FEV_1/FVC<70\%$	$FEV_1/FVC<70\%$
	Exposure to risk	$FEV_1 \geq 80\%$	$50\% \leq FEV_1 < 50\%$	$30\% \leq FEV_1 < 50\%$	$FEV_1 < 30\%$ or $FEV_1 < 50\%$

	factors				predicted plus chronic respiratory failure
	Normal spirometry	With or without symptoms	With or without symptoms	With or without symptoms	
	Avoidance of risk factor(s); influenza vaccination				
		Add short-acting bronchodilator when needed			
			Add regular treatment with one or more long-acting bronchodilators		
			Add rehabilitation		
				Add inhaled glucocorticosteroids if repeated exacerbations	
					Add long-term oxygen if chronic respiratory failure
					Consider surgical treatments

FEV_1, forced expiratory volume in 1 sec; *FEV,* forced vital capacity.

Reprinted with permission from Global Initiative for Chronic Obstructive Lung Disease (GOLD). Global Strategy for the Diagnosis, Management, and

Prevention of Chronic Obstructive Pulmonary Disease. Updated 2006. www.goldcopd.org.

Figure 49-4. Stepped care approach to bronchodilators in COPD. AC, anticholinergic; LA, long acting; PDE, phosphodiesterase; SA, short acting.

(2) Mechanism of action. Ipratropium bromide, tiotropium bromide, and atropine produce bronchodilation by competitively inhibiting cholinergic responses. Ipratropium bromide and tiotropium bromide also reduce sputum volume without altering viscosity. Some studies have shown an increased response to these agents in COPD when they are combined with β-agonists. Tiotropium has greater affinity for cholinergic receptors than ipratropium.

(3) Administration and dosage

(a) Ipratropium bromide is three to five times more potent and has significantly fewer side effects than atropine, which is rarely used today since the development of nebulized ipratropium.

(b) Initial MDI dosing of ipratropium bromide is two inhalations (40 μg) four times daily, but dosing can be increased to six inhalations four times daily without significant risk. These higher doses are often required to achieve therapeutic

benefit. Administration should be via MDI with spacer or MDI alone using a closed-mouth technique.

(c) Dosing of ipratropium bromide solution is 500 µg/2.5 mL (1 unit dose vial) or more via nebulizer four times daily.

(d) Tiotropium bromide capsules contain 22.5 µg tiotropium bromide monohydrate, equivalent to 18 µg tiotropium.

(i) Tiotropium is an inhalation powder contained in a hard capsule. It should be administered once daily only via a HandiHaler device, which delivers 10 µg tiotropium.

(ii) Patients should generally not be placed on both ipratropium and tiotropium because of the increased risk of anticholinergic side effects, and no additional bronchodilation is likely achieved by adding ipratropium. For example, if a COPD patient is currently on ipratropium/albuterol (Combivent, DuoNeb), and tiotropium is started, the albuterol should be continued as the short-acting bronchodilator and ipratropium discontinued.

e. β-Agonists (see I.I.1; Table 49-4)

(1) Indications. β_2-Agonists may be used as first-line bronchodilators or in conjunction with anticholinergic agents in the maintenance treatment of COPD. Short-acting agents are used regularly or on an as-needed basis for symptoms. Some patients may respond clinically to the prolonged treatment with β_2-agonists even after demonstrating

lack of acute reversibility (spirometry testing showing <12% or <200-mL increase in FEV_1) to short-acting agents.

(2) Mechanism of action. β_2-Agonists relieve dyspnea caused by airway obstruction, although the response is usually not as significant as in patients with asthma. These agents may also increase mucociliary clearance by stimulating ciliary activity (helps patients expectorate sputum).

(3) Administration and dosage

(a) β_2-Agonists are administered via inhalation (e.g., dry-powder inhaler, nebulizer, MDI with or without a spacer), unless the patient cannot use the drug properly; then an oral agent is used cautiously.

(b) β_2-Agonists of the same duration should not be used in combination because an adequate dose of a single agent provides peak bronchodilation. However, it is reasonable to administer a long-acting product (e.g., salmeterol, formoterol) on a regular basis with a short-acting agent reserved for as-needed or rescue therapy.

(c) Salmeterol and formoterol (long-acting β-agonists) are administered twice daily. They may also be used in combination with ipratropium bromide or tiotropium. Neither agent is used on an as-needed basis for rescue therapy, although formoterol does have a rapid onset of action.

(d) Inhaler devices that require a rapid inspiratory rate may result in suboptimal lung deposition in the COPD patient with limited inspiratory capacity. An MDI or nebulizer may be more optimal in this type of patient.

f. Theophylline (see I.I.5)

(1) Indications. Theophylline compounds typically are added to the drug regimen after an unsuccessful trial of ipratropium bromide and β-adrenergics. Theophylline appears to have a greater clinical role in COPD than in asthma. Other similar agents (phosphodiesterase inhibitors) are in development.
(2) Mechanism of action. In COPD, theophylline compounds are used because they increase mucociliary clearance, stimulate the respiratory drive, enhance diaphragmatic contractility, improve the ventricular ejection fraction, and stimulate renal diuresis. Their bronchodilator properties are modest, at best. Theophylline may be used in lieu of other long-acting bronchodilators or in combination.
(3) Administration and dosage. A trial of 1-2 months with the serum drug level maintained at 5-12 μg/mL and maximized
(a) Because of the nonbronchodilator effects of methylxanthines, they may be continued in the face of a clinical response, even in the absence of improved FEV_1.
(b) If no change occurs in the patient's clinical condition and/or FEV_1, theophylline therapy should be discontinued owing to the potential for side effects.
(4) Precautions and monitoring effects. Serum drug levels should be closely monitored in all patients, especially those with signs of toxicity (tachycardia, nausea, vomiting) as well as with liver impairment, congestive heart failure and/or cor pulmonale as a result of reduced theophylline metabolism. Potential drug interactions (e.g. with ciprofloxacin) may warrant blood testing.
g. Corticosteroids (see I.I.2; Table 49-5)
(1) Indications
(a) Systemic corticosteroids (preferably oral) are indicated in the treatment of acute COPD exacerbations and chronically in some severe patients.
(b) Inhaled corticosteroids play a less prominent role in COPD than in asthma.
(c) Candidates for prolonged use of inhaled corticosteroid therapy should
(i) Be symptomatic and have a documented spirometric response (i.e., an increase in FEV_1 of at least 15% and 200 mL after 6 weeks to 3 months of use)
(ii) Have an FEV_1 <50% predicted, with a history of repeated exacerbations requiring systemic corticosteroids or antibiotics
(d) Long-term use of systemic steroids should be avoided if possible. Osteoporosis of the spine and ribs is especially common in COPD patients receiving frequent or maintenance systemic steroids. It has been recently recognized that inhaled steroids increase the risk of bacterial pneumonia in COPD patients.
(2) Administration and dosage
(a) For oral use in outpatient management of acute exacerbations, prednisone or prednisolone is administered at a dosage of 40 mg/day for 10 days.
(b) The dose of oral (e.g., prednisolone) or intravenous corticosteroids (e.g., methylprednisolone) for hospital management of acute COPD exacerbations is not established.

However, doses and duration of therapy should be limited (e.g., 30-40 mg/day of prednisolone for 10-14 days) to avoid significant adverse effects.
(c) In COPD, inhaled steroids are not as efficacious as in asthma patients.

(d) In appropriate patients, corticosteroids may be administered via dry-powder inhaler or MDI with spacer.
(e) Response to oral corticosteroids does not predict response to inhaled corticosteroids.
(f) Medium doses of inhaled corticosteroids are recommended for COPD (e.g., Flovent 110 µg 2 puffs twice a day or the combination of Advair 250 µg 1 puff twice a day).
(g) Inhaler devices that require a rapid inspiratory rate (e.g., Pulmicort Flexhaler) are generally not desirable in COPD patients.

h. Antibiotics

(1) Indications

(a) Antibiotics are used to treat exacerbations with suspected infection as evidenced by an increase in volume or change in color or viscosity of the sputum, along with dyspnea.
(b) Prevention of infection with chronic antibiotic therapy is controversial and should be considered only in patients with multiple exacerbations annually (i.e., more than two per year).

(2) Antibiotic therapy

(a) Ambulatory antibiotic treatment of exacerbations in patients with COPD is recommended when there is evidence of worsening dyspnea and cough with purulent sputum and increased sputum volume.
(i) Hospital or laboratory antibiograms should be reviewed when selecting an appropriate agent for *S. pneumoniae, M. catarrhalis,* and *H. influenzae.*
(ii) Agents may include either a second-generation cephalosporin (e.g., cefuroxime, cefaclor), trimethoprim-sulfamethoxazole, a β-lactam with or without a β-lactamase inhibitor (e.g., amoxicillin, amoxicillin-clavulanate), macrolides (azithromycin [Zithromax]), or an oral fluoroquinolone (ciprofloxacin [Cipro], levofloxacin [Levaquin]).
(iii) If infection with *M. pneumoniae* or *Legionella pneumophila* is a concern, although uncommon in COPD flares, a macrolide or fluoroquinolone may be added.
(b) Antibiotic treatment of pneumonia in hospitalized patients with COPD includes either a second- or third-generation cephalosporin (e.g., cefuroxime, ceftriaxone, cefotaxime) or a β-lactam with or without a β-lactamase inhibitor (e.g., amoxicillin-clavulanate - [Augmentin], piperacillin-tazobactam [Zosyn]), a macrolide, or fluoroquinolone.
(c) COPD exacerbations are treated for 3-10 days, depending on the agent used (e.g., moxifloxacin 400 mg × 5 days) and the patient.

i. Mucolytics (e.g., iodinated glycerol) may improve sputum clearance and disrupt mucus plugs.

j. Expectorants (e.g., guaifenesin) may be used. Potassium iodide should be avoided because of side effects associated with iodine therapy.

k. Antioxidants (e.g., *N*-acetylcysteine) may reduce exacerbation frequency. However, routine use cannot be recommended based on currently available data.

l. Influenza virus vaccine is recommended because of its ability to reduce death and serious illness by almost 50%.

2. Nonpharmacological Therapy

a. Vaccinations

(1) Influenza vaccination administered each Fall/Winter. **Polyvalent pneumococcal** vaccine is recommended by the American Thoracic Society

b. Oxygen Therapy

(1) Recommended for hypoxemia chronically or during exacerbations. Currently recommended to administer oxygen at least 15 hours/day.

(2) Reverses hypoxemia (particularly at night and during exercise).

(3) Indications for home oxygen treatment include

(a) PaO_2 < 55 mm Hg or SaO_2 < 88%

(b) PaO_2 of 55-60 mm Hg or SaO_2 < 89% with evidence of cor pulmonale, pulmonary hypertension, or polycythemia (hematocrit > 55%).

(4) Patients hospitalized for COPD exacerbations should receive controlled oxygen to keep PaO_2 > 60 mm Hg or SaO_2 > 90%. Arterial blood gas (ABG) tests may be performed 30 min after placing the patient on oxygen to identify and minimize CO_2 retention.

c. Chest physiotherapy loosens secretions, helps reexpand the lungs, and increases the efficacy of respiratory muscle use. Techniques include postural drainage, chest percussion and vibration, coughing, and deep breathing. These efforts may help patients with lobar atelectasis or who produce large quantities (i.e., > 25 mL/day) of sputum.

d. Physical rehabilitation improves the patient's exercise tolerance and quality of life. A pulmonary rehabilitation program usually includes physical conditioning and social, psychological, and nutritional interventions. This can be an effective intervention.

e. Smoking cessation and avoidance of other irritants has been shown to slow the rate of decline in FEV_1 in COPD patients. It is obviously one of the most important interventions. Nicotine gum, patches, inhalers, lozenges, bupropion, varenicline (Chantix), and clonidine may be useful in smoking cessation. Behavior intervention significantly enhances the effectiveness of pharmacological therapy in smoking cessation.

f. Surgery. There is a growing body of evidence that lung volume reduction surgery may be beneficial to patients with severe emphysema. Clinical trials have now delineated proper patient selection for this type of surgery. Lung transplantation is also performed in selected patients.

H. Complications of COPD

1. Pulmonary hypertension. With decreased pulmonary vascular bed space (owing to lung congestion), pulmonary arterial pressure increases. In some cases, pressure increases enough to cause **cor pulmonale** (right ventricular hypertrophy) with consequent heart failure.

2. Acute respiratory failure. In advanced stages of COPD, the brain's respiratory center may become seriously compromised, leading to poor cerebral oxygenation

and an increased $PaCO_2$ level. Hypoxia and respiratory acidosis may ensue. If the condition progresses, respiratory failure occurs.

3. Infection. In chronic bronchitis, trapping of excessive mucus, air, and bacteria in the tracheobronchial tree sets the stage for infection. In addition, impairment of coughing and deep breathing, which normally cleanses the lungs, leads to destruction of respiratory cilia. Once an infection sets in, reinfection can easily occur.

4. Polycythemia. An increase in red blood cells infrequently can lead to hypercoagulable states, embolism, and stroke. This happens uncommonly today due to the widespread use of supplemental oxygen in COPD patients.

STUDY QUESTIONS

Directions for questions 1-7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The symptoms of allergen-mediated asthma result from which of the following?

(A) Increased release of mediators from mast cells

(B) Increased adrenergic responsiveness of the airways

(C) Increased vascular permeability of bronchial tissue

(D) Decreased calcium influx into the mast cells

(E) Decreased prostaglandin production

View Answer***1. The answer is A[see I.D.4.(a);].*****2. Acute exacerbations of asthma can be triggered by all of the following *except***

(A) Bacterial or viral pneumonia.

(B) Hypersensitivity reaction to penicillin.

(C) Discontinuation of asthma medication.

(D) Hot, dry weather.

(E) Stressful emotional events.

View Answer***2. The answer is D[see].*****3. A 45-year-old male with a history of asthma has a peak expiratory flow rate (PEFR) of 65%, nocturnal wheezing once a month, and daytime wheezing usually less than twice a week. According to the National Institutes of Health (NIH) guidelines for the treatment of asthma, he has which type?**

(A) Mild intermittent

(B) Mild persistent

(C) Moderate persistent

(D) Severe persistent

View Answer***3. The answer is C[see].*****4. The patient in question 3 should be treated with which *two* agents?**

(A) Inhaled steroid and ipratropium

(B) Inhaled steroid and albuterol MDI (as needed)

(C) Inhaled steroid and aspirin

View Answer***4. The answer is B[see].*****5. A 15-year-old female is brought to the emergency department. She is breathing 30 times per minute, is unable to speak in full sentences, and has a peak expiratory flow rate (PEFR) < 50% predicted. The preferred first-line therapy for her asthma exacerbation is**

(A) Theophylline

(B) β-agonist

(C) Corticosteroid

(D) Cromolyn sodium

(E) A and B

(F) B and C

View Answer***5. The answer is F[see].*****6. The primary goals of asthma therapy in an adult patient include all of the following *except***

(A) Maintain normal activity levels.

(B) Maintain control of symptoms.

(C) Avoid adverse effects of asthma medications.

(D) Prevent acute exacerbations and chronic symptoms.

(E) Prevent destruction of lung tissue.

View Answer***6. The answer is E[see].*****7. Which of the following tests is used at home to assess therapy and determine if a patient with asthma should seek emergency care?**

(A) Forced expiratory volume in one second (FEV_1)

(B) Forced vital capacity (FVC)

(C) Total lung capacity (TLC)

(D) Peak expiratory flow rate (PEFR)

(E) Residual volume (RV)

View Answer***7. The answer is D[see].***P.1091

Directions for question 8: The incomplete statement in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

8. The disease process of chronic bronchitis is characterized by

I. the destruction of central and peripheral portions of the acinus.

II. an increased number of mucous glands and goblet cells.

III. edema and inflammation of the bronchioles.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***8. The answer is D[seeand].*****Directions for questions 9-11:** Each description in this section is most closely associated with **one** of the following agents. The agents may be used more than once or not at all. Choose the **best** answer, **A-E.**

9. Decreases theophylline clearance

A cimetidine

B albuterol

C ipratropium bromide

D epinephrine

E atropine

View Answer***9. The answer is A[see].*****10. Has anticholinergic activity with few side effects**

A cimetidine

B albuterol

C ipratropium bromide

D epinephrine

E atropine

View Answer***10. The answer is C[see].*****11. Has high β_2-adrenergic selectivity**

A cimetidine

B albuterol

C ipratropium bromide

D epinephrine

E atropine

View Answer***11. The answer is B[see].***P.1092

ANSWERS AND EXPLANATIONS

1. The answer is A *[see I.D.4.(a);* Figure 49-1*].*

In asthma, airborne antigen binds to the mast cell, activating the IgE-mediated process. Mediators (e.g., histamine, leukotrienes, prostaglandins) are then released, causing bronchoconstriction and tissue edema.

2. The answer is D *[see* I.D; Figure 49-1*].*

Exacerbations of asthma can be triggered by allergens, respiratory infections, occupational stimuli (e.g., fumes from gasoline or paint), emotions, and environmental factors. Studies have shown that cold air can cause release of mast cell mediators by an undetermined mechanism. Hot, dry air does not cause this release.

3. The answer is C *[see* Table 49-3*].*

The patient has moderate persistent asthma. All three parameters are consistent with mild persistent asthma. If any one of the three parameters indicated moderate persistent asthma, then the patient would be classified as moderate asthma (PEFR = 65%).

4. The answer is B *[see* Figure 49-3*].*

Inhaled steroids are the anti-inflammatory drug of choice owing to proven efficacy. All patients should be prescribed a short-acting β_2-agonist to use as rescue therapy for worsening symptoms. If chronic symptoms worsen, a long-acting β_2-agonist can

be added (e.g., Adavir). Remember that increasing the dose of the inhaled steroid may not improve symptoms, a long-acting bronchodilator is more likely to do so.

5. The answer is F *[see* Figure 49-3*].*

Patient is obviously in respiratory distress. Aggressive treatment with oxygen, systemic steroids, and short-acting bronchodilators is indicated. Ipratropium could also be added to the albuterol in the acute setting.

6. The answer is E *[see* I.F, I.H.1; II.D*].*

Asthma is characterized by reversible airway obstruction in response to specific stimuli. Mast cells release mediators, which trigger bronchoconstriction. After an acute attack, in most cases symptoms are minimal, and pathological changes are not permanent. Unlike asthma, chronic obstructive pulmonary disease does cause progressive airway destruction, chronic bronchitis by excessive mucus production and other changes, and emphysema by destruction of the acinus.

7. The answer is D *[see* I.G.2.a.(3)*].*

For home monitoring, PEFR is the best test for assessment of therapy, trigger identification, and the need for referral to emergency care. It is recommended for patients who have had severe exacerbations of asthma, who are poor perceivers of asthma symptoms, and those with moderate to severe disease.

8. The answer is D (II, III) *[see* II.D.1 *and* 2*].*

Chronic bronchitis is characterized by an increase in the number of mucous and goblet cells owing to bronchial irritation. This results in increased mucus production. Other changes include edema and inflammation of the bronchioles and changes in smooth muscle and cartilage. Emphysema is a permanent destruction of the central and peripheral portions of the acinus distal to the bronchioles. In this disease, adequate oxygen reaches the alveolar duct, owing to increased rate of breathing, but perfusion is abnormal.

9. The answer is A *[see* Table 49-8*].*

10. The answer is C *[see* II.G.1.a*].*

11. The answer is B *[see* Table 49-4*].*

Cimetidine, an H_2-receptor antagonist, decreases theophylline clearance by inhibiting hepatic microsomal mixed-function oxidase metabolism, thus increasing serum theophylline concentrations. Theophylline clearance can be decreased by 40% during the first 24 hr of concurrent therapy. Anticholinergic agents such as atropine and ipratropium bromide produce bronchodilation by competitively inhibiting cholinergic receptors. The disadvantages of atropine include dry mouth, tachycardia, and urinary retention. Ipratropium bromide is three to five times more potent than atropine and does not have these side effects. Albuterol is one of the most β_2-selective adrenergic agents available. Other such agents include terbutaline, bitolterol, and pirbuterol. Agents with β_2-selectivity dilate bronchioles without causing side effects related to β_1-stimulation (e.g., increased heart rate).

Osteoarthritis and Rheumatoid Arthritis

Tina Harrison Thornhill

I. DEFINITION AND CAUSE

A. Osteoarthritis (OA) is a common chronic condition of cartilage degeneration. Secondary changes can occur in the bone, leading to pain, decreased functioning, and even disability. OA affects nearly 21 million middle-aged and elderly Americans. It is the most common form of arthritis. Although not always symptomatic, most people over the age of 55 years have radiological evidence of the disease. Until age 55 years, OA affects men more frequently than women, but after age 55, women are more likely to have the disease.

B. Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease that involves inflammation in the membrane lining of the joints and often affects internal organs. Most patients exhibit a chronic fluctuating course of disease that can result in progressive joint destruction, deformity, and disability. RA affects 1% of the U.S. population. It occurs two to three times more often in women, and the peak onset occurs between the 4th and 6th decades of life.

II. NORMAL JOINT ANATOMY AND PHYSIOLOGY

A. The **synovial joint** consists of two bone ends covered by articular cartilage. The roles of articular cartilage include

1. Enabling frictionless movement of the joint

2. Distributing the load across the joint (shock absorber), to prevent damage

3. Promoting stability during use

B. Cartilage is avascular and aneural. It is metabolically active and undergoes continual internal remodeling. It is composed primarily of water but is also made from chondrocytes and extracellular matrix.

C. Chondrocytes control the synthesis and degradation of the matrix. They produce proteoglycans and collagen in the extracellular matrix to maintain the integrity of the matrix in healthy cartilage.

D. The **joint capsule** is a fibrous outer layer that encapsulates the joint. The joint capsule is lined by **synovium,** a membrane that produces a viscous fluid that lubricates the joint.

E. The **synovial fluid** is composed, in part, of hyaluronic acid. Glucosamine is a component of hyaluronic acid. The role of hyaluronic acid is to maintain functional and structural characteristics of the extracellular matrix.

F. Bursae are small sacs that are lined with synovial membrane and filled with fluid to provide cushioning and lubrication for the movement of the joint.

III. OSTEOARTHRITIS

A. Pathophysiology. The disease is not a normal part of the aging process; however, there are many age-related changes that contribute to the development of OA.

1. The strength of tendons, ligaments, and muscles declines with advancing age and may contribute to the development of the disease.

2. The number of chondrocytes declines owing to apoptosis (cell death), decreased proliferation, or both.

3. The synthesis of normal proteoglycans is reduced.

4. Chondrocytes lose the ability to promote healing and cartilage remodeling, resulting in cartilage matrix degradation. Proteoglycans are depleted.

5. Matrix metalloproteinases (MMPs) and proinflammatory cytokines promote cartilage degradation.

6. Interleukin 1 (IL-1) has several roles in the development of OA:

a. Responsible for the induction of chondrocytes and synovial cells to synthesize MMPs

b. Inhibits the synthesis of type II collagen and proteoglycans, preventing collagen from repairing itself

c. Enhances nitric oxide production and induces chondrocyte apoptosis

7. Pain occurs as a result of

a. Osteophytes (spurs of cartilage and bone at the joint)

b. Synovitis

c. Bursitis

d. Tendonitis

B. Risk factors for OA include advanced age, female gender, muscle weakness, obesity, joint trauma, heredity, congenital or developmental anatomical defects, and repetitive stress.

C. Clinical presentation. OA is characterized by a deep, localized ache in a joint. Pain and stiffness usually occurs with rest or immobility and lasts < 30 minutes. Inflammation, if present, is mild. Patients will often complain of crepitus, a popping or cracking noise, heard in the joint upon moving. OA most commonly affects the hips, knees, neck, and hands.

D. DIAGNOSIS

1. Physical examination. Joint tenderness, diminished range of motion, crepitus, abnormalities in joint shape.

2. Laboratory tests. No specific lab tests are diagnostic for OA; however, if arthrocentesis is performed, synovial fluid will reveal mild leukocytosis with predominance of mononuclear lymphocytes.

3. Radiography. Narrowing of joint space (owing to loss of cartilage), subchondral sclerosis, and osteophytes are seen.

4. The American College of Rheumatology (ACR) has defined **criteria for OA of the hip, knee, and hand:**

a. OA of the hip is characterized by hip pain and at least two of the following:
(1) Erythrocyte sedimentation rate (ESR) < 20 mm/hr
(2) Radiographic evidence of femoral or acetabular osteophytes
(3) Radiographic evidence of joint space narrowing
b. OA of the knee is characterized by knee pain, radiographic evidence of osteophytes, and at least one of the following:
(1) Age > 50 years
(2) Morning stiffness that lasts < 30 minutes
(3) Articular crepitus on motion
c. OA of the hand is characterized by hand pain, aching, or stiffness and at least three of the following:
(1) Hard tissue enlargement of ≥ 2 distal interphalangeal (DIP) joints
(2) Hard-tissue enlargement of ≥ 2 selected joints (2nd and 3rd DIP and/or proximal interphalangeal [PIP], and the 1st carpometacarpal joints of both hands)
(3) Fewer than three swollen metacarpophalangeal (MCP) joints
(4) Deformity of at least one of ten selected joints

E. Treatment

1. Goals

a. Control pain and other symptoms
b. Maintain or improve joint mobility
c. Correct or minimize functional limitations and disability

2. Nonpharmacological treatments

a. Patient education may include tips on joint protection, community exercise programs, and support groups.
b. Weight loss (if overweight) has been shown to decrease pain and symptoms of OA.
c. Aerobic exercise programs; bedrest and immobility are not necessary with OA.
d. Physical therapy for range-of-motion exercises and strengthening.
e. Assistive devices (e.g., canes, walkers, crutches) may help decrease the load on a joint; however, patients should be instructed on their proper use for safety.
f. Acupuncture leads to improvements in pain and function after 26 weeks, compared to placebo or arthritis education in patients with mild knee OA.
g. Wedge insoles can help reduce mechanical stress in persons with medial knee OA.
h. Thermal therapy (e.g., hot shower or tub, ice pack) may be of benefit for some patients with OA.

3. Pharmacological treatment

a. Acetaminophen (APAP) is considered first-line therapy by the ACR for OA of the hip or knee. It has excellent analgesic and antipyretic activity, but no anti-inflammatory effects.

(1) A dose of ≤ 4 g/day is recommended to avoid toxicity. Concomitant use of other medications with acetaminophen should be evaluated closely to avoid overdose.

(2) Hepatotoxicity can occur in patients taking > 4 g acetaminophen a day. Symptoms can include nausea, vomiting, abdominal pain, malaise, and diaphoresis. In patients with chronic stable liver disease, doses of up to 4 g/day did not cause any evidence of hepatotoxicity.

(3) Because there is little, if any, inflammation in the OA joint, APAP has been shown to be equally efficacious as ibuprofen and naproxen in patients with mild to moderate OA pain.

(4) Studies have shown either APAP immediate-release or extended-release is effective in treating mild to moderately-severe OA pain.

b. Nonsteroidal anti-inflammatory drugs (NSAIDs) and **cyclooxygenase 2 (COX-2) specific inhibitors** are indicated in OA treatment when the response to APAP is inadequate (Table 50-1).

(1) Mechanism of action. NSAIDs are nonselective inhibitors of COX-1 and -2 as well as thromboxane synthetase.

(2) Analgesia is seen with a short treatment duration and at lower doses (e.g., ibuprofen ≤ 1200 mg/day).

(3) Anti-inflammatory response is seen with higher doses and usually requires several days of therapy to achieve anti-inflammatory affect.

Table 50-1. Selected Anti-Inflammatory Drugs

Generic (Brand)	Initial Daily Dose	Maximum Daily Dose
Nonacetylated salicylates		
Salsalate (Disalcid)	1000 mg twice a day	3000 mg
Nonsteroidal anti-inflammatory drugs		
Aspirin (various)	650 mg every 4 hr	6000 mg
Diclofenac (Voltaren)	75 mg twice a day	200 mg
Ibuprofen (Motrin, Advil)	400 mg three times a day	3200 mg

Naproxen (Naprosyn, Aleve)	500 mg twice a day	1500 mg
Nabumetone (Relafen)	1000 mg once a day	2000 mg
Sulindac (Clinoril)	150 mg twice a day	400 mg
Tolmetin (Tolectin)	400 mg three times a day	1800 mg
Cyclooxygenase 2 inhibitor		
Celecoxib (Celebrex)	100 mg twice a day	400 mg

(4) Adverse effects. The FDA mandates that a published NSAID Medication Guide be issued with all NSAID prescriptions informing patients about the potential adverse effects.

(a) Gastrointestinal (GI) toxicity is caused by direct mucosal injury and inhibition of prostaglandins. Symptoms include dyspepsia, ulceration, and bleeding.

(i) COX-2 inhibitors may be an option for patients with a history of peptic ulcer disease; however, the GI safety of these agents has not been demonstrated long term.

(ii) People at risk for GI toxicity include the elderly and those with a history of peptic ulcer disease, chronic alcohol use, high-dose or multiple NSAID use, concomitant corticosteroid use, and NSAID treatment of < 3 months.

(b) Renal toxicity results from the inhibition of prostaglandins. While the risks are low (~ 5%), it does not appear to be dose dependent and is usually reversible.

(i) Effects can include hyperkalemia, hyponatremia, increased serum creatinine, sodium and water retention, and acute renal failure.

(ii) People at risk for renal toxicity include the elderly and those with preexisting renal disease, hypertension, diabetes mellitus, congestive heart failure, cirrhosis, and volume depletion (e.g., hemorrhage, sepsis, diuretics, diarrhea).

(c) Hematological effects are the result of decreased platelet aggregation.

(d) Hepatic toxicity, although not common, can include elevated liver enzymes. Patients at risk include those with a history of hepatitis, alcoholism, and heart failure.
(e) CNS effects can include sedation, confusion, and mental status changes and are primarily seen in the elderly.
(f) Allergic reactions, such as asthma, urticaria, and photosensitivity, may be seen. Cross-sensitivity has been seen in patients allergic to aspirin.
(g) Cardiovascular (CV) effects (e.g., myocardial infarction, stroke, hypertension, and heart failure) have been reported. Rofecoxib and valdecoxib were voluntarily withdrawn from the market in 2005 owing to their association with CV disease and mortality. Studies of celecoxib have shown a dose-related increase in CV events in patients with a history of colorectal neoplasia who were at risk of recurrent adenomatous polyps. The U.S. Food and Drug Administration (FDA) recommends using celecoxib at the lowest possible dose for least time possible.

c. Other oral analgesics

(1) Tramadol (Ultram). Considered a good choice when the patient's pain is unrelieved by NSAIDs, when the patient cannot take NSAIDs, or when the patient experiences breakthrough pain while taking NSAIDs.
(a) Mechanism of action. Centrally acting analgesic that inhibits the reuptake of norepinephrine and serotonin and mildly binds to the μ-receptor.
(b) Dose. 50-100 mg every 4-6 hr, not to exceed 400 mg/day; and 300 mg/day in the elderly. In patients with impaired renal function (creatinine clearance [CrCl] < 30 mL/min), the dosage interval should be every 12 hr, with a maximum dose of 200 mg. The extended release formulation is dosed 100 mg daily with a maximum dose of 300 mg/day.
(c) Adverse effects. Although it is not an opioid analgesic, its side effects are similar: nausea, constipation, rash, dizziness, somnolence, and orthostatic hypotension.
(d) Drug interactions. Carbamazepine can decrease the effects of tramadol. Increased toxicity can occur with the concomitant use of quinidine, cimetidine, and selective serotonin reuptake inhibitors (SSRIs; e.g., paroxetine, sertraline, fluoxetine).
(2) Opiate analgesics (e.g., codeine, oxycodone) are usually reserved for patients who fail single- or multiple-analgesic therapy. They may also be useful for acute exacerbations of pain. Side effects can include constipation, sedation, nausea, respiratory depression, and confusion.
(3) Propoxyphene. The use of propoxyphene is controversial, as it has demonstrated efficacy similar to acetaminophen. The clinician must also consider the acetaminophen content (650 mg) of propoxyphene/acetaminophen (e.g., Darvocet-N 100 mg) and the potential for overdose. Propoxyphene should be avoided in the elderly.
(4) Topical analgesics (e.g., capsaicin) are effective in relieving OA pain in some patients. Topical therapy can be used in conjunction with oral

therapy or as monotherapy. Capsaicin is derived from hot chili peppers and with chronic use (> 2 weeks) works

by depleting stores of substance P. Patients should be counseled to wash hands thoroughly after application to avoid contact with other skin to avoid burning and stinging.

(5) Intra-articular injections

(a) Corticosteroids may be useful in knee OA when inflammation is present but are not routinely recommended in hip OA owing to administration difficulties. Duration of action is up to 4 weeks. Because of adverse effects on the bone, injections should be limited to three or four per year. Long-term benefits and safety have not been established definitively.

(b) Hyaluronic acid derivatives. Indicated for the treatment of knee OA when treatment failure to other therapies occurs. Intended to improve elasticity and viscosity of synovial fluid. **Sodium hyaluronate (Hyalgan;** 2 mL weekly for 5 weeks) and **hylan polymers (Synvisc;** 2 mL weekly for 3 weeks) are the two agents currently available. Most benefits are seen after the last dose; effects are superior to placebo and comparable to corticosteroid injections. These agents should be used with caution in patients with allergies to avian proteins, feathers, and egg products. Patients should be counseled to avoid strenuous or prolonged (> 1 hr) weight-bearing activities within 48 hr after treatment.

(6) Adjunctive treatments. These agents are widely used by patients; however, efficacy has not been consistently demonstrated in controlled trials.

(a) Glucosamine acts as a substrate for and promotes the synthesis of the glycosaminoglycans.

(i) The dose is 500 mg three times a day.

(ii) Side effects may include GI discomfort, fatigue, and skin rash.

(b) Chondroitin helps protect against the breakdown of collagen and proteoglycans. It is usually found in combination with glucosamine, but the added benefits are not clear.

(i) The dose is 1200 mg/day.

(ii) Side effects can include prolonged bleeding time and nausea.

(c) The mechanism of **S-adenosylmethionine (SAMe)** is unclear; however, it does play a role in maintaining cartilage. The dose is 600 mg/day for 2 weeks, then 400 mg/day.

(7) Surgical interventions (e.g., arthroscopy, joint replacement) are considered when pain is severe and not responding to medical treatment or when disability interferes with daily activities.

IV. RHEUMATOID ARTHRITIS

A. Etiology and pathogenesis. The cause of RA is not fully understood but appears to be multifactorial. It is considered an autoimmune disease, in

which the body loses its ability to distinguish between synovial and foreign tissue. Other factors involved in RA are as follows:

1. Environmental influences, such as bacterial and viral infections, are thought to play a role in the development of RA.

2. Genetic markers, such as human leukocyte antigen DR4 (HLA-DR4), have been associated with triggering the inflammatory process in RA. However, such markers are not considered diagnostic because as up to 30% of people with HLA-DR4 never develop RA.

3. Tumor necrosis factor α (TNF-α), **IL-1, IL-6,** and **growth factors** propagate the inflammatory process, and agents found to alter these cytokines show promise in reducing pain and deformity.

4. Inflamed synovium is a hallmark of the pathophysiology of RA. Synovium proliferates abnormally, growing into the joint space and into the bone, forming a pannus. The pannus migrates to the articular cartilage and into the subchondral bone. Through stimulation by the cytokines, the cells of the pannus produce proteolytic enzymes, which degrade cartilage. These same cytokines activate osteoclasts, which causes the demineralization of bone.

B. Clinical manifestations

1. The onset of RA is insidious. In early disease, symptoms include malaise and anorexia, accompanied by symmetrically tender and swollen joints. Pain in the joints is common and aggravated by movement.

2. Most commonly, the joints first affected by RA include the MCP and PIP joints of the hands, the metatarsophalangeal (MTP) joints, and the wrists. Other areas affected by RA include the spine, shoulder, ankle, and hip.

C. Clinical course. The severity of the disease is variable.

1. Within 4 months of diagnosis, irreversible joint damage is detectable on radiographic images. The rate at which joint damage occurs is greatest during the 1st year.

2. Prognosis is poorest with an early onset of the disease, significant functional disability during the 1st year, involvement of 20 or more joints, the presence of rheumatoid nodules, or extra-articular involvement.

3. Extra-articular manifestations can include rheumatoid nodules, anemia, peripheral neuropathy, kidney disease, CV effects, and pulmonary disease.

4. Osteoporosis may occur secondary to RA in patients receiving treatment with corticosteroids.

D. Diagnosis and clinical evaluation. The ACR classifies RA by having at least four of the following seven criteria, and the first four criteria must have been present for at least 6 weeks:

1. Morning stiffness for 1 hr

2. Arthritis of three or more joint areas of the hand, wrist, elbow, knee, ankle, or foot

3. Arthritis of hand joints—swelling in at least one area in a wrist, MCP, or PIP joint
4. Symmetrical arthritis—simultaneous involvement of the same joint areas on both sides of the body
5. Rheumatoid nodules—observable subcutaneous nodules, over bony prominences or extensor surfaces
6. Serum rheumatoid factor and anti-cyclic citrullinated peptide antibody (see VIII.E.3)
7. Radiological changes (see VIII.F)

E. Laboratory assessment

1. Rheumatoid factor (RF) is found in > 60% of patients with RA; however, as many as 5% of healthy individuals will have elevated titers of RF. If initially negative, the test can be repeated in 6-12 months. The most commonly found rheumatoid factors are IgM and IgG. IgA is also a good indicator because it correlates well with the erythrocyte sedimentation rate (ESR). RF is not an accurate measure of disease progression.
2. ESR and C-reactive protein (CRP) are markers of inflammation and are usually elevated in patients with RA. They can also help indicate the activity of the disease, but they do not indicate disease severity.
3. Anti-cyclic citrullinated peptide antibodies (anti-CCP) are found in most patients with RA and are useful in predicting erosive disease.
4. Because anemia is a common feature of RA, a **complete blood count (CBC)** should be regularly obtained. Anemia associated with RA tends to be hypochromic in 50%-100% of RA cases, and mild leukocytosis is evident in 25% of cases.
5. The **antinuclear antibody (ANA)** test is positive in 15% of patients with RA.

F. Radiographic examination. Baseline evaluations of the feet and hands are important to ascertain structural damage. As the disease progresses, evidence of periarticular osteopenia becomes apparent. The radiograph is a good indicator of the extent of bone erosion and cartilage loss. An MRI study detects the proliferative pannus.

G. Treatment objectives. The goals in the management of RA are
1. To prevent or control joint damage
2. To prevent loss of function
3. To decrease pain
4. To maintain the patient's quality of life
5. To avoid or minimize adverse effects of treatment

H. Prognosis. Poor prognostic factors include active disease with multiple tender and swollen joints, evidence of erosions seen on radiographs, elevated RF and/or Anti-CCP antibody, and elevated ESR and/or CRP. Additionally, worse outcomes, including disability and morbidity, are

associated with female gender, advancing age, cigarette smoking, and genotype.

I. Therapy. The American College of Rheumatology (ACR) published updated treatment recommendations in 2008 on non-biological and biological disease modifying drugs. Nonpharmacological therapy and treatment with anti-inflammatory drugs was not included in the 2008 report.

1. Nonpharmacological. Optimal therapy involves both drug- and nondrug therapy; however, non-drug therapy is considered adjuvant. Patients should be instructed on joint protection and range-of-motion exercises. Regularly scheduled rest periods are important to reduce physical stress on the joints. Physical therapy and occupational therapy may help patients maintain their activities of daily living. Arthritis support groups may help with psychological well-being.

2. Pharmacological. Drug therapy for RA involves the treatment of symptoms for pain management and the use of disease modifying agents. Drugs with anti-inflammatory activity are the agents of choice for the symptomatic relief of RA, but these should not be used as monotherapy. These drugs are commonly used as “bridge therapy” as most disease modifying agents have a delayed onset of action. Factors such as cost, toxicity, compliance, and onset of action influence the selection of the disease-modifying drugs.

a. Anti-inflammatory drugs (e.g., salicylates, NSAIDs, and COX-2 inhibitors) reduce joint pain and swelling, but they do not alter the course of the disease or prevent joint destruction (Table 50-1).

b. Corticosteroids. Low-dose systemic corticosteroids (e.g., prednisone, methylprednisolone) can work well either orally or parenterally. They have excellent anti-inflammatory activity and are immunosuppressant. The lowest effective dose should be used because of adverse effects (e.g., hyperglycemia, GI toxicity, osteoporosis). These agents have shown to slow joint damage; however, they are often used to “bridge” therapy as patients start on disease-modifying antirheumatic drugs or during an acute attack.

c. Non-biological disease-modifying antirheumatic drugs (DMARDs) (Table 50-2) are used to reduce or prevent joint damage and preserve joint function and should be considered within 6 months of diagnosis. NOTE—the 2008 recommendations only assessed the use of methotrexate (MTX), leflunomide, sulfasalazine, hydroxychloroquine (HCQ), and minocycline. Other non-biological DMARDs were not mentioned due to lack of clinical efficacy, side effects, or both.

(1) Methotrexate (MTX; Rheumatrex) works by inhibiting dihydrofolate reductase and is considered standard therapy for RA. It is approved as monotherapy for RA, and is often used concurrently with other DMARDs or biologicals if response is poor to monotherapy or disease burden is high. Toxicity is often dose-related (e.g., GI, liver, pulmonary, hematologic) and can occur at anytime during therapy.

(2) Leflunomide (Arava) inhibits pyrimidine synthesis and is indicated as monotherapy for RA or can be used in combination with MTX.
(i) Liver toxicity can develop within 6 months of use. Liver function tests should be performed as recommended by the manufacturer.
(ii) In the event of serious adverse drug reactions or if the patient wishes to become pregnant, the use of cholestyramine is recommended to aid in the elimination of leflunomide because elimination can take up to 2 years without a binding agent.
(3) Sulfasalazine, Hydroxychloroquine (HCQ), and minocycline can be used as monotherapy or in conjunction with MTX. Sulfasalazine is recommended in patients without poor prognostic indicators regardless of disease duration or disease burden. Hydroxychloroquine and minocycline may be used if the duration of disease activity is ≤24 months or <6 months respectively, and if the disease burden is low.
P.1100

P.1101

Table 50-2. Disease-Modifying Antirheumatic Drugs (DMARDs)

Agent (Brand)	Time to Effect (months)	Starting Dose	Adverse Effects	Monitoring Parameters	Some Drug Interactions
Traditional DMARDs					
Methotrexate (Rheumatrex)	0.5-6	7.5-15 mg PO weekly	Nausea, diarrhea, mouth ulcers, hepatotoxicity, pulmonary toxicity, myelosuppression	LFTs, SrCr, CBC, chest x-ray Hepatitis B and C serology	Penicillin, cyclosporine, NSAIDs
Sulfasalazine (Azulfidine)	1-3	500 mg PO	Nausea, diarrhea, rash,	CBC, LFTs, SrCr	Iron, digoxin, warfarin

		BID; gradually increase to 2-3 g/day in 2-4 divided doses	photosensitivity		
Hydroxychloroquine (Plaquenil)	2-6	200-300 mg PO BID	Ocular toxicity, rash, nausea, myopathy	Eye exam, SrCr, CBC, LFTs	Cimetidine
Minocycline (Dynacin)	n/d	100 mg PO BID	GI, rash	CBC, LFTs	Calcium, magnesium, aluminum, iron
Biologicals					
Leflunomide (Arava)	1-4	100 mg/day PO × 3 days (load), then 10-20 mg/day	Diarrhea, nausea, infection, rash, HTN, alopecia, liver toxicity	LFTs, CBC, SrCr, PPD, Hepatitis B and C serology	MTX, rifampin, warfarin
Etanercept (Enbrel)	0.25-3	50 mg SC weekly	Abdominal pain, HA, injection site reactions,	PPD, CBC, LFTs, SrCr	cyclophosphamide

			infections		
Infliximab (Remicade)	0.5	3 mg/kg IV over 2 hr at weeks 0, 2, and 6; then every 8 weeks	Nausea, HA, abdominal pain, dizziness, hepatic, hematologic, infections	PPD, CBC, LFTs, SrCr	None known
Adalimumab (Humira)	0.25-1	40 mg SC every 2 weeks	Injection site reactions, infection, rash, HA	PPD, CBC, LFTs, SrCr	None known
Anakinra (Kineret)	0.25-1	100 mg/day SQ	HA, injection site reactions, infection	CBC with neutrophil counts, LFTs, SrCr	Entanercept, thalidomide
Abatacept (Orencia)	n/d	10 mg/kg IV at day 0; then 2 weeks, 4 weeks, and continuing every 4 weeks	Injection site reactions, infections, HA, nausea, HTN, nasopharyngitis	PPD, CBC, LFTs, SrCr	Anakinra, TNF-antagonists

Rituximab (Rituxan)	n/d	1000 mg IV at days 0 and 14	Injection site reactions, HTN, infections, nausea, arthralgia	Hepatitis B serology, CBC, LFTs, SrCr	Cisplatin
Less Frequently Used DMARDs					
Gold Salts (Aurolate)	3-6	25-50 mg IM every 2-4 weeks	Itching, rash, stomatitis, proteinuria, conjunctivitis	CBC with differential, SrCr, urinalysis	Penicillamine
D-penicillamine (Cuprimine)	3-6	125-250 mg PO daily; increase gradually to 250 mg TID	Nausea, rash, photosensitivity, myelosuppression	CBC, SrCr	Gold, iron, zinc, antacids, digoxin, antimalarials
Azathioprine (Imuran)	2-3	50-150 mg/day	Chills, fever, N/V, diarrhea, leucopenia	CBC, LFTs	Allopurinol
Cyclosporine (Neoral)	2-4	3-10 mg/kg/day	HTN, HA, nausea, paresthesia, leukopenia	BP, SrCr, LTFs, serum drug levels	CYP-450 3A/4 inhibitors, MTX, digoxin, allopurinol

					, glucocorticoids

BP, blood pressure; *CBC,* complete blood count; *HA,* headache; *HTN,* hypertension; *IM,* intramuscularly; *IV,* intravenously; *LFTs,* liver function tests; *MTX,* methotrexate; *n/d,* no data available; *N/V,* nausea and vomiting, *NSAIDs,* nonsteroidal anti-inflammatory drugs; *PO,* by mouth; *PPD,* tuberculosis skin test; *SC,* subcutaneously; *SrCr,* serum creatinine; including 2008 recommendations by the ACR.

d. The newest class of agents used as RA disease modifiers are the **Biological DMARDs** (Table 50-2). These agents should be used only after failure of nonbiological DMARDs. They can also reduce or prevent joint damage and preserve joint function. NOTE: the only biologicals included in the 2008 guidelines are abatacept, adalimumab, etanercept, infliximab, and rituximab. The remaining biologic DMARDs were not included because of very infrequent use, the high incidence of side effects, or both.

(1) TNF-alpha blockers (e.g., etanercept (Enbrel), Infliximab (Remicade), and adalimumab (Humira)) inhibit the inflammatory response mediated in immune cells. Etanercept and adalimumab can be used as monotherapy or in conjunction with MTX. Infliximab is only F.D.A. approved for use with MTX in RA. These drugs are recommended if high disease activity is present early in the course of the illness (<3 months) with features poor prognosis. These drugs are usually considered when patients do not achieve an acceptable response to MTX o other non-biological DMARDs.

(2) Abatacept (Orencia) is the first selective modulator of a co-stimulatory signal required for full T cell activation. It is used as monotherapy or concomitantly with non-biologic DMARDs; however, concurrent administration with TNF antagonists or anakinra is not recommended. Patients with chronic obstructive pulmonary disease should be monitored closely for worsening respiratory status. The 2008 recommendations state abatacept should be used in patients with at least moderate disease activity and poor prognostic indicators who fail MTX and other DMARDs.

(3) Rituximab (Rituxan) is an anti-CD20 monoclonal antibody. Depletion of the CD20+ B cells appears to affect the autoimmune response and helps with the chronic synovitis associated with RA. It is used when the patient fails MTX and/or multiple DMARDs and has high disease burden and poor

prognosis. Severe, even fatal, infusion reactions have been reported. A dose is given at weeks 0 and 14; time to re-treat is undetermined.

(4) Anakinra (Kineret) is an IL-1 receptor antagonist. It is used as monotherapy or in conjunction with any DMARD except a TNF blocker. The manufacturer recommends that a baseline neutrophil count be obtained and then re-evaluated monthly for 3 months; and quarterly thereafter for the first year.

e. Combination therapy. Concurrent use of several non-biological DMARD agents has been studied. The 2008 guidelines support the following combinations: MTX + HCQ, MTX + sulfasalazine, MTX + leflunomide, and sulfasalazine + HCQ + MTX. Some patients currently receiving DMARD therapy with new or worsening symptoms have benefited from combination therapy. Combination therapy with multiple biological DMARDs were not recommended in the 2008 guidelines due to increased side effects and/or lack of efficacy.

f. Treatment recommendations are published by the American College of Rheumatology and are available at www.rheumatology.org.

3. Surgical treatment (e.g., carpal tunnel release, total joint arthroplasty, joint fusion) may be considered when pain is severe, range of motion is lost, or joint function is poor owing to joint damage. Patients with good preoperative functional status generally have a relatively fast rate of recovery.

STUDY QUESTIONS

Directions for questions 1-3: The questions in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

1. Which of the following statements best characterizes osteoarthritis (OA)?

(I) OA is a systemic disease that is characterized by profound, diffuse inflammation, resulting in joint destruction, deformity, and disability.

(II) OA is a common disorder characterized by cartilage degeneration that can cause joint pain, decreased functioning, and disability.

(III) OA, the most common form of arthritis, can result from age-related changes in the joint, loss of function of the chondrocytes, and proteoglycan depletion.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***1. The answer is D(I, II) [see IA;and].*****For questions 2-3:** Betty is 65 years old; is obese; and has Type 2 diabetes mellitus, diabetic nephropathy, renal insufficiency, and hypertension. She works as a seamstress. She was active as a younger woman, played several sports and skied. She injured her right knee in a skiing accident. She complains of hand pain and stiffness and right knee pain and stiffness. Morning stiffness lasts < 30 min. No crepitus is heard on joint manipulation.

2. All of the following nonpharmacological treatments should be recommended for Betty *except*

(I) lose weight

(II) engage in aerobic exercise programs

(III) limit activity to ≤ 30 min at one time and rest the joint as often as possible

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***2. The answer is B(III) [see].*****3. Which of the following pharmacological agents is relatively contraindicated for the treatment of Betty's osteoarthritis (OA)?**

(I) oxycodone

(II) acetaminophen

(III) diclofenac

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***3. The answer is B(III) [see III.E.4.b.(ii)].*****Directions for questions 4-8:** Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

4. Which set of factors is associated with a poor prognosis of rheumatoid arthritis (RA)?

(A) absence of rheumatoid factor (RF), minimal inflammation, limited joint involvement at the onset

(B) family history of the disease, high serum concentrations of erythrocyte sedimentation rate (ESR) and c-reactive protein (CRP)

(C) poor response to aspirin or other nonsteroidal anti-inflammatory drugs (NSAIDs), and female gender

(D) good response to methotrexate (MTX), presence of rheumatoid factor, low ESR and/or CRP

(E) high RF and anti-cyclic citrullinated peptide (anti-CCP) antibody titers, radiographic evidence of multiple joint erosions

View Answer***4. The answer is E[see].*****5. All of the following statements are true about the use of hyaluronic acid derivatives *except* which one?**

(A) Injections must be given in weekly intervals, and optimal effects are seen after the last dose.

(B) These are viable options for patients with osteoarthritis (OA) of the hip.

(C) Patients should avoid strenuous activities for 2 days after treatment.

(D) Use caution when prescribing these products to patients with allergy to eggs or feathers.

(E) These are considered second-line therapy when other treatments have failed.

View Answer***5. The answer is B[see].***P.1104

6. Which of the following agents necessitates an ophthalmic examination to monitor for toxicity?

(A) penicillamine

(B) methotrexate

(C) hydroxychloroquine

(D) cyclosporine

(E) auranofin

View Answer***6. The answer is C[see].*****7. Which of the following biological disease-modifying antirheumatic drugs (DMARDs) can be given orally?**

(A) Leflunomide

(B) Etanercept

(C) Abatacept

(D) Anakinra

(E) Infliximab

View Answer***7. The answer is A[see].*****8. Osteoporosis is associated with the use of which of the following drugs used in rheumatoid arthritis (RA)?**

(A) leflunomide

(B) prednisone

(C) methotrexate

(D) penicillamine

(E) hydroxychloroquine

View Answer***8. The answer is B[see].***P.1105

ANSWERS AND EXPLANATIONS

1. The answer is D *(I, II) [see IA;* III.A.1, 2, 3, 4, 5, 6 *and 7].*

Osteoarthritis is not considered a disease of inflammation. Although there are times of minor inflammation (e.g., OA flare), it is localized to the affected joint(s).

2. The answer is B *(III) [see* III.E.2*].*

Nonpharmacological treatment should include aerobic exercise, physical therapy, joint protection, thermal therapy, and weight loss (if the patient is overweight).

3. The answer is B *(III) [see III.E.4.b.(ii)].*

Patients at higher risk of renal toxicity include the elderly; patients with hypertension, diabetes, heart failure, or cirrhosis; patients who are volume depleted; and patients who have preexisting renal disease.

4. The answer is E *[see* IV.H*].*

Factors associated with a poor prognosis for RA include active disease with multiple tender and swollen joints, evidence of erosions seen on radiographs, elevated RF and/or Anti-CCP antibody, and elevated ESR and/or CRP. Additionally, worse outcomes, including disability and morbidity, are associated with female gender, advancing age, cigarette smoking, and genotype.

5. The answer is B *[see* III.E.3.c;5.b.*].*

Hyaluronic acid derivatives are indicated only for OA of the knee.

6. The answer is C *[see* Table 50-2*].*

An ophthalmic exam is recommended when patients are receiving hydroxychloroquine.

7. The answer is A *[see* Table 50-2*].*

The only biological DMARD that can be given orally is leflunomide.

8. The answer is B *[see* IV.I.2.b.*].*

Steroid (e.g., prednisone) use can lead to osteoporosis; therefore, patients taking prednisone should consider therapy with calcium and a bisphosphonate.

51

Hyperuricemia and Gout

Larry N. Swanson

I. INTRODUCTION

A. Definitions

1. Hyperuricemia refers to a serum uric acid level that is elevated more than two standard deviations above the population mean. In most laboratories, the upper limit of normal is 7 mg/dL (uricase method). However, the level varies with the laboratory method used; the upper limit of normal is about 1 mg/dL lower for women than for men.

2. Gout is a disease that is characterized by recurrent acute attacks of urate crystal-induced arthritis. It may include **tophi**—deposits of monosodium urate—in and around the joints and cartilage and in the kidneys, as well as uric acid nephrolithiasis.

B. General information

1. The prevalence of gout is believed to be 8.4 per 1000 individuals in the United States but this estimate is based on patient self-reporting; thus this figure may overestimate the true prevalence.

2. Most gout victims are men (approximately 95% of cases); most women with the disease are postmenopausal.

3. The mean age at disease onset is 47 years.

4. The risk of developing gout increases as the serum uric acid level rises. Virtually all gout patients have a serum uric acid level > 7 mg/dL.

5. Research shows that among patients with a serum uric acid level above 9 mg/dL, the cumulative incidence of gout reached 22% after 5 years.

6. Gout has a familial tendency; 10%-60% of cases occur in family members of patients with the disease.

7. Obesity, hypertension, hyperlipidemia, atherosclerosis, and alcohol abuse are often associated with hyperuricemia and gout. Certain nutritional strategies (i.e., achieving ideal body weight or limitation of alcohol intake) can treat both the hyperuricemia and the associated conditions.

C. Uric acid production and excretion

1. Uric acid, an end product of **purine metabolism,** is produced from both dietary and endogenous sources. Its formation results from the conversion of adenine and guanine moieties of nucleoproteins and nucleotides (Figure 51-1).

2. Xanthine oxidase catalyzes the reaction that occurs as the final step in the degradation of purines to uric acid.

3. The body ultimately excretes uric acid via the kidneys (300-600 mg/day; two thirds of total uric acid) and via the gastrointestinal (GI) tract (100-300 mg/day; one third of the total uric acid).

4. Uric acid has no known biological function.

5. The body has a total uric acid content of 1.0-1.2 g; the daily turnover rate is 600-800 mg.

6. At a pH of 4.0-5.0 (i.e., in urine), uric acid exists as a poorly soluble free acid; at physiological pH, it exists primarily as **monosodium urate salt.**

7. Uric acid filtration, reabsorption, and secretion sites are shown in Figure 51-2.

P.1107

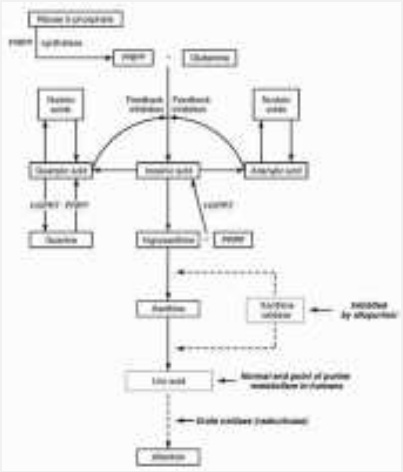

Figure 51-1. Uric acid formation. *HGPRT,* hypoxanthine-guanine phosphoribosyltransferase; *PRPP,* phosphoribosyl-1-pyrophosphate. [Adapted with permission from DiPiro J, Talbert R, Yee G, et al. Pharmacotherapy—A Pathophysiologic Approach, 5th ed. The McGraw-Hill companies, 2002:1660.]

D. Cause. Hyperuricemia and gout may be primary or secondary.

1. Primary hyperuricemia and **gout** apparently result from an innate **defect in purine metabolism** or **uric acid excretion.** The exact cause of the defect usually is unknown.

a. Hyperuricemia may result from **uric acid overproduction, impaired renal clearance of uric acid,** or a **combination** of these.

b. Some patients with primary hyperuricemia and gout have a known enzymatic defect, such as hypoxanthine-guanine phosphoribosyltransferase (HGPRT) deficiency or phosphoribosyl-1-pyrophosphate (PRPP) synthetase excess (Figure 51-1).

c. Principally for therapeutic purposes, patients with primary hyperuricemia and gout can be classified as **overproducers** or **underexcretors** of uric acid.

(1) Overproducers (about 10% of patients) synthesize abnormally large amounts of uric acid and excrete excessive amounts: > 800-1000 mg daily on an unrestricted diet

P.1108

or > 600 mg daily on a purine-restricted diet. These individuals generally have a markedly increased miscible urate pool (> 2.5 g).

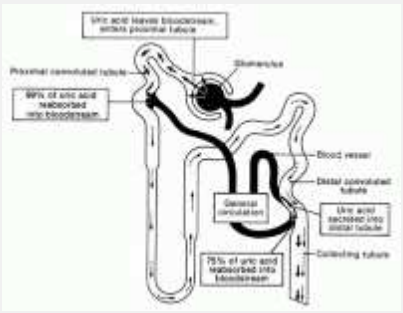

Figure 51-2. Uric acid filtration, reabsorption, and secretion sites. At the glomerulus, uric acid is filtered and enters the proximal tubule. There, approximately 99% of uric acid is reabsorbed into the bloodstream. At the distal tubule, uric acid is secreted; subsequently, about 75% of the amount secreted is reabsorbed. Therefore, almost all urinary uric acid is excreted at the distal tubule.

(2) Underexcretors (about 90% of patients) generally produce normal or nearly normal amounts of uric acid but excrete < 600 mg daily on a purine-restricted diet. They generally have only a slightly increased miscible urate pool. Some underexcretors are also overproducers.

2. Secondary hyperuricemia and **gout** develop during the course of another disease or as a result of drug therapy.

a. Hematological causes of hyperuricemia and gout (associated with increased nucleic acid turnover and breakdown to uric acid)

(1) Lymphoproliferative disorders

(2) Myeloproliferative disorders

(3) Certain hemolytic anemias and hemoglobinopathies

b. Chronic renal failure. In this condition, reduced renal clearance of uric acid can lead to hyperuricemia.

c. Drug-induced disease

(1) Aspirin and **other salicylates** inhibit tubular secretion of uric acid when given in low doses (e.g., < 2 g/day of aspirin). At high doses, these agents frequently cause uricosuria.

(2) Cytotoxic drugs increase uric acid concentrations by enhancing nucleic acid turnover and excretion.

(3) Diuretics (except spironolactone) may cause hyperuricemia; most likely, this occurs either via volume depletion, which, in turn, increases proximal tubular reabsorption, or via impaired tubular secretion of uric acid.

(4) Ethambutol and **nicotinic acid** increase uric acid concentrations by competing with urate for tubular secretion sites, thereby decreasing uric acid excretion.

(5) Cyclosporine decreases renal urate clearance, as do **pyrazinamide** and **levodopa.**

(6) Ethanol alters uric acid metabolism both by **increasing uric acid production** through an increase in adenine nucleotide catabolism and by **suppressing renal**

uric acid excretion as a result of lactate inhibition of renal tubular uric acid secretion.

d. Miscellaneous disorders. Diabetic ketoacidosis, psoriasis, and chronic lead poisoning are examples of conditions that may cause hyperuricemia.

E. Pathophysiology

1. Gouty arthritis develops when **monosodium urate crystals** are deposited in the synovium of involved joints.

2. An **inflammatory response** to monosodium urate crystals leads to an attack of acute gouty arthritis; painful joint swelling is characterized by redness, warmth, and tenderness. A systemic reaction may accompany joint symptoms.

3. If gout progresses untreated, **tophi,** or **tophaceous deposits** (deposits of monosodium urate crystals) eventually lead to joint deformity and disability; kidney involvement may lead to renal impairment. However, these developments are uncommon in the general gout population and represent late complications of hyperuricemia.

4. Renal complications of hyperuricemia and gout can have serious consequences.

a. Acute tubular obstruction

(1) This complication may develop secondary to uric acid precipitation in the collecting tubules and ureters, with subsequent blockage and renal failure. It is most common in patients with gout secondary to myeloproliferative or lymphoproliferative disorders, particularly after chemotherapy when allopurinol is omitted.

(2) Another agent, **urate oxidase** (Rasburicase), may be used in the prophylaxis and treatment of hyperuricemia in pediatric patients with leukemia, lymphoma, and solidtumor malignancies who are receiving anticancer therapy. This agent works by converting uric acid into allantoin, which is five times more soluble in urine than uric acid.

b. Urolithiasis. Occurring in about 20% of gout patients, urolithiasis is characterized by formation of uric acid stones in the urinary tract. Low urine pH seems to be a contributing factor. The risk of urolithiasis rises as serum and urinary uric acid levels increase.

c. Chronic urate nephropathy. In this complication, urate deposits arise in the renal interstitium. Most clinicians agree, however, that chronic hyperuricemia rarely, if ever, leads to clinically significant nephropathy. The presence of concomitant disease (e.g., diabetes mellitus, hypertension) may explain the finding of nephropathy in gout patients.

F. Clinical presentation. Clinical evaluation and the need for intervention depend on the clinical presentation.

1. Asymptomatic hyperuricemia

2. Acute gouty arthritis

3. Intercritical gout

4. Chronic tophaceous gout

II. ASYMPTOMATIC HYPERURICEMIA

is characterized by an elevated serum uric acid level but has no signs or symptoms of deposition disease (arthritis, tophi, or urolithiasis).

A. Clinical presentation. No definitive evidence indicates that asymptomatic hyperuricemia is harmful. Serum urate levels of up to 13 mg/dL in men and 10 mg/L in women have not been shown to cause a deterioration in renal function. Clinicians cannot predict which asymptomatic patients will develop gout symptoms or hyperuricemia-related complications. However, the risk of symptom development and complications increases as the serum uric acid level rises.

B. Therapy. Asymptomatic hyperuricemia does not have any adverse effects before the development of gout. Therefore, **drug treatment is not required,** although it is prudent to determine the causes of the hyperuricemia and correct them, if possible. **Supportive interventions** may include maintenance of adequate urine output (to prevent uric acid stone formation), avoidance of high purine foods, and regular medical appointments to monitor the serum uric acid level and check for clinical evidence of deposition disease.

III. ACUTE GOUTY ARTHRITIS.

This clinical presentation of gout is characterized by **painful arthritic attacks** of sudden onset.

A. Pathogenesis. Monosodium urate crystals form in articular tissues; this process sets off an inflammatory reaction. Trauma, exposure to cold, or another triggering event may be involved in the development of the acute attack.

B. Signs and symptoms

1. The **initial attack** is abrupt, usually occurring at night or in the early morning as synovial fluid is reabsorbed. This severe arthritic pain progressively worsens and generally involves only one or a few joints.

a. The **affected joints** typically become hot, swollen, and extremely tender. Seventeenthcentury British physician Thomas Sydenham described his personal experience with gout this way: “Now it is a violent stretching and tearing of the ligaments—now, it is a gnawing pain and now a pressure and tightening. So exquisite and lively ... is the feeling of the part affected, that it cannot bear the weight of bedclothes nor the jar of a person walking in the room.”

b. The **most common site** of the initial attack is the **first metatarsophalangeal joint;** an attack there is known as **podagra.** Other sites that may be affected include the instep, ankle, heel, knee, wrist, elbow, and fingers.

2. The first few untreated attacks typically last 3-14 days. Later attacks may affect more joints and take several weeks to resolve.

3. During recovery, as edema subsides, local desquamation and pruritus may occur.

4. Systemic symptoms during an acute attack may include fever, chills, and malaise.

C. Diagnostic criteria

1. Definitive diagnosis of gouty arthritis can be made by demonstration of **monosodium urate crystals** in the synovial fluid of affected joints. These needle-shaped crystals are termed negatively birefringent when viewed through a polarized light microscope.
2. Serum analysis usually reveals an above-normal uric acid level: however, this finding is not specific for acute gout. Other **common serum findings** include leukocytosis and a moderately elevated erythrocyte sedimentation rate.
3. A **dramatic therapeutic response to colchicine** may be helpful in establishing the diagnosis, but this is not absolute because other causes of acute arthritis may respond as well.
4. When fluid cannot be aspirated from the affected joint, a **diagnosis of gout is supported by:**
a. A prior **history of acute monarticular arthritis** (especially of the **big toe**) followed by a **symptom-free period**
b. The presence of **hyperuricemia**
c. Rapid **resolution of symptoms after colchicine** therapy
5. Other conditions that may **mimic** gout include pseudogout (calcium pyrophosphate dihydrate crystal disease) or septic arthritis.
D. Treatment goals
1. To relieve pain and inflammation
2. To terminate the acute attack
3. To restore normal function to the affected joints
E. Therapy
1. General therapeutic principles
a. The affected joint (or joints) should be immobilized.
b. Anti-inflammatory drug therapy should begin immediately. For maximal therapeutic effectiveness, these drugs should be kept on hand so that the patient may begin therapy as soon as a subsequent attack begins.

c. Urate-lowering drugs **should not be given until the acute attack is controlled,** as these drugs may prolong the attack by causing a change in uric acid equilibrium.
2. Specific drugs. Any of the following agents may be used:
a. Nonsteroidal anti-inflammatory drugs (NSAIDs)
(1) Indications. Most physicians consider these drugs the agents of choice, especially the newer NSAIDs. These drugs may be preferred when treatment is delayed significantly after symptom onset or when the patient cannot tolerate the adverse GI effects of colchicine.
(a) Indomethacin (Indocin) is usually given in a dose of 50 mg three times daily until pain is tolerable; then the dose is rapidly reduced to complete cessation of the drug. Definite relief of pain usually occurs within 2-4 hr. Tenderness and heat usually subside in 24-36 hr, and swelling gradually disappears in 3-5 days. Do not use the sustained-release dosage form.

(b) Specific NSAIDs—such as **naproxen** (Naprosyn) 750 mg followed by 250 mg every 8 hr until the attack subsides or **sulindac** (Clinoril) 200 mg twice a day to start, reducing the dose with satisfactory response (7 days of therapy are usually adequate)—are specifically approved for this indication, but many other NSAIDs have been used successfully. There is no evidence that any particular NSAID is more effective than others in the treatment of an acute gouty attack. Some have also used selective cyclooxygenase 2 (COX-2) inhibitors for these attacks.

(2) Precautions and monitoring effects

(a) Adverse effects of indomethacin are usually dose related. These effects occur in 10%-60% of patients and may warrant drug discontinuation. They primarily include GI complaints of nausea and abdominal discomfort and central nervous system (CNS) effects of headaches and dizziness. Indomethacin should be taken with food or milk to minimize gastric mucosal irritation.

(b) Precautions. NSAIDs, in general, require cautious use in patients with a history of hypertension, congestive heart failure (CHF), peptic ulcer disease, or mild to moderate renal failure.

b. Colchicine. The traditional drug for relieving pain and inflammation and ending the acute attack, colchicine is most effective when initiated 12-36 hr after symptoms begin (the period of maximal leukocyte migration). Some would use this agent only if the patient is intolerant to NSAIDs or for those who have used colchicine successfully in the past.

(1) Mechanism of action. Colchicine apparently **impairs leukocyte migration** to inflamed areas and disrupts urate deposition and the subsequent inflammatory response.

(2) Dosage and administration

(a) Oral regimen

(i) The effective dose of colchicine in patients with acute gout is close to that which causes GI symptoms. The drug usually is administered orally in a dose of 1.2 mg initially, followed by 0.6 mg every 2 hr until pain relief occurs or abdominal discomfort or diarrhea develops or a total dose of 6 to 8 mg has been administered. Except in patients who have renal or hepatic dysfunction or are elderly and frail, colchicine given in this way is safe, although it entails some discomfort for the patient.

(ii) Most patients have some pain relief by 18 hr and diarrhea by 24 hr; joint inflammation subsides gradually within 48 hr for 75%-80% of patients.

(iii) During **subsequent attacks,** patients may receive half of the total dose administered for the initial attack, then receive the remaining half as 0.6 mg every 1-2 hr.

(b) Intravenous (IV) regimen. This route is used rarely now when NSAIDs are contraindicated or when patients cannot take oral medications.

(i) A single dose of 2 mg usually is given in 30 mL of normal saline solution and infused slowly over 5 min. Two additional doses of 1 mg each may be given at 6-hr intervals, but the total dose should **never exceed 4** mg. The doses should be reduced by at least 50% in patients with hepatic or renal disease or in elderly

patients. Because it causes tissue irritation, colchicine should **never be given intramuscularly or subcutaneously.**

(ii) IV administration may relieve acute gouty arthritis more rapidly than oral administration. However, severe toxicity may occur without warning because the early signs of toxicity (e.g., GI hypermobility) may not occur.

P.1112

(3) Precautions and monitoring effects

(a) GI **distress** (e.g., nausea, abdominal cramps, diarrhea) occurs in up to 80% of patients receiving oral colchicine. This dosage form should be avoided in patients with peptic ulcer disease and other GI disorders.

(b) Local extravasation (causing local pain and necrosis) can occur with administration of IV colchicine. This risk can be reduced by use of a secure IV line.

(c) Colchicine therapy may cause bone marrow depression. This rare effect develops mainly in patients who receive excessive doses or who have underlying renal or hepatic disease. Excessively high acute doses (especially given intravenously) or long-term therapy may result in neurological, renal, hepatic, or other toxicity.

c. Corticosteroids

(1) Intra-articular injections of a corticosteroid are usually very effective in patients with acute monarticular gout, and their use is becoming more widespread as experience with the diagnostic aspiration of joints increases. Aspiration alone can sometimes greatly reduce the pain of gout. The appropriate dose of corticosteroids is related to the size of the joint: An intra-articular dose of **triamcinolone hexacetonide** (e.g., Aristospan intra-articular) 20-40 mg for a large joint such as the knee and lower doses for smaller joints

(2) Systemic corticosteroid therapy is administered usually only when NSAIDs and colchicine have been ineffective or are contraindicated. There are reports of good responses, without a rebound effect, to **oral prednisone** (30-50 mg per day initially, with the dose tapered during a period of 7-10 days). **IV glucocorticoids** or **subcutaneous ACTH** are options if patients can't receive oral prednisone. One approach is to give 40-80 USP units of adrenocorticotropic hormone (ACTH) twice daily for 2 days and then once daily for several additional days as needed. Others have used 40 U as a single injection.

IV. INTERCRITICAL GOUT

is the symptom-free period after the first attack. This phase may be interrupted by the recurrence of acute attacks.

A. Onset of subsequent attacks varies. In most patients, the second attack occurs within 1 year of the first, but in some it may be delayed for 5-10 years. A small percentage of patients never experience a second attack. If hyperuricemia is insufficiently treated, subsequent attacks may become progressively longer and more severe and may involve more than one joint.

B. Treatment goals

1. To reduce the frequency and severity of recurrent attacks
2. To minimize urate deposition in body tissues, thereby preventing progression to chronic tophaceous gout
C. Therapy. Gout can be prevented by identifying and correcting the cause of hyperuricemia or by administering drugs that inhibit the synthesis of urate or increase its excretion.
1. Nondrug urate-reducing measures. Potentially reversible factors that contribute to increased urate production include a high-purine diet (e.g., all meats, including organ meats, seafood, beans, peas, asparagus), obesity, and regular alcohol consumption. The purine content of the diet does not usually contribute more than 1.0 mg/dL to the serum urate concentration, but moderation in dietary purine consumption should be considered. Weight reduction sometimes reduces the serum uric acid level slightly; however, crash diets should be avoided. Drinking two or more beers increased the risk of gout by 2.5-fold in one study vs. a 1.6-fold increase for other spirits. Wine was not associated with an increased risk of gout.
2. Prophylaxis after resolution of an acute gout attack may consist of **low-dose colchicine,** 0.6 mg twice daily in the patient with normal renal function.
a. Adverse effects from colchicine at these doses are usually uncommon. In patients, particularly the elderly, who develop loose or diarrheal stools, 0.6 mg daily or every other day might suffice.
b. Low-dose NSAIDs may also be used, but the incidence of side effects is typically higher than with low doses of colchicine.

c. Generally, prophylaxis is administered for 6 months after normal serum uric acid levels are achieved. Prolonged use of these agents may prevent recurrent episodes of gouty arthritis, but they do not prevent the development of silent bony erosions and tophi deposits.
3. Urate-reducing drug therapy. Gout may be prevented by reducing serum urate concentrations to values < 6.0 mg/dL. A reduction to < 5.0 mg/dL may be required for the resorption of tophi. The decision to begin drug therapy should be carefully considered, as urate-lowering drug treatment should be lifelong. Urate-reducing drugs include **uricosurics,** which increase renal uric acid excretion, and the xanthine oxidase inhibitor, **allopurinol,** which reduces uric acid production.
a. Indications for therapy with a drug that lowers serum urate concentrations should be considered when **all** of the following criteria are met:
(1) The cause of the hyperuricemia cannot be corrected or, if corrected, does not lower the serum urate concentration to < 7.0 mg/dL.
(2) The patient has had two or three definite attacks of gout or has tophi.
(3) The patient is convinced of the need to take medication regularly and permanently.
b. Specific drug
(1) The only available **Uricosuric** on the U.S. market is now **probenecid** (Benemid). This drug is preferred for underexcretors. Long-term uricosuric therapy reduces the

incidence of gouty arthritis attacks, prevents formation of new tophi, and helps resolve existing tophi.

(a) Mechanism of action. Probenecid blocks uric acid reabsorption at the proximal convoluted tubule, thereby increasing the rate of uric acid excretion (Figure 51-2).

(b) Indications. Uricosurics generally are used to reduce hyperuricemia in patients who excrete < 600 mg of uric acid per day.

(c) Dosage and administration

(i) Probenecid is given initially in two daily oral doses of 250 mg for 1 week, then increased to 500 mg twice daily every 1-2 weeks until the serum uric acid level drops below 6 mg/dL. Most patients respond to a dose of 1.5 g/day or less.

(d) Precautions and monitoring effects

(i) Uricosuric therapy **should not be initiated during an acute gout attack.** During the first 6-12 months of therapy, these drugs may increase the frequency, severity, and duration of acute attacks (by changing the equilibrium of body urate). Therefore, some clinicians administer prophylactic colchicine concomitantly during the early months of uricosuric therapy.

(ii) The **risk** is **minimized** by concurrently **administering prophylactic drugs** (see IV.C.2), delaying urate-lowering therapy until several weeks after the last attack of gout, and starting therapy with a low dose of the drug that is chosen. When used concurrently with urate-lowering drugs, colchicine may be discontinued after the serum urate level becomes normal and is stable for 6 months.

(iii) Patients should maintain a **high fluid intake** (at least 2 L/day) and a high urine output during uricosuric therapy to decrease renal urate precipitation. The **greatest potential risks** of therapy with uricosuric drugs are the formation of **uric acid crystals** in urine and the deposition of **uric acid** in the **renal tubules, pelvis,** or **ureter,** causing renal colic or the deterioration of renal function. These risks can be reduced by initiating therapy with a low dose and increasing the dose slowly and by maintaining a high urine volume. Alkalinization of the urine is usually not necessary (but can be achieved with 1 g of sodium bicarbonate taken 3-4 times daily; plus a high fluid intake of at least 2 L/day).

(iv) Uricosurics are **contraindicated** in patients with urinary tract stones.

(v) These drugs generally are ineffective in patients with creatinine clearances below 50-60 ml/min.

(vi) Aspirin and **other salicylates** antagonize the action of uricosurics. **Daily low dose aspirin** for antiplatelet function **probably does not have this effect.**

In a small study, the addition of low dose aspirin to probenecid therapy did not alter the daily excretion of uric acid nor the serum uric acid level.

(vii) Probenecid is well tolerated by most patients, but it occasionally causes **adverse effects**—for example, GI distress (8%) and hypersensitivity reactions (5%).

(2) The only **xanthine oxidase inhibitor** available on the U.S. market is **allopurinol.**

(a) Mechanism of action. Allopurinol and its long-acting metabolite, **oxypurinol,** block the final steps in uric acid synthesis by inhibiting xanthine oxidase, an

enzyme that converts xanthine to uric acid (Figure 51-1). Thus the drug reduces the serum uric acid level while increasing the renal excretion of the more soluble oxypurine precursors; this decreases the risk of uric acid stones and nephropathy.

(b) Indications. Allopurinol is considered by many to be the drug of choice for lowering uric acid levels because of its effectiveness in both underexcretors and overproducers, but it is specifically the preferred urate-reducing agent for patients in the following categories:

(i) Patients who are clearly overproducers (overexcretors) of uric acid

(ii) Patients with recurrent tophaceous deposits or uric acid stones

(iii) Patients with renal impairment (but dose needs to be decreased)

(c) Dosage and administration. Allopurinol is given initially in a daily dose of 100-300 mg (preferably as a single dose), then increased in weekly increments if needed. Typically, the uric acid level starts to fall after 1-2 days with maximal effect for a given dose in 7-10 days. A dose of 300 mg/day reduces serum urate concentrations to normal values in 85% of patients with gout. The normal dose of 300 mg/day is for a patient with normal renal function; the dose should be decreased to 200 mg/day for a patient with a creatinine clearance (CrCl) of 60 mL/min and to 100 mg/day for a patient with a CrCl of 30 mL/min.

(d) Precautions and monitoring effects. Allopurinol is generally well tolerated.

(i) A **rash** develops in approximately 2% of patients treated with allopurinol and in approximately 20% of those receiving both allopurinol and ampicillin. The rash usually subsides after the allopurinol has been discontinued and may not recur if therapy is resumed with a lower dose.

(ii) The most serious side effect of allopurinol, which occurs in < 1 in 1000 cases, is **exfoliative dermatitis,** often with **vasculitis, fever, liver dysfunction, eosinophilia,** and **acute interstitial nephritis.** Up to 20% of patients with this type of reaction become very sick. It is more likely to occur in patients with renal disease or those receiving diuretic therapy. Prednisone seems to be effective in such patients, but the discontinuation of allopurinol and the use of supportive therapy may be sufficient in cases that are not severe.

(iii) Allopurinol may induce more frequent acute gout attacks. This risk can be minimized by administration of low doses and concurrent colchicine therapy.

(3) Other drugs that increase uric acid excretion

(a) Losartan (Cozaar), an angiotensin II receptor blocker (ARB), might be a useful antihypertensive agent in the patient who has **both hyperuricemia and hypertension** because this agent can lower serum uric acid levels by inhibiting the uptake of uric acid by the urate anion exchange transporter in the proximal tubule. This effect is minimal or not seen in other ARBs.

(b) Fenofibrate (TriCor) is a fibric acid agent used to treat elevated cholesterol and triglyceride levels. It has been shown to decrease serum uric levels by increasing renal uric acid clearance and would be a useful agent in the patient with **both hyperlipidemia and hyperuricemia.**

(c) Febuxostat, a non-purine-base analog xanthine oxidase inhibitor, is an investigational agent that may eventually reach the U.S. market.

V. CHRONIC TOPHACEOUS GOUT.

This rare clinical presentation may develop if hyperuricemia and gout remain untreated for many years.

A. Pathogenesis. Persistent hyperuricemia leads to the development of tophi in the synovia, olecranon bursae, and various periarticular locations. Eventually, articular cartilage may be destroyed, resulting in joint deformities, bone erosions, deposition of tophi within tissues, and renal disease.

P.1115

B. Clinical evaluation

1. Patients may develop large subcutaneous tophi in the pinna of the external ear (the classic site) as well as in other locations.

2. Typically, the urate pool is many times the normal size.

C. Therapy. Allopurinol and probenecid may be given in combination to treat severe cases.

P.1116

STUDY QUESTIONS

Directions for questions 1-3: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. All of the following statements concerning an acute gouty arthritis attack are correct *except* which one?

(A) The diagnosis of gout is ensured by a good therapeutic response to colchicine because no other form of arthritis responds to this drug.

(B) To be ensured of the diagnosis, monosodium urate crystals must be identified in the synovial fluid of the affected joint.

(C) Attacks frequently occur in the middle of the night.

(D) An untreated attack may last up to 2 weeks.

(E) The first attack usually involves only one joint, most frequently the big toe (first metatarsophalangeal joint).

View Answer***1. The answer is A[seeand].*****2. A 42-year-old obese man has been diagnosed with gout. He has had three acute attacks this year, and his uric acid level is presently 11.5 mg/**dL **(upper limit of normal is 7 mg/**dL**). He has no other diseases. Rational treatment of this patient during the interval period between gouty attacks might include any of the following *except***

(A) acetaminophen or aspirin 650 mg as needed for joint pain.

(B) probenecid.

(C) colchicine.

(D) allopurinol.

(E) a decrease in caloric intake.

View Answer***2. The answer is A[see].*****3. A 45-year-old man is admitted to the hospital with the diagnosis of an acute attack of gout. His serum uric acid is 10.5 mg/**dL **(normal is 3-7 mg/**dL**). Which of the following would be the most effective initial treatment plan?**

(A) Before treating this patient, immobilize the affected joint and obtain a 24-hr urinary uric acid level to determine which drug, either allopurinol or probenecid, would be the best agent to initiate therapy.

(B) Begin oral colchicine 1.2 mg initially, followed by 0.6 mg every 2 hr until relief is obtained, gastrointestinal distress occurs, or a maximum of 8 mg has been taken; also, begin probenecid 250 mg twice a day concurrently.

(C) Administer oral indomethacin 50 mg three times a day for 2 days; then gradually taper the dose over the next few days.

(D) Administer oral naproxen 750 mg, followed by 250 mg every 8 hr for 3 weeks.

(E) Give colchicine 0.5 mg intramuscularly followed by 1 mg intravenous piggyback every 12 hr for 2 weeks.

View Answer***3. The answer is C[see].***P.1117

Directions for question 4: The question in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

4. Allopurinol is recommended instead of probenecid in the treatment of hyperuricemia in which of the following situations?

(I) when the patient has several large tophi on the elbows and knees

(II) when the patient has an estimated creatinine clearance of 15 mL**/min**

(III) when the patient has leukemia and there is concern regarding renal precipitation of urate

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***4. The answer is E(I, II, III) [see].*****Directions for question 5:** The incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

5. In a patient who has had documented gouty arthritis and hyperuricemia and who also has hypertension, a preferred antihypertensive agent would be

(A) hydrochlorothiazide

(B) losartan

(C) clonidine

(D) lisinopril

(E) irbesartan

View Answer***5. The answer is B[see***P.1118

ANSWERS AND EXPLANATIONS

1. The answer is A *[see* III.B.1 *and* 2; III.C.1; III.C.3*].*

Other forms of acute arthritis may respond to colchicine, so that the diagnosis of gout cannot be established unequivocally by a good response to this agent. A definitive diagnosis requires the presence of urate crystals in the affected joint, although the presence of other symptoms or laboratory findings may suggest a probable diagnosis of gout.

2. The answer is A *[see* I.D.2.c.(1); IV.C*].*

Aspirin in doses < 2 g/day can inhibit uric acid secretion. Weight reduction, allopurinol or probenecid to lower the serum uric acid levels, and prophylactic colchicine are all appropriate interventions in the interval phase to reduce the incidence of acute gouty attacks.

3. The answer is C *[see* III.E.1.c; III.E.2.a; III.E.3.b.(1).(d).(i); IV.C*].*

Of the selections, the most effective initial plan in treating an acute attack of gout is to administer indomethacin orally, giving 50 mg three times a day for 2-3 days, then gradually tapering the dosage over the next few days. Even though joint immobilization is an appropriate initial step, drugs for pain relief should be administered as soon as possible. Uric acid modification therapy (allopurinol or probenecid) should not be initiated until the acute attack is under control. Initiating therapy with probenecid at this point may prolong the resolution of an acute attack of gouty arthritis, which can usually be accomplished within 7 days of NSAID therapy. Colchicine should never be given intramuscularly because it causes tissue irritation.

4. The answer is E *(I, II, III) [see* IV.C*].*

In the treatment of hyperuricemia, allopurinol is indicated rather than probenecid when large tophi are present, when the creatinine clearance is < 50-60 mL/min (probenecid would be ineffective, but the allopurinol dosage would have to be decreased), when the patient is an overproducer of uric acid, and when there is a need to prevent the formation of large amounts of uric acid (e.g., when conditions such as leukemia are present).

5. The answer is B *[see* IV.C.3.b.(3).(a)]

Losartan, an angiotensin II receptor blocker has been shown to increase urinary uric acid secretion and can, therefore, lower serum uric acid levels. Hydrochlorothiazide actually decreases urinary uric acid excretion and must be used cautiously in gout patients, if at all. The other antihypertensive agents mentioned have minimal or no effects on the serum uric acid.

52

Peptic Ulcer Disease and Related Acid-Associated Disorders

Paul F. Souney

Anthony E. Zimmermann

I. INTRODUCTION

A. Definition

1. Peptic ulcer disease (PUD) refers to a group of disorders characterized by circumscribed lesions of the mucosa of the upper gastrointestinal (GI) tract (particularly the stomach and duodenum). The lesions occur in regions exposed to gastric juices.

2. Gastroesophageal reflux disease (GERD) refers to the retrograde movement of gastric contents from the stomach into the esophagus. Reflux may occur without consequences and thus be considered a normal physiological process, or it may lead to profound symptomatic or histological conditions (e.g., GERD). When reflux leads to inflammation (with or without erosions or ulcerations) of the esophagus, it is called **reflux (erosive) esophagitis.** Most patients (50%-70%) report typical symptoms but lack evidence of esophageal mucosal injury **(nonerosive reflux disease; NERD).**

3. Dyspepsia is defined as persistent or recurrent abdominal pain or abdominal discomfort centered in the upper abdomen.

B. Manifestations

1. Duodenal ulcers almost always develop in the duodenal bulb (the first few centimeters of the duodenum). A few, however, arise between the bulb and the ampulla.

2. Gastric ulcers form most commonly in the antrum or at the antral-fundal junction.

3. Less common forms of peptic ulcer disease

a. Stress ulcers result from serious trauma or illness, major burns, coagulopathy not related to anticoagulant therapy, need for mechanical ventilation > 48 hr, or ongoing sepsis. The **most common site** of stress ulcer formation is the proximal portion of the stomach.

b. Zollinger-Ellison syndrome is a severe form of peptic ulcer disease in which intractable ulcers are accompanied by extreme gastric hyperacidity and at least one gastrinoma (a non-β-islet cell tumor of the pancreas or another site).

c. Stomal ulcers (also called marginal ulcers) may arise at the anastomosis or immediately distal to it in the small intestine in patients who have undergone ulcer surgery and have experienced subsequent ulcer recurrence after a symptom-free period.

d. Drug-associated ulcers occur in patients who chronically ingest substances that damage the gastric mucosa, such as nonsteroidal anti-inflammatory drugs (NSAIDs).

4. Reflux esophagitis is most often recognized by the presence of recurrent symptoms (e.g., heartburn) or altered epithelial morphology visualized radiologically, endoscopically, or histologically.

a. Heartburn is substernal burning or regurgitation that may radiate to the neck. Other symptoms include belching, water brash, chest pain, asthma, chronic cough, hoarseness, and laryngitis.
b. Endoscopic evaluation detected **Barrett esophagus (BE)** in 6% of patients with frequent heartburn. Barrett's esophagus is a premalignant condition that may lead to adenocarcinoma of the esophagus or esophagogastric junction.

C. Epidemiology
1. Incidence. Peptic ulcer disease is the most common disorder of the upper GI tract.
a. Duodenal ulcers affect 4%-10% of the U.S. population; **gastric ulcers** occur in 0.03%-0.05% of the population.
b. Nearly 80% of peptic ulcers are duodenal; the others are gastric ulcers.
c. Most duodenal ulcers appear in people between age 20 and 50; onset of gastric ulcers usually occurs between age 45 and 55.
d. The 1-year point prevalence of active gastric or duodenal ulcer in the United States in men and women is about 1.8%; the lifetime prevalence of peptic ulcer ranges from 11% to 14% for men and 8% to 11% for women.
e. Approximately 10%-20% of gastric ulcer patients also have a concurrent duodenal ulcer.
f. In the United States, 44% of the adult population experience **heartburn** at least once a month; 14% take some type of “indigestion” medication at least twice a week. Of patients with GERD symptoms who have undergone endoscopy, 50%-65% have apparent esophagitis.
g. The annual prevalence of dyspepsia in Western countries is approximately 25%; 2%-5% of primary-care consultations are for dyspepsia.
2. Hospitalization
a. Hospitalization rates in the United States for peptic ulcers have been declining; these rates dropped from 25.2 per 10,000 in 1965 to 16.5 per 10,000 in 1981. This reflects a decrease in hospitalization for uncomplicated cases owing to increased outpatient diagnosis and treatment. There has been little change in hospitalization rates since then.
b. There has been little or no decrease in duodenal ulcer perforations and only a slight decrease in hemorrhages.
3. Mortality
a. The mortality rate for gastric ulcers declined between 1962 and 1979 from 3.5 per 100,000 to 1.1 per 100,000.
b. For duodenal ulcer, the mortality rate declined from 3.1 per 100,000 to 0.9 per 100,000.
c. Although death from GERD is uncommon, morbidity is not, because of the prevalence of the well-recognized complications such as esophageal ulceration (5%), stricture formation (4%-20%), and the development of Barrett columnar-lined esophagus (8%-20%).

D. Description

1. Ulcer size. The average duodenal ulcer typically has a diameter < 1 cm; most gastric ulcers are somewhat larger (1-2.5 cm in diameter).

2. Most ulcers are sharply demarcated and have a round, oval, or elliptical shape.

3. The mucosa surrounding the ulcer typically is inflamed and edematous.

4. Ulcers penetrate the **muscularis propria** and, in some cases, extend into the serosa or even into the pancreas.

5. Fibrous tissue, granulation tissue, and necrotic debris form the ulcer base. During ulcer healing, a scar forms as epithelium from the edges covers the ulcer surface.

6. Nearly all duodenal ulcers are benign; up to 10% of gastric ulcers are malignant.

E. Cause. The two major observations regarding PUD are the causal relationship among NSAID intake; gastroduodenal mucosal injury; the pathogenesis of gastric ulcer and, to a lesser extent, duodenal ulcer; and the association of **Helicobacter pylori** infection in the pathogenesis of duodenal ulcer (and to a lesser extent, gastric ulcer).

1. *H. pylori* (formerly *Campylobacter pylori*) is a gram-negative microaerophilic, spiral bacterium with multiple flagella that lives and infects the gastric mucosa. This bacterium is able to survive in the acidic gastric environment by its ability to produce urease, which hydrolyzes urea into ammonia. Ammonia neutralizes gastric hydrochloric acid (HCl), creating a neutral cloud surrounding the organism.

a. In the United States, the **prevalence** of *H. pylori* increases with age from approximately 10% at 20 years of age to approximately 50% at 60 years of age; approximately 17% of *H. pylori*-positive individuals will develop a duodenal ulcer. Prevalence is higher in developing countries.

b. *H. pylori* is associated with several common GI disorders.

(1) Always present in the setting of active chronic gastritis

(2) Present in the vast majority of duodenal (> 90%) and gastric (60%-90%) ulcers. Recent studies indicate a decline in the prevalence of *H. pylori* in duodenal ulcer patients.

(3) Sometimes present with nonulcer dyspepsia (probably in 50% of cases); eradication of *H. pylori,* when present, leads to symptom improvement in only about one half of treated patients.

(4) In gastric cancer, 85%-95% (Although the association is strong, no causal relationship has yet been proven in gastric cancer. The World Health Organization has classified *H. pylori* as a Group 1 carcinogen.)

c. *H. pylori* **eradication** can cure peptic ulcers and reduce ulcer recurrence; it can eliminate the need for maintenance therapy in many ulcer patients.

2. Genetic factors

a. The lifetime prevalence of developing an ulcer in **first-degree relatives** of ulcer patients is about threefold greater than in the general population. This may be secondary to clustering of *H. pylori* within families.

b. People with **blood type O** have an above-normal incidence of duodenal ulcers.

3. Smoking. Smokers have an increased risk of developing peptic ulcer disease. In addition, cigarette smoking delays ulcer healing and increases the risk and rapidity of relapse after the ulcer heals. Nicotine decreases biliary and pancreatic bicarbonate secretion. Smoking also accelerates the emptying of stomach acid into the duodenum.

4. NSAIDs. When ingested chronically, aspirin, indomethacin, and other NSAIDs promote gastric ulcer formation.

a. These drugs may injure the gastric mucosa by allowing back-diffusion of hydrogen ions into the mucosa.

b. NSAIDs also inhibit the synthesis of prostaglandins, which are substances with a cytoprotective effect on the mucosa.

c. Selective cyclooxygenase 2 (COX-2) inhibitors, celecoxib or rofecoxib, are associated with fewer ulcers than nonselective NSAIDs, with rates comparable to placebo at 3 months. Questions regarding long-term safety of COX-2 inhibitors remain. With the recent documentation of increasing COX-2 expression with the progression of BE to cancer, trials have been initiated using COX-2 selective inhibitors in BE patients to prevent development of cancer.

5. Alcohol. A known mucosal irritant, alcohol causes marked irritation of the gastric mucosa if ingested in large quantities at concentrations of 20% or greater. The only association between ethanol intake and ulcer disease exists in patients with portal cirrhosis.

6. Coffee. Both regular and decaffeinated coffee contain peptides that stimulate release of gastrin, a hormone that triggers the flow of gastric juice. However, a direct link between coffee and peptic ulcer disease has not been proven.

7. Corticosteroids. Controversy over whether systemic corticosteroid therapy is associated with increased risk for the development of peptic ulcer disease has, for the most part, been resolved. Evidence for this direct association has always been weak in previous retrospective reviews/trials and reflected the concurrent use of an NSAID. Current data support no link between steroids and peptic ulcer disease in the absence of concurrent NSAID use.

8. Associated disorders. Peptic ulcer disease is more common in patients with hyperparathyroidism, emphysema, rheumatoid arthritis, and alcoholic cirrhosis.

9. Advanced age. Degeneration of the pylorus permits bile reflux into the stomach, creating an environment that favors ulcer formation.

10. Psychological factors. Once assigned key roles in the pathogenesis of PUD, stress and personality type now are viewed as relatively minor influences.

F. Pathophysiology. Ulcers develop when an imbalance exists between factors that protect gastric mucosa and factors that promote mucosal corrosion. Approximately 90% of patients with duodenal ulcer and 70% of patients with gastric ulcer have *H. pylori* infection.

1. Protective factors

a. Normally, the mucosa secretes a thick mucus that serves as a barrier between luminal acid and epithelial cells. This barrier slows the inward movement of hydrogen ions and allows their neutralization by bicarbonate ions in fluids secreted by the stomach and duodenum.
b. Alkaline and neutral pancreatic biliary juices also help buffer acid entering the duodenum from the stomach.
c. An **intact mucosal barrier** prevents back-diffusion of gastric acids into mucosal cells. It also has the capacity to stimulate local blood flow, which brings nutrients and other substances to the area and removes toxic substances (e.g., hydrogen ions). Mucosal integrity also promotes cell growth and repair after local trauma.
2. Corrosive factors. Peptic ulcer disease reflects the inability of the gastric mucosa to resist corrosion by irritants, such as pepsin, HCl, and other gastric secretions.
a. Exposure to gastric acid and **pepsin** is necessary for ulcer development.
b. Disrupted mucosal barrier integrity allows gastric acids to diffuse from the lumen back into mucosal cells, where they cause injury.
3. Physiological defects associated with peptic ulcer disease. Researchers have identified various physiological defects in patients with duodenal and gastric ulcers.
a. Duodenal ulcer patients may have the following defects:
(1) Increased capacity for gastric acid secretion
(a) Some duodenal ulcer patients have up to twice the normal number of parietal cells (which produce HCl).
(b) Nearly 70% of duodenal ulcer patients have elevated serum levels of **pepsinogen I** and a corresponding increase in pepsin-secreting capacity.
(2) Increased parietal cell responsiveness to gastrin
(3) Above-normal postprandial gastrin secretion
(4) Defective inhibition of gastrin release at low pH, possibly leading to failure to suppress postprandial acid secretion
(5) Above-normal rate of gastric emptying, resulting in delivery of a greater acid load to the duodenum
b. Gastric ulcer patients typically exhibit the following characteristics:
(a) Deficient gastric mucosal resistance, direct mucosal injury, or both
(b) Elevated serum gastrin levels (in acid hyposecretors)
(c) Decreased pyloric pressure at rest and in response to acid or fat in the duodenum
(d) Delayed gastric emptying
(e) Increased reflux of bile and other duodenal contents
(f) Subnormal mucosal levels of prostaglandins (these levels normalize once the ulcer heals)
4. GERD requires both initiation and perpetuation of the reflux of gastric contents. Esophagitis develops when noxious substances in the refluxate (i.e., acid, pepsin) are in contact with the esophageal mucosa long enough to cause irritation and inflammation.
a. In patients with GERD, 65% of reflux events occur via transient relaxation (TLESR). The main difference between normal individuals and those with GERD is

the frequency of TLESR. GERD patients have more frequent and prolonged TLESR. TLESR represents a decrease in lower esophageal sphincter (LES) pressure that is not associated with swallowing or peristalsis.

b. Other mechanisms of LES incompetence are increased abdominal pressure and spontaneous reflux during periods of very low LES pressure.

c. Such motility problems are permissive—that is, they allow reflux of acid and other noxious substances.

5. Many diseases cause dyspeptic symptoms, including PUD, GERD, gastric cancer, and biliary tract disease. However, in many cases, no clear pathological reason for a patient's symptoms can be determined. Dyspepsia in the absence of an identifiable organic cause is frequently described as “functional” or “nonulcer” dyspepsia.

G. Clinical presentation. Signs and symptoms of PUD vary with the patient's age and the location of the lesion. Only about 50% of patients experience classic ulcer symptoms. The remainder are asymptomatic or report vague or atypical symptoms.

1. Pain. Patients typically describe heartburn or a gnawing, burning, aching, or cramp-like pain. Some patients report abdominal soreness or hunger sensations. It is unclear whether peptic ulcer pain results from chemical stimulation or from spasm.

a. Duodenal ulcer pain usually is restricted to a small, midepigastric area near the xiphoid. Pain may radiate below the costal margins into the back or the right shoulder. Pain from a duodenal ulcer frequently awakens the patient between midnight and 2 A.M.; it is almost never present before breakfast.

b. Gastric ulcer pain is less localized. It may be referred to the left subcostal region. Gastric ulcer rarely produces nocturnal pain.

c. GERD patients most commonly present with heartburn, belching, regurgitation, or water brash; **atypical presentations** include chest pain, hoarseness/laryngitis, loss of dental enamel, asthma, chronic cough, or dyspepsia. Complications of GERD include esophageal ulceration, strictures, BE, and adenocarcinoma of the esophagus or esophagogastric junction.

d. Dyspepsia applies broadly to a range of symptoms, including abdominal or retrosternal pain and discomfort, heartburn, nausea, vomiting, and other symptoms referable to the proximal GI tract.

e. Food usually relieves duodenal ulcer pain but may cause gastric ulcer pain. This finding may explain why duodenal ulcer patients tend to gain weight, whereas gastric ulcer patients may lose weight. Pain characteristically occurs 90 min to 3 hr after meals in duodenal ulcer patients, whereas pain in gastric ulcer patients is usually present 45-60 min after a meal. Food aggravates reflux disease.

2. Nausea and **vomiting** may occur with either ulcer type.

3. Disease course. Both duodenal and gastric ulcers tend to be chronic, with spontaneous remissions and exacerbations. Within a year of the initial symptoms, most patients experience a relapse.

a. In many cases, relapse is seasonal, occurring more often in the spring and autumn.
b. All patients with a confirmed duodenal or gastric ulcer should be tested for *H. pylori* infection. If the patient is *H. pylori*-positive, eradication therapy will reduce the recurrence rate significantly and preclude the need for maintenance medication.
c. GERD is also a chronic disease; most patients with reflux esophagitis who are healed with antisecretory drug therapy will experience a recurrence within 6 months of discontinuation of the healing regimen. Maintenance therapy reduces the recurrence of esophagitis.

H. Clinical evaluation

1. Physical findings. Patients with peptic ulcer disease may exhibit superficial and deep epigastric tenderness and voluntary muscle guarding. With duodenal ulcer, patients also may show unilateral spasm over the duodenal bulb. Gastric ulcer patients may have weight loss.
2. Diagnostic test results
a. Blood tests may show hypochromic anemia.
b. Stool tests may detect occult blood if the ulcer is chronic.
c. Gastric secretion tests may reveal hypersecretion of HCl in duodenal ulcer patients and normal or subnormal HCl secretion in gastric ulcer patients.
d. Upper GI **series** (barium x-ray) reveals the ulcer crater in up to 80% of cases. Duodenal bulb deformity suggests a duodenal ulcer.
e. Upper GI **endoscopy,** the most specific test, may be done if barium x-ray yields inconclusive results. This procedure confirms an ulcer in at least 95% of cases and may detect ulcers not demonstrable by radiography.
f. Biopsy might be necessary to determine whether a gastric ulcer is malignant.
g. *H. pylori* status is determined by noninvasive tests (not requiring endoscopy) or invasive methods (requiring endoscopy).
(1) Noninvasive. Serology, the test of choice when endoscopy is not indicated, is inexpensive. Several office tests are available. Breath tests can also be used to detect the organism and are uniquely suited as noninvasive means of confirming eradication of *H. pylori* after therapy. False-negative breath tests may occur in patients receiving proton pump inhibitors, antibiotics, or bismuth compounds.
(2) Invasive. These methods include histological visualization of *H. pylori* or measurement of urease activity, which require biopsy.

I. Treatment objectives

1. Relieve pain and other symptoms and promote healing
2. Prevent complications
3. Minimize recurrence (eradicate *H. pylori* in PUD)
4. Maintain adequate nutrition
5. Teach the patient about the disease to improve therapeutic compliance
6. Maintain the patient symptom free

II. THERAPY

A. Drug therapy. Peptic ulcer patients usually are treated with antacids, histamine 2- (H_2-) receptor antagonists, or proton pump inhibitors; other drugs are added as necessary. Drug regimens that suppress nocturnal acid secretion are found to result in the highest duodenal ulcer healing rates. Drug therapy typically provides prompt symptomatic relief and promotes ulcer healing within 4-6 weeks (Figure 52-1). GERD management requires more aggressive acid suppression regimens; the pharmacodynamic end point is to maintain the pH in the esophagus at 4 or more (Figure 52-2).

1. Antacids. These compounds, which neutralize gastric acid, are used to treat ulcer pain and heal the ulcer. Studies show antacids and H_2-receptor antagonists to be equally effective. Antacids are available as **magnesium, aluminum,** or **calcium.** The most widely used antacids are mixtures of aluminum hydroxide and magnesium hydroxide (Table 52-1). Duodenal ulcers rarely occur in the absence of acid or when the hourly maximum acid output is < 10 mEq. Peptic activity decreases as acidity decreases; experimental ulcer formation is inhibited by antacids; and acid-reducing operations cure ulcers.

a. Mechanism of action and therapeutic effects. Antacids reduce the concentration and total load of acid in the gastric contents. By increasing gastric pH, antacids also inhibit pepsin activity. In addition, they strengthen the gastric mucosal barrier.

b. Choice of agent

(1) Nonsystemic antacids (e.g., magnesium or aluminum substances) are preferred to systemic antacids (e.g., sodium bicarbonate) for intensive ulcer therapy because they avoid the risk of alkalosis.

(2) Liquid antacid forms have a greater buffering capacity than tablets. However, tablets are more convenient to carry. With either dosage form, the size and frequency of doses may limit patient compliance.

(3) Antacid mixtures (e.g., aluminum hydroxide with magnesium hydroxide) provide more even, sustained action than single-agent antacids and permit a lower dosage of each compound. In addition, compounds in a mixture may interact so as to negate each other's untoward effects. For instance, the constipating effect of aluminum hydroxide may counter the diarrhea that magnesium hydroxide frequently produces.

(4) Calcium carbonate usually is avoided because it causes acid rebound, may delay pain relief and ulcer healing, and induces constipation. Another potential adverse effect of this compound is hypercalcemia; the risk is increased if calcium carbonate is taken with milk or another alkaline substance. The milk-alkali syndrome (i.e., hypercalcemia, alkalosis, azotemia, nephrocalcinosis) can also occur.

c. Administration and dosage

(1) Antacids differ greatly in acid-neutralizing capacity (ANC), defined as the number of milliequivalents (mEq) of a 1 N solution of HCl that can be brought to a pH of 3.5 in 15 min. For most duodenal ulcer patients, approximately 50 mEq/hr of available antacid is needed for ongoing neutralization of gastric contents. Therefore, the required dosage depends on the ANC of the specific antacid.

(2) In the fasting state, antacids have only a transient intragastric buffering effect (15-20 min). When ingested 1 hr after a meal, they have a much more prolonged effect, about 3-4 hr; therefore, they should optimally be taken 1 and 3 hr after meals and before sleep. Consequently, the typical antacid regimen calls for doses 1 and 3 hr after meals and at bedtime.

P.1125

Figure 52-1. Treatment strategy for management of duodenal ulcer. *CLO, Campylobacter*-like organism; *DU,* duodenal ulcer; *GI,* gastrointestinal; *NSAIDs,* nonsteroidal anti-inflammatory drugs.

(3) Dosage

(a) Because the ANC of antacid products varies widely, no standard dosage can be given in terms of milliliters of suspension or number of tablets. However, patients with duodenal ulcers generally require individual dosages of 80-160 mEq of ANC (equivalent to 30-60 mL of Mylanta or Maalox). Thus the total daily dosage may be as much as 420 mL of Mylanta or Maalox if the standard seventimes-daily dosing regimen is used. Because of the large doses required, increase in adverse effects, need for frequent administration, and poor patient compliance, their role in the management of PUD is limited.

(b) Antacid therapy usually continues for 6-8 weeks.

d. Precautions and monitoring effects

(1) Calcium carbonate- and magnesium-containing antacids should be used cautiously in patients with severe renal disease.

P.1126

Figure 52-2. Treatment strategy for management of gastroesophageal reflux disease. *EGD,* esophagogastroduodenoscopy; *H_2RA,* histamine 2-receptor antagonist; OTC, over the counter; *PPI,* proton pump inhibitor. [Adapted with permission from Peterson WL. GERD evidence-based therapeutic strategies [AGA Consensus Development Panel], 2002. Available at www.gastro.org/user-assets/documents/GERDmonograph.pdf.]

(2) Sodium bicarbonate is contraindicated in patients with hypertension, congestive heart failure (CHF), severe renal disease, and edema. It should not be used for ulcer therapy.

(3) All antacids should be used cautiously in elderly patients (particularly those with decreased GI motility) and renally impaired patients.

(4) Aluminum-containing antacids should be used cautiously in patients who suffer from dehydration or intestinal obstruction.

Table 52-1. Comparison of Common Antacids

Brand Name	Acid-Neutralizing Capacity (mEq/mL or tablet)	Therapeutic Amount (140 mEq) (mL or number of tablets)	Sodium Content (mg/5 mL or tablet)

Aluminum hydroxide			
Amphojel	16.0	8.75	0.080

(5) The combination of calcium carbonate with an alkaline substance (e.g., sodium bicarbonate) and milk may cause the milk-alkali syndrome.
(6) Always check brand name extension products for major ingredient changes (i.e., Maalox Total Stomach Relief contains bismuth subsalicylate).
(7) Chronic administration of calcium carbonate-containing antacids should be avoided because of hypercalcemia and calcium ion stimulation of acid secretion.
(8) Aluminum or magnesium toxicity is unlikely in patients with normal renal function. The encephalopathy of tissue deposition of aluminum occurs only in dialysis patients receiving aluminum hydroxide for control of hyperphosphatemia. Chronic use of magnesium-containing antacids is not advisable in patients with renal insufficiency.
(9) Constipation can occur in patients using calcium carbonate- and aluminum-containing antacids.
(10) Diarrhea is a common adverse effect of magnesium-containing antacids. If diarrhea occurs, the patient may alternate the antacid mixture with aluminum hydroxide.
(11) Hypophosphatemia and osteomalacia can occur with long-term use of aluminum hydroxide, but these conditions can also occur with short-term use in severely malnourished patients, such as alcoholics.
e. Significant interactions. Because antacids alter gastric pH and affect absorption of ingested substances, they have a high potential for drug interactions. To ensure consistent absorption and therapeutic efficacy, orally administered drugs should be given 30-60 min before antacids.

(1) Antacids bind with **tetracycline and fluoroquinolones,** inhibiting the absorption and reducing therapeutic efficacy.

(2) Antacids may destroy the coating of **enteric-coated drugs,** leading to premature drug dissolution in the stomach.

(3) Antacids may interfere with the absorption of many drugs, including **cimetidine, ranitidine, digoxin, isoniazid, anticholinergics, iron products,** and **phenothiazines** (see II.A.2.e.(3)).

(4) Antacids may reduce the therapeutic effects of **sucralfate** (see II.A.3.d).

2. H_2-receptor antagonists. These drugs may be preferred to other antiulcer agents because of their convenience and lack of effect on GI motility. Although reasonably effective in treating mild to moderate GERD symptoms, H_2-receptor antagonists are less reliable for healing erosive esophagitis. All current choices require multiple, divided doses for GERD management.

a. Mechanism of action and therapeutic effects. H_2-receptor antagonists competitively inhibit the action of histamine at parietal cell receptor sites, reducing the volume and hydrogen ion concentration of gastric acid secretions (Figure 52-3 and Table 52-2). These agonists accelerate the healing of most ulcers.

b. Choice of agent. Cimetidine (Tagamet), ranitidine (Zantac), famotidine (Pepcid), or **nizatidine (Axid)** may be administered to treat peptic ulcers or hypersecretory states (e.g., Zollinger-Ellison syndrome).

(1) Cimetidine, the first H_2-receptor antagonist approved for clinical use, reduces gastric acid secretion by approximately 50% (at a total daily dosage of 1000 mg).

(2) Ranitidine, a more potent drug, causes a 70% reduction in gastric acid secretion (at a total daily dosage of 300 mg).

(3) Famotidine is the most potent H_2-receptor antagonist. After a 40-mg dose, mean nocturnal gastric acid secretion is reduced by 94% for up to 10 hr.

(4) Nizatidine, the newest H_2-receptor antagonist, may be used to treat and prevent recurrence of duodenal ulcers.

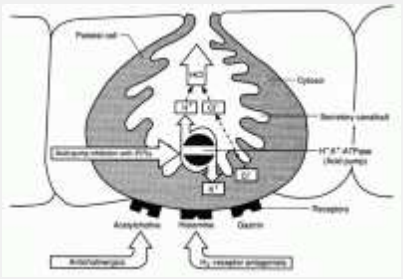

Figure 52-3. Sites of drug action in a parietal cell. *HCl,* hydrochloric acid; *PPIs,* proton pump inhibitors.

Table 52-2. H_2-Receptor Antagonists

Characteristic		Cimetidine (Tagamet)	Ranitidine (Zantac)	Famotidine (Pepcid)	Nizatidine (Axid)
Ring structure		Imidazole	Furan	Thiazole	Thiazole
Relative potency		1	4-10	4-10	20-50
Evening dose (mg)					
	Active ulcer	800	300	40	300
	Maintenance	400	150	20	150
Bioavailability (F) (%)		60-70	50-60	40-45	90-100
Peak time (t_{max}) (hr)		1-3	1-3	1-3.5	0.5-3
Volume of distribution (L/kg)		1	1.4	1.1-1.4	0.8-1.6
Protein binding (%)		20	15	15-22	32-35
Renal elimination (%)		60-75	30 oral; 70 intravenous	65-70	65-75
Half-life (hr)					
Normal		2	2-3	2.5-4	1.6
Anuric		4-5	4-10	20+	6-8.5
Clearance (L/h)		30-48	46	19-29	40-60

for the treatment of acid-related disorders. In Zakim D, Dannenberg AJ, eds. Peptic Ulcer Disease and Other Acid-Related Disorders. New York, Academic Research Associates, 1991:343.

c. Administration and dosage

(1) Cimetidine usually is administered orally in a dosage of 300 mg four times daily (with meals and at bedtime) for up to 8 weeks.

(a) Alternatively, duodenal ulcer patients may receive 400 mg twice daily or 800 mg at bedtime. An 800-mg bedtime dose is also effective in treating gastric ulcers.

(b) Hospitalized patients may receive parenteral doses of 300 mg intravenously every 6 hr.

(c) For duodenal ulcer prophylaxis, 400 mg may be given orally at bedtime. (However, in 20%-40% of patients, the ulcer recurs despite cimetidine prophylaxis.) Is FDA-approved for prevention of UGIB at 50 mg/hour as a continuous infusion.

(2) Ranitidine usually is given orally in a dosage of 150 mg twice daily. Duodenal ulcer patients may receive 300 mg at bedtime, alternatively. Therapy continues for up to 8 weeks.

(a) Hospitalized patients may receive ranitidine by the intravenous or intramuscular route (50 mg every 6-8 hr).

(b) Prophylactic therapy may be administered to reduce the risk of ulcer recurrence. The approved prophylactic dosage is 150 mg at bedtime.

(c) Ranitidine 150 mg twice daily can be administered to maintain healing of erosive esophagitis; for this purpose, it is better than placebo but less effective than the proton pump inhibitors.

(d) Ranitidine bismuth citrate, combined with antibiotics such as clarithromycin, is indicated for eradication of *H. pylori* in patients with duodenal ulcer.

(3) Famotidine, administered to duodenal ulcer patients, is given in an oral dosage of 40 mg at bedtime for acute therapy for a maximum of 8 weeks. For prophylactic therapy, the dosage is 20 mg at bedtime.

(a) Hospitalized patients may receive an intravenous injection of 20 mg every 12 hr.

(b) As with cimetidine and ranitidine, the ulcer may recur after drug discontinuation.

(4) Nizatidine, for the treatment of duodenal ulcers, is given orally in a dosage of 300 mg once daily at bedtime or 150 mg twice daily for up to 8 weeks. For prophylactic therapy, the dosage is 150 mg at bedtime.

d. Precautions and monitoring effects

(1) Ranitidine must be used cautiously in patients with hepatic impairment. Hepatotoxicity is unusual and occurs most often during intraveous administration. Cimetidine has also been associated with hepatotoxicity.

(2) Cimetidine may cause such hematological disorders as thrombocytopenia, agranulocytosis, and aplastic anemia.
(3) All of these agents may cause headache and dizziness. Cimetidine additionally may lead to confusion, particularly if patients are > 60 years of age or if the dosage is not adjusted for patients with decreased kidney or liver function. All agents require dosage reductions in patients with impaired renal function.
(4) Cimetidine has a weak androgenic effect, possibly resulting in male gynecomastia and impotence.
(5) Cimetidine and ranitidine rarely can cause bradycardia, which is reversible on discontinuation of therapy.
(6) Evaluate *H. pylori* status in any patient with confirmed ulcer disease; eradication of *H. pylori* reduces the need for maintenance therapy in patients with duodenal or gastric ulcers. Patients with complicated ulcer disease should continue maintenance therapy until the eradication of *H. pylori.*
(7) Tolerance develops frequently to histamine 2-receptor antagonists (H_2RAs) and may explain diminished responses to these agents over time.
e. Significant interactions
(1) Cimetidine binds the cytochrome P450 system of the liver and thus may interfere with the metabolism of such drugs as **phenytoin, theophylline, phenobarbital, lidocaine, warfarin, imipramine, diazepam,** and **propranolol.**
(2) Cimetidine decreases hepatic blood flow, possibly resulting in reduced clearance of **propranolol** and **lidocaine.**
(3) Antacids impair absorption of cimetidine and ranitidine and should be given 1 hr apart from these drugs.
(4) Cimetidine inhibits the excretion of procainamide by competing with the drug for the renal proximal tubular secretion site.
3. Sucralfate (Carafate). This mucosal protectant is a nonabsorbable disaccharide containing sucrose and aluminum.
a. Mechanism of action and therapeutic effects. Sucralfate adheres to the base of the ulcer crater, forming a protective barrier against gastric acids and bile salts.
(1) Sucralfate's ulcer-healing efficacy compares favorably to that of the H_2RAs.
(2) Duodenal ulcers respond better than gastric ulcers to sucralfate therapy.
b. Administration and dosage
(1) An oral agent, sucralfate usually is given in a dosage of 1 g four times daily (1 hr before meals) and at bedtime. Unless radiography or endoscopy documents earlier ulcer healing, therapy continues for 4-8 weeks.
(2) Continued sucralfate therapy after remission postpones ulcer relapse more effectively than does cimetidine therapy.

(3) There is no evidence that combining sucralfate with H_2RAs improves healing or reduces recurrence rates.

c. Precautions and monitoring effects. Constipation is the most common adverse effect of sucralfate.

d. Significant interactions

(1) Antacids may reduce mucosal binding of sucralfate, decreasing its therapeutic efficacy and thus should be given 30-60 min apart from sucralfate if used in combination ulcer therapy.

(2) Sucralfate may interfere with the absorption of orally administered **digoxin, tetracycline, phenytoin, iron, ciprofloxacin and other fluoroquinolones,** and **cimetidine** if doses are given simultaneously.

4. GI **anticholinergics** (e.g., belladonna leaf, atropine, propantheline) sometimes are used as adjunctive agents for relief of refractory duodenal ulcer pain. However, these agents have no proven value in ulcer healing.

a. Mechanism of action. Anticholinergics decrease basal and stimulated gastric acid and pepsin secretion.

(1) Given in combination with antacids, anticholinergics delay gastric emptying, thereby prolonging antacid retention. They are most effective when taken at night and in large doses.

(2) Anticholinergics occasionally are used in patients who do not respond to H_2-receptor antagonists alone.

b. Administration and dosage

(1) Taken 30 min before food, anticholinergics inhibit meal-stimulated acid secretion by 30%-50% for a duration of 4-5 hr.

(2) The optimal effective dose varies from patient to patient.

c. Precautions and monitoring effects

(1) All anticholinergics have side effects to varying degrees, such as dry mouth, blurred vision, tachycardia, urinary retention, and constipation.

(2) These drugs are contraindicated in patients with gastric ulcers because they prolong gastric emptying. They also are contraindicated in patients with narrow-angle glaucoma and urinary retention.

5. Prostaglandins. These agents suppress gastric acid secretion and may guard the gastric mucosa against damage from NSAIDs. **Misoprostol (Cytotec)** has been approved for use in the prevention of gastric ulcers caused by NSAIDs.

a. Mechanism of action. Misoprostol has both antisecretory (inhibiting gastric acid secretion) and mucosal protective properties. NSAIDs inhibit prostaglandin synthesis, and a deficiency of prostaglandin within the gastric mucosa may lead to diminishing bicarbonate and mucus secretion, contributing to the mucosal damage caused by NSAIDs. Misoprostol increases bicarbonate and mucus production at doses of 200 µg and above—doses that can also be antisecretory. Misoprostol also maintains mucosal blood flow.

b. Administration and dosage

(1) Misoprostol is indicated for the prevention of NSAID-induced gastric ulcers in patients at high risk for complications from gastric ulcers (e.g., patients > 60 years of age, patients with concomitant debilitating disease, patients with a history of ulcers).
(2) Misoprostol has not been shown to prevent duodenal ulcers in patients taking NSAIDs.
(3) The recommended adult dosage is 200 µg four times daily with food; it must be taken for the duration of NSAID therapy. If this dose cannot be tolerated, 100 µg four times daily can be used.
(4) Adjustment of dosage in renally impaired patients is not routinely needed.
c. Precautions and monitoring effects
(1) Misoprostol is contraindicated in pregnant women because of its abortifacient property. Patients must be advised of the abortifacient property and warned not to give the drug to others.
(2) Misoprostol should not be used in women with childbearing potential unless the patient requires NSAID therapy and is at high risk of complications from gastric ulcers associated with use of the NSAIDs or is at high risk of developing gastric ulceration. In such a patient, misoprostol may be prescribed if the patient:
(a) Is capable of complying with effective contraceptive measures
(b) Has received both oral and written warnings of the hazards of misoprostol, the risk of possible contraception failure, and the danger to other women of childbearing potential should the drug be taken by mistake
(c) Had a negative serum pregnancy test within 2 weeks before beginning therapy
(d) Will begin misoprostol only on the 2nd or 3rd day of the next normal menstrual period
(3) The most frequent adverse effects are diarrhea (14%-40%) and abdominal pain (13%-20%). Diarrhea is dose-related, usually develops early in the course (> 2 weeks), and is often self-limiting. Discontinuation of misoprostol is necessary in about 2% of patients. Administration with food minimizes the diarrhea.
d. Significant interactions. None has been reported.
6. Proton pump inhibitors (PPIs). Omeprazole (Prilosec) was the first PPI available in the United States, followed by **lansoprazole (Prevacid), rabeprazole (Aciphex), pantoprazole (Protonix), and esomeprazole (Nexium)** (Table 52-3). The intravenous forms of esomeprazole, lansoprazole and pantoprazole have been approved by the U.S. Food and Drug Administration (FDA).
a. Mechanism of action and therapeutic effects. The gastric proton pump H^+/K^+-ATPase has a sulfhydryl group near the potassium-binding site on the luminal side of the canalicular membrane. Omeprazole sulfonamide (the active form) forms a stable disulfide bond with this specific sulfhydryl, thereby inactivating the ATPase and shutting off acid secretion. All other PPIs exhibit a similar irreversible mechanism of action.

Table 52-3. Pharmacokinetics Proton Pump Inhibitors

Characteristic	Omeprazole (Prilosec)	Lansoprazole (Prevacid)	Rabeprazole (Aciphex)	Pantoprazole (Protonix)	Esomeprazole (Nexium)
Bioavailability (%)	30-40	80-85	52	77	64-89
Time to peak plasma concentration (hr)	0.5-3.5	1.7	2.0-5.0	1.1-3.1	1.56
Plasma elimination half-life (hrs)	0.5-1	1.3-1.7	1.0-2.0	1.0-1.9	0.85-1.25
Protein binding (%)	95	97	96	98	97
Urinary excretion of oral dose (%)	77	14-23	30-35	71-80	80

(1) Because of the potency and marked reduction in gastric acidity, the PPIs are more rapidly effective than other approved agents in treating peptic ulcer disease (i.e., PPIs tend to control symptoms and heal ulcers more rapidly than other antiulcer drugs). PPIs provide effective healing of duodenal ulcers; healing rates at 4 weeks are similar to those reported for H_2-receptor antagonist therapy at 8 weeks.
(2) All PPIs are effective in healing erosive esophagitis, provide more rapid symptom relief and more consistent healing than H_2-receptor antagonists, and are also effective in maintenance of healing of erosive esophagitis.
(3) All PPIs except pantoprazole have been approved in various combinations of antibiotics for the eradication of *H. pylori* (Table 52-4).

Table 52-4. Food and Drug Administration-Approved Oral Regimens Used to Eradicate *Helicobacter pylori* and Reduce the Risk of Duodenal Ulcer Recurrence

Drug Combination	Dose and Frequency	Duration
Omeprazole	20 mg	Days 1-10
	20 mg every day b.i.d.	Days 11-28[a]
Clarithromycin	500 mg b.i.d.	Days 1-10
Amoxicillin	1 g b.i.d.	Days 1-10
Lansoprazole	30 mg b.i.d.	14 days
Amoxicillin	1 g tid	14 days
Clarithromycin	500 mg b.i.d.	14 days
Lansoprazole	30 mg b.i.d.	10 days
Amoxicillin	1 g b.i.d.	10 days
Clarithromycin	500 mg b.i.d.	10 days
Esomeprazole	40 mg every day	10 days
Amoxicillin	1 g b.i.d.	10 days
Clarithromycin	500 mg b.i.d.	10 days
Rabeprazole	20 mg b.i.d.	7 days
Amoxicillin	1 g b.i.d.	7 days
Clarithromycin	500 mg b.i.d.	7 days
Bismuth subsalicylate	525 mg q.i.d.	Days 1-14

Metronidazole	250 mg q.i.d.	Days 1-14
Tetracycline HCl	500 mg q.i.d.	Days 1-14
H_2RA of choice	Ulcer healing regimen	Days 1-28

[a] In patients with an ulcer present at the time of initiation of therapy, additional omeprazole treatment is recommended for ulcer healing and relief of symptoms.

H_2RA, H_2-receptor antagonist; *HCl,* hydrochloric acid.

(4) PPIs have resulted in significant improvement in patients with pathological hypersecretory conditions (e.g., Zollinger-Ellison syndrome) and GERD compared to H_2-receptor antagonists.
(5) Esomeprazole and lansoprazole have been approved by the FDA for healing and prevention of NSAID-induced gastric ulcers.
(6) Omeprazole and lansoprazole have been approved by the FDA for use in infants and children for the short-term treatment of GERD and erosive esophagitis. Omeprazole is approved for use in children ages 2-16 years, and lansoprazole is approved for use in children 1-11 years old.

b. Administration and dosage

(1) PPIs are more potent than H_2-blockers. In the usual dosage (omeprazole 20 mg daily), these agents inhibit > 90% of 24-hr acid secretion in most patients, rarely producing achlorhydria. Esomeprazole 40 mg daily provided significantly higher intragastric pH values above 4 during 24-hr monitoring compared to lansoprazole 30 mg, rabeprazole 20 mg, omeprazole 20 mg, and pantoprazole 40 mg.
(2) PPIs should optimally be taken in the morning 30-60 min before eating; food activates parietal cells, maximizing the effect of the PPI. Optimal binding to proton pumps occurs when the pumps are actively secreting.
(3) Recommended adult dosages
(a) Erosive esophagitis initially is healed with 20 mg omeprazole or equivalent doses of other PPIs for 8-12 weeks; only omeprazole has a demonstrated dose response in GERD patients (patients failing omeprazole 20 mg daily may benefit from higher doses; this has not been demonstrated with esomeprazole, lansoprazole, rabeprazole, or pantoprazole). In addition, esomeprazole 40 mg every day has been shown to produce significantly higher healing rates than omeprazole 20 mg or lansoprazole 30 mg across all grades of erosive esophagitis.

(b) Esomeprazole 20-40 mg, lansoprazole 30 mg, omeprazole 20 mg, rabeprazole 20 mg, and pantoprazole 40 mg may be used to manage GERD symptoms in patients who have failed previous therapy with H_2-receptor antagonist therapy.
(c) The recommended dosage to maintain healing of erosive esophagitis is esomeprazole 20 mg, omeprazole 20 mg, lansoprazole 15 mg, pantoprazole 40 mg, or rabeprazole 20 mg daily for as long as medically necessary.
(d) Duodenal ulcer healing requires omeprazole 20 mg, lansoprazole 15 mg, or rabeprazole 20 mg once daily. Most patients heal within 4 weeks.
(4) Esomeprazole, lansoprazole, and omeprazole are delayed-release capsules and should be taken before eating, can be used concomitantly with antacids, and should not be chewed or crushed. Capsule contents can be sprinkled on foods (i.e., applesauce) or mixed with acidic juices. Suspensions of omeprazole or lansoprazole in sodium bicarbonate have been used for administration to patients with nasogastric and jejunostomy tubes.
(5) Rabeprazole and pantoprazole are available as enteric-coated tablets that should not be crushed or chewed.
(6) Lansoprazole is available as the first orally disintegrating tablet formulation. It is placed on the tongue, with or without water, until dissolved. However, it needs to be swallowed to be absorbed.
(7) Omeprazole in sodium bicarbonate powder for suspension (Zegerid) is the first PPI approved by the FDA for reduction in the risk of upper GI bleeding in critically ill patients. It has a peach/mint flavor that is tolerable. It is dosed at 40 mg every 6 hr times two doses (as a loading dose), then 40 mg daily.
(8) No dosing adjustments are necessary in patients with impaired renal or hepatic function or in the elderly.
(9) Intravenous pantoprazole is indicated for management of erosive esophagitis and treatment of Zollinger-Ellison syndrome. Esomeprazole, lansoprazole, and pantoprazole are currently being widely used for the treatment of acute bleeding gastric ulcers, though not FDA approved.
(10) Intravenous esomeprazole (20-40 mg daily) and lansoprazole (30 mg daily) are FDA approved for the short-term use in patients with GERD with a history of erosive esophagus unable to take oral medications.
(11) In patients with nocturnal signs and symptoms of GERD, twice daily PPIs have been effective when taken appropriately. The addition of an H_2RA to the twice-daily PPI has shown little added benefit and is not recommended.

c. Precautions and monitoring effects
(1) Headache, diarrhea, abdominal pain, nausea and vomiting, and flatulence have been reported in > 1% of patients.
(2) Fever, fatigue, malaise, elevated liver enzymes, dizziness, vertigo, skin rash, and itching have been reported in < 1% of patients.
d. Significant interactions

(1) Omeprazole interferes with the hepatic microsomal enzyme metabolism (cytochrome P450) of **diazepam, warfarin,** and **phenytoin, although clinically significant interactions are infrequent.**
(2) Lansoprazole may increase clearance of theophylline by approximately 10%.
(3) Because gastric pH plays a role in the bioavailability of **ketoconazole, ampicillin esters,** and **iron salts,** prolonged gastric acid inhibition with PPIs may decrease the absorption of these agents.
(4) Antacids may be used concomitantly with all PPIs.
(5) No clinically significant drug interactions have been reported to date with esomeprazole, rabeprazole, or pantoprazole.
(6) Food may reduce the bioavailability of esomeprazole and lansoprazole by 50%; food does not reduce the bioavailability of omeprazole or rabeprazole.
7. Bismuth compounds. In the United States, bismuth subsalicylate (Pepto-Bismol) is the only available bismuth product.
a. Mechanism of action. Bismuth prevents adhesion of *H. pylori* to gastric mucosa, decreases resistance when used with other anti-*H. pylori* agents, inhibits release of proteolytic enzymes, and suppresses *H. pylori* growth.
b. Administration and dosage
(1) Bismuth subsalicylate is highly effective when combined with PPIs and/or antibiotics. Eradication rates with these combinations are > 80% (Table 52-4).
(2) Preferred regimen with bismuth: bismuth subsalicylate 525 mg four times a day, metronidazole 250 mg four times a day, tetracycline 500 mg four times a day plus PPI (omeprazole 20 mg every day or lansoprazole 30 mg every day) for 2 weeks total. This regimen provides consistently high eradication rates (> 90%) and may be useful for patients who have failed previous therapy. This regimen is not currently FDA approved.
c. Precautions and monitoring effects
(1) CNS toxicity with higher doses, including neurotoxicity
(2) Tinnitus, hyperpyrexia, tachycardia, and confusion (salicylism) from high doses of bismuth subsalicylate
d. Reversible proton pump inhibitors are currently under development by a number of pharmaceutical companies (AstraZeneca and Altana). When compared with the currently available irreversible proton pump inhibitors, these agents are expected to offer more rapid symptom resolution, control pH more quickly, achieve higher pH levels, and sustain these more aggressive pH levels consistently over a 24-hr period.
8. Prokinetic agents. Cisapride (Propulsid) is currently the only approved agent in this class; however, the manufacturer (Janssen Pharmaceutica) has **discontinued marketing** of cisapride in the United States owing to the agent's highly arrhythmogenic potential. The manufacturer will supply cisapride through a limited-access program for those who meet specific eligibility criteria and for whom other therapies are not effective. Metoclopramide and erythromycin have well-studied prokinetic effects, and prucalopride is still under review by the FDA.
a. Mechanism of action. Cisapride produces release of acetylcholine from the myenteric plexus and thereby may increase gastric emptying and LES pressure;

cisapride does not affect TLESR. It does not increase or decrease gastric acid secretion.

b. Administration and dosage. Cisapride is indicated for the relief of nocturnal symptoms of reflux; it is administered in doses of 10-20 mg four times a day.

c. Precautions and monitoring

(1) The **most common** side effects are diarrhea, abdominal pain, and headache. Other less common effects include bronchospasm, angioedema, and depression.

(2) Cisapride is contraindicated in patients with a history of ischemic heart disease, respiratory failure, congestive heart failure, renal failure, severe dehydration, arrhythmias, or medications that prolong the QT interval. Serious cardiac arrhythmias, including ventricular tachycardia and torsades de pointes, have been reported.

d. Significant interactions

(1) Ketoconazole potently inhibits the metabolism of cisapride, resulting in an eightfold increase in the area under the curve (AUC) of cisapride. Co-administration of cisapride and ketoconazole can result in prolongation of the QT interval on the electrocardiogram (ECG). Co-administration of itraconazole, fluconazole, or intravenous miconazole is similarly contraindicated.

(2) The following oral or intravenous drugs are contraindicated with cisapride. These may lead to elevated cisapride blood levels and increased potential for arrhythmias.

a. Antibiotics: erythromycin, clarithromycin, sparfloxacin

b. Protease inhibitors: indinavir, ritonavir

c. Antiarrhythmics: quinidine, procainamide, sotalol

(3) The acceleration of gastric emptying by cisapride could affect the rate of absorption of other drugs. Patients receiving narrow therapeutic drugs or other drugs that require careful titration should be monitored closely.

(4) Coagulation times in patients receiving oral anticoagulants have increased in some cases.

(5) Cimetidine may increase peak plasma concentration and AUC of cisapride.

e. γ-Aminobutyric acid B ($GABA_B$) agonists (i.e., baclofen) have been shown to significantly reduce reflux episodes in healthy volunteers and GERD patients. Several compounds are under development that have greater peripheral specificity and are expected to provide fewer CNS-related adverse effects, while providing effective normalization of TRLES.

f. Tegaserod (Zelnorm), a selective 5-hydroxytryptamine 4 (5-HT4) receptor agonist, is a promotility drug that is available through a restricted access program only. Early studies have demonstrated that tegaserod reduces esophageal acid exposure by enhancing esophageal acid clearance and gastric emptying and/or reducing TRLES but more definitive studies are needed. Initial studies in patients with heartburn have shown a decrease in esophageal pain.

9. Sedatives are useful adjuncts in promoting rest for highly anxious ulcer patients.

B. Other therapeutic measures

1. Modification of diet and social habits

a. Previously emphasized in ulcer therapy, strict dietary limitations now are considered largely unnecessary.

(1) Bland or milk-based diets formerly were recommended; however, research indicates that these diets do not speed ulcer healing. In fact, most experts now advise ulcer patients to **avoid milk** because recent studies show that milk increases gastric acid secretion. Also, because milk leaves the stomach quickly, it lacks an extended buffering action.

(2) Small, frequent meals, also previously recommended, can worsen ulcer pain by causing acid rebound 2-4 hr after eating.

b. Current dietary guidelines emphasize avoiding foods and beverages known to exacerbate gastric discomfort or promote acid secretion. This category typically includes coffee, caffeinated beverages, and alcohol.

c. Smoking. Patients who smoke should be encouraged to quit because smoking markedly slows ulcer healing, even during optimal ulcer therapy.

d. NSAIDs should be avoided by ulcer patients.

2. Surgery. An ulcer patient who develops complications may require surgery—sometimes on an emergency basis (see III). Incapacitating recurrent ulcers also may warrant surgery.

a. Types of surgical procedures for ulcer disease include antrectomy and truncal vagotomy (Billroth I procedure), partial gastrectomy and truncal vagotomy (Billroth II procedure), highly selective (proximal gastric) vagotomy, and total gastrectomy (the treatment of choice for Zollinger-Ellison syndrome that is unresponsive to medical management).

(1) A **vagotomy** severs a branch of the vagus nerve, thereby decreasing HCl secretion.

(2) An **antrectomy,** by removing the antrum, eliminates some acid-secreting mucosa as well as the major source of gastrin.

b. The general indications for antireflux surgery are failure of medical therapy to heal or prevent relapse of erosive esophagitis, inability of medical therapy to prevent recurrence of stricture, or a patient whose lifestyle is adversely affected by the need for medical

therapy. **Laparoscopic fundoplication** is currently the gold standard for GERD and successfully relieves symptoms and heals lesions in approximately 85% of patients. However, recent studies have demonstrated that most patients require continued medical therapy after fundoplication.

3. Emerging endoscopic therapies. Three endoscopic techniques to treat GERD have recently been introduced.

a. Augmentation of LES pressure may be achieved by delivery of radiofrequency energy to the muscle of the gastroesophageal junction (Stretta procedure). The radiofrequency is delivered by means of a flexible catheter made up of a bougie tip, a balloon-basket combination, and four-needle delivery sheaths.

b. Another endoscopic procedure, the EndoCinch, augments the LES by suturing of the mucosa.

c. The third endoscopic/endoluminal treatment is by use of Enteryx injection.

d. Early studies have demonstrated good feasibility in performing these procedures and an overall satisfactory safety profile. Further studies are necessary to assess long-term failure rate, early versus late complications, and success rate in the different GERD groups.

III. COMPLICATIONS

of peptic ulcer disease cause approximately 7000 deaths in the United States annually.

A. Hemorrhage. This life-threatening condition develops from widespread gastric mucosal irritation or ulceration with acute bleeding.

1. Clinical features. The patient may vomit fresh blood or a coffee grounds-like substance. Other signs include passage of bloody or tarry stools, diaphoresis, and syncope. With major blood loss, manifestations of **hypovolemic shock** may appear: The pulse rate may exceed 110, or systolic blood pressure may drop below 100.

2. Management

a. Patient stabilization, bleeding cessation, and measures to prevent further bleeding are crucial.

(1) Airway, breathing, and circulation must be ensured.

(2) Intravenous crystalloids and colloids (e.g., hetastarch) should be infused as needed.

(3) The patient's electrolyte status must be monitored and any imbalances corrected promptly.

b. Gastric lavage may be performed via a nasogastric or orogastric tube; iced saline solution is instilled until the aspirate returns free of blood.

c. Vasoconstrictors or continuous infusion proton pump inhibitors have been administered with good response.

(1) Decrease rebleeding rates were found when the continuous infusion PPI maintained the gastric pH to 6 or above. The doses required were much higher than normal doses (e.g. pantoprazole 80 mg bolus plus 8 mg/hr or lansoprazole 90 mg bolus plus 9 mg/hr). However, none of the intravenous PPIs are currently FDA approved for this indication.

(2) Vasopressin, an agent that causes contraction of the GI smooth muscle, may be given to constrict vessels and control bleeding but only in patients with hemorrhagic gastritis.

d. Emergency surgery usually is indicated if the patient does not respond to medical management.

B. Perforation. Penetration of a peptic ulcer through the gastric or duodenal wall results in this acute emergency. Perforation most commonly occurs with ulcers located in the anterior duodenal wall.

1. Clinical features. Sudden acute upper abdominal pain, rigidity, guarding, rebound tenderness, and absent or diminished bowel sounds are typical manifestations. Several hours after onset, symptoms may abate somewhat; this

apparent remission is dangerously misleading because peritonitis and shock may ensue.

2. Management. Emergency surgery is almost always necessary.

C. Obstruction. Inflammatory edema, spasm, and scarring may lead to obstruction of the duodenal or gastric outlet. The pylorus and proximal duodenum are the most common obstruction sites.

1. Clinical features. Typical patient complaints include postprandial vomiting or bloating, appetite and weight loss, and abdominal distention. Tympany and a succussion splash may be audible on physical examination. Gastric aspiration after an overnight fast typically yields more than 200 mL of food residue or clear fluid contents. (Gastric cancer must be ruled out as the cause of obstruction.)

2. Management

a. Conservative measures (as in routine ulcer therapy) are indicated in most cases of obstruction.

b. Patients with marked obstruction may require **continuous gastric suction** with careful monitoring of fluid and electrolyte status. A **saline load test** may be performed after 72 hr of continuous suction to test the degree of residual obstruction.

c. If < 200 mL of gastric contents are aspirated, liquid feedings can begin. **Aspiration** is performed at least daily for the next few days to monitor for retention and to guide dietary modifications as the patient progresses to a full regular diet.

d. Surgery is indicated if medical management fails.

D. Postsurgical complications

1. Dumping syndrome. Affecting about 10% of patients who have undergone partial gastrectomy, this disorder is characterized by rapid gastric emptying.

a. Causes. The mechanism underlying dumping syndrome is poorly defined. However, intestinal exposure to hypertonic chyme may play a key role by triggering rapid shifts of fluid from the plasma to the intestinal lumen.

b. Clinical features. The patient may experience weakness, dizziness, anxiety, tachycardia, flushing, sweating, abdominal cramps, nausea, vomiting, and diarrhea.

(1) Manifestations may develop 15-30 min after a meal (early dumping syndrome) or 90-120 min after a meal (late dumping syndrome).

(2) Reactive hypoglycemia may partly account for some cases of late dumping syndrome.

c. Management. The patient usually is advised to eat six small meals of high protein and fat content and low carbohydrate content. Fluids should be ingested 1 hr before or after a meal but never with a meal. **Anticholinergics** may be given to slow food passage into the intestine.

2. Other postsurgical complications include reflux gastritis, afferent blind loop syndrome, stomal ulceration, diarrhea, malabsorption, early satiety, and iron-deficiency anemia.

E. Refractory ulcers. Ulcers that fail to heal on a prolonged course of drug treatment should not be confused with ulcers that recur after therapy is stopped. It is difficult to predict which patients will have a refractory ulcer.

1. Differential diagnosis. Any compliant patient who continues to have dyspeptic symptoms after 8 weeks of therapy should have gastroscopy and biopsy to exclude rare causes of ulceration in the duodenum, such as Crohn disease, tuberculosis, lymphoma, pulmonary or secondary carcinoma, and cytomegalovirus (CMV) infection in immunodeficient patients. Fasting plasma gastrin concentration should be measured to exclude Zollinger-Ellison syndrome.

2. Treatment

a. Available data indicate that only maximum acid inhibition, with a regimen such as omeprazole (20 mg twice a day) or lansoprazole (30 mg twice a day), offers advantages over continued therapy with standard antiulcer regimens.

b. Eradication of *H. pylori* infection, when present, is likely to facilitate healing and alter the natural history of refractory ulcers.

c. Every effort should be made to discover and reduce or eliminate NSAID use.

d. Perform surgery.

F. Maintenance regimens

1. Despite healing after withdrawal of therapy, 70% of ulcers recur in 1 year, and 90% in 2 years. Similarly, erosive esophagitis will recur in more than 80% of individuals within 1 year after discontinuation of antisecretory therapy.

2. Candidates for long-term maintenance therapy include patients with serious concomitant diseases; four relapses per year; or a combination of risk factors, producing a more severe

natural history of peptic disease (e.g., old age, male sex, a long history of aspirin or NSAID use, heavy alcohol intake, cigarette smoking, a history of peptic ulcer disease in an immediate relative, high maximal acid output, and a history of ulcer complications).

3. Patients with confirmed ulcer disease should be evaluated for presence of *H. pylori.* Eradication of *H. pylori* minimizes the recurrence of ulcer disease. Patients with a history of complicated ulcer disease should have *H. pylori* eradication confirmed.

STUDY QUESTIONS

Directions for questions 1-6: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. ZZ is a 43-year-old female with a chief complaint of hematemesis and abdominal pain. Serology is positive for *H. pylori.* Which of the following would be the best regimens to treat ZZ?

(A) omeprazole 20 mg daily plus clarithromycin 500 mg b.i.d. × 14 days
(B) lansoprazole 30 mg b.i.d. plus tetracycline 500 mg q.i.d. × 14 days
(C) rabeprazole 20 mg b.i.d. plus amoxicillin 1g b.i.d. plus clarithromycin 500 mg b.i.d. × 7 days
(D) esomeprazole 40 mg b.i.d. plus amoxicillin 500 mg b.i.d. plus clarithromycin 500 mg b.i.d. × 7 days
(E) pantoprazole 40 mg b.i.d. plus amoxicillin 1g b.i.d. plus clarithromycin 500 mg t.i.d. × 10 days

View Answer***1. The answer is C[see].Helicobacter pylori,*****2. All of the following statements concerning antacid therapy used in the treatment of duodenal or gastric ulcers are correct *except* which one?**
(A) Antacids may be used to heal the ulcer but are ineffective in controlling ulcer pain.
(B) Antacids neutralize acid and decrease the activity of pepsin.
(C) If used alone for ulcer therapy, antacids should be administered 1 hr and 3 hr after meals and before bedtime.
(D) If diarrhea occurs, the patient may alternate the antacid product with aluminum hydroxide.
(E) Calcium carbonate should be avoided because it causes acid rebound and induces constipation.

View Answer***2. The answer is A[see].*****3. As part of a comprehensive management strategy to treat peptic ulcer disease, patients should be encouraged to do all of the following *except***
(A) decrease caffeine ingestion.
(B) eat only bland foods.
(C) stop smoking.
(D) avoid alcohol.
(E) avoid the use of milk as a treatment modality.

View Answer***3. The answer is B[see].*****4. A gastric ulcer patient requires close follow-up to document complete ulcer healing because**
(A) perforation into the intestine is common.
(B) spontaneous healing of the ulcer may occur in 30%-50% of cases.
(C) there is the risk of the ulcer being cancerous.
(D) symptoms tend to be chronic and recur.
(E) weight loss may be severe in gastric ulcer patients.

View Answer***4. The answer is C[see].*****5. IT is a 58-year-old male admitted to the intensive care unit with acute respiratory failure and thrombocytopenia. He is at high risk for an upper gastrointestinal bleed. Which of the following agents are approved by the U.S. Food and Drug Administration (FDA) for the prevention of this type of bleed?**
(A) sucralfate
(B) famotidine
(C) esomeprazole
(D) lansoprazole
(E) omeprazole

View Answer***5. The answer is E[see II.6.B].*****6. All of the following provide acid suppression similar to omeprazole 20 mg every day *except***

(A) lansoprazole 30 mg every day.

(B) pantoprazole 40 mg every day.

(C) rabeprazole 20 mg every day.

(D) famotidine 20 mg twice a day.

(E) all provide equivalent acid suppression.

View Answer***6. The answer is D[see].***P.1140

Directions for questions 7-8: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A-E.**

7. Correct statements concerning cigarette smoking and ulcer disease include which of the following?

(I) Smoking delays healing of gastric and duodenal ulcers.

(II) Nicotine decreases biliary and pancreatic bicarbonate secretion.

(III) Smoking accelerates the emptying of stomach acid into the duodenum.

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***7. The answer is E(I, II, III) [see].*****8. When administered at the same time, antacids can decrease the therapeutic efficacy of which of the following drugs?**

(I) sucralfate

(II) ranitidine

(III) cimetidine

A if **I only** is correct

B if **III only** is correct

C if **I and II** are correct

D if **II and III** are correct

E if **I, II, and III** are correct

View Answer***8. The answer is E(I, II, III) [see].*****Directions for questions 9-13:** Each description in this section is most closely associated with **one** of the following agents. Each agent is used only **once.** Choose the **best** answer, **A-E.**

9. may cause diarrhea

A sodium bicarbonate

B aluminum hydroxide

C calcium carbonate

D magnesium hydroxide

E propantheline

View Answer***9. The answer is D[see].*****10. cannot be used by patients with heart failure**

A sodium bicarbonate
B aluminum hydroxide
C calcium carbonate
D magnesium hydroxide
E propantheline

View Answer***10. The answer is A[see].***11. **if used with milk and an alkaline substance can cause milk-alkali syndrome**

A sodium bicarbonate
B aluminum hydroxide
C calcium carbonate
D magnesium hydroxide
E propantheline

View Answer***11. The answer is C[see].***12. **may cause dry mouth**

A sodium bicarbonate
B aluminum hydroxide
C calcium carbonate
D magnesium hydroxide
E propantheline

View Answer***12. The answer is E[see].***13. **can be alternated with an antacid mixture to control diarrhea.**

A sodium bicarbonate
B aluminum hydroxide
C calcium carbonate
D magnesium hydroxide
E propantheline

View Answer***13. The answer is B[see].***P.1141

ANSWERS AND EXPLANATIONS

1. The answer is C *[see* Table 52-4*].*
Though all agents are useful in the treatment of *Helicobacter pylori,* only the combination of rabeprazole with amoxicillin and clarithromycin for 7 days is correct. The other doses and duration of therapy are incorrect.

2. The answer is A *[see* II.A.1*].*
Antacids have been shown to heal peptic ulcers, and their main use in modern therapy is to control ulcer pain. Antacids should be taken 1 hr and 3 hr after meals because the meal prolongs the acidbuffering effect of the antacid. If diarrhea becomes a problem with antacid use, an aluminum hydroxide product can be alternated with the antacid mixture; this takes advantage of the constipating property of aluminum. Because calcium carbonate causes acid rebound and constipation, its use should be avoided.

3. The answer is B *[see* II.B.1.a.(1)*].*
Bland food diets are no longer recommended in the treatment of ulcer disease because research indicates that bland or milk-based diets do not accelerate ulcer

healing. Studies show that patients can eat almost anything; however, they should avoid foods that aggravate their ulcer symptoms.

4. The answer is C *[see* I.D.6*].*

Between 5% and 10% of gastric ulcers may be the result of cancer. The ulcer may respond to therapy; however, failure of the ulcer to decrease satisfactorily in size and to heal with therapy may suggest cancer. Close follow-up is necessary to document complete ulcer healing.

5. The answer is E *[see II.6.B].*

Though all of these agents have been used with success in the prevention of GI bleeds in critically ill patients, only omeprazole (as a powder for oral suspension) has been FDA approved for this indication.

6. The answer is D *[see* II.A.6.b.(1)*].*

Doses of omeprazole 20 mg, lansoprazole 30 mg, pantoprazole 40 mg, and rabeprazole 20 mg administered once daily provide similar levels of acid suppression. All provide significantly better acid inhibition than famotidine, even at doses of 20 mg twice a day or more.

7. The answer is E *(I, II, III) [see* I.E.3; II.B.1.c*].*

Clinical studies have shown that smoking increases susceptibility to ulcer disease, impairs spontaneous and drug-induced healing, and increases the risk and rapidity of recurrence of the ulcer. These findings may result in part from nicotine's ability to decrease biliary and pancreatic bicarbonate secretion, thus decreasing the body's ability to neutralize acid in the duodenum. Also, the accelerated emptying of stomach acid into the duodenum may predispose to duodenal ulcer and may decrease healing rates.

8. The answer is E *(I, II, III) [see* II.A.1.e.(3); II.A.3.d*].*

The mean peak blood concentration of cimetidine and the area under the 4-hr cimetidine blood concentration curve were both reduced significantly when cimetidine was administered at the same time as an antacid. The absorption of ranitidine is also reduced when it is taken concurrently with an aluminum magnesium hydroxide antacid mixture. To avoid this interaction, the antacid should be administered 1 hr before or 2 hr after the administration of cimetidine or ranitidine. Antacids may reduce mucosal binding of sucralfate, decreasing its therapeutic efficacy. Antacids should, therefore, be given 30-60 min before or after sucralfate.

9. The answer is D *[see* II.A.1.b.(3)*].*

10. The answer is A *[see* II.A.1.d.(2)*].*

11. The answer is C *[see* II.A.1.d.(5)*].*

12. The answer is E *[see* II.A.4.c.(1)*].*

13. The answer is B *[see* II.A.1.b.(3)*].*

Magnesium-containing products tend to cause diarrhea, possibly because of magnesium's ability to stimulate the secretion of bile acids by the gallbladder. Because of its sodium content, sodium bicarbonate is contraindicated in patients

with CHF, hypertension, severe renal disease, and edema. Sodium bicarbonate is no longer used in peptic ulcer therapy. In addition to causing acid rebound, calcium carbonate, if taken with milk and an alkaline substance for long periods, may cause milk-alkali syndrome. It also may cause adverse effects such as hypercalcemia, alkalosis, azotemia, and nephrocalcinosis. Propantheline, like other anticholinergic agents, may cause dry mouth, blurred vision, urinary retention, and constipation. These agents sometimes are used as adjuncts to relieve duodenal ulcer pain. They are contraindicated in gastric ulcer because they delay gastric emptying. Aluminum hydroxide is constipating and can be alternated with the patient's current antacid when that antacid product is causing diarrhea.

53

Diseases of the Bowel: Inflammatory Bowel Disease and Irritable Bowel Syndrome

Eric Coldiron

I. INTRODUCTION

A. Definition

1. Inflammatory bowel disease (IBD) is a designation commonly used to **describe** two idiopathic diseases of the gastrointestinal tract with closely related clinical presentations. These diseases are **ulcerative colitis (UC)** and **Crohn disease (CD).**

2. UC is a chronic inflammatory condition of the gastrointestinal tract mucosa and is primarily found in the rectum and colon.

3. CD is chronic transmural inflammation of the gastrointestinal mucosa and can be found throughout the gastrointestinal tract from the mouth to the anus. CD most commonly affects the small bowel and colon.

4. Irritable bowel syndrome (IBS) has been defined as a functional bowel disorder in which abdominal pain or discomfort is associated with defecation or changes in bowel habits and with features of disordered defecation.

B. Manifestations

1. IBD

a. UC onset is frequently insidious with increasing stool urgency and frequency. In addition to urgency, bloody stool and mucus in the stool can also gradually increase. The general course of UC can be generalized as bouts of varied disease intensity interspersed with asymptomatic periods.

b. CD onset is typically insidious but can be as severe or fulminate disease. Despite similarities of CD presentation, there are patterns of symptoms that relate to disease location and type (e.g., inflammatory, fibrostenotic, fistulizing) that can be useful in determining therapy decisions.

2. IBS

a. IBS can be characterized by pain relieved by defecation, alternating bowel habits, abdominal distention, mucus in the stool, and a sensation of incomplete defecation. IBS usually occurs as either constipation predominant or diarrhea predominant.

b. Constipation-predominant IBS tends to present with pain and periodic constipation alternating with normal periods of bowel function. Pain has been described as colicky, periodic, and/or a continuous dull ache. Defecation may relieve the pain and eating can commonly trigger symptoms. Other common symptoms are bloating, nauseas, dyspepsia, flatulence, and heartburn.

c. Diarrhea-predominant IBS is commonly characterized by precipitous diarrhea occurring immediately on rising or during meals or immediately postprandially. Nocturnal episodes are rare. Other common presenting complaints are pain, bloating, rectal urgency, and incontinence.

d. IBS can also be alternating from constipation to diarrhea on a continual basis.

C. Epidemiology of IBD. It has been estimated that approximately 1 million Americans have IBD. It is estimated that roughly half have UC and half have CD.

1. UC incidence and prevalence rates have remained relatively constant in North America and northern Europe and appear to be increasing in southern Europe and East Asia. UC historically has been more common than CD.
P.1144

a. UC incidence rates in North America are reported to be around 11 cases per 100,000 patients. Recent prevalence rates for UC in North America are reported to be 169-229 per 100,000 patients. Rates are comparable in northern European countries.
b. UC incidence and prevalence rates are lower in southern Europe, Asia, and Latin America.
2. CD incidence and prevalence rates have seen a marked rise since the early 1950s. There is a great variance in published incidence rates of CD. Areas of higher CD incidence are generally similar to those of higher UC incidence. CD has recently become more common than UC in some areas.
a. Reported CD incidence rate for North America is estimated to be 5 cases per 100,000 patients. CD prevalence rates in North America are estimated to be around 50 cases per 100,000 patients. CD rates for northern Europe are comparable to those in North America.
b. Rates for southern Europe, Africa, and Asia have been reported to be lower than those seen in North America and northern Europe.
3. Geographical-related components
a. Northern regions have historically reported higher rates of IBD than southern regions. Rates in southern Europe have recently seen increasing incidence rates compared to historical rates.
b. CD rates have been reported to be higher in urban areas.
c. UC rates have been reported to be higher in rural areas.
d. IBD rates have historically been higher in developed countries compared to less-developed countries. This difference has been shown to decrease as less-developed areas are developed and a more Western diet is adopted.
4. Ethnic, racial, and socioeconomic components
a. The risk for IBD and CD in particular is higher in Jews of European descent than in non-Jews. While IBD prevalence is reported to be higher in Jews compared to non-Jews there is considerable variation within Jewish populations from different geographical locations.
b. Non-Jewish whites historically have been considered to be at higher risk for IBD compared to African Americans, but that difference has been questioned in recent reports. Blacks in Africa tend to be at less risk for IBD than either North American whites or African Americans.
c. Asians appear to be at lower risk for developing IBD than whites. However, migrant Asians to the United Kingdom have been shown to be at higher risk for UC than nonmigrants, nearly equaling the risk of developing CD as UK-born whites.
d. Incidence rates of IBD have historically been reported to be higher in higher socioeconomic classes.

5. Age- and sex-related components

a. IBD is more common in young adult patients than older patients.

b. CD has historically demonstrated a bimodal distribution in regard to age of diagnosis; a large peak is seen in the 2nd and 3rd decades and a second, smaller peak appears in later decades.

c. The average age of UC diagnosis is in the 4th decade.

d. Men and women are at similar risk of developing IBD.

e. Women are at increased risk of developing CD compared to men.

f. Men are at slightly increased risk of developing UC compared to women, although the difference approaches unity.

6. Other contributing factors

a. Smoking has been associated with a decrease in UC rates, but the risk factors to general health do not warrant forgoing counseling patients on the benefits of smoking cessation.

(1) Former smokers are at increased risk of developing UC.

(2) Smoking has been shown to be a risk factor for developing CD. CD patients who actively smoke also have increased morbidity compared to CD patients who stop smoking.

b. Appendectomy has been shown to be protective in regard to development of UC.

c. Use of **oral contraceptives** has been associated with increased risk of developing IBD.

7. Genetic predisposition to IBD is an area of recent research.

a. Genetic predisposition to IBD is suggested by, among other factors, epidemiologic studies, studies of twins, family aggregation studies, and ethnic differences in disease patterns.

b. The nucleotide oligomerization domain 2 (*NOD2*)/caspase activation and recruitment domain 15 (*CARD15*) genetic mutation for example is seen more often in CD than in the general population. The mutation has been associated with altered immune response to bacteria. There are limitations to the usefulness of *NOD2/CARD15* in clinical practice; however, the identification of this mutation and others has opened the door for more work concerning genetic predisposition and possible disease mechanism, which, in turn, may lead to new modes of therapy.

D. Epidemiology of IBS

1. IBS is reported to be more common in women than men.

2. There is a decrease in IBS frequency in elderly patients.

3. Prevalence seems to be equal in whites and blacks and lower in Hispanics. Overall prevalence rates are estimated at 2.9%.

4. IBS appears to be as common in Asia, South America, and India as in Western countries.

5. IBS usually presents between the ages of 30 and 50, with significant decreases at ages > 50.

E. Description

1. IBD is chronic inflammation of the gastrointestinal tract.
2. UC is chronic recurring mucosal inflammation of the colon.
a. Proctitis. Inflammation of the rectum
b. Proctosigmoiditis. Colitis affecting the rectum and sigmoid colon
c. Left-sided colitis. Disease starting at the rectum and extending retrograde to the splenic flexure of the colon
d. Pancolitis. Disease affecting the entire colon
e. Backwash ileitis. Inflammation of the terminal ileum owing to retrograde flow of colonic contents in pancolitis patients
3. CD is chronic recurring transmural inflammation of the gastrointestinal tract.
a. Ileocolitis. The most common form of CD, affecting the ileum and colon
b. Ileitis. CD affecting the ileum
c. Gastroduodenal Crohn disease. CD affecting the stomach and duodenum
d. Jejunoileitis. CD producing inflammation of the jejunum and ileum
e. Crohn's (granulomatous) colitis. CD affecting only the colon
4. IBS
a. IBS is recognized as being part of **functional bowel disease.**
b. IBS is characterized by symptoms of abdominal pain or discomfort that is associated with disturbed defecation patterns. IBS is typically of a constipation (IBS-C) or diarrhea predominant (IBS-D) type with a minority of patients alternating between the two (IBS-A) or of a mixed presentation (IBS-M or mixed).
F. Cause
1. IBD is thought to be caused by a poorly understood compilation of environmental and genetic factors and possibly infectious agents. IBD is likely a result of multiple environmental factors that elicit an abnormal immune response in genetically susceptible individuals.
a. There is significant overlap between the clinical presentations of UC and CD, the two main idiopathic inflammatory disease states that make up IBD. Thus a clear differential diagnosis between UC and CD is not always possible.
b. There is clear evidence of immune system activation with subsequent infiltration of the tissue by lymphocytes, macrophages, and other cells. The exact trigger of this apparent poorly regulated immune response has yet to be defined.
c. Possible mechanisms postulated for IBD disease initiation include virus or bacterial infection, dietary antigens or inappropriate immune response to normally nonantigenic microbes, and the possibility of an inappropriate immune response to intestinal autoantigens expressed on the intestinal epithelium.

d. Regardless of cause, there appears to be failure of normal suppressor mechanisms with a resultant overly vigorous and abnormally long immune response to a disease trigger.
e. IBD occurs 30-100 times more frequently in first-degree relatives of IBD patients compared to the general population

f. Infectious colitis can mimic IBD. Differential diagnosis includes bacterial, protozoal, and viral pathogens (notably *Clostridium difficile,* fungal protozoal viral, and helminthic pathogens).
g. Ischemic colitis and **neoplastic** diseases such as cecal adenocarcinoma, lymphoma, and metastatic cancers may also present like IBD.
h. Microscopic colitis and other inflammatory diseases such as **celiac sprue,** and **eosinophilic colitis** can present in much the same manner as IBD.
i. Drug-induced enterocolitis can induce IBD-like symptoms. The most commonly implicated classes of drugs are nonsteroidal anti-inflammatory drugs (NSAIDs), gold compounds, oral contraceptives, enteric potassium supplements, pancreatic enzymes, phosphosoda bowel preps, and thermal injury secondary to colostomy irrigation.
j. Other possibly confounding diseases include **endometriosis** and **diverticular disease.**

2. IBS

a. The exact cause of IBS is unknown, and no anatomic cause has yet to be elucidated.
b. Possible comorbid factors—such as viral gastroenteritis, emotional health, diet, environment, concurrent drug therapy, and hormones—have been implicated in gastrointestinal (GI) dysmotility.
c. Anxiety disorders, particularly panic disorder; major depressive disorder; and somatization disorder have also been implicated as possible initiating factors for IBS.
d. Learned aberrant illness behavior, in which patients may tend to express emotional conflict as a GI complaint, usually abdominal pain, may also be a contributing disease state. The clinician evaluating patients with IBS, particularly those with refractory symptoms, should investigate for unresolved psychological issues, including the possibility of sexual or physical abuse.

G. Pathophysiology

1. IBD

a. UC. Physiologic changes in UC begin with edema followed by loss of fine vascular pattern and increased mucosal friability. Ulceration, exudates, and pseudopolyps may also be present. With longer disease history, the colon may begin to become featureless and tubular in nature. UC tends to occur in a **contiguous** manner.
b. CD. Inflammation and subsequent injury of tissue known as cryptitis leads to crypt abscess and subsequently focal aphthoid ulceration. The inflammatory process can progress with influx and proliferation of macrophages and other inflammatory cells. Transmural inflammation may lead to lymphedema and bowel wall thickening. This thickening can lead to fibrosis. Affected areas are usually sharply demarcated from normal adjacent tissue and give rise to the **skip lesion** appearance of CD.

2. IBS

a. Abnormalities in intestinal motility in IBS appear to be related to underlying muscle dysfunction as well as hyperactive response to initiating factors, such as food or parasympathomimetic drugs.

b. Abnormal increases in frequency and amplitude of contractions can lead to functional constipation, whereas diminished motor function of the underlying musculature can lead to diarrhea.
c. Hypersensitivity to normal amounts of intraluminal distention exists, as does a heightened perception of pain in the presence of normal quantity and quality of intestinal gas.
d. The pain of IBS may be caused by abnormally strong contraction of the intestinal smooth muscle or by increased sensitivity of the intestine to distention.
e. Hypersensitivity to the hormones gastrin and cholecystokinin may also be present. However, hormonal fluctuations have not correlated with clinical symptoms.
f. The caloric density of food intake may increase the magnitude and frequency of myoelectrical activity and gastric motility. Fat ingestion may cause a delayed peak of motor activity, which can be exaggerated in IBS.
g. The first few days of menstruation can lead to transiently elevated prostaglandin E_2 (PGE_2), resulting in increased pain and diarrhea.
P.1147

H. Clinical presentation
1. UC. Most patients will present with symptoms related to altered stool frequency, bowel sensation, and abdominal pain.
a. Most UC cases begin as mild disease and worsens as the disease course progresses.
b. UC usually follows a chronic intermittent course.
c. Quiescent periods tend to be long, with interspersed acute attacks.
d. Attacks or flares can last weeks to months.
e. Some patients suffer from continuous disease.
f. Severe UC can result in **toxic megacolon,** a life-threatening condition.
g. Elderly patients can rarely present with constipation secondary to rectal spasm.
h. Typical presenting symptoms of UC are as follows:
(1) Increased stool frequency
(2) Hematochezia
(3) Tenesmus
(4) Lower left quadrant pain
(5) Nausea, vomiting, and weight loss (usually only in severe disease)
i. Extraintestinal manifestations of UC
(1) Arthralgias
(2) Ankylosing spondylitis
(3) Pyoderma gangrenosum, erythema nodosum
(4) Aphthous ulcers
(5) Iritis and uveitis
2. CD. Many patients present with acute symptoms mimicking appendicitis or intestinal obstruction. CD can be exacerbated by infections, smoking, and NSAID use. While not well correlated in controlled trials, stress is often implicated by patients and family members as a contributing factor.

a. A significant number of patients have a history of perianal disease, especially fissures and fistulas, which are sometimes the most prominent or even initial complaint.

b. Extraintestinal manifestations can be more prominent than GI symptoms in pediatric patients.

c. Typical presenting symptoms of CD are as follows:

(1) Abdominal pain

(2) Diarrhea

(3) Weight loss

(5) Fever

d. Extraintestinal manifestations of CD

(1) Arthralgias

(2) Acute peripheral arthritis

(3) Ankylosing spondylitis, peripheral arthritis

(4) Erythema nodosum, pyoderma gangrenosum, Sweet syndrome

(5) Iridocyclitis, uveitis, and episcleritis

3. IBS

a. IBS symptoms are frequent in patients with active disease.

b. Symptoms may be classified with either the new **Rome III criteria** or may still be classified with the **Rome II criteria** which center around bowel movement and abdominal pain. The clinical symptoms are the same regardless of how they are classified.

(1) Abdominal pain has been characterized as crampy, localized to the lower left abdomen with variable intensity. Patient presentation is highly variable with regard to intensity, location and duration of pain. Some women will have exacerbations coinciding with menstrual periods.

(2) Alteration of bowel habits is the second major identifying symptom of IBS. They include diarrhea, constipation, and alternating diarrhea and constipation.

(3) IBS can also present with bloating, gas, belching, heartburn, reflux disease, achalasia, early feeling of fullness on eating and nausea, painful menstruation, sexual dysfunction, and frequent or urgent urination.

c. IBS tends to wax and wane over the long term; patients have acute bouts of disease interspersed with periods of no disease. While total prevalence numbers remain relatively constant, studies of defined patient populations at various time periods show the same number of active patients but the individual patients may be different.

Table 53-1. Differences between Ulcerative Colitis (UC) and Crohn Disease (CD)

Characteristic	UC	CD
Abdominal pain	Infrequent	Frequent
Bloody diarrhea	Frequent	Occasional
Perianal involvement	Rare	Frequent
Perianal fistula	Rare	Frequent
Rectovaginal fistula	Rare	Common
Fever	Occasional	Frequent
Weight loss	Occasional	Frequent
Palpable mass	Rare	Common
Intra-abdominal abscess	Rare	Common
Bowel obstruction	Rare	Common
Antibiotic response	Rare	Frequent
Skip lesions	Rare	Frequent
Contiguous disease	Frequent	Infrequent
Effect of smoking	Often improves	Often worsens
Serologic markers		
ASCA positive	15%	65%
p-ANCA positive	70%	20%

ASCA, anti-*Saccharomyces cerevisiae* antibody; *p-ANCA,* perinuclear antineutrophil cytoplasmic antibody.

I. Clinical evaluation

1. IBD Differences in typical clinical presentation between UC and CD are summarized in Table 53-1.

a. UC

(1) Patient symptoms are usually the first signs of disease. Diarrhea, bleeding, tenesmus, mucus in the stool, and pain are the most common.

(2) The severity of symptoms correlates with disease severity.

(3) Acute disease can be associated with increased C-reactive protein, platelet count, erythrocyte sedimentation rate (ESR), and a decrease in hemoglobin.

(4) Serum albumin can fall quickly in severe disease.

(5) Sigmoidoscopy can be useful for assessing disease severity and extent before therapy. Care must be used in severe disease as risk of perforation is increased

b. UC disease classification according to extent (distal vs. extensive) and severity is of use in determining therapy.

(1) Mild UC has been defined as less than four stools per day with or without blood, normal ESR.

(2) Moderate UC has been defined as more than four stools per day but minimal signs of toxicity (fever, tachycardia, anemia, or elevated ESR).

(3) Severe UC has been defined as more than six bloody stools per day, evidence of toxicity as demonstrated by fever, tachycardia, anemia, or elevated ESR. (*Note:* Elevated ESR is not always present, even in the most severe UC.)

(4) Fulminate UC has been defined as more than ten bowel movements, continuous bleeding, toxicity, abdominal tenderness and distension, need for blood transfusion, and colonic dilation (toxic megacolon).

(5) In addition to classifying UC as mild to fulminate, it is useful to ascertain the effect the disease is having on patient activity with a global assessment approach, including extraintestinal manifestations (ocular, oral, joint, skin, moods), general health (laboratory evaluation for anemia, liver function tests), and quality of life (impairment at work or school, interpersonal relationships).

b. CD

(1) CD patients may present with elevated ESR; C-reactive protein; and, in more severe disease, with hypoalbuminemia, anemia, and leukocytosis.
(2) CD can occur throughout the bowel; the site of disease affects the disease course and treatment choices.

(3) Ileocolitis is the most common form of CD. It has been characterized by right lower quadrant pain and diarrhea and can mimic acute appendicitis. Pain can be colicky and usually precedes defecation and is relieved by defecation.
(4) Jejunoileitis. Extensive inflammation can lead to loss of absorptive surfaces with resultant malabsorption and steatorrhea. This malabsorptive state can lead to dietary deficiency, hypoalbunemia, electrolyte imbalances, coagulopathy, and increased risk of bone fractures.
(5) Colitis patients tend to present with low-grade fever, diarrhea, vomiting, and epigastric pain.
(6) Perianal CD patients may present with incontinence, stricture, anorectal fistula, and perirectal abscess.
c. CD classification based on severity and location is useful for determining therapy.
(1) Mild to moderate disease has been used to define CD in patients who are ambulatory; who are able to take food orally; who have no symptoms of dehydration, no signs of toxicity (high fever, rigors, prostration), no abdominal tenderness, no painful mass, and no obstruction; or who have weight loss > 10%.
(2) Moderate to severe disease describes patients who have failed to respond to therapy for mild to moderate disease or those with more prominent symptoms of fever, significant weight loss, abdominal pain or tenderness, intermittent nausea or vomiting (without obstruction), or anemia.
(3) Severe to fulminant disease describes patients with persisting symptoms despite therapy with steroids as outpatients or patients with high fever, persistent vomiting, obstruction, rebound tenderness, cachexia, or evidence of abscess.
(4) Remission refers to patients who have responded to acute medical therapy or who have had surgical intervention and do not have gross evidence of residual CD. Patients who require steroids to maintain control of CD are considered **steroid dependant** and are not considered to be in remission.
(5) CD disease location is often classified as being ileocolic, small bowel, colonic, or anorectal. The **Vienna classification** of disease location and type of CD is also often used. CD type is known to change in regard to type and location during the disease course.
(a) Terminal ileum disease is CD in less than one third of the small bowel, with or without spillover into the cecum.
(b) Colon CD is colonic involvement anywhere from the cecum to the rectum, without small bowel or upper gastrointestinal disease.
(c) Ileocolon is CD of the terminal ileum and any location between the ascending colon and the rectum.

(d) Upper GI CD is disease in any location proximal to the terminal ileum, with or without involvement distal to the terminal ileum.
(e) The type of disease is described as **inflammatory, stricturing,** or **penetrating.**
(6) The **Crohn Disease Activity Index (CDAI)** is a validated measurement tool used to assess clinical improvement. The CDAI is a complete scoring system of subjective aspects and objective observations. It is not normally used in clinical practice but is extensively used in clinical research. CD severity, as defined by the CDAI, breaks down into the following stratifications:
(a) A score of ≤ 150 is considered clinical remission
(b) A score of < 150 and up to 450 is considered mild to moderate disease.
(c) A score of > 450 is considered severe disease.
2. IBS
a. Diagnosis of IBS commonly includes identifying positive symptoms by medical history. This can be guided by older **Rome II criteria** or the recently published **Rome III criteria.** Physical exam is also done to exclude non-IBS disease (abdominal mass, palpable liver etc) as the majority of IBS patients do not have these physical abnormalities. Both patient history and physical exam are also needed to exclude IBD and microscopic and eosinophilic colitis which can present in similarly to IBS.
b. Rome II diagnostic criteria for IBS
(1) At least 12 weeks, which need not be consecutive, in the preceding 12 months of abdominal discomfort or pain that has 2 of 3 features:

(a) Pain relieved by defecation; and/or
(b) Pain onset associated with a change in frequency of stool; and/or
(c) Pain onset associated with a change in form (appearance) of stool
(2) Symptoms that cumulatively support the diagnosis of IBS:
(a) Abnormal stool frequency (for research purposes, “abnormal” may be defined as greater than 3 bowel movements per day and less than 3 bowel movements per week);
(b) Abnormal stool form (lumpy/hard or loose/watery stool);
(c) Abnormal stool passage (straining, urgency, or feeling of incomplete evacuation);
(d) Passage of mucus;
(e) Bloating or feeling of abdominal distension. The diagnosis of a functional bowel disorder (IBS) always presumes the absence of a structural or biochemical explanation for the symptoms.
c. Rome III diagnostic criteria for IBS
(1) Recurrent abdominal pain or discomfort at least 3 days per month in the last 3 months associated with 2 or more of the following:
(a) Improvement with defecation
(b) Onset associated with a change in a frequency of stool
(c) Onset associated with a change in form (appearance) of stool

(2) Criteria fulfilled for the last 3 months with symptoms onset at least 6 months prior to diagnosis.

(3) Discomfort means an uncomfortable sensation not described as pain.

(4) In pathophysiology research and clinical trials, a pain/discomfort frequency of at least 2 days a week during screening evaluation for subject eligibility

d. Routine blood testing is normal in most suspected IBS patients and helps rule out other possible diagnosis.

e. Sigmoidoscopy and colonoscopy are done to visualize the bowel when clinically appropriate to exclude other possible diagnoses.

J. Treatment objectives

1. IBD

a. Induce remission with control of acute inflammatory flare

b. Maintain remission as long as possible

d. Normalize bowel function when possible

e. Maintain nutritional status

f. Improve quality of life (QOL)

2. IBS

a. Alleviate discomfort

b. Normalize bowel habits

c. Minimize negative effect on patient QOL

II. THERAPY

A. Agents used in IBD

1. Aminosalicylates are generally considered to be effective therapy of UC and CD (Table 52-2).

a. Description. The commercially available agents all deliver the active 5-aminosalycilate moiety.

(1) The oldest agent sulfasalazine (Azulfidine) contains a 5-aminosalicylic acid (5-ASA) molecule azo-bound to sulfapyridine. This bond is cleaved by intestinal flora to release the active 5-ASA moiety.

(2) Newer agents have been developed to allow dosing without the sulfapyridine moiety, which has been implicated in many of the common adverse events and intolerances to sulfasalazine.

(3) Sulfasalazine is considered by many to be the first choice owing to its long history of use, convincing clinical trial data, and relatively low cost.

Table 53-2. Aminosalicylates

Drug (Brand)	How Supplied	Formulation	Delivery Site
Oral agents			
Azo bond			
Balsalazide (Colazal)	750 mg	Aminobenzoyl-alanine carrier	Colon
Olsalazine (Dipentum)	250 mg	5-ASA dimer	Colon
Sulfasalazine (Azulfidine)	500 mg	Sulfapyridine carrier	Colon
Delayed release			
Mesalamine (Asacol)	400 mg	Eudragit S (pH 7)	Distal ileum, colon
Mesalamine (Claversal, Mesasal, Salofalk)	250 mg	Eudragit L (pH 6)	Ileum-colon
Sustained release			
Mesalamine (Pentasa)	250 mg, 500 mg	Ethylcellulose granules	Stomach, colon
Topical agents			
Mesalamine (Rowasa)	4 g	60-mL suppositories	Rectum, splenic flexure

Mesalamine (Canasa)	500 mg, 1000 mg	Suppositories	Rectum

5-ASA, 5-aminosalicylic acid

(4) Disadvantages of sulfasalazine are increased incidence of adverse events.
(5) Topical 5-ASA has been added to oral 5-ASA with improved response and time to response.

b. Mechanism of action. 5-ASA differs from salicylic acid by the addition of an amino group.

(1) 5-ASA drugs have variable effects on arachidonic acid metabolites, unlike the salicylates, which block prostaglandin synthesis by inhibiting cyclooxygenase 1 (COX-1) and COX-2 enzymes.

(2) At low concentrations, 5-ASA drugs increase prostaglandin production, and at higher concentrations they inhibit prostaglandins and prostacyclins.

c. Administration and dosage. There are currently several 5-ASA derivatives available (Table 53-2). Dosages in UC are based on disease location, severity, and overall patient condition.

d. Precautions and adverse effects

(1) Sulfasalazine.

(a) Most common adverse events: fever, dizziness, headache, itching, rash, photosensitivity, GI upset, nausea, vomiting, diarrhea, and reversible oligospermia.
(b) Less common: Stevens-Johnson syndrome, Lyell syndrome, granulocytopenia, leucopenia, thrombocytopenia, aplastic anemia, hemolytic anemia, and hepatitis.
(c) Intolerance of the sulfapyridine moiety of sulfasalazine is common and is implicated in many adverse events associated with sulfasalazine.

(2) Mesalamine (Asacol).

(a) Most common adverse events: diarrhea, headache, abdominal pain, cramps, flatulence, and gas.
(b) Less common: alopecia and skin rash.
(c) Rare: pericarditis and myocarditis.

(3) Olsalazine (Dipentum).

(a) Most common adverse events: diarrhea and loose stools.
(b) Less common: abdominal pain, rash, and itching.
(c) Rare but serious: pancreatitis, hepatotoxicity, interstitial nephritis, and bone marrow suppression.

e. Significant interactions

(1) The **aminosalicylates** may increase risk of toxicity and leukopenia when given in combination with mercaptopurine by decreasing mercaptopurine clearance.

(1) The **5-ASA drugs** have also been associated rarely with exacerbation of IBD.

2. Steroids. Steroids are useful for patients refractory to 5-ASA and patients with severe symptoms requiring rapid control.

a. Systemic corticosteroids are effective treatment for acute UC and CD. Use as maintenance therapy for IBD is normally avoided as the risk of systemic adverse effects outweighs limited benefit. **Steroid dependency**—when a patient is unable to be tapered completely off of steroids—does occur and should not be confused with maintenance.

b. Topical and nonsystemic steroids in the form of enemas, suppositories, and ileal release formulations have been effective in treating IBD. The rectally delivered topical formulations of steroids are of particular use in left-sided disease. Budesonide (Entocort) is an oral steroid delivered in an ileal controlled-release formulation that acts in a topical manner secondary to very high first-pass metabolism by the liver. Budesonide has been shown to be effective in IBD when the targeted-release formulation is able to reach the site of disease.

c. Mechanism of action. The glucocorticoid and mineralocorticoid effects of the steroids used in IBD are wide ranging. The anti-inflammatory effects are likely the result of glucocorticoid suppression of proinflammatory cytokines.

d. Precautions and adverse effects. Therapy with oral and intravenous (IV) corticosteroids produce systemic affects, can effect multiple organ systems, and should be closely monitored for adverse events.

(1) Adverse effects of steroids in IBD therapy are related to dose and length of dosing and are the typical glucocorticoid and mineralocorticoid effects seen with exogenous steroid therapy.

(2) Systemic steroids are more prone to inducing adverse effects. Topical delivery and targeted delivery of low bioavailability steroids have been developed to reduce the risk of adverse effects.

(3) Minimizing duration of therapy as well as tapering patients off of systemic steroids are also methods of minimizing adverse effects as much as possible.

(4) Affects on bone mass may be of significant importance because IBD patients are often also at risk of nutritional deficit.

3. Azathioprine (Imuran) and 6-mercaptopurine (6-MP; Purinethol) are effective at inducing and maintaining remission in IBD. Response is slow and may take months to be fully effective. 6-MP or azathioprine is effective for patients who do not respond to oral steroids but are not so acutely ill so as to require IV therapy.

a. Mechanism of action. Azathioprine and 6-MP are purine antimetabolite drugs which interfere with DNA synthesis, disrupting the inflammatory response seen in IBD.

b. Dosing and administration. There is known metabolic differences in regard to **thiopurine methyltransferase (TPMT)** activity, which can lead to toxicity in patients with low or absent TPMT activity. Testing for TPMT phenotype can be useful in initial dosing.

(1) Consensus on the value of monitoring of metabolite levels during therapy has not been reached.

(2) Monitoring complete blood counts 4 weeks after starting therapy and then monthly during therapy should be done to monitor for toxicity.

(3) Azathioprine is 50% 6-MP by molecular weight and equivalent doses are twice that of 6-MP.

c. Precautions and adverse effects

(1) Bone marrow suppression

(2) Both azathioprine and 6-MP have been implicated in increased risk for Epstein Barr-related non-Hodgkin lymphoma. This risk appears to be small but is serious.

4. Methotrexate (Rheumatrex) given parenterally is an effective treatment for inducing remission, maintaining remission, and steroid sparing in CD. Oral methotrexate is also effective for maintaining remission in CD. Methotrexate appears to be of little use in UC.

a. Mechanism of action. Methotrexate is a folate analog and inhibits dihydrofolate reductase with multiple modes of anti-inflammatory effects.

b. Dosing and administration.

(1) Inducing remission of active CD: 25 mg intramuscularly (IM) weekly has been shown to be effective.

(2) Maintaining remission and as steroid-sparing therapy: 15 mg IM weekly has been shown to be effective.

(3) Oral methotrexate 12.5-25 mg per week does not appear to be as effective as parenteral dosing.

c. Precautions and adverse effects

(1) Methotrexate is a known teratogen and should be avoided or used with extreme caution in patients of child-bearing age (female and male) and only when all other therapies have been ineffective and the patients understand the risks involved.

(2) The doses used in CD are lower than those used in oncology and the adverse events seen are generally less severe.

(3) The most common risks are rash, nausea, pneumonitis or *Mycoplasma* pneumonia, and elevated serum transaminases.

(4) IBD patients treated with methotrexate appear to be at low risk for hepatic toxicity.

(5) It is important to avoid alcohol consumption because it can increase the risk of hepatic toxicity in IBD patients on methotrexate.

5. Cyclosporine (Neoral) and tacrolimus (Prograf) are potent immunosuppressive agents that have been shown to be effective in IBD. They are typically used for

severe IBD because there are little data to support efficacy in mild disease to offset the potential toxicities of these agents.

a. Mechanism of action. Both cyclosporine and tacrolimus are calcineurin inhibitors and are potent inhibitors of T lymphocyte activation.

b. Dosing and administration. Before therapy is initiated patients should be screened for potential drug interactions, normal renal function, cholesterol levels, blood pressure, and electrolyte status to help avoid toxicity.

(1) Cyclosporine is started at 2-4 mg/kg/day IV and titrated to levels of 250-350 ng/mL.

(2) Tacrolimus is initiated at 0.1- 0.15 mg/kg twice weekly and titrated to trough concentrations of 10 to 20 ng/mL.

(3) Patients who respond are discharged on oral drug. Oral cyclosporine is dosed at twice the intravenous dose, divided twice a day.

(4) Azathioprine or 6-MP is added as soon as possible and oral systemic steroids are often given concomitantly for 3-4 months.

(5) Cyclosporine and tacrolimus are normally stopped at 3-4 months. A steroid taper is also started at 3-4 months and should be done over 48 weeks.

c. Precautions and adverse events. Cyclosporine and tacrolimus both have short- and long-term adverse events that can be serious. The most commonly seen in IBD patients are paresthesias, hypertension, hypertrichosis, renal insufficiency, infection, gingival hyperplasia, and seizure.

(1) Patients should be monitored for effects on blood pressure, electrolytes, renal function, and cholesterol.

(2) Hypocholesterolemia and hypomagnesemia increase the risk of seizure.

d. Significant interactions. Care must be used in concomitant dosing of these agents with other drugs that can adversely affect renal function such as NSAIDs. Cyclosporine has been noted to increase methotrexate and methotrexate metabolite concentrations.

6. Biologics. Infliximab (Remicade), adalimumab (Humira), and certolizumab pegol (Cimzia) are currently the main biologic therapies used in IBD. These agents are **anti-tumor necrosis factor (anti-TNF)** therapy.

(1) Infliximab, adalimumab and certolizumab pegol are effective for inducing and maintaining clinical remission of CD. Infliximab has been shown to be effective in treating enterocutaneous fistulae. Infliximab is also effective in UC.

(2) Infliximab and adalimumab have also been shown to be effective for treating ankylosing spondylitis. Other biologics of note are listed in Table 53-3.

a. Anti-TNF therapy mechanism of action. TNF is a cytokine involved in multiple proinflammatory and proliferative pathways in IBD. Infliximab is a chimeric mouse-human monoclonal TNF antibody made up of human immunoglobulin G_1 (IgG_1) constant regions, human κ light chains, and monoclonal murine regions that recognize TNF. Adalimumab is a recombinant human IgG1 monoclonal antibody with human heavy and light chain variable regions and human IgG1:k constant regions. Certolizumab is a recombinant, humanized antibody Fab' fragment to human TNF alpha which is conjugated to a 40 kDa polyethylene glycol. These agents bind TNF,

preventing the cytokine from binding to cell surface receptors and subsequently decreasing inflammation due to activated T lymphocytes and monocytes.

Table 53-3. Biologic Therapies of Note in Inflammatory Bowel Disease (IBD)

Drug (Brand)	Mechanism	Efficacy in IBD/Comments
Adalimumab (Humira)	Humanized IgG_1 monoclonal antibody to TNF	Effective in CD
Infliximab (Remicade)	Chimeric (mouse/human) IgG_1 monoclonal antibody to TNF	Effective in CD and UC
Certizumab pegol (Cimzia®)	Humanized pegylated Fab' fragment TNF antibody	Effective in CD
Natalizumab (Tysabri)	Humanized IgG_4 monoclonal antibody to α4 integrin, which selectively inhibits leukocyte adhesion	Removed from U.S. market in 2005 secondary to association with progressive multifocal leukoencephalopathy (PML). Natalizumab was made available again in 2006 via a restrictive company administered access program for use in multiple sclerosis. Place in therapy is yet to be fully elucidated and the benefit must clearly outweigh the risks.
Etanercept (Enbrel)	p75-Soluble TNF receptor FC fusion protein that binds TNF	Not of benefit

CD, Crohn disease; *IgG,* immunoglobulin G; *PML,* progressive multifocal leukoencephalopathy; *TNF,* tumor necrosis factor; *UC,* ulcerative colitis.

b. Dosing and administration.

(1) Infliximab initial dosing is 5 mg/kg in a three-dose induction regimen. A dose is given at 0, 2, and 6 weeks to help reduce **human antichimeric antibodies (HACA)** formation. Duration of therapeutic effect appears to be 8-10 weeks and dosing every 8 weeks has been advocated. HACA formation and infusion-related adverse reactions can also be decreased with concomitant administration of azathioprine, 6-MP, or methotrexate. These immunosuppressant drugs have not been shown to improve clinical disease control when given concomitantly with infliximab.
(2) Adalimumab is initially dosed 160 mg on day one as four 40 mg injections on the first day or two 40 mg injections per day for two days, followed by 80 mg two weeks later or at day 15. Two weeks later (day 29) maintenance therapy is begun at 40 mg every other week.
(3) Certolizumab pegol is given as 400 mg on day one and at weeks 2 and 4 as two 200 mg subcutaneous injections, followed by 400 mg every 4 weeks.
c. Precautions and adverse effects. Anti-TNF therapy is generally considered safe in long-term therapy of CD.
(1) Acute anaphylactoid infusion-related reactions occur in approximately 22% of patients treated with infliximab. These reactions are more common in patients who test positive for antibody to infliximab and are less frequent in patients given concomitant immunosuppressive drugs. Severe anaphylactic reactions are rare. Hypersensitivity reactions are reported to be rare with adalimumab and certolizumab pegol.
(2) Delayed hypersensitivity reactions, including myalgias, rash, fever, arthralgias, pruritus, edema, urticaria, sore throat, and dysphagia occur 3-12 days after infliximab infusion and are much less common, seen in approximately 2% of patients receiving maintenance infliximab therapy.
(3) All three agents carry **black box warnings** for increased risk of tuberculosis and other opportunistic infections.
(4) Increased rates of malignancies have also been associated with anti-TNF therapy.
7. Antibiotics. No specific infectious agent as been identified in either UC or CD.
a. Metronidazole (Flagyl) and **ciprofloxacin (Cipro)** are used widely by convention as

maintenance therapy in CD but controlled trial results do not conclusively support this use.
b. Use of broad-spectrum antibiotics in UC is limited to empiric treatment of fulminant disease or in patients with toxic megacolon for whom short-term use of these antibiotics can be justified owing to the increased risk of perforation or bacteremia. Metronidazole has been useful in patients suffering from **pouchitis** after bowel resection surgery that involves formation of a pouch.
c. Rifaximin (Xifaxan^{TM}) is a novel nonsystematic antibiotic currently available for treating travelers diarrhea caused by noninvasive strains of *E. coli* and is under study for treating IBD. Conclusive evidence does not exist to support this use to date.

8. Probiotic and prebiotic therapy. Probiotic therapy involves using exogenously administered bacteria such as *Lactobacillus* GG, *Saccharomyces boulardii,* and nonpathogenic *E. coli,* for example, in an attempt to normalize the intestinal environment flora and thus decrease inflammatory triggers.

a. Controlled trials of probiotic therapy in IBD have yet to define clinical utility.

b. Remission maintenance of pouchitis with VSL#3, a probiotic preparation of four lactobacilli strains, three *Bifidobacterium* strains, and one *Streptococcus* strain was shown to be of benefit.

c. Probiotics are orally administered substances like nondigested carbohydrates with the goal of facilitating growth of commensal gut flora to displace possible antigenic microorganisms.

d. There are currently little data to support the use of probiotics.

9. Antispasmodics and antidiarrheals. Cramping and abdominal IBS-like symptoms are often noted in IBD patients. Use of symptomatic therapies is not well defined in the published IBD literature because most research is aimed at the inflammatory process. Once active inflammation is controlled or ruled out, anticholinergic antispasmodics are frequently used judiciously to treat cramping or discomfort in IBD inflammation, as are antidiarrheals in mild or quiescent disease. All of these agents should be avoided in serious disease because they may further impair the colon and increase risk of toxic megacolon.

10. Antidepressants and anxiolytics have been used when specific patient symptoms warrant their use as adjuvant therapy.

11. Analgesics. There is rarely a need for pain control in UC as the disease is limited to the mucosa of the colon with limited involvement of tissue containing pain receptors. Narcotics are to be avoided in UC therapy outside of perioperative situations because they increase the risk of toxic megacolon and can mask signs of perforation. NSAID medications should be avoided because they have been implicated in inducing IBD flares.

12. Surgery. Surgical resection of the colon is considered curative in UC. Surgical resection of bowel in CD is not curative because the disease will often recur at the resection site as well as other sites.

a. Surgery in UC is most commonly indicated for disease refractory to medical therapy, inability to wean the patient off of high corticosteroid dosages, serious drug side effects or intolerance, and occurrence of premalignant or malignant changes in the colon.

b. Approximately one third of UC patients eventually undergo colectomy. Patients with extensive disease (pancolitis) undergo colectomy more than patients with less extensive (distal) disease and also usually require colectomy sooner than patients with less extensive disease.

c. UC surgery can be divided into two types: those that preserve continence and those that do not and subsequently require appliances to collect the fecal material.

(1) Proctocolectomy with permanent ileostomy is the oldest procedure and involves formation of an abdominal stoma connected to the ileum. An external appliance is used to collect fecal material.

(2) Proctocolectomy with continent ileostomy involves creation of a pouch inside the abdomen using the terminal ileum. A small leakproof opening is created in the abdomen wall and the pouch is periodically drained.
(3) Colectomy with ileorectal anastomosis involves removing diseased large bowel and reattaching the remaining small intestine to a preserved rectum. While bowel movements via the rectum are preserved, patients are at risk of relapse because the rectum is often involved in UC.

(4) Ileal pouch anal anastomosis (IPAA) is the most common surgical procedure done for IBD. The large bowel and rectum are removed, with preservation of the anal sphincter. A tubular pouch is formed from the small intestine and attached to the preserved sphincter, which allows bowel movements without external bags or appliances. A temporary ileostomy is often used during healing.
d. CD surgery, while not curative, is required in a very high percentage of patients. Surgical intervention can be limited to specific areas of diseased bowel or total ileostomy or colectomy. Surgery is most commonly indicated in CD refractory to medical therapy, medication side effects, or steroid dependency.
(1) Small bowel resection is preferred in most patients with ileal or ileocolic CD. Primary anastomosis versus ileostomy (permanent or temporary) choice is based on patient status and CD severity.
(2) Large bowel CD may require some degree of resection secondary to the typical CD disease course involving “skip lesions.” Primary anastomosis of the preserved bowel may be preferred for patient QOL reasons but has been linked to earlier reoccurrence of CD.
(3) Colectomy with ileorectal anastomosis, while increasing risk of earlier CD recurrence, is useful in young patients for whom ileostomy may adversely affect QOL.
(4) Proctocolectomy and ileostomy is preferred in patients with extensive perianal disease or pancolitis CD.
(5) Strictureplasty can also be useful in stricturing CD.
e. Pouchitis is the most common complication of continent ileostomy and IPAA. It has been characterized as a syndrome including acute nonspecific inflammation of the reservoir pouch formed during surgery with unknown cause.
(1) Idiopathic pouchitis must be differentiated from inflammation of the pouch owing to anastomotic stricture and infection as a result of known pathogens.
(2) Broad-spectrum antibiotics have been the main medical therapy used for pouchitis. Metronidazole and ciprofloxacin have both been effective for acute pouchitis and have also been used as maintenance therapy.
(3) Probiotic therapy with VSL#3 has also been of benefit.
(4) Pharmacologic therapy used in IBD has been shown to be of mixed efficacy in pouchitis. Surgical revision may be required in chronic pouchitis unresponsive to medical therapy.
13. Other therapy

a. Nutritional issues are important to consider in IBD. While conclusive evidence does not exist showing that particular foods cause IBD, special attention to diet in patients with IBD can be beneficial.

(1) Nutritional and hydration deficiencies can occur secondary to a poorly functioning GI tract and the chronic nature of IBD.

(2) Foods that are known to exacerbate an individual patient's IBD should be avoided, and a well-balanced diet should be encouraged to maintain nutritional status. Restrictive diets are not normally required. Simply limiting offending foods while encouraging a balanced diet is usually sufficient to maintain nutritional status.

(3) Parenteral feeding is seldom used long term in IBD but can be useful to improve or maintain nutritional status in severely ill patients.

c. Emotional factors. Owing to the chronic nature of IBD, many sufferers have need for emotional support during the course of their disease. While IBD does not appear to be directly affected by emotional state, the QOL experienced by these sufferers can be noticeably affected in a negative manner. Many will benefit greatly by support groups and continued open dialogue with their healthcare providers; sometimes formal counseling or pharmacologic therapy may be needed.

B. Drug Therapy for IBD and UC

1. Classifying UC based on anatomic disease extent is useful for determining medical therapy. Distal disease (below the splenic flexure) can be treated effectively with topical therapy. Extensive disease (extending proximal to the splenic flexure) normally requires systemic therapy. Severity of acute UC is also useful in determining medical therapy. Severity is generally defined as mild, moderate, severe, or fulminate.

2. Management of mild to moderate UC distal disease. Patients with mild to moderate distal UC respond well to oral and topical aminosalicylates or topical steroids for inducing remission (control of inflammation).

a. Topical mesalamine is superior to topical steroids or oral aminosalicylates.

b. Topical mesalamine plus oral aminosalicylate is superior to either alone.

c. Topical mesalamine may be effective in patients refractory to oral aminosalicylates or topical steroids.

d. Infrequently, oral corticosteroids may be needed in patients refractory to topical/oral aminosalicylates and topical steroids in maximal doses.

e. Therapy is largely determined by patient preference to therapy modality.

f. Oral 5-ASA doses for inducing remission in mild to moderate distal disease are as follows:

(1) Sulfasalazine 4-6 g per day in four divided doses

(2) Mesalamine 2-4.8 g per day in three divided doses

(3) Balsalazide 6.75 g per day in three divided doses

(4) Olsalazine 1.5-3 g per day in divided doses

g. The oral 5-ASA drugs tend to work in 2-4 weeks and are effective in a high percentage of patients.

h. Oral corticosteroids. Budesonide is an oral corticosteroid that offers relatively lower systemic exposure compared to prednisone secondary to high first-pass metabolism. Budesonide has been effective in UC treatment but is limited to UC when the ileal release formulation can reach the location of disease.

i. Topical therapy generally induces remission more quickly than oral therapy, and it offers less frequent dosing than oral therapy. Suppositories reach the disease approximately 10 cm proximally. Hydrocortisone foam reaches the disease 15-20 cm proximally. Enemas reach the disease approximately to the splenic flexure (52-56 cm)

j. Topical 5-ASA for inducing and maintaining remission of UC

(1) Mesalamine suppositories 500 mg twice a day (proctitis)

(2) Mesalamine enemas 1-4 g per day (distal colitis proximally to the splenic flexure)

k. Topical corticosteroids for inducing remission of UC

(1) Hydrocortisone enema 100 mg per day

(2) Hydrocortisone foam, 10% 1 application every day to twice a day

l. Oral plus topical therapy consisting of oral mesalamine 2.4 g per day in divided doses plus mesalamine 4 g per day enema may induce remission of UC more quickly.

3. Maintenance of distal disease

a. 5-ASA preparation dosages for maintaining remission of distal disease

(1) Balsalazide 3-6 g per day

(2) Mesalamine Eudragrit-S 3.2 g per day

(3) Mesalamine suppository 500 mg every day or twice a day

(4) Mesalamine enema 2-4 g daily, every other day, or every third day

(5) Olsalazine 1 g per day

(6) Sulfasalazine 2 g per day

(7) Mesalamine 1.6 g orally per day plus 4-g enemas twice weekly is also effective

b. Corticosteroids, topical and oral, are not effective in maintaining UC remission and should not be used.

4. Mild to moderate extensive or relapsing disease

a. Oral 5-ASA

(1) Sulfasalazine 4-6 g per day in four divided doses. Doses > 2 g per day appear to offer little benefit.

(2) Newer 5-ASA preparations are generally considered to be equal to sulfasalazine in regard to efficacy and are likely superior in regard to adverse events and tolerance; but they are more expensive. The dosages used are a minimum of 2 g per day of active 5-ASA moiety titrated up to a maximum of 4.8 g per day.

b. Oral steroids

(1) Prednisone 40-60 mg per day (modest efficacy gain with 60 mg compared to 40 mg) until significant clinical effect is seen followed by a dose taper of 5-10 mg weekly until a daily dose of 20 mg is reached. Tapering generally continues from here at 2.5 mg per week until the patient is weaned from oral steroids.

(2) Higher doses for longer periods increase risk of corticosteroid-associated risk.

(3) IBD patients receiving corticosteroids for > 3 months should be evaluated and may benefit from dual-energy x-ray absorptiometry (DEXA) bone testing and possibly preventative

therapy with bisphosphonates, alendronate (Fosamax), risedronate (Actonel), and etidronate (Didrocal).

(4) For patients on long-term corticosteroid therapy and who have significant risk factors, such as previous fractures, bisphosphonates, calcium supplementation at 1-1.5 g per day, and vitamin D supplementation at 800 mg per day should also be considered.

(5) Corticosteroid-induced osteoporosis has also been shown to respond to treatment with bisphosphonates.

5. Maintenance of mild to moderate relapsing disease. Sulfasalazine is as effective as equivalent doses of newer 5-ASA agents and is less costly in long-term therapy. Systemic corticosteroids as a rule are not accepted as long-term therapy options owing to adverse events and questionable therapeutic effect. 6-MP or azathioprine has been useful as a steroid sparing agent and as a long-term option to wean patients off corticosteroids.

a. Oral 5 ASA therapy

(1) Balsalazide 3-6 g per day

(2) Mesalamine 2-4 g per day

(3) Olsalazine 1 g per day

(4) Sulfasalazine 2-4 g per day

b. 6-MP and azathioprine 100-250 mg per day, maximum of 2.5 mg/kg/day

6. Moderate to severe disease. UC patients with moderate to severe disease are able to be managed on an outpatient basis or may require hospitalization. Patients with severe disease who are refractory to maximal oral therapy and patients with signs of toxicity should be hospitalized. Infection with enteric pathogens should be ruled out. Failure to demonstrate significant improvement within 7-10 days is an indication for surgical resection or alternate intravenous therapy such as with cyclosporine.

a. Intensive IV steroid therapy is indicated for patients with severe disease who are hospitalized. Doses with prednisolone (40-60 mg), hydrocortisone (300 mg), or methylprednisolone (32-48 mg per day in divided doses or as continuous infusion) have been shown to be effective. Higher doses are of limited benefit and increase the risks of steroid toxicity.

b. Empiric broad-spectrum antibiotics are of little use in moderate to severe UC.

c. When possible, patients should be maintained on oral feedings with a modified diet to reduce abdominal discomfort and diarrhea and bowel frequency. Total parenteral nutrition is used when oral feeds are not tolerated and can be especially useful in patients with severe nutritional depletion.

d. In patients with signs of toxicity, narcotics, antidiarrheals, and anticholinergics should be avoided because they can increase the risk of worsening colonic dilation and perforation.

e. 5-ASA should be stopped in the acute setting to avoid intolerance issues and the rare instances of 5-ASA exacerbating colitis.
f. Topical steroids may provide benefit in patients with rectal urgency or tenesmus.
g. Intravenous cyclosporine at 2-4 mg/kg per day and titrated to blood levels between 200 and 400 ng/mL has been effective in a high percentage of patients who do not respond to maximal parenteral steroids.
h. Oral cyclosporine at twice the daily intravenous dose is given in divided doses (twice a day) with oral steroids once clinical remission is reached with intravenous cyclosporine.
i. Relapse on 5-ASA therapy alone after remission induced with cyclosporine is frequent, and azathioprine or 6-MP can be beneficial when added for maintenance.
j. Sulfamethoxazole/trimethoprim (Bactrim) should be added as prophylaxis against *Pneumocystis* pneumonia for patients on cyclosporine.
7. Fulminant disease. Patients with fulminant colitis or toxic megacolon should be treated as noted for severe disease and should not take anything by mouth. Broad-spectrum antibiotics are often used empirically owing to the high risk of perforation. Any worsening of disease as evidenced by radiologic, clinical, or laboratory changes while on medical therapy is an indication for immediate colectomy.
C. Drug therapy for CD depends on the disease location, disease severity and any complications.
1. Mild to moderate CD
a. 5-ASA orally
(1) Mesalamine 3.2-4 g per day
(2) Sulfasalazine 3-6 g per day

(3) Specific disease locations may dictate which preparation to use based on site of delivery
(4) Sulfasalazine may be more effective than newer 5-ASAs. It also is less expensive but less well tolerated
b. Oral broad-spectrum antibiotics have been used with limited controlled clinical data to support such use.
(1) Added to 5-ASA therapy for failures
(2) Metronidazole 750-1500 mg per day
(3) Ciprofloxacin 1000 mg per day
c. Budesonide orally
(1) Targeted delivery to the ileum, works well in ileal or proximal colon disease.
(2) Dose at 9 mg per day for 8-16 weeks
(3) Tapered 3 mg per week over 2-4 weeks
d. If these fail, the presentation can be considered refractory and treated as moderate to severe.
2. Moderate to severe CD
a. Systemic steroids
(1) Prednisone 40-60 mg per day

(2) Hospitalization for intravenous corticosteroids may also be considered

b. Azathioprine, 6-MP, and methotrexate

(1) Effective for steroid failure

(2) Azathioprine 2-3 mg/kg/day or 6-MP 1-1.5 mg/kg/day

(3) Methotrexate 25 mg/week IM, tapered to 15 mg/week IM after 16 weeks

(4) Azathioprine, 6-MP, and methotrexate are all antimetabolite drugs and will take considerable time to reach full effect, up to 3-4 months may be required.

(5) Concomitant use of oral 5-ASA or antibiotics with immunosuppressant therapy have not been shown to be of benefit in controlled trials.

c. Anti-TNF therapy

(1) For patients refractory to or do not tolerate systemic steroids and immunosuppressant therapy.

(2) In perianal fistulizing CD infliximab is effective therapy.

(3) Infliximab 5 mg/kg at 0, 2, and 6 weeks

(a) Relapse at one year is high if infliximab stopped

(b) HACA formation is common in noncontinuous therapy and may decrease efficacy of future courses of therapy. HACA formation may be limited with concomitant dosing of azathioprine, 6-MP, or methotrexate.

(c) Concomitant therapy with 5-ASA, steroids, or antibiotics is of little added benefit.

(4) Adalimumab 160 mg day one and 80 mg day 15 followed by 40 mg every other week starting at day 29.

(5) Certolizumab pegol 400 mg day one and weeks 2 and 4 followed by 400 mg every 4 weeks.

3. Severe or fulminant CD includes active disease of a severe nature, toxic enteritis or colitis, megacolon, small bowel obstruction, and abdominal abscess. Patients often require hospitalization because of the severity of the disease and risk of complications.

a. Typical therapy may include

(1) Intravenous fluids and bowel rest (parenteral nutrition)

(2) Intravenous antibiotics with metronidazole, aminoglycosides, and broad-spectrum penicillin or third-generation cephalosporins empirically for possible abscess or infections.

(3) Intravenous corticosteroids

b. Anti-TNF therapy may be useful for patients who do not respond to intravenous corticosteroids.

c. Surgical intervention may be required in patients who do not respond to intravenous corticosteroids and infliximab.

4. Maintenance of remission strategies have been of questionable efficacy. Historically, long-term treatment with 5-ASA agents and broad-spectrum antibiotics has been advocated with a lack of convincing controlled clinical data to support these measures. Newer evidence-based approaches may change therapy strategies.

a. 5-ASA

(1) May be of benefit but clinical data are mixed

(2) Mesalamine 2.4-4.8 g per day or sulfasalazine 2-4 g per day

b. Budesonide

(1) Doses of 6-9 mg per day have been used with positive effect.

(2) Appears to be safe compared to long-term systemic steroids

c. Immunosuppressants

(1) Azathioprine, 6-MP, methotrexate, and anti-TNF therapy have been used in maintenance; but adverse events must be weighed carefully, especially in patients with mild disease.

(2) Azathioprine, 6-MP, and methotrexate may be useful in patients unable to wean off systemic steroids.

(3) Anti-TNF therapy is effective at inducing and maintaining clinical remission in Crohn's disease. Concomitant azathioprine, 6-MP, or methotrexate can also reduce HACA formation with infliximab injections and may increase efficacy.

d. Systemic steroids are normally avoided in long-term therapy secondary to systemic toxicity; convincing data to support their use are lacking.

d. Antibiotics have not been shown in controlled clinical trials to be effective in maintaining medically induced remission.

D. IBS

1. The treatment of IBS is based on the nature and severity of symptoms, correlation of symptoms to food intake and/or defecation, degree of functional impairment, and the presence of psychosocial or psychiatric disorders. Treatment is highly personalized and can be generalized as follows.

2. Mild IBS is the most common disease presentation, and patients normally suffer from few psychosocial problems.

a. Education about the disease and support can be of great benefit.

b. Diet and lifestyle changes

(1) Specific foods are usually not as important as the size of meals; smaller meals are preferable. Care should be used and restrictive diets should be avoided.

(2) Decrease fatty foods, gas-producing foods

(3) Decrease alcohol

(4) Decrease caffeine

(5) Avoid dairy in lactose-intolerant patients

(6) Excess fiber can also increase IBS symptoms

(7) Prepare strategies to handle stress

3. Moderate IBS symptoms are normally intermittent but can be disabling at times. These patients suffer from more symptom-related distress. Patient symptoms historically are also associated with more gut reactivity (worse with eating and better with defecation).

a. Anticholinergics used as antispasmodics

(1) Dicyclomine (Bentyl) 20 mg by mouth four times a day

(2) Hyoscyamine (Anaspaz) 0.15-0.3 mg by mouth four times a day

(3) Clidinium plus chlordiazepoxide (Librax) 2.5/5 mg 1-2 tabs by mouth before every meal and at bedtime

(4) Hyoscyamine + scopolamine, atropine, phenobarbital (Donnatal) 1-2 tablets every 6-8 hr

b. Antidiarrheals

(1) Diphenoxylate plus atropine (Lomotil) 0.025/2.5 mg 2 tabs by mouth four times a day, maximum of 8 tablets per day

(2) Loperamide (Imodium) 4 mg followed by 2 mg after each unformed bowel movement up to a maximum of 16 mg per day

c. Tegaserod (Zelnorm) is a 5HT4 agonist for constipation predominant IBS in women and is only available in the USA through a manufacturer sponsored access program.

(1) Access in the US via a manufacturer administered program

(2) IBS dosing (**women only**) is 6 mg by mouth twice a day before meals

(3) Chronic constipation dosing is 6 mg by mouth twice a day before meals

d. Alosetron (Lotronex) is a 5-HT3 antagonist available in the United States through a manufacturer-sponsored access program; it is to be used only for diarrhea-predominant IBS in women. The dose for severe IBS in **women only** is 0.5-1 mg by mouth twice a day.

e. Low-dose tricyclic antidepressants (TCAs) can be effective for pain control. The dosages typically used are below the effective doses used for clinical depression. TCA also may slow GI transit time and be useful in diarrhea-predominate patient cases.

f. Lubiprostone (Amitiza™) is a chloride channel activator indicated for idiopathic constipation. There is limited data on the use of lubrprostone in IBS-C but it has been used increasingly secondarily to the suspension of marketing of tegaserod in the U.S. market.

g. Polyethylene glycol (Miralax® and others) is a laxative solution that increases the amount of water in the intestinal tract to stimulate bowel movements. Potassium, sodium, and other minerals are also included to replace electrolytes that are passed from the body in the stool. Polyethylene glycol is available by prescription or OTC and is generally considered to be very safe for constipation and may be of benefit to IBS-C patients. Caution should be used in severely constipated patients or patients who may have an obstruction.

4. Severe IBS is a very small proportion of the entire IBS population. GI complaints can be refractory and of continuous nature. Psychosocial and psychiatric comorbidities are common.

a. Antidepressants, including the selective serotonin reuptake inhibitors, are often useful in severe IBS patients owing to the increase in psychosocial components to patient presentation.

b. Anxiolytic drugs, including diazepam, are occasionally used for IBS when patients are experiencing acute anxiety that is worsening their symptoms. In light of the risk of dependency, these drugs should be taken for only short periods of time.

III. COMPLICATIONS

A. IBD

1. UC and CD have many similar presenting features as well as commonalities in complications. The majority of UC patients will have a chronic relapsing disease course. Length of disease is related to risk of colectomy and colorectal cancer. Mortality is similar to rates in non- UC populations. CD may impose a slight increase in mortality with long standing disease.

2. Musculoskeletal manifestations of IBD are the most common extraintestinal manifestations of the disease.

a. Arthralgias in the absence of arthritis signs are the most common complaint.

b. Between 5% and 20% of IBD patients experience peripheral arthritis pain that is self-limiting and coincides with IBD flares and resolves with successful treatment of IBD. Occurrence is nearly equal between males and females.

c. Ankylosing spondylitis in IBD is less common, at approximately 5%, and is equal in UC and CD. Males are affected more than females and the course is usually not related to the course of IBD.

3. CD fistulas and abscess. Long-standing inflammation may progress into penetrating disease, abscess formation, and fistula formation. These penetrating communications can be from diseased organ to neighboring organ, peritoneum, and skin. Fistula types include perianal, enteroenteric, enterocutaneous, enterovesical, and rectovaginal.

4. Hemorrhage in the colon is relatively rare in UC but is serious. Acute hemorrhage accounts for a significant percentage of urgent colectomies in UC. Severe bleeding tends to occur early in the course of disease. Hemorrhage in CD is extremely rare.

5. Strictures or narrowing of the colon or rectum occurs in a small percentage of the UC population. It is important that nearly one third of such strictures may be related to malignancy and so should be carefully evaluated.

6. Toxic megacolon is a serious complication mainly seen in UC but occasionally in CD as well. It occurs when the inflammatory process causes the colon to dilate, with subsequent bowel wall thinning. This results in the bowel becoming more fragile. The major risk is bowel perforation. Bowel dilation that does not respond to therapy within 72 hr is considered an indication for surgical resection.

7. Cancer. Overall, UC patients are at higher risk of developing **colorectal cancer** compared to patients without IBD. The risk to individuals is variable and is related to duration and extent of UC as well as patient-specific risk factors. Risk is greatest in patients with pancolitis of long-standing duration. Colorectal cancer is also a risk in CD patients, especially if it is CD involving the colon. Risk of cancer of the small intestine has been noted in CD as well.

8. Primary sclerosing cholangitis (PSC) is the most common hepatobiliary complication of IBD. PSC affects men more than woman. PSC is more common in UC than in CD.
9. Osteoporosis as evidenced by increased fractures and diminished bone density has been shown in CD patients.
10. Quality of life. While most IBD patients are able to lead nearly normal lives, many do suffer significantly during active flares of disease. The chronic nature of disease also has a negative effect on patient QOL.
B. IBS. Although IBS has been shown to produce substantial physical discomfort and emotional distress, most patients with IBS do not develop serious or long-term health complications. Most patients learn to control their individual symptoms with diet and lifestyle modification or medical therapy as needed.

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.
For questions 1-2: A 35-year-old male presents to his physician with the primary complaints of abdominal pain and frequent bowel movements over the past few weeks. Upon examination and routine laboratory testing, he is found to have a low-grade fever and an elevated erythrocyte sedimentation rate (ESR). Further questioning reveals he is having four to five loose bowel movements each day. The patient is a past smoker. Stool antigen tests are negative for known gastrointestinal (GI) pathogens. Physical examination and colonoscopy reveal contiguous areas of inflammation of the rectum and most of the descending colon. The physician diagnoses moderately severe ulcerative colitis.
1. Which therapy would be the most effective for inducing remission?
(A) topical corticosteroids
(B) topical 5-aminosalicylic acid (5-ASA)
(C) oral budesonide
(D) topical 5-ASA plus oral 5-ASA

View Answer***1. The correct answer is D[see].*****2. Once remission is achieved, which therapy is most appropriate for maintenance?**
(A) sulfasalazine 2 g per day
(B) balsalazide 2 g per day
(C) olsalazine 4 g per day
(D) topical corticosteroids

View Answer***2. The correct answer is A[see].*****For questions 3-4:** An 18-year-old female with mild Crohn's disease who is being treated with oral sulfasalazine 4 g per day presents to her physician because her symptoms have returned. She is ambulatory with no signs of toxicity or weight loss. Her disease is mainly of the ileum.

3. What would be a logical next step in therapy?

(A) intravenous corticosteroids

(B) budesonide 9 mg per day

(C) prednisone 40 mg orally per day

(D) azathioprine 1 mg/kg per day

View Answer***3. The correct answer is B[see].*****4. The patient fails this next therapy and is determined to be refractory. Her symptoms are increasing and her schooling is beginning to suffer. She is also noted to have been intolerant of a trial of 2.5 mg/kg day of 6-mercaptopurine (6-MP) therapy. What would be a logical next step in therapy?**

(A) azathioprine 1mg/kg per day

(B) metronidazole 750 mg per day

(C) surgical resection with ostomy

(D) infliximab 5 mg/kg at 0, 2, and 6 weeks

View Answer***4. The correct answer is D[see].*****For question 5:** A man with diarrhea-predominant IBS is experiencing interruption of his work as a truck driver because of frequent bouts of diarrhea. He states his symptoms are worse after eating, especially fried foods. His physician discusses the possible benefit of avoiding fat in his diet. The patient agrees to try but also asks for something to use in emergencies.

5. What would be the most appropriate therapy to use?

(A) alosetron 0.5 mg twice a day

(B) hyoscyamine 0.15 mg by mouth as needed

(C) loperamide 4 mg then 2 mg as needed up to 16 mg per day

(D) fluoxetine 40 mg every day

View Answer***5. The correct answer is C[see].*****6. Which is most appropriate for a woman with constipation-predominant IBS?**

(A) a restrictive bland diet

(B) tegaserod 6 mg by mouth twice a day

(C) alosetron 1 mg by mouth twice a day

(D) excess dietary fiber

View Answer***6. The correct answer is B[see].*****7. Patients with ulcerative colitis and Crohn's disease present in similar ways. There are several clinical differences between the diseases that can help differentiate them. Which of the following clinical features is more common in Crohn's disease than in ulcerative colitis?**

(A) abnormal bowel movements

(B) slow onset of disease

(C) joint pain

(D) fistula formation

View Answer***7. The correct answer is D[see].***P.1164

ANSWERS AND EXPLANATIONS

1. The correct answer is D *[see* II.B.2*].*
Topical 5-ASA therapy plus oral 5-ASA therapy has been shown to be superior to either alone or topical steroids at inducing remission in mild to moderate UC. Budesonide ileal release will not likely reach the site of disease in this patient because he has left-sided disease.
2. The correct answer is A *[see* II.B.3*].*
The correct dose for balsalazide is 3-6 g per day and for olsalazine is 1 g per day. Topical steroids have no place in maintenance of UC.
3. The correct answer is B *[see* II.C.1*].*
This patient has not responded to 5-ASA therapy for inducing remission of her mild disease. The patient is not showing signs of severe disease or toxicity and as such neither intravenous nor oral therapy with systemic corticosteroids is warranted at this time. A dose of 1 mg/kg per day of azathioprine is below the recommended dose for inducing remission. Azathioprine also may take several months to induce remission. Budesonide is an ileal-release therapy, and her disease is mainly confined to that area. Budesonide has been shown to be effective in mild and moderate CD.
4. The correct answer is D *[see* II.C.2*].*
This patient is intolerant to azathioprine and it should not be used. Broad-spectrum antibiotics are unlikely to be of any benefit in this patient and should not be used. While likely to be beneficial, surgery with a permanent ostomy would also be severely limiting to a young patient because of social and QOL concerns. Infliximab has been shown to be effective for refractory CD.
5. The correct answer is C *[see* II.D.3*].*
This patient is male and as such alosetron is not an appropriate option for him. Hyoscyamine is an effective antispasmodic but will likely do little for his diarrhea. The patient makes no complaint of serious effect on his life and does not show signs of severe disease. Full-dose antidepressant fluoxetine dosing is not warranted. Loperamide can be of use in managing mild to moderate symptoms of IBS.
6. The correct answer is B *[see* II.D.3*].*
Tegaserod 6 mg by mouth twice a day with meals is appropriate and effective therapy for women suffering from constipation-predominant IBS. Alosetron is effective in women with diarrhea-predominant IBS. Restrictive diets are not normally of benefit, and excess dietary fiber can increase IBS symptoms.
7. The correct answer is D *[see* I.B.1*].*
While the overlap of clinical presentation of these two diseases is substantial, fistula formation is extremely rare in ulcerative colitis.

54

Diabetes Mellitus

Peggy C. Yarborough

I. INTRODUCTION

A. Definition. Diabetes mellitus (DM) is a chronic, progressive, systemic disease characterized by dysfunction in the following:

1. Metabolism of fats, carbohydrates, protein, and insulin

2. Function and structure of blood vessels and nerves

B. Classification. There are four clinical classes of diabetes: type 1, type 2, gestational diabetes mellitus (GDM), and other specific types (secondary DM). Although *not* a type of diabetes, prediabetes is included with the classification of glucose abnormalities.

1. Type 1. Previously described as insulin-dependent diabetes mellitus (IDDM), juvenileonset diabetes, or ketosis-prone diabetes. Results from β cell destruction, usually leading to absolute deficiency of insulin secretion. β cell destruction may be from immune or nonimmune factors.

a. Most common in children and in adults < 30 years old, but may occur at any age

b. Immune mediated. More than 90% of type 1 is immune mediated.

(1) Markers of immune destruction of β cells are present. Also related to environmental factors that are still poorly defined.

(2) Predisposed to **ketoacidosis,** accumulation of ketone bodies in body tissues and fluids (see II.B.1).

(3) Depends on exogenous insulin-replacement therapy to prevent ketoacidosis and sustain life.

(4) Patients are also **prone to other autoimmune disorders**—for example, Graves disease, Hashimoto thyroiditis, Addison disease, vitiligo, celiac sprue, autoimmune hepatitis, myasthenia gravis, and pernicious anemia.

(5) Rate of β cell destruction is variable; rapid in some (mainly infants and children) and slow in others (mainly adults)

(6) Latent autoimmune diabetes in adults (LADA), also described as type 1.5 diabetes, slowly progressive type 1 diabetes, latent type 1 diabetes, youth-onset diabetes of maturity, and LADA-type 1 and LADA-type 2. Good glycemic control may be maintained for several years with sulfonylureas, but patient eventually becomes insulin dependent.

c. Idiopathic type 1 diabetes. No known cause; < 10% of type 1 is idiopathic.

(1) Strongly inherited, lacks immunological evidence for β cell autoimmunity, and is not human leukocyte antigen (HLA) associated.

(2) May have permanent insulinopenia and be prone to ketoacidosis.

(3) Or may have episodic ketoacidosis and exhibit some degree of insulin deficiency between episodes. An absolute requirement for insulin-replacement therapy may come and go.

(4) Most are of African or Asian ancestry

d. The essential difference between type 1 and type 2 DM is that insulin production and secretion in type 1 is destroyed; in type 2 DM, insulin production and secretion may be altered or reduced but is not totally lacking.

2. Type 2. Previously described as non-insulin-dependent diabetes mellitus (NIDDM) or adultonset diabetes. Results from a progressive insulin secretory defect on the background of insulin resistance.

a. Approximately **90%** of individuals with diabetes in the United States have type 2 diabetes, with a disproportionate representation among certain ethnic groups and the elderly.

b. May present as predominantly **insulin resistance** with relative insulin deficiency to predominantly an insulin secretory defect with insulin resistance.

c. Most patients are **obese** at diagnosis (approximately 80%), either by traditional weight criteria or by increased percentage of body fat distributed predominantly in the abdominal region.

d. Usually diagnosed in adults >30 years old, but may occur at any age. The incidence of type 2 DM in adolescents is increasing, apparently related to an increasing incidence of obesity in this age group, decreasing exercise/physical activity, and genetic and other lifestyle factors.

e. Insulin resistance may improve by interventions (weight loss, exercise, medications), but **seldom returns to normal.**

f. Endogenous insulin levels may appear normal, increased, or decreased, and the requirement for exogenous insulin is variable. Despite apparently "normal" or "increased" insulin levels, β cell dysfunction is manifest by a *relative insulin insufficiency* to maintain euglycemia, especially in the face of significant insulin resistance.

g. Diminished incretin effects develop early or later into the disease

h. Not prone to ketosis except during periods of severe physical stress such as infections, trauma, or surgery.

3. Gestational diabetes mellitus. Defined as any degree of glucose intolerance that has its onset or is first detected during pregnancy.

a. Occurs in 2%-4% of pregnant women, generally during the second or third trimester.

b. A follow-up glucose tolerance test should be performed at 6 weeks after pregnancy. Glucose regulation would then be reclassified as DM, impaired fasting glucose (IFG), impaired glucose tolerance (IGT), or normoglycemia. In the majority of cases, glucose regulation returns to normal postpregnancy.

c. Occurrence of GDM increases future risk for developing type 2 diabetes.

4. Other specific types (secondary diabetes). Broad term used to classify patients who have unusual causes of diabetes owing to certain diseases of the pancreas, genetic defects, endocrinopathies, or drugs.

5. Prediabetes. Term used to refer to an intermediate metabolic stage between normal glucose homeostasis and diabetes. Prediabetes is a risk factor for future DM and cardiovascular disease (CVD).

C. Diabetes demographics and statistics

1. In the United States, an estimated **6.3%** of the population has DM, and nearly half as many individuals remain undiagnosed.

2. Type 1 DM accounts for approximately 10% of cases and type 2 for about 90%

3. DM is listed as the **sixth leading cause of death** in the United States;[1] but it likely contributes to other significant causes, such as heart disease (number one cause of death), cerebrovascular diseases (number three), and kidney disease (number nine).

D. Cause. Various factors contribute to the development of DM.

1. Type 1 DM. Genetic predisposition, environmental factors, and autoimmunity have been proposed.

a. Genetics. Certain genetic markers in the HLA system have been strongly linked with type 1 DM, and the risk of developing diabetes is substantially increased in the offspring of individuals diagnosed with diabetes.

b. Environment. Not all individuals at genetic risk for type 1 DM develop the disease. Some type of trigger, such as a virus (e.g., rubella) or toxic chemical, is needed for the expression of the genetic propensity for type 1 DM.

c. Autoimmunity. An autoimmune component, perhaps stimulated by the environmental trigger, is involved in the development of type 1 diabetes. Anti-insulin or anti-β cell antibodies are present in the blood of most individuals at the time of diagnosis of type 1 DM.

2. Type 2 DM. Genetic factors, a β cell defect, and peripheral site defects have been implicated.

a. Genetics. There is a greater than 90% concordance rate between monozygotic twins if one has type 2 diabetes. It has been estimated that offspring of individuals with type 2 diabetes have approximately a 15% chance of developing the disease.

b. Diminished **β cell function** is postulated to cause abnormalities in insulin secretion, resulting in a relative deficiency of insulin.

c. A **peripheral site defect** is postulated to lead to **insulin resistance** (tissue insensitivity to the biological activity of insulin). This condition is thought to result primarily from postbinding abnormalities.

3. Secondary diabetes may arise from such conditions as endocrine disorders (e.g., Cushing syndrome), pancreatic disease, and the use of

drugs that antagonize insulin (e.g., thiazide diuretics, adrenocorticosteroids).

II. PATHOPHYSIOLOGY OF THE DIABETIC STATE

A. Normal glucose regulation requires the intricate balance of insulin, counterregulatory hormones, intestinal incretins, and amylin hormone. Alterations in these key components form the basis for medication selection for the diabetic state.

1. Insulin is responsible for a variety of effects throughout body tissues.

a. Stimulates **glucose transport** across cell membranes and promotes the storage of glucose as glycogen in muscle and liver cells

b. Enhances fat storage (**lipogenesis**) and prevents the mobilization of fat for energy (**lipolysis** and **ketogenesis**)

c. Inhibits production of glucose from liver or muscle glycogen (**glycogenolysis**)

d. Promotes incorporation of **amino acids into proteins**

e. Inhibits the formation of glucose from amino acids (**gluconeogenesis**)

f. Decreases the breakdown of fatty acids to ketone bodies

2. Counterregulatory hormones antagonize the glycemic effects of insulin.

a. Glucagon (produced in the α cells of the pancreas)

b. Epinephrine

c. Norepinephrine

d. Growth hormone

e. Cortisol

3. Intestinal hormones, notably **glucagon-like peptide 1 (GLP-1)** and **glucose-dependent insulinotropic polypeptide (GIP),** Hormones secreted by the intestines, in response to ingestion of food, enhance the ability of orally administered glucose to stimulate pancreatic β cell secretion of insulin.

a. These effects are referred to as “incretin effects.” *Incretin* stands for intestinal (stimulators for) secretion of insulin.

b. Incretins do not directly stimulate insulin secretion but instead enhance the ability of glucose to stimulate insulin secretion.

c. Postprandial secretion of GLP-1 is **diminished** in DM. GLP-1 actions include

(1) Reduced rate of gastric emptying

(2) Inhibited glucagon secretion by pancreatic α cells

(3) Inhibited appetite

(4) Altered β cell biosynthesis, resulting in increased β cell mass and increased insulin secretory capacity

d. GIP secretion is normal or increased in DM, but β cell **response is diminished.**

4. Amylin. A neurohormone normally co-secreted with insulin, by pancreatic β cells in response to food intake.

a. Amylin secretion is diminished when there is β cell destruction or dysfunction.
b. Amylin **lowers postprandial concentrations** by
(1) Slowing gastric emptying on ingestion of food, thus reducing the rate of glucose influx into the bloodstream

(2) Suppressing nutrient-stimulated secretion of glucagon, thus reducing hepatic glucose output after meals
(3) Modulating appetite by enhancing satiety, resulting in decreased food intake
B. Abnormal glucose regulation/hyperglycemic emergencies associated with diabetes. In untreated type 1 and type 2 DM, the disease follows a predictable progression from initial abnormalities of glucose metabolism to life-threatening diabetic ketoacidosis or hyperglycemic hyperosmolar nonketotic syndrome.
1. Diabetic ketoacidosis (DKA; type 1 DM)
a. Insulin deficiency results in hyperglycemia.
(1) Impaired glucose uptake in the peripheral tissues (primarily muscle)
(2) Reduction in the conversion of glucose to glycogen (impaired **glycogenesis**), primarily in the liver
(3) Impaired insulin-induced suppression of hepatic glucose production (**neoglucogenesis** and **glycogenolysis**)
b. As blood glucose (BG) concentrations increase, the glucose reabsorptive capacity of the kidneys will be exceeded. This occurs at about 180 mg/dL, referred to as the **renal threshold for glucose.** Glucose is then excreted into the urine, resulting in an **osmotic diuresis** with subsequent **dehydration** and **electrolyte abnormalities.**
c. Insufficient glucose uptake in the peripheral tissues (owing to insulin deficiency) causes the cells to use protein and fat as energy sources rather than glucose.
d. Breakdown of protein yields carbohydrate/glucose moieties, but with insufficient insulin, the additional glucose worsens hyperglycemia rather than serving as an energy source.
e. Breakdown of triglycerides (the stored form of fat) yields **free fatty acids** and **glycerol** through the process of **lipolysis.** Without the administration of insulin, type 1 DM will progress to ketonemia and ketoacidosis, as described below:
(1) Increasing amounts of glycerol leads to enhanced hepatic glucose production, further worsening hyperglycemia.
(2) Free fatty acids are broken down in the liver into **ketone bodies,** which are excreted by the kidneys (**ketonuria**). Acetoacetate (a ketone body) is converted in the liver to acetone, which is excreted through the lungs. This

is associated with a fruity odor and can sometimes be detected on the breath of the patient.
(3) As the utilization (breakdown) of adipose tissue continues, ketone production exceeds the capacity for excretion, leading to accumulation in the bloodstream (**ketonemia**).
(4) Increasing levels of free fatty acids contribute to the development and worsening of **acidosis.**
(5) Initially, there is compensation for acidosis by changes in breathing patterns (**Kussmaul breathing**) and by buffering systems of the blood (e.g., proteins, bicarbonate).
(6) As acidosis continues, breathing compensation and bicarbonate stores are insufficient or depleted. A state of ketosis with acidosis (**ketoacidosis**) then exists.
(7) If ketoacidosis is not promptly treated by insulin, coma and death will ensue in type 1 DM.
(8) The total lack of insulin in type 1 DM is a predisposing factor for DKA. Patients with type 1 DM are described as **ketosis prone.**
2. Hyperosmolar hyperglycemic state (HHS) (type 2 DM)
a. Insulin deficiency, often with concomitant insulin resistance, results in hyperglycemia
(1) Impaired glucose uptake in the peripheral tissues (primarily muscle)
(2) Reduction in the conversion of glucose to glycogen (impaired **glycogenesis**), primarily in the liver
(3) Impaired insulin-induced suppression of hepatic glucose production (**neoglucogenesis** and **glycogenolysis**)
b. Increasing blood glucose concentrations exceed the glucose reabsorptive capacity of the kidneys (occurs at about 180 mg/dL, referred to as the **renal threshold for glucose**). Glucose is then excreted into the urine, resulting in an **osmotic diuresis** with subsequent **dehydration** and **electrolyte abnormalities.**
c. Insufficient glucose uptake in the peripheral tissues (owing to insulin deficiency and/or insulin resistance) causes the cells to use protein as energy sources rather than glucose. Breakdown of protein yields carbohydrate/glucose moieties; however, with

insufficient insulin, the additional glucose worsens hyperglycemia rather than serving as an energy source.
d. In type 2 DM, the presence of even minimal blood levels of endogenous insulin usually prevents the breakdown of fats and subsequent ketonemia and ketoacidosis. Thus patients with type 2 DM are described as **ketosis resistant.**
e. Although sufficient to suppress ketosis, endogenous insulin secretion in type 2 DM is insufficient for glycemic control. If insulin is not administered,

profound dehydration with very high blood glucose levels may occur; this state is described as **HHS syndrome.** Coma and death may result.

III. CLINICAL EVALUATION

A. Physical findings

1. Symptom severity and onset help differentiate type 1 from type 2 DM.

a. Type 1 DM typically presents with an abrupt onset and an acute presentation.

b. Symptoms in individuals with type 2 DM generally develop gradually, with some patients being asymptomatic or having only mild symptoms upon diagnosis.

2. Classic signs and symptoms of DM include polydipsia (excessive thirst), polyuria (excessive urination), and polyphagia (excessive hunger). Other common findings include dry skin, fatigue, weakness, frequent skin and vaginal infections, weight alterations, and visual disturbances.

3. Individuals with type 1 DM may additionally present with unintentional weight loss, with or without signs and symptoms of ketoacidosis.

4. Some of the progressive changes of long-standing DM may be evident at the time of diagnosis of type 2 DM: deterioration in function or structure of the retina, kidneys, peripheral nervous system, and integumentary system.

B. Diagnostic testing or screening for prediabetes and diabetes[2]

1. Diabetes in nonpregnant adults

a. The preferred test to diagnose DM in nonpregnant adults is the fasting plasma glucose (**FPG**). The 75-g oral glucose tolerance test (**OGTT**) is more sensitive and more specific than FPG, but OGTT is rarely performed correctly in the outpatient setting. Because of ease of process, acceptability to patients, and lower cost, the FPG is the preferred diagnostic tool.

b. Three types of findings are accepted as the diagnosis of DM:

(1) A random (casual) plasma glucose (PG) level **> = 200 mg/**dL with classic symptoms of DM, including polydipsia, polyuria, polyphagia, and weight loss.

(2) FPG level **> = 126 mg/**dL. Fasting = no caloric intake for at least 8 hours.

(3) A 2-hr plasma glucose **> = 200 mg/**dL during an OGTT using 75 g anhydrous glucose dissolved in water.

c. In the absence of unequivocal hyperglycemia with acute decompensation, the above criteria should be **confirmed with repeat testing** on a different day.

d. Note that these criteria do not distinguish between type 1 and type 2 DM; rather, they only **identify the presence** of clinical diabetes.

2. Gestational diabetes

a. Risk assessment for GDM should be undertaken at the **first prenatal visit.** Marked obesity, personal history of GDM, glycosuria, delivery of a

previous large-for-gestationage infant, polycystic ovary syndrome, or a strong family history of DM would constitute a high risk for GDM.

b. High-risk women

(1) Perform glucose testing as soon as possible

(2) A FPG **> 125 mg/**dL or casual PG **> = 200 mg/**dL**,** confirmed on a subsequent day

unless unequivocal symptoms of hyperglycemia are present, constitutes a diagnosis of DM.

(3) High-risk women not found to have GDM at the initial screening should be tested **between 24 and 28 weeks** of gestation. Testing should follow one of two approaches:

(a) One-step approach. Perform a diagnostic 100-g OGTT.

(b) Two-step approach

(i) Initial screening of **50-g oral glucose load** (glucose challenge test; GCT). A 1-hr plasma or serum glucose threshold value of > = 140 mg/dL identifies ~ 80% of GDM and > = 130 mg/dL identifies 90% of GDM.

(ii) Perform a diagnostic 100-g OGTT on the subset of women exceeding the threshold values for the GCT. Diagnosis of GDM may be made if two values equal or exceed the following:

{**a**} Fasting: 95 mg/dL

{**b**} 1 hr: 180 mg/dL

{**c**} 2 hr: 155 mg/dL

{**d**} 3 hr: 140 mg/dL

(iii) Alternatively, a 75-g two-hour glucose tolerance test may be used; but that test is not as well validated for detection of GDM.

c. Low-risk women. Require no GDM screening, but this status is limited to individuals meeting *all* of the following criteria:

(1) Younger than 25 years of age

(2) Normal body weight before pregnancy

(3) Ethnic group with a low prevalence of GDM (e.g., *not* Hispanic, African American, Asian, or Native American)

(4) No first-degree relative with DM

(5) No history of poor obstetrical outcome

3. Type 2 DM in children

a. Glucose testing should be performed in children at **10 years of age** or at onset of puberty (if puberty occurs < 10 years of age) who exhibit the following risk factors for DM:

(1) Overweight, defined as: body mass index (BMI) > 85th percentile for age and sex, weight for height > 85th percentile, or weight > 120% of ideal for height.

(2) *Plus* any two of the following:

(a) Family history of type 2 DM in first- or second-degree relative

(b) Race/ethnicity (Native American, African American, Latino, Asian American, or Pacific Islander)
(c) Signs of insulin resistance or conditions associated with insulin resistance—for example, acanthosis nigricans, hypertension, dyslipidemia, polycystic ovary syndrome (PCOS)
(d) Maternal history of DM or GDM
b. Diagnostic criteria for DM are the same as listed for nonpregnant adults (see III.A.2).
c. FPG is the preferred test for children because of its ease of testing and reproducibility.
d. Repeat every 2 years if testing is negative for DM.
4. Screening for DM or prediabetes in asymptomatic individuals
a. Screening should be considered in individuals beginning at **age 45,** particularly in those with a **BMI** > **25 kg/m**^{2}.
b. Screening should also be considered in individuals < 45 years if they are overweight and have one or more risk factor for DM, such as
(1) Habitually physically inactive
(2) Have a first-degree relative with DM
(3) Member of a high-risk ethnic population (African American, Latino, Native American, Asian American, Pacific Islander)
(4) Given birth to a baby weighing 9 lb or has been diagnosed with GDM
(5) Hypertension
(6) High-density lipoprotein (HDL) cholesterol level < 35 mg/dL and/or a triglyceride level > 250 mg/dL
(7) PCOS
(8) On previous testing, had IGT or IFG

(9) Other clinical condition associated with insulin resistance (e.g., acanthosis nigricans)
(10) History of vascular disease
c. A **FPG** test or 2-hr 75-g **OGTT** may be used for screening.
d. If normal, repeat screening **every 3 years.**
e. Diagnosis of prediabetes. Nonpregnant individuals not meeting the criteria for diabetes but with abnormal test results can be classified as having **IFT** or **IGT.** In 2002, IFG and IGT were officially termed **prediabetes.** Use of this term better communicates to individuals the seriousness of this abnormality in the context of progression to DM.
(1) IFT. Fasting plasma glucose level > **110 mg/**dL **and** < **126 mg/**dL
(2) IGT. A 2-hr OGTT plasma glucose > **140 mg/**dL **and** < **200 mg/**dL

IV. DESIRED OUTCOMES OF DIABETES MANAGEMENT

would include, but are not limited to, the following (adapt for individual patient):

A. Mortality outcomes Avoid diabetes-related premature death. Life expectancy for American males is 75.2 years and for American females, 80.4 years[3]

B. Morbidity outcomes

1. Retard progression of the disease

2. Prevent or in a timely manner treat acute complications

3. Prevent, detect early, or adequately treat vascular and neuropathic disease and prevent or treat risk factors associated with those diseases (e.g., hypertension, tobacco use, triglycerides, cholesterol, obesity)

4. Prevent or minimize drug-related problems

a. Side effects—adverse drug reactions (ADRs)

b. Toxicity

c. Drug interactions (drug-drug, drug-disease, drug-food, drug-laboratory)

C. Behavioral outcomes

1. Annual eye exams

2. Routine self-monitoring of blood glucose (SMBG)

3. Development of a consistent support system

4. Adherence to medication regimen

5. Routine and timely medical examinations and laboratory tests

6. Avoidance of life-style or other behaviors—for example, alcohol, caffeine, nicotine, certain over-the-counter (OTC) medications—that may increase the risk of diabetes-associated problems

D. Pharmacoeconomic outcomes

1. Drug and treatment costs within patient resources

2. Cost-effective and efficient use of healthcare resources

E. Quality-of-life outcomes

1. Match, or only minimally change, patient lifestyle and activities with disease treatment

2. Patient satisfaction with pharmaceutical care and healthcare team

3. Positive but realistic outlook for the future

V. DESIRED THERAPEUTIC END POINTS FOR DIABETES MANAGEMENT

include, but are not limited to, the following (adapt for the individual patient):

A. Nonpharmacological end points

1. Attain and/or maintain BMI < 27.

2. Cessation of alcohol intake, or limit to no more than 1 oz. per day for adult females or no more than 2 oz. per day for adult males.

3. Nicotine/tobacco cessation

4. Moderate sodium reduction to at least 2300 mg/day. Individuals with symptomatic heart failure should restrict sodium intake to less than 2000 mg/day.[4]

5. At least 150 min/week of moderate-intensity aerobic physical activity, (50-70% of maximum heart rate), distributed over most, ideally all, days of the week.[5]

6. In the absence of contraindications, individuals with type 2 DM should perform resistance exercise 3 times a week, targeting all major muscle groups, progressing to attain three sets of 8-10 repetitions at a weight that cannot be lifted more than 8-10 times.[6]

B. Pharmacological end points

1. Attain or maintain glycemic control.

a. ADA glycemic goals[7]

(1) Glycosylated hemoglobin AIC **(HbAIC) goal: < 7%** (based on 6% as upper limit of normal), for patients in general. For an individual patient's goal, the HbAIC should be as close to normal as possible without significant hypoglycemia.

(2) Preprandial capillary plasma glucose: 70-130 mg/dL

(3) Peak 1-2 hr **postprandial** capillary plasma glucose: < 180 mg/dL

b. General experiential, clinical goals

(1) SMBG standard deviation < 40, based on daily testing (at least once daily, alternating prebreakfast and presupper, with occasional 2-hr postprandial, largest meal)

(2) SMBG values: 50% within target of 70-140 mg/dL; not more than 30% above 200 mg/dL

(3) No more than one to two episodes of mild hypoglycemia per 1-2 weeks

2. Attain or maintain lipid profile within target range.[8]

a. Low-density lipoprotein **(LDL) < 100 mg/**dL. For individuals with overt CVD, a target of < 70 mg/dL should be considered. If maximal, tolerated drug therapy fails to achieve LDL targets, an acceptable alternative goal is a reduction of ~40% from baseline.

b. Triglycerides (TGs) < 150 mg/dL. When TGs exceed 200 mg/dL, a “non-HDL cholesterol” goal (total cholesterol minus HDL) of 130 mg/dL should be used.

c. HDL > 40 mg/dL for males and > 50 mg/dL for females

3. Blood pressure (BP**) < 130/80mm Hg,** with minimal or no signs or symptoms of orthostatic hypotension

4. Minimal or no peripheral edema

5. Urinary albumin excretion < 30 µg **albumin/mg creatinine** in a spot collection (adjust end point based on results of initial microalbumin test)

6. Retention of recognition of hypoglycemia symptoms

VI. THERAPY OF PREDIABETES.

Modest weight loss (5-10% weight loss) and regular physical activity (~30 min/day) have been shown to reduce the rate of progression of prediabetes to type

2 DM.[9] Other CVD risk factors such as tobacco use, hypertension, and dyslipidemia should also be aggressively managed. Selected patients may benefit by adjunct drug therapy. Metformin, acarbose, orlistat, and rosiglitazone have also been shown to reduce progression to DM in single, or few, trials, but not as effectively as intensive lifestyle interventions.[10] However, the ADA Consensus Panel recommends that metformin should be the only drug considered for use in diabetes prevention, and that its use be limited to obese individuals less than 60 years of age.

VII. THERAPY OF DIABETES MELLITUS.

Medical nutrition therapy, physical activity, pharmacotherapy, SMBG, and patient self-management education—especially concerning decision-making skills—are essential for successful management of the metabolic aspects of DM and for the prevention of diabetes-related conditions. Although some patients with “early” type 2 diabetes may not need pharmacotherapy for a while, the progressive nature of the disease ultimately results in the requirement of drug therapy.

A. Medical nutrition therapy (MNT). MNT incorporates the principles of good nutrition applied to the individual's diabetes control goals, eating preferences and habits, and concurrent medical conditions. Successful MNT intervention is generally assessed by blood glucose and HbAIC level, LDL and HDL cholesterol and triglyceride levels, blood pressure, and body weight.

1. An effective MNT plan will not be merely a “diet sheet” given to all people with diabetes. However, some of the common approaches to diabetes MNT include the following:

2. Carbohydrate (CHO) counting. The individual is taught to identify and quantify the amounts of CHO foods consumed at each meal and throughout the day. Both the **amount (grams**) as well as the type of CHO (**glycemic index/glycemic load**) in a food influence blood glucose level. Usually CHO intake is 45%-60% of total calories, based on current diabetes control, TG levels, kidney function, and other medical concerns as well as patient choice.

a. When DM therapy includes a premeal short-acting insulin dose (bolus), patients may be taught to adjust the bolus dose to match the CHO intake.

b. Even when bolus insulin is not employed, patients need to be taught to maintain consistent CHO intake at designated meals and across the day to match the antidiabetes effects of oral medications or intermediate-acting insulins. *All patients with diabetes should be taught the principles of carbohydrate counting and identification.*

c. Sugar and simple CHOs are to be counted as part of the CHO intake for the meal.

3. Fat intake and type of fat.[4], [11] Saturated and trans-fatty acids are the principal dietary determinant of plasma LDL cholesterol, the major risk factor for CVD.

a. Limit intake of saturated fat to 7% of total calories.

b. Intake of *trans* fat should be minimized.

c. Limit dietary cholesterol to 200 mg/day.

d. Two or more servings of fish per week are recommended.

4. Protein intake and type of protein. There is insufficient evidence to demonstrate that intake of protein in the range of 15%-20% of total calories (which is the average U.S. protein consumption) is a risk factor for the development of diabetic nephropathy.[4] It is recommended that diabetes patients adhere to the suggested RDA protein intake **(0.8** g **high-quality protein/kg/day**), which would be about **10% of total calories.** Note that in general, cereals, grains, nuts, and vegetables are not included as sources of “high-quality” protein.

5. Fiber intake (e.g., bran, beans, fruits, whole-grain products, vegetables) is to be encouraged; however, there is no evidence that people with diabetes need a greater amount of fiber than other Americans. Very large amounts of fiber may benefit glycemic control, hyperinsulinemia, and plasma lipids; but the palatability and gastrointestinal side effects of such amounts of fiber may be unacceptable to most people.

6. Spaced intervals between meals may be helpful for matching the hypoglycemic actions of insulin or insulin secretagogues or when postprandial glycemic normalization is delayed.

7. Dietary adjustment algorithms. Alteration of dietary intake based on factors that change the blood glucose level, such as stress, illness, or exercise. For example, consumption of additional carbohydrate and/or protein before vigorous exercise.

B. Physical activity (exercise). A carefully planned and consistent program of physical activity enhances glucose uptake to cells, thereby reducing the BG level. In addition, exercise may improve CHO metabolism and insulin sensitivity in patients with type 2 DM; may reduce levels of triglyceride-rich very low density lipoprotein (VLDL); may reduce blood pressure, especially in hyperinsulinemic subjects; may enhance weight loss and weight maintenance; may reduce risk of CVD; and may prevent progression of prediabetes to DM.

1. Physical activity has potential problems for individuals with diabetes.

a. Patients with severe (proliferative) **retinopathy** must consult an ophthalmologist before beginning any type of exercise program. Strenuous activity may precipitate vitreous hemorrhage or traction retinal detachment

in these patients. These individuals should avoid anaerobic exercise and physical activity that involves straining, jarring, or Valsalva-like maneuvers.
b. Patients with **cardiovascular disease;** those > 35 years of age; and individuals with autonomic neuropathy, peripheral vascular disease, or microvascular disease should receive a cardiovascular evaluation and stress test before beginning an exercise program.
c. Patients with significant **peripheral neuropathy** (with loss of protective sensation in the feet) should limit weight-bearing exercise. Repetitive exercise on insensitive feet can lead to ulceration and fractures. Treadmill exercises, jogging, prolonged walking, and step exercises are contraindicated; swimming, bicycling, rowing, chair exercises, arm exercises, and other non-weight-bearing exercise should be recommended.
d. High-intensity or strenuous physical activity should probably be discouraged in individuals with **overt nephropathy** (albuminuria > 200 mg/min), unless blood pressure is carefully monitored during exercise.
2. Aerobic activity (e.g., swimming, walking, running) is the preferred type of exercise because of its desirable hypoglycemic effects (promotes utilization of glucose as fuel), as well as desirable effects on cardiovascular health, hypertension, lipid profiles, circulation, and weight-loss efforts. Recommendations:
a. At least 150 min/week of moderate-intensity aerobic physical activity (50%-70% of maximum heart rate),
b. And/or at least 90 min/week of vigorous aerobic exercise (> 70% of maximum heart rate).
c. Distribute exercise over at least 3 days/week, with no more than 2 consecutive days without physical activity.
3. Anaerobic activity (e.g., weight lifting) should generally be avoided by people with diabetes unless it has been specifically approved by appropriate medical specialists such as a cardiologist (because it could have potential deleterious cardiovascular or blood pressure

effects) or an ophthalmologist (because it could have potential deleterious effects upon underlying retinopathy). In the absence of contraindications, recommendations for people with type 2 diabetes include
a. Perform resistance exercise three times a week, targeting all major muscle groups
b. Progress to three sets of 8-10 repetitions at a weight that cannot be lifted more than 8-10 times
4. The physical activity plan should be consistent in regard to frequency (daily, or at least 3-4 days per week), intensity, and duration.
5. General guidelines that may prove helpful in regulating the glycemic response to physical activity include
a. Assess metabolic control before physical activity. Avoid physical activity if glucose level is > 250 mg/dL and ketosis is present; use caution if

glucose level is > 300 mg/dL with no ketosis. Ingest additional carbohydrate if glucose level is < 100 mg/dL.

b. Monitor blood glucose before and after physical activity (up to several hours postexercise) to identify when/if changes in insulin or food intake are necessary and to learn individual glycemic responses to different physical activity conditions.

c. Consume added carbohydrate as needed to avoid hypoglycemia; CHO-based food should be readily available during and after physical activity.

C. Insulin and insulin analog

1. Types of insulin. Refers to onset and duration of insulin preparation (Table 54-1)

a. Rapid-acting insulin. Lispro (Humalog), aspart (NovoLog), and glulisine (Apidra) insulins

b. Short-acting insulin. Regular insulin (Humulin regular, Novolin regular)

c. Intermediate-acting insulins. Isophane insulin suspension (neutral protamine Hagedorn; NPH) insulin and detemir (Levemir) insulin

d. Long-acting insulin. Glargine (Lantus) insulin.

e. Premixed insulin products. Each mixture gives a rapid- or short-acting insulin as a premeal bolus plus an intermediate-acting insulin to control later hyperglycemia or the subsequent meal.

(1) 50/50 insulin: 50% protamine lispro insulin with 50% lispro insulin, or 50% regular insulin with 50% NPH insulin

(2) 70/30 insulin: 70% insulin aspart protamine with 30% aspart insulin or 70% NPH with 30% regular insulin

(3) 75/25 insulin: 75% protamine lispro insulin with 25% lispro insulin

f. Extemporaneous mixtures. Two insulins mixed in one syringe, before administration. Extemporaneous mixtures allow the ratio to be tailor made to match the patient's blood glucose reading, anticipated eating or physical activity, or other factors influencing the requirement for specific insulin action.

Table 54-1. Types of Insulin—Onset, Peak, and Duration of Action[a]

Agent	Onset (hr)	Peak (hr)	Effective Duration (hr)	Variability in Absorption and Duration
Rapid acting				
Lispro (Humalog)	< 0.5	0.5-1.5	3-4	Minimal
Aspart (NovoLog)	< 0.5	0.7-1	3-5	Minimal

	Glulisine (Apidra)	< 0.5	0.5-1.5	3-5	Minimal
Short-acting					
	Regular	0.5-1	2-4	5-8	Moderate
Intermediate-acting					
	NPH	2-4	6-10	10-16	High
	Detemir (Levemir)	3-4	6-12	12-18	Minimal
Long-acting					
	Glargine (Lantus)	5	n/a	20-24	Minimal-Moderate

[a]Approximate time action in nonpregnant adult, with normal renal function.
n/a, not applicable, *NPH,* neutral protamine Hagedorn

P.1176

2. Chemical sources of commercial insulin available in the United States

a. Biosynthetic human, also called human insulin. Produced by recombinant DNA techniques

b. Insulin analog. Produced by chemical alteration of human insulin

3. Concentration of insulin products available in the United States

a. U-100: a concentration of 100 Units/mL

b. U-500: concentration of regular insulin of 500 Units/mL, for patients with insulin resistance. Because of its high concentration, bioactivity of U-500 regular insulin mimics an intermediate-acting insulin. U-500 insulin is a prescription item.

4. Indications. Insulin therapy is required for all patients with type 1 DM and for those with type 2 DM when other injectable or oral antidiabetes therapies do not achieve the desired DM control. Insulin and insulin analogs

may be used in combination with certain oral or other injectable antidiabetes agents in type 1 or type 2 DM. When diet and physical activity fail to achieve glycemic control in GDM or when a woman with diabetes becomes pregnant, insulin therapy should be instituted rather than oral antidiabetes agents.

5. Mechanism of action. Insulin lowers blood glucose and contributes to glucose homeostasis by a variety of physiological actions, including

a. ↑Glucose uptake and utilization by peripheral tissues

b. ↑Glycogenesis (conversion of glucose to glycogen in liver and muscle)

c. ↓Glycogenolysis (production of glucose from glycogen)

d. ↓Gluconeogenesis (formation of glucose from noncarbohydrates, such as amino acids)

e. ↓Lipolysis and ketogenesis (breakdown of fats to ketone bodies)

f. ↑Formation of protein from amino acids

g. ↑Formation of adipose tissue from triglycerides and fatty acids

6. Initial dosage of insulin. Assuming a waking time in the morning, meals/snacks spaced consistently during the day and waking hours, and a late evening bedtime, *the following are examples only and do not include all insulin options.*

a. Type 1 DM, without concomitant infection or physiologic stress condition. A typical initial total daily dose (TDD) is estimated as 0.5 Units/kg/day, which is divided into three or four injections per day. Regimens employing only one or two injections per day do not achieve euglycemia in type 1 DM.

(1) Three injections per day

(a) Prebreakfast injection. Two thirds of TDD. 25%-35% of the total breakfast dose is given as lispro, aspart, glulisine, or regular insulin; 65%-75% of the total breakfast dose is given as NPH insulin (1:2 ratio). May be mixed extemporaneously or may be a commercial premixed product.

(b) Presupper injection. Between 10% and 20% of TDD. Given as lispro, aspart, glulisine, or regular insulin

(c) Bedtime (10 p.m.) injection. Between 10% and 25% of TDD. Given as NPH or detemir insulin

(2) Four injections per day

(a) Premeal injections (three injections). Total of 40%-50% of TDD. Total amount is divided between the three meals in a ratio proportional to the desired/usual ratio of CHO ingestion at those three meals. Given as lispro, aspart, glulisine, or regular insulin before each meal

(b) Bedtime injection. Between 50% and 60% of TDD, given as NPH, detemir, or glargine insulin. *Caveat:* If NPH or detemir insulin is used for the bedtime injection in type 1 DM, the premeal insulin must be regular insulin.

(3) Insulin pump therapy (use of external pump to provide continuous subcutaneous insulin infusion)

(a) Premeal and presnack boluses. Dosage based on premeal BG level and anticipated CHO intake for the meal. Initial estimate would be similar to the initial estimate for the four-injection regimen (see VII.C.6.a.(2)). Given as lispro, aspart, or glulisine insulin
(b) Basal insulin. Programmed to be delivered continuously. Initial estimate is 50%-60% of TDD but may be subsequently altered to give differing basal infusions at certain times of the day. Initial rate is often 0.5-1.25 Units/hr, given as lispro, glulisine, or aspart insulin

b. Type 2 DM. Initial TDD is 0.15-0.4 Units/kg/day but will vary greatly, depending on degree of concomitant insulin resistance and degree of β cell dysfunction.
(1) One injection per day. Bedtime insulin only, 0.25 Units/kg/day, given as NPH, detemir, or glargine insulin. Bedtime insulin is most often used in combination with one or more oral antidiabetes medication. Monotherapy bedtime insulin is most successful in the early stages of type 2 DM.
(2) Two injections per day
(a) Prebreakfast injection. Two thirds of TDD, given as a premix insulin (70/30, 75/25, or 50/50; choice depends on anticipated CHO intake at breakfast and lunch)
(b) Presupper injection. One third of TDD, given as a premix insulin (70/30, 75/25, or 50/50; choice depends on anticipated CHO intake at supper)
(3) Three or four injections per day. Types, initial ratios, and regimens are similar to type 1 (see VII.C.6.a.).
c. Adjust initial doses and regimen based on ongoing SMBG, symptoms of hypoglycemia or hyperglycemia, and periodic AIC results.
7. Routes of insulin administration
a. Subcutaneous injection. For routine self-administration of insulin
(1) Successful insulin therapy requires predictable and consistent insulin absorption and insulin action from day to day.
(2) In many patients, absorption of regular insulin is fastest from the abdomen, followed by the arm, buttocks, and thigh.
(a) Upon initiation of insulin therapy, patients should carefully monitor and record their own variations in absorption. If it is determined that the variation is sufficiently great, then a given injection (e.g., presupper dose) should always be given in the same anatomical region (e.g., arms). Random rotation of injection regions should be avoided in these individuals.
(b) Physical exercise increases blood flow to the exercising area, thus accelerating absorption of insulin injected at that site. To a lesser extent, hot showers, baths, and massage may have a similar effect. Patients should be advised to avoid giving an injection into a limb that will be subsequently exercised or heated. The abdomen may be preferable for the preexercise

injection because that area is the least likely to have significant increases in absorption.

(3) Within an anatomical region, the injection site should be rotated to avoid lipohypertrophy and fibrosis.

b. Continuous intravenous (insulin drip) administration of regular insulin, primarily in the hospital setting. Used for treatment of acute hyperglycemia, ketoacidosis, HHS, or during surgical procedures or delivery.

c. Continuous subcutaneous infusion (insulin pump therapy)

(1) Rapid-acting insulin is infused continuously during the day in a patient-specific pattern to deliver low doses of insulin (basal insulin) to offset the glycemic effects of daily patterns of counterregulatory hormones.

(2) Before each meal, the patient sets the pump to deliver a bolus dose of rapid-acting insulin to control the glycemic effects of the meal. The bolus dose is determined by algorithms that consider the premeal glucose level, anticipated dietary intake, and activity.

(3) Offers the potential for tighter glycemic control.

(4) Indicated for selected individuals with diabetes with widely fluctuating blood glucose levels; irregular or inconsistent work schedules, lifestyles, or meals; or who achieve less-than-desired control using frequent injection routines.

(5) Requires frequent SMBG; thorough training in the use of the infusion equipment; and an advanced understanding and application of exercise, dietary, and insulin adjustment protocols.

8. Alterations in insulin requirement

a. Infection, exacerbations of other medical problems, weight gain, puberty, inactivity, hyperthyroidism, and Cushing disease tend to increase insulin needs.

b. Renal failure, adrenal insufficiency, nutrient malabsorption, hypopituitarism, weight loss, and increased exercise tend to reduce insulin needs.

c. Drug-drug or drug-disease interactions may increase or decrease insulin requirements.

D. Insulin secretagogues (oral hypoglycemic agents)

1. Agents

a. Sulfonylureas

(1) Chlorpropamide (Diabinese)

(2) Glyburide (DiaBeta, Micronase, Glynase)

(3) Glipizide (Glucotrol)

(4) Glimepiride (Amaryl)

b. Meglitinides: Repaglinide (Prandin)

c. Phenylalanine derivatives: Nateglinide (Starlix)

2. Indications/contraindications

a. Use in type 2 DM predicated on

(1) Adequate control not attained by medical nutrition therapy and physical activity alone

(2) *Or* pharmacological intervention is required based on the presenting blood glucose levels and diabetes symptomatology

(3) *And* there are sufficient numbers of functioning β cells

(4) May be used as monotherapy or in combination with other oral antidiabetes drugs, exenatide, or insulin

b. Use in type 1 DM not indicated. Pharmacological action depends on functioning pancreatic β cells.

c. Insulin secretagogues

(1) Are not recommended for children, pregnant and lactating women

(2) Should not be used for metabolic control during stressful conditions such as severe infection, injury, or surgery (all of which stimulate the release of counterregulatory hormones), which increase the risk of hyperglycemia. Insulin therapy should be instituted during these conditions.

d. Sulfonylurea agents

(1) Are contraindicated in patients with allergy to sulfa agents.

(2) Have been associated with a possible increased risk of cardiovascular morbidity and mortality.

(3) Pose a risk of cholestatic jaundice

e. Certain agents should not be used in patients with severe renal or hepatic impairment.

3. Mechanisms of action

a. Predominant effect is to stimulate pancreatic secretion of insulin

b. Improve “first phase” release of insulin/increase sensitivity of β cells to glucose stimulus

c. Lessor effects

(1) Increase hepatic sensitivity to insulin

(2) Increase number and/or sensitivity of insulin receptors in muscle and adipose tissue

(3) Reduce postreceptor defect (transport defect) in muscle and adipose tissue

4. Choice of agent. The most clinically significant difference among the oral hypoglycemic agents is duration of action (Table 54-2), which then affects frequency of dosing and potential compliance issues. Other considerations include frequency and consistency of eating and exercise, additional patient-specific risk factors for severe hypoglycemia (e.g., hypoglycemia unawareness), patient-specific contraindications, and cost considerations.

a. Glimepiride exhibits an insulin-sparing effect compared to other members of this class, reportedly by its relatively greater extrapancreatic effect.

b. β Cell stimulation of insulin secretion is more glucose dependent with repaglinide and nateglinide than with sulfonylurea agents. This action,

along with its very short action, may present a reduced risk of late postprandial hypoglycemia for selected individuals.

c. Chlorpropamide has the longest duration of action and poses a risk to patients with renal or hepatic impairment. It also causes more severe and frequent side effects (including hypoglycemia and hyponatremia) than other sulfonylureas.

d. Glyburide has been associated with severe or prolonged hypoglycemia in the elderly.

5. Administration and dosage (Table 54-2)

6. Patient education and other concerns

a. Adverse effects include gastrointestinal (GI) disturbances (e.g., nausea, gastric discomfort, vomiting, constipation), tachycardia, headache, skin rash, and hematological problems (e.g., agranulocytosis, pancytopenia, hemolytic anemia)

Table 54-2. Oral Monotherapy: Type 2 Diabetesa

Agent	Initial dose	Maximum Dose/Comments
α-glucosidase inhibitors	25 mg/day with first bite of meal Instruct patient to increase dosage as tolerated (GI distress) Anticipate weeks to reach maximal therapeutic effect Sometimes given with just largest meal or may be given before each meal	50-100 mg four times a day with meals. 50 mg four times a day if TBW < 60 kg Diarrhea, abdominal distress may limit dosing or rate of dosage increase; GI effects usually diminish with continued use Increase in liver enzymes may occur When used with a hypoglycemic agent (sulfonylurea or insulin), patient must be taught importance of treating hypoglycemia with glucose-based product
Acarbose (Precose)		
Miglitol (Glyset)		
Insulin sensitizers	500 mg once or	Short-acting: 2550

	Metformin (Glucophage, Glucophage XR, Riomet solution)	500 mg once or twice a day with meals Instruct patient to increase dosage as tolerated (usually weekly) Daily dose of 1500 mg will likely be needed for therapeutic effect Metformin extended release 500 mg daily taken with evening meal	Short-acting: 2550 mg/day (850 mg four times a day). *Note:* 1000 mg two times a day gives maximum therapeutic effect Long-acting: 2000 mg/day Nausea and diarrhea, which usually subside after 5-10 days, may limit rate of dosage increase Teach patient lactic acidosis issues—for example, muscle aches, weakness Contraindicated in renal or liver disease, ETOH abuse, severe cardiopulmonary disease
	Pioglitazone (Actos)	15 or 30 mg/day without regard to meals	45 mg/day in one dose
	Rosiglitazone (Avandia)	2 mg/day without regard to meals	8 mg/day in one or two doses
Sulfonylurea agents		Glucotrol 2.5 mg/day Glucotrol XL 5 mg/day	Short acting: 40 mg, give in two doses when dose reaches 15 mg Extended length: 20 mg, give in one or two doses
	Glipizide (Glucotrol, Glucotrol XL)		
	Glyburide (Diabeta, Micronase, Glynase) Glimepiride (Amaryl) Tolazamide	Diabeta, Micronase 2.5 mg/day Glynase 1.5 mg/day 2 mg qd 125 mg/day	20 mg in one or two doses Glynase microcrystalline 12 mg 6 mg/day in one or two doses 1000 mg, give in two

			doses when dose reaches 500 mg
	Chlorpropamide (Diabinese)	100 mg/day	750 mg in one dose
	Tolbutamide	250 mg/day	3000 mg in two or three doses
Meglitinides		Not previously treated with hypoglycemic agent and HbA_{Ic} < 8.0%: 0.5-1.0 mg with each meal	4 mg with each meal or 16 mg total daily dose
	Repaglinide (Prandin)		
		Previously treated with hypoglycemic agent or HbA_{Ic} > 8.0%: 1-2 mg with each meal	
Phenylalanine derivatives		120 mg four times a day, 1-30 min before each meal 60 mg four times a day for patients near target HbA_{Ic}	180 mg with each meal Uric acid levels may be elevated
	Nateglinide (Starlix)		
DPP-4 Inhibitors		Normal renal	100 mg, 50 mg, or 25

			respiratory tract infection, nasopharyngitis, and headache. Generally weight neutral.

[a]Consult package insert for detailed prescribing details. Dosage should be reduced if frequent hypoglycemia occurs without apparent cause (such as medication error; changes in diet, exercise, or timing of regimen). When dosage reaches the minimum for a therapeutic agent, an attempt should be made to control diabetes by diet and exercise alone.
ETOH, ethyl alcohol; *GI,* gastrointestinal; *HbA*$_{Ic}$, glycosylated hemoglobin A$_{Ic}$; *TBW,* total body weight.

b. Best if taken 30-45 min before meals, but may take with meal if GI distress. *Except:* repaglinide or nateglinide *must* be taken 15-30 min before a meal.

c. Notify prescriber if skin changes occur

d. Teach patient prevention, recognition, treatment of hypoglycemia

e. Sunburn precautions

f. Notify prescriber if unexpected/unintended weight gain occurs

g. Hypoglycemia and alcohol intolerance may occur with chlorpropamide. Alcohol intolerance is less common with other agents.

h. Primary failure. The agent fails to control hyperglycemia within the first 4 weeks after initiation. This most likely represents insufficient numbers of functioning β cells.

i. Secondary Failure. The drug controls hyperglycemia initially but fails to maintain control. Between 5% and 30% of initial responders experience secondary failure. In most instances, this represents progression of the DM, with a diminishing number of functioning β cells, rather than a drug failure.

E. Insulin sensitizers

1. Agents

a. Biguanides: metformin (Glucophage, Riomet)

b. Thiazolidinediones (TZD)

(1) Pioglitazone (Actos)

(2) Rosiglitazone (Avandia)

c. Combination products

(1) Metformin/glyburide (Glucovance)

(2) Metformin/glipizide (Metaglip)

(3) Metformin/rosiglitazone (Avandamet)
(4) Metformin/pioglitazone (Actoplus met)
2. Indications/Contraindications
a. Insulin sensitizers are indicated in individuals with a significant component of insulin resistance.
b. Use in type 2 DM
(1) Monotherapy use in type 2 DM predicated on
(a) Adequate control not attained by medical nutrition therapy and physical activity alone
(b) *Or* pharmacological intervention is required based on the presenting blood glucose levels and diabetes symptomatology
(c) *And* patient has adequate endogenous insulin
(2) Combination therapy, with other oral antidiabetes agents and/or insulin
c. Use in type 1 DM. As adjunct to insulin; must not be used as monotherapy
d. Metformin contraindications and cautions

(1) Situations with potential for increased risk of lactic acidosis. Lactic acidosis is a rare but serious complication and is fatal in 50% of cases
(a) Renal dysfunction (serum creatinine [SCr] > 1.4 mg/dL in females and > 1.5 mg/dL in males). Confirm adequate renal function in the elderly, even in the face of “low” SCr levels.
(b) Hypoperfusion (hypoxic states)—for example:
(i) During surgery
(ii) Severe cardiovascular/pulmonary dysfunction
(iii) Acute myocardial infarction or heart failure
(c) Radiographic procedures using intravenous iodinated contrast agents (potential for transient renal dysfunction). Discontinue metformin during the procedure; reinitiate when renal function is reestablished and confirmed.
(d) Chronic or binge ingestion of ethanol
(e) Liver disease (hepatic function important for clearance of blood lactate)
(2) Serum vitamin B_{12} levels may decline, usually without clinical manifestations.
(3) Follow labeled recommendations for monitoring liver function, renal function, and vitamin B_{12} status.
e. TZD contraindications and cautions
(1) Hepatic disease: idiosyncratic hepatic failure, a rare but serious event, has occurred during therapy with troglitazone, a thiazolidinedione removed from the U.S. market in 1999. Because of their structural similarity to troglitazone, pioglitazone and rosiglitazone should be used cautiously in patients with hepatic disease. Clinical data have not shown evidence of drug-induced hepatoxicity from pioglitazone or rosiglitazone.
(2) Follow labeled guidelines for routine monitoring of liver function.

(3) Warning for use in patients with severe heart failure—New York Heart Association (NYHA) class III or IV cardiac status—owing to possible increase in plasma volume (found in human studies) and heart enlargement (found in animal studies).
(4) Safety in children or during pregnancy has not been established.
(5) Do not use TZD at maximum labeled dose when combined with insulin.

3. Mechanisms of action

a. These agents are pharmacologically antihyperglycemic agents rather than hypoglycemic agents.
b. Increase hepatic sensitivity to insulin, thereby suppressing hepatic glucose production. Major action for metformin; secondary action for pioglitazone and rosiglitazone.
c. Reduce postreceptor defect (transport defect) in muscle and adipose tissue; this defect appears to be the major component of naturally occurring insulin resistance. Major action for pioglitazone and rosiglitazone; secondary action for metformin.
d. Increase number and/or sensitivity of insulin receptors in muscle and adipose tissue, thereby addressing the cell surface binding defect; this defect correlates most significantly with hyperinsulinemia. Major action for pioglitazone and rosiglitazone; secondary action for metformin.

4. Administration and dosage (Table 54-2)

5. Patient education and other concerns

a. Metformin
(1) Most notable subjective side effect: GI disturbances (loose stools or diarrhea), usually subsiding after 7-10 days
(2) Take with meals to minimize GI upset.
(3) Optimal BG effects not seen for 5-10 days
(4) Hypoglycemia is not likely caused by metformin but may occur if used with insulin or insulin secretagogue,
(5) Often associated with small weight loss
(6) Metformin is excreted into breast milk.
b. Thiazolidinediones (TZD)
(1) Most notable subjective side effects: edema, weight gain, headache, fatigue
(2) Hypoglycemia is not likely caused by TZD but may occur if used with insulin or secretagogue.
(3) Optimal BG effects not seen for 6-10 weeks
(4) Teach patient signs and symptoms of liver toxicity and to report to prescriber if noticed

(5) Watch for weight gain, shortness of breath, girth expansion

(6) Animal studies suggest that pioglitazone and rosiglitazone are secreted in breast milk, but it is not known if these drugs or metabolites are excreted in human milk.
(7) Premenopausal anovulatory women may resume ovulation during therapy, placing the patient at risk of pregnancy.

F. α-Glucosidase inhibitors

1. Agents

a. Acarbose (Precose)

b. Miglitol (Glyset)

2. Indications/contraindications

a. Used in individuals with significant postprandial hyperglycemia. These drugs have minimal effect on preprandial or fasting blood glucose levels.
b. Use in type 2 DM
(1) Monotherapy use in type 2 DM predicated on
(a) Adequate control (especially postprandial) not attained by medical nutrition therapy and physical activity alone
(b) *Or* pharmacological intervention is required based on the presenting postprandial blood glucose levels and diabetes symptomatology
(c) *And* patient has adequate endogenous or exogenous insulin.
(2) Combination therapy, with insulin or other oral antidiabetes agents, notably insulin secretagogues
c. Use in type 1 DM
(1) As an adjunct to insulin therapy; may be useful in individuals with delayed absorption of subcutaneous insulin
(2) Not to be used as monotherapy
d. Contraindicated in inflammatory bowel disease, colonic ulceration, or obstructive bowel disorders; chronic intestinal disorders of digestion or absorption; or any medical condition that might deteriorate with increased intestinal gas formation.
e. Contraindicated in cirrhosis of the liver.
f. Not indicated during pregnancy, in breast-feeding women, or in children.

3. Mechanism of action

a. Inhibits the intestinal enzyme α-glucosidase (a class of enzymes). Intestinal absorption of complex carbohydrates such as starch, dextrins, and disaccharides (e.g., sucrose, maltose) requires the action of intestinal α-glucosidase.
b. Inhibition of α-glucosidase retards the degradation and thus the absorption of carbohydrates, resulting in a slower and smaller rise in blood glucose following the meal.

4. Administration and dosage (Table 54-2)

5. Patient education and other concerns

a. Most notable subjective side effects: Gastrointestinal effects, occurring primarily at initiation of therapy or when dosage is increased: diarrhea, abdominal pain, and flatulence (about 30%, 10%-20%, and 42%-77%, respectively).

(1) GI side effects are usually self-limiting and resolve in several weeks.
(2) GI side effects can be minimized by starting with a low dose and then slowly titrating dosage upward.
b. Take with first bite of meal. Medication will be ineffective more than 30-45 min after eating carbohydrates.
c. Hypoglycemia not likely caused by this drug, but may occur if used with insulin or insulin secretagogue.
d. Hypoglycemia *must* be treated with glucose, not complex carbohydrate.
e. Follow labeled recommendations for routine liver function monitoring.

G. Incretin mimetics

1. Agent: Exenatide (Byetta)

2. Indications/contraindications

a. Used as an adjunct to metformin and/or a sulfonylurea agent, to reduce postprandial hyperglycemia and to improve HbAIC in patients with type 2 DM who have not achieved desired glycemic control using metformin and/or sulfonylurea.

b. Exenatide is not recommended (has not been studied) in patients taking insulin, TZDs, meglitinides, or glucosidase inhibitors.

3. Mechanisms of actions. Reduces postprandial glucose rise; antihyperglycemic agent, not a hypoglycemic agent

a. Stimulates glucose-mediated insulin secretion; improves/restores first phase of insulin release
b. Inhibits postprandial glucagon release
c. Delays gastric emptying
d. Improves satiety and thus reduces dietary intake; progressive weight loss has occurred, even after 18 months
e. Lowers postprandial BG but also lowers hyperglycemia if injected during fasting state

4. Administration and dosage

a. Initial: twice a day 5 µg subcutaneously taken 30 min before breakfast and before supper, for 30 days.
b. Maintenance: If 5-µg dose is tolerated, advance to 10 µg subcutaneously twice a day before meals thereafter.
c. Dose should be omitted if that meal is skipped.
d. If the patient is taking sulfonylurea, the dose of sulfonylurea should be reduced when exenatide is started. The dose of metformin (if taking) does not need to be changed.

5. SMBG is an important component of dosage titration.

a. BG testing before meals and 2-hr postprandial breakfast and supper until dose is established and determined to be effective.
b. Frequent SMBG is also important if dose of sulfonylurea agent has been adjusted.

c. Once the doses of exenatide, sulfonylurea, and/or metformin are stable, test before meal and at bedtime plus occasional 2 hr after meal, depending on strip coverage.

6. Patient education and other concerns

a. Inject no more than 1 hr before meal

b. Inject in thigh, abdomen, or upper arm

c. Available in prefilled syringes, each containing 60 doses.

(1) Two sizes: 5 µg/dose and 10 µg/dose; premeasured dose requires no dosing choices

(2) Pen needles must be purchased separately

(3) Each pen must be primed before initial dose

(4) Clear, colorless injection

(5) Refrigerate, even after opening. Discard after 30 days

d. Most common side effect: mild to moderate nausea, which dissipates over time. Increased occurrence of hypoglycemia, in patients taking sulfonylurea

H. Aymlin receptor agonist

1. Agent: Pramlintide (Symlin)

2. Indications/contraindications

a. Used as an adjunct to insulin to reduce postprandial hyperglycemia and to improve HbAIC in patients with type 1 DM or insulin-requiring type 2 DM who have not achieved desired glycemic control using insulin.

b. Patients *not* appropriate for pramlintide therapy (because of lack of studies, or potential harm):

(1) Poor compliance with current insulin regimen or SMBG

(2) HbAIC > 9%

(3) History of recurrent severe hypoglycemia requiring assistance during the past 6 months

(4) Hypoglycemia unawareness

(5) Confirmed diagnosis of gastroparesis or using drugs that stimulate gastrointestinal motility

(6) Pediatric patients and pregnant or nursing women

3. Mechanisms of action. Reduces postprandial glucose rise; antihyperglycemic agent not hypoglycemic agent

a. Delays gastric emptying

b. Suppresses glucose-stimulated secretion of glucagon

c. Enhances satiety, resulting in decreased appetite and decreased food intake

4. Administration and dosage

a. Dosing for type 1 DM

(1) Step 1—initiation

(a) Reduce premeal insulin dose (rapid-acting, short-acting, or fixed-mix) by 50%
(b) Start pramlintide at a dose of 15 µg subcutaneously just before each major meal
(c) Monitor blood glucose frequently (before and after meals and at bedtime)
(2) Step 2—titration
(a) Increase pramlintide in 15-µg increments to a maintenance dose of 30 µg or 60 µg, as tolerated
(b) Increase dose to the next increment when no nausea for 3 days
(c) If nausea persists at the 45 µg or 60 µg doses, reduce dose to 30 µg
(d) If the 30 µg dose is not tolerated, consider discontinuation
(3) Step 3—when a stable pramlintide regimen has been established, adjust insulin doses to optimize glycemic control.
(4) Step 4—instruct patients to contact healthcare professional at least once a week until pramlintide dose is stable and well tolerated and BG levels are stable. Notify provider if nausea and/or hypoglycemia is ongoing, frequent, or increasingly severe.
b. Dosing for type 2 DM
(1) Step 1—initiation
(a) Reduce premeal insulin dose (rapid-acting, short-acting, or fixed-mix) by 50%
(b) Start pramlintide at a dose of 60 µg subcutaneously just before each major meal
(c) Monitor blood glucose frequently (before and after meals and at bedtime)
(2) Step 2—titration
(a) Increase pramlintide to a maintenance dose of 120 µg when no nausea for 5-7 days
(b) If nausea persists at the 120-µg dose, reduce dose to 60 µg
(3) Step 3—when a stable pramlintide regimen has been established, adjust insulin doses to optimize glycemic control.
(4) Step 4—instruct patients to contact healthcare professional at least once a week until pramlintide dose is stable and well tolerated and BG levels are stable. Notify provider if nausea and/or hypoglycemia is ongoing, frequent, or increasingly severe.
c. Dose only when major meal is consumed, defined as > 250 kcal or > 30 g CHO
d. Dose should be omitted if that meal is skipped.
5. SMBG is an important component of dosage titration.
a. Conduct SMBG at least before and after meals and at bedtime.
b. Frequent SMBG is essential, because the doses of insulin and pramlintide will need to be adjusted frequently as the proper doses are established and the patient is able to tolerate the maximum dose

c. Once the doses of insulin and pramlintide are stable, test before meals and at bedtime plus occasional 2 hr after a meal, depending on strip coverage

6. Patient education and other concerns

a. Most common side effects: nausea 30%-40% (usually transient), increased occurrence of hypoglycemia (particularly in patients with type 1 DM), loss of appetite, vomiting, and headache.

b. Available in 5-mL vial containing 0.6 mg/mL, for use with a syringe

(1) Symlin is labeled in milligrams per liter (mg/mL), not units, and is dosed in micrograms (μg).

(a) The U-100 insulin syringes are usually used for dosing (preferably a 0.3-cc syringe); 6 μg = 1 U on the syringe

(b) This labeling and the necessity for converting to volume for use in a U-100 insulin syringe may be confusing to patients.

(c) The U-100 syringes are generally not available in other countries, which may further compound the dosing confusion for patients traveling abroad.

(2) Patient education is critical to proper dosing.

c. Inject in abdomen or thigh (not arm)

d. The decision to dose before a given meal is based on the carbohydrate (or calories) content of the meal. Thus it is essential that the patient knows the basics of carbohydrate identification and quantification (carbohydrate counting).

e. Do not mix Symlin injection (pH ~ 4) in the same syringe with insulin (pH ~ 7). Give at two separate injections, at least 2 in. apart.

f. Clear, colorless injection

g. Refrigerate until use. Opened vials may be kept in the refrigerator or at room temperature. After opening, discard any remainder after 28 days.

I. Dipeptidyl Peptidase-4 (DPP-4) Inhibitors

1. Agents

a. Sitagliptin (Januvia)

b. Combination products

(1) Sitagliptin/metformin (Janumet)

2. Indications/Contraindications

a. Type 2 diabetes: used to reduce fasting and postprandial hyperglycemia and to improve A1C in patients who have not achieved desired glycemic control using diet and exercise, with or without other oral antidiabetes agents.

(1) Monotherapy

(2) Combination therapy with metformin, thiazolidinediones, sulfonylureas

(3) Successful sitagliptin therapy requires adequate levels of endogenous incretin hormones. Sitagliptin will be most useful in the early stages of type

2 diabetes; in advanced stages of type 2 diabetes, levels of GLP-1 and GIP are significantly reduced or absent.
b. Type 1 diabetes: contraindicated
c. Use in pediatric patients: safety and efficacy has not been established, and is therefore not recommended.
d. Pregnancy Category B: Merck & Company has established a registry to monitor prenatal sitagliptin exposure and pregnancy outcomes. Any prenatal exposure to sitagliptin should be reported to the Registry by calling (800) 986-8999.
e. Use in nursing women: Sitagliptin is secreted in the milk of lactating rats, but it is not known whether it is excreted in human milk. Use caution, or avoid use during lactation.
3. Mechanisms of Action
a. DPP-4 is an endogenous enzyme which rapidly inactivates incretin hormones, notably GLP-1 and GIP. Sitagliptin inhibits DPP-4, thereby slowing the inactivation of the incretin hormones and resulting in increased levels and prolonged action of these hormones.
b. The therapeutic effects of DPP-4 inhibition will enhance (and therefore mimic) the actions of GLP-1 and GIP (see II.A.3.)
c. Other substrates for DPP-4 include substance P, growth hormone-releasing hormone (GHRH), neuropeptide Y (NPY) and peptide YY (PYY). Reports of nasopharyngitis in human subjects treated with DPP-4 inhibitors may be related to altered levels of substance P. The clinical impact of DPP-4 inhibition upon other substrates is unclear or found not to be significant.
d. At therapeutic doses, sitagliptin appears to be selective for DPP-4 and does not inhibit DPP-8 or DPP-9 activity in vitro.
4. Administration and dosage (Table 54-2)
5. Patient education and other concerns
a. Most notable side effects (≥5% incidence): upper respiratory tract infection, nasopharyngitis, headache
b. Less frequent side effects (<5%): gastrointestinal reactions such as abdominal pain, nausea, diarrhea
c. Side effects reported from postmarketing experience (incidence not known): hypersensitivity reactions, including anaphylaxis, angioedema, rash, urticaria
d. Hypoglycemia with monotherapy is rare. Sitagliptin is an anti-hyperglycemic agent rather than a hypoglycemic agent.
e. Hypoglycemia may occur when sitagliptin is used with a sulfonylurea agent.
(1) dosage of the sulfonylurea may need to be adjusted
(2) educate patient on the signs, symptoms, prevention, and treatment of hypoglycemia
f. Notify prescriber if symptoms of fever, infection, or hypersensitivity reaction occur.

g. (Females) Notify prescriber if you intend to become pregnant, or think you are pregnant, or if you plan to breast-feed your baby.
h. A patient information leaflet is available from Merck & Company and should be dispensed with each dispensing of Januvia.

VIII. PATIENT EDUCATION AND SELF-CARE.

Patient education about the disease and patient participation in medical care are the most important aspects of DM management. *Without patient involvement and participation, even the ideal pharmacotherapy, dietary, or other intervention will fail.* **Patient education** improves understanding of the disease; promotes optimal patient choices regarding diet, medication, and exercise; and facilitates decision-making skills. National, state, and local diabetes professional groups have published guidelines to ensure thorough and effective teaching content and methods. Examples of patient education topics include, but are not limited to, the following:
A. Prevention, recognition, and treatment of acute hypoglycemic and hyperglycemic episodes.
B. Reduction of modifiable risk factors for the development of chronic complications
1. Achievement of HbAIC < 7% (based on upper limit of normal = 6%)
2. Smoking cessation
3. Normalization of blood pressure
4. Normalization of blood lipid profile
5. Reduction of weight to at least a BMI of 25, if applicable
6. Routine assessment/screening for and early treatment of chronic complications
C. Pattern control. Adjustment algorithms for diet, exercise, and/or medications based on trends in BG control.
D. Implementation of **specific self-care measures**
1. Foot care. Neuropathy, peripheral vascular disease, trauma, and infection increase the risk for lower-extremity complications and amputation, causing hospitalizations, disability, morbidity, and mortality.
a. Inspect feet and interdigital areas daily, looking for changes in color or skin integrity.
b. Inspect shoes daily before putting them on, to detect loose objects or rough shoe materials that may injure or irritate the skin.
c. Clean feet daily, and dry thoroughly. Use forearm, elbow, or a thermometer to check water temperature if the patient has neuropathy-induced sensation loss.
d. Moisturize dry skin with hand lotion or Vaseline. Avoid area between the toes.
e. Cut toenails straight across, or follow the natural curve of the toe.
f. Avoid self-treatment of corns, calluses, or ingrown toenails.

g. Wear well-fitting shoes and soft cotton socks. Avoid going barefoot.
h. Seek prompt medical attention for any problems identified (e.g., cuts, blisters, calluses, unhealing wounds, or signs of infections such as redness, swelling, drainage, pus, or fever).
2. Skin care. Dry skin occurs frequently in individuals with DM owing to dehydration (secondary to hyperglycemia-induced diuresis) and/or anhidrosis (secondary to autonomic neuropathic condition, resulting in little or no perspiration). Elevated blood glucose levels and impaired circulation also increase the risk for the development of skin infections.
a. Inspect skin daily for abrasions, pain, or swelling. Consult the healthcare provider promptly if problems are noted.
b. Keep skin clean using a mild soap and warm (not hot) water.
c. Use moisturizing lotion (alcohol free and not oiled based) on dry skin areas.
d. Use sunscreen products throughout the year. As a physical stress, severe sunburn may raise BG.
e. Avoid situations with potential for local trauma, especially to legs and feet. If injury occurs, the lesion should be covered with sterile gauze and first-aid measures applied.

3. Dental care. Periodontal disease is often accelerated in people with long-standing or poorly controlled diabetes.
a. A yearly dental exam is recommended.
b. Effective brushing and flossing are essential.
4. Eye care. Diabetes is a leading cause of vision impairment in the United States and the leading cause of blindness for individuals between the ages of 20 and 74 years of age. A yearly dilated eye exam is recommended, with more frequent follow-up guided by the severity of disease.

IX. ASSESSMENT OF GLYCEMIC CONTROL

A. Self-monitoring of blood glucose

1. Indicated for all individuals with diabetes. The frequency and time of testing vary according to type of diabetes, type of antidiabetes medication, and goals of therapy.
2. Involves the patient in the treatment process
3. Allows the patient and the healthcare provider to assess the individual's response to various factors (e.g., lifestyle modifications, nutritional alterations, medication adjustments, stress, illness, infection, trauma, changes in physical activity)
4. Gives immediate feedback and data for the patient to use in the application of diet, exercise, or insulin adjustment algorithms (decision-making skills)

5. A variety of testing products and product features are available. The use of meters with test memory functions and the capacity to download (via computer) SMBG results provides efficient access and analysis of SMBG trends.

6. Continuous glucose monitoring (CGM). Recently, the technology for continuous monitoring of interstitial glucose has become commercially available.

a. Interstitial fluid glucose correlates highly with blood glucose. The CGM system usually employs a sensor device inserted into the subcutaneous tissue, and a mechanism for transmitting the data to a device which then displays the glucose level as well as some statistical glucose data.

b. These systems do not replace SMBG readings. SMBG values are needed for system calibration and are recommended for making treatment decisions.

c. CGM may be a supplemental tool to SMBG for selected type 1 patients, especially those with hypoglycemia unawareness (the CGM device has alarms for hypo- and hyperglycemia), widely fluctuating BG patterns, or the desire and motivation to optimize glycemic control throughout the day.

B. Urine glucose testing. No longer recommended because it provides only retrospective information and does not reflect current blood glucose. Reserved only for individuals unable or unwilling to perform SMBG.

C. Urine ketone monitoring. An essential component of diabetes management, particularly under the following conditions:

1. During illness in all patients with diabetes because even those with type 2 DM can become ketotic during periods of severe stress, infection, or trauma

2. Patients with type 1 DM when blood glucose is consistently > 240 mg/dL

3. Pregnant women with diabetes (including gestational diabetes)

4. Individuals actively trying to lose weight by calorie restriction

D. Long-term monitoring of glycemic control

1. HbAIC test

a. Reflects average blood glucose level over the preceding **2-3 months.**

b. Based on an upper limit of normal being 6% for HbAIC; anHbAIC level of 7.0% or lower indicates good overall glycemic control, whereas > 7.0% reveals the need for additional intervention. For many individuals, a goal closer to normal may be desirable, provided it does not pose undue risk for hypoglycemia.

c. Underlying hemoglobinopathies may cause anomalous values.

d. In general, the frequency of HbAIC testing is at least **twice a year** in patients with stable glycemic control and at least quarterly in patients whose therapy has recently changed or who are in poor control.

2. Glycosylated fructosamine test

a. Measures glycemic control over the preceding 2-3 weeks

b. Useful for short-term follow-up of recently implemented interventions, when timely assessment of the intervention is important (e.g., changes in diabetes therapy during pregnancy).

c. Provides an alternative test for glycemic control in patients with abnormal hemoglobin, which interferes with the anion-exchange chromatography methods for hemoglobin A1C

X. ACUTE CHANGES IN GLYCEMIC CONTROL

A. Hyperglycemia

1. Mild to moderate severity. Rapid onset (within hours), no metabolic abnormalities

a. Acute-onset hyperglycemia. Owing to unplanned event such as illness, emotional distress, or excessive caloric intake

b. Hyperglycemia following prolonged or severe hypoglycemia. Somogyi effect or rebound hyperglycemia (notably type 1 DM)

c. Hyperglycemia occurring as a pattern in the early morning.

(1) Caused by counterregulatory hormones (i.e., dawn phenomenon)

(2) Caused by nocturnal hepatic glucose production (notably type 2 DM)

2. Moderate to severe severity (BG > 250 mg/dL). Short duration (one to several days), with acidosis and ketosis—**diabetic ketoacidosis (DKA)** (see II.B.1)

a. Often the presenting disorder in children with previously undiagnosed type 1 DM

b. Precipitating factors include stress, infection, exercise, excessive alcohol consumption, improper insulin therapy, and dietary noncompliance.

c. Physical findings include Kussmaul respirations, acetone breath odor, dehydration, dry skin, poor skin turgor, reduced level of consciousness (ranging from confusion to coma), and abdominal pain.

d. Laboratory findings include hyperglycemia, ketosis, low arterial pH and carbon dioxide partial pressure (P_{CO2}) values, and abnormal serum electrolyte values.

e. Therapy involves fluid, intravenous insulin by continuous infusion, electrolyte replacement, and hospitalization. Without treatment, death ensues.

3. Severe (BG > 500 mg/dL). Intermediate duration (days to weeks), with profound dehydration, diminished central nervous system (CNS) function and increased serum osmolality, without ketosis or acidosis—**HHS** coma.

a. Occurs primarily in type 2 DM

b. Has a higher mortality rate than DKA

c. Precipitating factors include illnesses and conditions that increase insulin requirements and predispose the patient to dehydration.

(1) Examples include severe burns, GI bleeding, CNS injury, and acute myocardial infarction.

(2) Use of glucogenic drugs (e.g., steroids, glucagon, thiazide diuretics, cimetidine, propranolol)
(3) Medical procedures or hypertonic high-glucose products such as intravenous hyperalimentation, peritoneal dialysis, and enteral nutrition
d. Physical findings include polyuria, polydipsia, dehydration, hypotension, rapid respirations, abdominal discomfort, nausea, vomiting, tachycardia, palpitations, and profound signs of neurological deficits (such as confusion, coma, generalized or focal seizures, myoclonic jerking, and hemiparesis).
e. Laboratory findings include hyperglycemia (often substantially above 500 mg/dL), absence of ketosis, and serum osmolarity > 320 mOsm/kg. Calculated as follows:

$$2\left[\frac{(\text{sodium} + \text{glucose})}{18}\right]$$

where sodium is measured in milliequivalents per liter and glucose is measured in milligrams per deciliter.
f. Therapy involves fluid, insulin, and electrolyte replacement.
B. Hypoglycemia
1. Mild hypoglycemia. Primarily adrenergic symptoms (tachycardia, palpitations, shakiness) or cholinergic (sweating) symptoms, or effects of mild CNS glucopenia (inability to concentrate, dizziness, hunger, blurred vision), but symptoms are not severe enough to interfere with self-medication for the hypoglycemia.
2. Moderate hypoglycemia. The CNS is more markedly deprived of glucose, eliciting symptoms of confusion, inappropriate behavior, and impairment of motor function. The patient is minimally capable of self-treatment, and assistance is usually needed. The patient is *not* unconscious.
3. Severe hypoglycemia. Coma, seizure, and/or impairment of motor function to the extent that self-treatment is not possible.
4. Pseudohypoglycemia. Patient perceives hypoglycemic symptoms (usually adrenergic), but BG may be normal, or slightly above normal, and may be rapidly falling.
5. Hypoglycemia unawareness. Patient perceives no or minimal symptoms. Family or co-workers may notice neurological impairment or sweating. BG may be low to seriously low.
6. Precipitating factors
a. Relative or absolute excess of insulin or oral hypoglycemic agent
b. Delayed or insufficient food intake
c. More exercise than usual

d. Alcohol ingestion

e. Drug interaction resulting in potentiation of hypoglycemic medication or a direct hypoglycemic effect

f. Subtle causes

(1) Hormonal changes (e.g., drop in progesterone level as part of menstrual cycle)

(2) Patient switches to a new bottle of insulin and, unknown to the patient or physician, the previous bottle had lost some of its potency

(3) Gastroparesis (delayed emptying of the stomach following a meal), an autonomic neuropathy complication of diabetes

(4) Change in insulin injection sites, especially if injection was given at a subcutaneous site associated with muscles used for exercise (blood flow, and thus insulin absorption, is increased owing to the exercising muscle)

g. Treatment

(1) Conscious patient. Use **10-15 g** fast-acting (simple) oral carbohydrate, such as 4 oz. of fruit juice, milk, or regular soda; 2-4 glucose tablets or hard candy. Honey or a glucose gel product may be placed into the patient's mouth, if the person is too confused or unresponsive for self-treatment. Treatment may be repeated in 10-15 min if BG does not return to normal.

(2) Unconscious patient

(a) Intravenous glucose, using 10% or 50% dextrose solution

(b) Glucagon injection. Between 0.5 and 1 mg given subcutaneously, intramuscularly, or intravenously

XI. LONG-TERM COMPLICATIONS

A. Macrovascular complications (coronary artery, cerebrovascular and peripheral vascular disease)

1. Atherosclerosis (coronary, cerebrovascular, and peripheral vessels) occurs at an earlier age than nondiabetic individuals. Women with diabetes lose their gender protection from atherosclerosis.

2. Peripheral vascular disease may lead to pain (intermittent claudication), chronic cold feet, or insufficient circulation to enable healing of distal lesions (ultimately leading to gangrene and amputation).

3. Hypertension (HTN)

a. Co-existence of HTN and DM strikingly increases the risk of **cardiovascular disease,** doubles the risk of cardiovascular death, and increases incidence of **stroke** and **transient ischemic events** in DM individuals.

b. Severity or lability of hypertension is determined by factors such as age, race, sex, greater body mass, duration of DM, and persistence of proteinuria.

c. Associated with acceleration of retinopathy, nephropathy, and atherosclerosis

d. Hyperinsulinemia and/or insulin resistance may be a significant factor in the development of DM hypertension.

4. Mortality from **coronary artery disease** (CAD) is twofold to fourfold greater in both men and women with diabetes than those without DM, and mortality from cerebrovascular disease is three to five times greater.

5. May present as atypical presentation of CAD, including **silent myocardial infarction** and lack of chest pain (owing to autonomic neuropathy). Symptoms may be limited to nausea, shortness of breath, sweating, and vomiting.

6. Modifiable risk factors include hyperglycemia, hypertension, dyslipidemia, tobacco use, obesity, nutrition, increased insulin levels, physical inactivity, and increased homocysteine levels.

7. Prevention and treatment strategies to slow the development and/or progression of disease.

a. Aggressive management of hypertension, hyperlipidemia, and hyperglycemia

b. Smoking cessation

c. Increased physical activity

d. Daily aspirin therapy for those individuals with no contraindications

e. Drug therapy appropriate for the complication, including angiotensin-converting enzyme (ACE) inhibitor therapy as a component of HTN therapy and a cardioselective β-blocker agent for cardiac disease.

B. Eye diseases

1. Diabetic **retinopathy**

a. A consequence of microvascular changes

b. Most prevalent eye complication and is often detectable within 5 years after the diagnosis of DM. Present in > 90% of patients with type 1 and 55%-80% of patients with type 2 DM, after 15 years of diabetes.

c. Leading cause of new blindness in the United States

d. Categories of retinopathy

(1) Nonproliferative (background) retinopathy. Vascular abnormalities include retinal microaneurysms (early, mild stage), blot hemorrhages, and retinal edema with or without “hard” exudates. May progress to macula edema.

(2) Preproliferative retinopathy. With increasing abnormality of the tiny vessels, retinal ischemia occurs, giving rise to the appearance of white patches of oxygen-starved retina, known as soft or cotton wool spots.

(3) Proliferative retinopathy

(a) In response to the lack of oxygen, new but weak vessels begin to grow (neovascularization).

(b) The new vessels grow (proliferate) out from the retinal surface, into the vitreous cavity. These vessels are fragile and may bleed into the vitreous.

Hemorrhages into the vitreous can obscure vision, but they are usually reabsorbed in 1-3 months.
(c) Traction retinal detachment. Scar tissue, and more new blood vessels, continue to grow onto the vitreous. The vitreous pulls (traction) on the retina and detaches it.
e. Generally does not result in visual alterations until advanced stages are reached
f. Treatment. Loss of vision can be reduced by 50% with laser photocoagulation if ocular changes are identified and treated in a timely manner.

2. Other ocular complications include cataracts, primary open-angled glaucoma, and ischemic optic neuropathy.
3. Modifiable risk factors include hyperglycemia, hypertension, dyslipidemia, and nicotine use.
4. Prevention strategies
a. Aggressive management of hypertension, hyperlipidemia, and blood glucose
b. Smoking cessation
c. Routine ophthalmologic screening and follow-up, including an annual dilated eye exam

C. Diabetic nephropathy

1. DM is the most common single cause of end-stage renal disease (**ESRD**) in the United States and Europe.
2. Renal failure occurs in 30%-40% of individuals with type 1 DM within 30 years after diagnosis and 20%-30% of patients with type 2 DM.
3. Findings/progression
a. First evidenced by the presence of urinary **microalbuminuria** (> 30 mg albumin/24 hr)
b. Clinical or dipstick positive **albuminuria** (> 300 mg/24 hr)
c. Proteinuria often associated with hypertension, which accelerates the rate of nephropathic changes
d. Progressive decrease in glomerular filtration rate with rising serum creatinine until ESRD occurs.
4. Modifiable risk factors include hyperglycemia, hypertension, tobacco use, and excessive dietary protein intake.
5. Prevention and treatment strategies to slow the development and/or progression of disease.
a. Aggressive management of HTN and blood glucose
b. Initiation of ACE inhibitor therapy
c. Smoking cessation

d. Limit daily dietary protein intake to 0.8 g/kg of ideal body weight. Note that lower protein meal plans should be used with caution to avoid malnutrition and associated muscle weakness.
e. Early identification and aggressive treatment of urinary tract infections
f. Yearly assessment of kidney function, including urinalysis for detection of microalbuminuria
g. For ESRD, fluid and electrolyte restriction as well as intermittent or chronic dialysis treatments, as indicated by severity of pathology, laboratory findings, and patient symptomatology
h. For ESRD, patient and caregiver counseling to prepare them for the psychosocial, financial, physical, medical, and quality-of-life changes that accompany dialysis and possible kidney transplantation

D. Diabetic neuropathies

1. Peripheral neuropathy

a. The sensorimotor nervous system is most often affected, but sympathetic or parasympathetic abnormalities may be present also.
b. Sensory deficits and symptoms originate in the distal portions of the lower extremities and gradually progress to the upper extremities, creating a stocking-glove distribution of pain and diminished sensation.
c. Signs and symptoms depend on the class and stage of nerve fiber loss.
(1) Small-fiber involvement impairs perception of pain and temperature and may lead to numbness/tingling or loss of sensation.
(2) Large-fiber involvement produces impaired balance and diminished proprioception.
(3) Motor nerve damage results in muscle weakness/atrophy.
(4) The majority of patients experience damage to more than one type of nerve.

2. Autonomic neuropathy involves multiple systems throughout the body.
a. Genitourinary impairment may lead to neurogenic bladder and sexual dysfunction in

both males (impotence, retrograde ejaculation) and females (diminished vaginal lubrication and orgasm frequency).
b. Gastrointestinal impairment may lead to gastroparesis, nocturnal diarrhea, fecal incontinence, or chronic constipation.
c. Cardiovascular impairment may lead to orthostatic hypotension or cardiac denervation syndrome.

3. Modifiable risk factors include hyperglycemia, alcohol use, tobacco use, and hypertension.

4. Prevention strategies

a. Aggressive management of blood pressure and blood glucose.
b. Smoking and alcohol cessation.
c. Proper foot care to prevent development of lower-extremity complications in the presence of peripheral neuropathy and diminished circulation.

E. Foot, skin, and mucous membrane complications stem from vascular changes and peripheral neuropathy that cause alterations in the nerves that control blood flow and skin hydration.

1. Individuals with DM are at increased risk for the development of skin infections caused by staphylococci, β-hemolytic streptococci, and fungus.

2. Common infections include

a. Cutaneous infections such as furunculosis and carbuncles

b. *Candida* infections of the genitalia, upper thighs, and under the breasts

c. Cellulitis and/or lower-extremity vascular ulcers

3. Atrophic lesions (round painless lesions) and diabetic dermopathy (reddish brown papular spots) are common, especially on the lower extremities

4. An ulcerating necrotic lesion called **necrobiosis lipoidica diabeticorum** may develop on the anterior leg surface or the dorsum of the ankle.

5. Approximately 50% of patients with DM of 15 years' duration have peripheral neuropathy that may result in a loss of protective sensation and inability to detect even minor trauma. This places the patient at significant risk for the development of ulcers.

6. Injury, infection, neuropathy, vascular disease, or ischemia may lead to gangrene, which is 20 times more common in people with DM.

7. Prevention strategies

a. Good glycemic control

b. Proper foot care (see VIII.D.1) and early detection/intervention of identified problems.

c. Proper skin care (see VIII.D.2)

d. Sensory exam of feet using a 5.07 (10-g) monofilament to identify patients with loss of protective sensation

e. Patient education concerning protective footwear (e.g., deep-soled shoes, individually molded shoes, orthotics) and avoidance of foot injury, especially when a loss of protective sensation is noted.

F. Importance of glycemic control as preventive of chronic complications

1. The **Diabetes Control and Complications Trial** (DCCT; 1993) demonstrated that intensive treatment of type 1 diabetic patients delays the onset and progression of diabetic retinopathy, nephropathy, and neuropathy.

2. The **United Kingdom Prospective Diabetes Study** (UKPDS; 1998) similarly demonstrated that the complications of type 2 DM may be reduced by strict glycemic control, regardless of the therapeutic agent chosen to attain that control.

3. The findings of the DCCT and UKPDS have been confirmed by numerous other clinical studies. There is today no reason for doubt that glycemic control is a major strategy for the prevention of diabetes-related conditions, reduced healthcare and societal costs, and preservation of quality-of-life issues.

XII. SIGNIFICANT DRUG INTERACTIONS AFFECTING GLYCEMIC CONTROL.

This is only a partial list of potential drug interactions that may affect glycemic control. Consult standard references or drug package inserts for more detailed information.

A. Potential hyperglycemia, as a dose-dependent, direct glucogenic effect. Corticosteroids, nicotinic acid, phenytoin, pentamidine (long-term effect), protease inhibitors, sympathomimetics, isoniazid, furosemide, thiazide diuretics

B. Potential hypoglycemia, as a direct hypoglycemic effect; monoamine oxidase (MAO) inhibitors, fluoxetine, salicylates (large doses), fenfluramine, alcohol, pentamidine (initial effect)

C. Prolonged hypoglycemia and masking of hypoglycemic symptoms. β-Blockers

D. Altered protein binding of, or other drug interaction with, sulfonylurea agents. Alcohol, salicylates, nonsteroidal anti-inflammatory drugs (NSAIDs), methyldopa, chloramphenicol, MAO inhibitors, clofibrate, probenecid

XIII. SPECIAL ISSUES IN DIABETES.

These situations cause unique problems in the management of diabetes, but are beyond the scope of this chapter. Readers are encouraged to learn about these, as these issues arise during the course of pharmacy practice.

A. Pregnancy in DM (not GDM)

B. Pediatrics

C. Adolescence

D. Geriatrics

E. Surgery

F. DM management during hemodialysis or peritoneal dialysis

G. Kidney transplantation

H. Self-care issues (e.g., SMBG, injections) in the visually impaired or blind DM patient

I. DM patients in institutionalized facilities

J. Pancreas and islet cell transplantation

STUDY QUESTIONS

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Current criteria used in the diagnosis of diabetes mellitus (DM) include all of the following symptoms *except*

(A) fasting hyperglycemia.

(B) polyuria.

(C) polydipsia.

(D) tinnitus.

(E) weight loss.

View Answer***1. The answer is D[seeand].*****2. The most useful glucose test used in monitoring diabetes mellitus (DM) therapy is**

(A) urine monitoring.

(B) blood monitoring.

(C) renal function monitoring.

(D) cardiovascular monitoring.

(E) vascular monitoring.

View Answer***2. The answer is B[seeand].*****3. Which of the following statements concerning insulin therapy is true?**

(A) Commercial insulin products vary little with respect to time, course, and duration of hypoglycemic activity.

(B) Regular insulin cannot be mixed with neutral protamine Hagedorn (NPH; isophane insulin suspension).

(C) Regular insulin cannot be given intravenously.

(D) Regulating carbohydrate consumption is a necessity for all diabetic patients.

(E) Insulin therapy does not have to be monitored closely.

View Answer***3. The answer is D[see].*****4. A mass of adipose tissue that develops at the injection site is usually the result of the patient's neglect to rotate the insulin injection site. This is known as**

(A) lipoatrophy.

(B) hypertrophic degenerative adiposity.

(C) lipohypertrophy.

(D) atrophic skin lesion.

(E) dermatitis.

View Answer***4. The answer is C[see].*****5. Sulfonylurea agents (as monotherapy or in combination) are a primary mode of therapy in the treatment of**

(A) type 1 diabetes mellitus patients.

(B) diabetes patients experiencing severe hepatic or renal dysfunction.

(C) pregnant women with diabetes.

(D) patients with diabetic ketoacidosis.

(E) non-insulin requiring (type 2) DM patients.

View Answer***5. The answer is E[see].*****6. Patients taking chlorpropamide should avoid products containing**

(A) acetaminophen.

(B) ethanol.

(C) vitamin A.

(D) penicillins.

(E) milk products.

View Answer***6. The answer is B[see].*****7. The standard recommended dose of glyburide is**

(A) 0.5-2 mg/day.

(B) 1.25-20 mg/day.

(C) 50-100 mg/day.

(D) 200 mg/day.

(E) 200-1000 mg/day.

View Answer***7. The answer is B[see].***P.1195

For questions 8-12: A 20-year-old previously healthy man presents to the emergency room with a 2-week history of polyuria, polydipsia, and a 20-lb unintentional weight loss. He complains of weakness, fatigue, nausea, and abdominal pain. Physical examination reveals dry, parched mucous membranes. Blood pressure is 110/70 mm Hg and the pulse is 90 beats per minute (bpm) supine; blood pressure is 90/60 mm Hg, and pulse is 120 bpm upright. Temperature is 100°F (axillary); respiratory rate is 24 breaths per minute. General examination of the heart and lungs is unremarkable. No retinopathy is present. The abdomen is soft with mild tenderness but no rebound. Laboratory values are as follows:

Blood glucose	420 mg/dL
Sodium (Na)	130 mEq/L
Potassium (K)	3.7 mEq/L
Chloride (Cl)	97 mEq/L
Bicarbonate (HCO_3)	10 mEq/L
Arterial blood gas	7.20 (pH)
Urinalysis	+3 glucose and moderate ketones
Chest radiograph	Unremarkable

Abdominal radiography	Unremarkable

8. What is the most likely diagnosis in this patient?

(A) type 2 diabetes mellitus (DM) with hyperosmolar state

(B) type 1 DM with diabetic ketoacidosis

(C) type 2 DM without hyperosmolar state

(D) type 1 DM without diabetic ketoacidosis

View Answer***8. The answer is B[see].*****9. Initial appropriate therapy includes**

(A) intravenous fluids and a sulfonylurea agent

(B) intravenous fluids alone

(C) intravenous fluids, 10 U of subcutaneous regular insulin, and discharge to home

(D) intravenous fluids, intravenous regular insulin by continuous drip at 6 Units/hr, and hospital admission

View Answer***9. The answer is D[see].*****10. After the acute illness has resolved, what therapy would be appropriate?**

(A) None, observe only

(B) Start a second-generation sulfonylurea, plus dietary modification and physical activity regimen

(C) Daily administration of a regimen of neutral protamine Hagedorn (NPH; isophane insulin suspension) and regular insulin, plus dietary modification and physical activity regimen

(D) Dietary modification alone

View Answer***10. The answer is C[see].*****11. Appropriate follow-up of the patient once discharged to home includes all of the following *except***

(A) periodic monitoring of hemoglobin AIC levels.

(B) periodic ophthalmologic examinations.

(C) home glucose monitoring with a glucose meter.

(D) weight-loss diet and an attempt to wean from insulin.

View Answer***11. The answer is D[see].*****12. The patient is at high risk for developing all of the following complications *except***

(A) hypoglycemia.
(B) coronary artery disease.
(C) retinopathy.
(D) nonketotic hyperglycemia hyperosmolar state.
View Answer***12. The answer is D[see].***P.1196

ANSWERS AND EXPLANATIONS

1. The answer is D *[see* III.A *and* B*].*
Frequent urination (polyuria), thirst (polydipsia), and weight loss are all common signs of diabetes. When these symptoms are present, it is necessary to have a fasting or random (casual) blood glucose level drawn to determine a diabetic state. A fasting blood glucose level > 125 mg/dL on more than one occasion is diagnostic of a diabetic state.
2. The answer is B *[see* IX.A *and* B*].*
Blood glucose monitoring is the most useful form of monitoring glucose levels. Urine monitoring provides only gross estimates of the current status and cannot rule out hypoglycemia. Renal function and cardiovascular functions provide evidence of long-standing disease and are not useful for monitoring daily progress.
3. The answer is D *[see* VII.A.1; VII.C.7; Table 54-1*].*
Many commercial insulin preparations vary with respect to duration of activity and time for peak plasma level. Regular insulin can be mixed with NPH and given intravenously. All insulin therapies should be monitored closely and on a daily basis. Careful regulation of carbohydrate intake is very important for all diabetic patients—carbohydrate consumption plays a major role in the balance of glucose metabolism and antagonizes the effects of insulin therapy.
4. The answer is C *[see* VII.C.7.a.(3)*].*
Lipohypertrophy consists of masses of adipose tissue that develop at the injection site, usually in patients who do not rotate the injection sites properly. The masses gradually disappear if injection in these sites is avoided.
5. The answer is E *[see* VII.D.2; X.A.2*].*
Sulfonylureas should not be used as primary therapy in insulin-dependent (type 1) diabetes mellitus patients, in those who have severe hepatic or renal dysfunction, or in those patients who are pregnant. DKA should never be treated with sulfonylureas; this condition must be treated with insulin, fluids, and electrolyte replacement. However, sulfonylureas help reduce blood glucose levels in type 2 DM that does not respond to diet alone.
6. The answer is B *[see* VII.D.6.g*].*
Acute ingestion of ethanol (alcohol) by patients who are taking any antidiabetic agent carries the risk of severe hypoglycemia particularly because of the potential hypoglycemic effects of ethanol (especially if

consumed in the fasting state). In addition, the interaction of chlorpropamide and ethanol (disulfiram-like reaction) is notable with this agent.

7. The answer is B *[see* Table 54-2*].*

The standard recommended dose of glyburide is 1.25-20 mg/day. Doses > 20 mg are not recommended by the manufacturer. Patients may be started on a low dose (e.g., 1.25 mg/day) and titrated up to an effective oral dose, as clinically indicated.

8. The answer is B *[see* II.B.1; X.A.2*].*

Type 1 DM with DKA is the most likely diagnosis in the patient described in the question. The patient presented with high blood sugar, weight loss, acidosis, and positive urine ketones (high level). This is a typical presentation of DKA.

9. The answer is D *[see* X.A.2.d*].*

Type 1 DM always requires insulin therapy; it can never be left untreated or treated with diet or liquids alone and can never be treated with sulfonylurea agents. DKA requires hospitalization and should be treated with an insulin drip until the acidosis clears. Patients with DKA are dehydrated and must be given intravenous fluids.

10. The answer is C *[see* VII.C.4*].*

11. The answer is D *[see* VII.C.4; VIII.D.4; IX.A; IX.D.1*].*

All diabetic patients should be followed with periodic hemoglobin AIC measurements and ophthalmologic examination annually. Home glucose monitoring is the optimal way to follow a patient's level of control. Weight loss and an attempt to wean from insulin are appropriate only for type 2 DM. Those patients with type 1 diabetes cannot be weaned from insulin therapy.

12. The answer is D *[see* II.B.2; X.A.3*].*

Hypoglycemia is a possible complication of insulin therapy. All diabetic patients are at risk for coronary artery disease and retinopathy. Nonketotic hyperglycemic hyperosmolar coma is typically a complication of type 2 DM.
