

Brief Quantum Mechanics (QM) Review

- QM results: *Utilization of*
The Schrödinger Equation
(time independent; see next slide)
describes electrons.
- Solutions to the **Schrödinger Equation** result in *quantized*
(discrete) **energy levels** for electrons.

Quantum Mechanics (QM)

- **The Schrödinger Equation:**
(time independent)

$$\mathbf{H}\psi = \mathbf{E}\psi$$

(this is a differential operator eigenvalue equation)

H \equiv Hamiltonian operator for the system

E \equiv Energy eigenvalues
(allowed energies)

ψ \equiv Wavefunction

Particles are QM waves!

- **The Schrödinger Equation:**

$$\mathbf{H}\psi = \mathbf{E}\psi$$

- *Particles are QM waves!*

$|\psi|^2 \equiv$ probability density

$|\psi|^2 d^3r \equiv$ Probability that an electron
is in differential volume d^3r

- ψ is a function of *ALL* coordinates
of *ALL* particles in the problem!

Electrons in Periodic Crystalline Materials

**Reduction to one
Electron Problem**

Hamiltonian for a Perfect, Periodic Crystal

N_e electrons, N_n nuclei; $N_e, N_n \sim 10^{23}$ (huge!)

Notation: i = electron; j = nucleus

- The general, the many-body Classical Hamiltonian:
(Gaussian units!)

$$\mathbf{H} = \mathbf{H}_e + \mathbf{H}_n + \mathbf{H}_{e-n}$$

\mathbf{H}_e = Pure Electronic Energy = $\mathbf{KE}(e^-) + \mathbf{PE}(e^- - e^-)$

$$\mathbf{H}_e = \sum_i (\mathbf{p}_i)^2 / (2m_i) + (1/2) \sum_i \sum_{i'} [e^2 / |\mathbf{r}_i - \mathbf{r}_{i'}|] \quad (i \neq i')$$

\mathbf{H}_n = Pure Nuclear Energy = $\mathbf{KE}(n) + \mathbf{PE}(n - n)$

$$\mathbf{H}_n = \sum_j (\mathbf{P}_j)^2 / (2M_j) + (1/2) \sum_j \sum_{j'} [Z_j Z_{j'} e^2 / |\mathbf{R}_j - \mathbf{R}_{j'}|] \quad (j \neq j')$$

\mathbf{H}_{e-n} = Electron-Nuclear Interaction Energy = $\mathbf{PE}(e^- - n)$

$$\mathbf{H}_{e-n} = - \sum_i \sum_j [Z_j e^2 / |\mathbf{r}_i - \mathbf{R}_j|]$$

Lower case $\mathbf{r}, \mathbf{p}, \mathbf{m}$: Electron position, momentum, mass

Upper case $\mathbf{R}, \mathbf{P}, \mathbf{M}$: Nuclear position, momentum, mass

- The Classical, *Many-Body* Hamiltonian:

$$\mathbf{H} = \mathbf{H}_e + \mathbf{H}_n + \mathbf{H}_{e-n}$$

- *Three Approximations*, rigorously justified in many advanced texts (QM & SS), after a lot of work, reduce the complexity of the problem significantly. This gives:

⇒ For electronic properties calculations

(bandstructures, etc.) \mathbf{H} is reduced to a

One Electron Hamiltonian!

One Electron Hamiltonian!

- This is the usual *Starting Point* (with no proof) for *ALL* elementary SS physics texts (including Kittel's book) !
- What follows is a brief outline of these approximations. Details left to the student!

Approximation #1:

Separate electrons into 2 types:

**Core Electrons &
Valence Electrons**

- **Core Electrons**: Those in *filled*, inner shells of the atoms. Play **NO** role in determining the electronic properties of the solid!

Example:

The **Si free atom** electronic configuration:

Core Electrons = $1s^2 2s^2 2p^6$ (filled shells!)

Localized around the nuclei & play **NO** role in the bonding.

⇒ Lump the core shells with the **Nuclei** ≡ **Ions**

(in \sum_i , include only the valence electrons)

Core Shells + **Nucleus** ≡ **Ion Core**

⇒ $H_{e-n} \rightarrow \rightarrow H_{e-i}$, $H_n \rightarrow \rightarrow H_i$

Valence Electrons

- Those in the unfilled, outer shells of the free atoms. These determine the electronic properties of the solid and take part in the bonding!

Example:

The **Si** free atom electron configuration:

(unfilled shells!)

- In the solid, these hybridize with electrons on neighbor atoms. This forms strong covalent bonds with the 4 **Si** nearest-neighbors in the **Si** lattice.

Approximation #2:

The Born-Oppenheimer

(Adiabatic) Approximation

Separates electron & ion motions.

- *Separates* the electron & ion motions.
- Rigorous proof needs many body QM.

Qualitative (semi-quantitative)

Justification: The ratio of the electron & ion masses is of the order:

$$(m_e/M_i) \sim 10^{-3} (\ll 1)$$

(or smaller!)

⇒ Classically, the massive ions move much slower than the very small mass electrons!

Typical ionic vibrational frequencies: $\nu_i \sim 10^{13} \text{ s}^{-1}$

\Rightarrow The time scale of the ion motion is: $t_i \sim 10^{-13} \text{ s}$

- Electronic motion occurs at energies of about a bandgap:

$$E_g = h\nu_e = \hbar\omega \sim 1 \text{ eV} \Rightarrow \nu_e \sim 10^{15} \text{ s}^{-1} \Rightarrow t_e \sim 10^{-15} \text{ s}$$

- So, classically,

*The electrons respond to the ion motion
~ instantaneously!*

\Rightarrow As far as the electrons are concerned,
the ions are ~ stationary!

\Rightarrow In the electron Hamiltonian, H_e ,
the ions can be treated as \approx stationary!

The Large Mass Ions

cannot follow the rapid, detailed motion of

The Small Mass Electrons.

⇒ The Ions ~ see an Average
Electron Potential!

⇒ In the ion Hamiltonian, H_i ,
the electrons can be treated in
an average way!

(As in Chs. 4 & 5 in Kittel on Lattice Vibrations)

Implementation: Born-Oppenheimer (Adiabatic) Approximation

- Write the vibrating ion coordinates as
 $\mathbf{R}_j = \mathbf{R}_{j_0} + \delta\mathbf{R}_j$, \mathbf{R}_{j_0} = equilibrium ion positions
 $\delta\mathbf{R}_j$ = (small) deviation from the equilibrium positions
- The many body electron-ion Hamiltonian is (schematic!):

$$\mathbf{H}_{e-i} \sim = \mathbf{H}_{e-i}(\mathbf{r}_i, \mathbf{R}_{j_0}) + \mathbf{H}_{e-i}(\mathbf{r}_i, \delta\mathbf{R}_j)$$

- The New many body Hamiltonian in this approximation :

$$\mathbf{H} = \mathbf{H}_e(\mathbf{r}_i) + \mathbf{H}_{e-i}(\mathbf{r}_i, \mathbf{R}_{j_0}) + \mathbf{H}_i(\mathbf{R}_j) + \mathbf{H}_{e-i}(\mathbf{r}_i, \delta\mathbf{R}_j) \quad (1)$$

(neglect the last 2 terms in the band calculations) **or**

$$\mathbf{H} = \mathbf{H}_E \text{ [1st 2 terms of (1)]} + \mathbf{H}_I \text{ [2nd 2 terms of (1)]}$$

Here, $\mathbf{H}_E = \text{Electron Part}$ (gives the energy bands)

$\mathbf{H}_I = \text{Ion Part}$ (gives the phonons in Chs. 4 & 5)

Summary: Born-Oppenheimer Approx.

⇒ For electronic properties (bands), this allows us to focus on the electronic part of the many-body Hamiltonian:

$$H_E = H_e(\mathbf{r}_i) + H_{e-i}(\mathbf{r}_i, \mathbf{R}_{j_0})$$

(schematic):

$H_e(\mathbf{r}_i)$ = electron kinetic energy + electron-electron (Coulomb) repulsion

$H_{e-i}(\mathbf{r}_i, \mathbf{R}_{j_0})$ = electron (Coulomb) attraction to the STATIONARY ions.

Summary:

Born-Oppenheimer Approximation:

⇒ For calculations of electronic properties (bands), *the vibrating ion part, H_I* of the many-body Hamiltonian *can be neglected.*

Born-Oppenheimer Approximation

⇒ *Focus on the electronic part* of \mathbf{H} :

$$\mathbf{H}_E = \mathbf{H}_e(\mathbf{r}_i) + \mathbf{H}_{e-i}(\mathbf{r}_i, \mathbf{R}_{j_0})$$

$$\mathbf{H}_E = \sum_i (\mathbf{p}_i)^2 / (2m_i) + (1/2) \sum_i \sum_{i'} [e^2 / |\mathbf{r}_i - \mathbf{r}_{i'}|] \\ - \sum_i \sum_j [Z_j e^2 / |\mathbf{r}_i - \mathbf{R}_{j_0}|] \quad (i \neq i')$$

- **NOTE!** So far, the Hamiltonian is still classical!

We want to do Quantum Mechanics!

⇒ Replace each electron momentum with its quantum operator: $\mathbf{p}_i \equiv -i\hbar \nabla_i$ (everywhere in \mathbf{H}_E !)

To Calculate Electronic Properties:

Solve the Schrödinger Equation with \mathbf{H}_E
(this is still a many electron problem!)

Approximation #3:

The Mean Field or

One Electron Approximation

Approximation #3: The Mean Field or One Electron Approximation

- For H_E : Make the

Mean Field Approximation

⇒ Every electron experiences the SAME average potential

due to all other electrons (Coulomb repulsion) plus all ions (Coulomb attraction).

- The N electron Hamiltonian H_E is then replaced by N IDENTICAL one-electron Hamiltonians:

$$H_{1e} = (p)^2/(2m_0) + V(r)$$

One Electron Approximation:

⇒ The many electron Hamiltonian is replaced by a one electron Hamiltonian:

$$\mathbf{H}_{1e} = (\mathbf{p})^2 / (2m_0) + V(\mathbf{r})$$

- Do Quantum Mechanics ⇒ $\mathbf{p} \equiv -i\hbar\nabla$
- $V(\mathbf{r}) \equiv$ **Effective Potential** \equiv Average potential of one electron interacting with all others + all the ions
- $V(\mathbf{r})$ is periodic & has the lattice symmetry!
- Given $V(\mathbf{r})$, solve the

One Electron Schrödinger Equation:

$$\mathbf{H}_{1e}\psi_{\mathbf{n}} = E_{\mathbf{n}}\psi_{\mathbf{n}}$$

\mathbf{n} = eigenvalue label (band index), $\psi_{\mathbf{n}}$ = one electron wavefunction

- The *Primary Justification* of the one-electron approximation is that

It explains VOLUMES of data

on electronic properties of

all types of solids

(metals, semiconductors & insulators!).

NOTE!

- There are some (specialized) data for which an explanation requires the many body \mathbf{H} .

But, ***MOST*** data needs only the one electron \mathbf{H} !

The One-electron Approximation:

- What about **spin effects**? These are neglected in H_E .
Spin can be included! (Also, we need the **Pauli Exclusion Principle**: Requires quantum field theory!)
- **Spin-orbit coupling**? This is neglected in H_E .
Spin-orbit coupling can be included. (Relativistic corrections are needed.)
- The **One-electron Approximation**: Is used *without discussion or justification* in *~ALL* elementary SS physics texts!
A Rigorous Justification: Is found in Hartree & Hartree-Fock theory of many electron QM. Also, in the **Local Density Approximation (LDA)** to *Density Functional Theory.*

The Bandstructure Problem

- *Begin with* the one-electron Hamiltonian:

$$H_{1e} = (\mathbf{p})^2 / (2m_0) + V(\mathbf{r})$$

$\mathbf{p} \equiv -i\hbar\nabla$, $V(\mathbf{r}) \equiv$ Periodic Effective Potential

- Solve the one-electron Schrödinger Equation:

$$H_{1e}\psi_n(\mathbf{r}) = E_n\psi_n(\mathbf{r})$$

*In general, this is still a very
complicated, highly
computational problem!*

The Bandstructure Problem

(Many people's careers over many years!)

- Start with the 1 e⁻ Hamiltonian:

$$\mathbf{H}_{1e} = -(\mathbf{i}\hbar\nabla)^2/(2m_0) + \mathbf{V}(\mathbf{r})$$

- **Step 1**: Determine the effective periodic potential $\mathbf{V}(\mathbf{r})$
- **Step 2**: Solve the one-electron Schrödinger Equation:

$$\mathbf{H}_{1e}\psi_n(\mathbf{r}) = \mathbf{E}_n\psi_n(\mathbf{r})$$

A complex, sophisticated, highly computational problem!

- There are *many schemes, methods, & theories to do this!*
- We'll give a brief overview of only a few!

- The 1 e⁻ Hamiltonian is:

$$H_{1e} = -(\hbar\nabla)^2/(2m_0) + V(\mathbf{r})$$

- Note!! Knowing the form of the effective periodic potential $V(\mathbf{r})$ is itself a difficult problem!
- However, we can go a long way towards understanding the physics behind the nature of bandstructures without specifying $V(\mathbf{r})!$

We can USE SYMMETRY!

- **Group Theory** \equiv A math tool which does this in detail.

$V(\mathbf{r}) \equiv$ **Periodic Crystal Potential.**

- Has all of the symmetries of the crystal lattice!

Translational Symmetry

Rotational Symmetry

Reflection Symmetry

- The most important symmetry is

Translational Symmetry.

- Using this considerably reduces the complexities of bandstructure calculations!
- We will illustrate bandstructure calculations with some model calculations first. Then, we will discuss real bandstructures.
